PREFACE

Manfred SCHRENK

Conference Director,
President CORP – Competence Center of Urban and Regional Planning

WELCOME to REAL CORP 2020, the 25th International Conference on Urban & Regional Development and Spatial Planning in the Information Society!

REAL CORP 2020 under the topic "Shaping Urban Change" tries to explore the common things in different trends which can be seen in urban development around the globe.

Historic administrative boundaries do not represent real urban structures any more, cities expand beyond these boundaries and form metropolitan regions, which may even result in transnational functional urban areas and agglomerations. In almost all cases it is of utmost importance to coordinate urban development between several governments, administrative authorities and institutions on different levels, but this task turns out to be a quite difficult one.

Cities and regions are hungry for resources and see themselves opposed to density and environmental problems as well as other threats, nevertheless sustainability, resilience, high quality of life and considerate exploitation of natural resources are central goals of urban development. New technologies and digitisation play an essential role in the development of cities, urban regions and metropolises – without appropriate urban, environmental and mobility technologies it would hardly be possible to see urban development, maintenance of functionality and creation of livable urban areas.

In some parts of the world – particularly in China and India, but also in Japan and South-East Asia, and in parts of South America, Africa and the Gulf region – cities and metropolises are growing undamped and hundreds of millions of people are attracted to cities. However, in numerous European cities and agglomerations we can currently see two kinds of processes which may appear to be contradictory at first glance: reurbanisation and regionalisation. The return to core cities as a place of life has a lot of reasons, but it is strongly linked to changes in the working environment and the trend to combine working and living much more as it were possible in suburban fringe areas. But many city centres are lacking affordable housing space, whereas there are plenty of vacancies in the surroudings. Wrong allocations create unnecessary commuter flows.

REAL CORP 2020 aims to discuss strategies and concepts for quality change management in the light of the challenges outlined above, which arise in neighbourhoods, cities, urban regions and metropolitan areas. This also raises the question of who the actual actors of current urban, regional and metropolitan regional development are and what role planners can play in the corresponding scenarios.

The renowned RWTH Aachen in the historical European medium sized city of Aachen, in the German federal state of North Rhine-Westphalia with its rich mining and industrial tradition, located in a cross-border city region in the border triangle Germany-Belgium-Netherlands, is the ideal place to discuss these developments and challenges with experts from all over the world.

This year we brought together some 250 participants from more than 40 countries worldwide. The main goal of the REAL CORP conference series isto bring together leading experts in the field of spatial planning, geoinformation and related disciplines to exchange their knowledge, share their ideas, discuss current developments and get together for face to face networking leading to the development of new thoughts, partnerships and projects. The success of the REAL CORP conferences is – clearly without doubt – the result of the efforts of participants, reviewers, and the conference organising team consisting of CORP association and RWTH Aachen – Department of Urban Design. We would like to acknowledge the Reviewer Team and Programme Committee members for their valueable voluntary help with the review process. Our thanks go to all participants and authors of the submitted papers as well.

The proceedings of this year's conference contain 135 scientific papers; 101 of them were selected after a double-blind, double-stage (for both abstracts and full papers) peer-review process for publication and presentation at the 25th International Conference on Urban Planning and Regional Development in the Information Society, REAL CORP 2020. The non-reviewed papers were accepted by the programme committee after a double-blind abstract review. The conference is held from 15 to 18 September 2020 in co-operation with RWTH Aachen – Department of Urban Design and Ministry for Regional Identity, Communities and Local Government, Building and Gender Equality of the Land of North Rhine-Westphalia.

Have a great conference!
Manfred SCHRENK, Clemens BEYER & the REAL CORP Team

PREFACE

Christa Reicher

RWTH Aachen,Professor and Head of Chair and Institute for Urban Design
Local Host of REAL CORP 2020

WELCOME to REAL CORP 2020, the 25th International Conference on Urban Planning, Regional Development, Information Society and Urban, Transport, and Environmental Technologies!

At the beginning of the 21st century, the question of how we should shape the future of our cities and regions is more important than ever. Urban spaces are becoming the central form of organization of almost all human societies. In the emerging and developing countries, the force of the urbanization surge is becoming visible. The urban population is growing as people move out of rural areas; this growth process is accompanied by social change. In many parts of Europe a fundamental paradigm shift is taking place: from a phase of shrinking and stagnation to enormous growth of cities and regions. It is not only the large cities that are coming under real pressure; medium-sized and small towns and cities are also facing the challenge of how to meet the demands of climate change and the associated need to secure open spaces on the one hand, and to densify and make available space for living and working on the other.

Many inner cities lack affordable housing, while at the same time the surrounding area suffers from vacancies. Incorrect allocations generate unnecessary commuter flows. Against this background, intermunicipal cooperation is an obvious way of achieving the necessary balance between different development dynamics. The current intensive discourse on "Low Carbon Cities" or "Smart Cities", the question of the future development of cities under the conditions of climate change, the use of energy-saving technologies and the foreseeable depletion of fossil resources, raises concrete questions about future urban development and urban design that can only be answered in part so far. In the search for concepts and strategies, sustainability, resilience, a high quality of life and careful use of natural resources are among the central objectives of urban and spatial development.

Within the framework of REAL CORP 2020, global transformation processes and experiences will be discussed on the one hand, while on the other hand there will be an in-depth examination of individual German regions such as "Rheinisches Revier" and Lausitz, where political decisions to phase out lignite mining have raised pressing questions about the future prospects of regions: What does a climate-neutral model region of the 21st century look like? What strategies, concepts and processes can be used to successfully restructure a region that has been characterised by mining, industry and resettlement since the 19th century?

The future urban planning objectives will have to provide answers to the general challenges as they apply more or less to all cities and urban regions – regardless of whether cities are growing or shrinking, regardless of whether cities want to become metropolises, regional cities or explicit green cities. Often such simplistic dualisms do not face each other anyway, but are part of a comprehensive and contradictory transformation process that cities go through in the course of their history.

Against the background of the transformation tasks ahead, it is clear that urban design is slowly but noticeably becoming a „supreme discipline" again. This is why REAL CORP 2020 is also the 1st Aachen Conference on Urban Design. This format is intended to lead the international discourse on a contemporary understanding of urban development and to promote an exchange of strategies and concepts between research, practice and politics. After all, urban design and urban development must offer spatial and strategic concepts that ensure a sustainable quality of life for all.

VORWORT

Ina Scharrenbach

Ministerin für Heimat, Kommunales, Bau und Gleichstellung des Landes Nordrhein-Westfalen

WELCOME to REAL CORP 2020, the 25th International Conference on Urban Planning, Regional Development, Information Society and Urban, Transport, and Environmental Technologies!

Die Städte und Regionen entwickeln sich weltweit mit einer atemberaubenden Dynamik. Rund um den Globus steht die Stadtplanung vor ähnlichen Fragestellungen: Wie sorgen wir trotz hoher Verdichtung für Lebensqualität? Wie machen wir die Städte widerstandsfähig gegenüber extremen Wetterlagen? Wie organisieren wir eine zukunftsfähige Mobilität? Wie kooperieren Großstädte und das Umland, mit dem sie immer enger verflochten sind?

„Shaping urban change" lautet das Gebot der Stunde. Wir müssen und wir können den Wandel der Städte gestalten – auch, indem wir innovative Technologien konsequent nutzen. Die Stadt der Zukunft wird „smart" sein. Wir brauchen digitale Anwendungen, um die begrenzten Ressourcen effizient zu nutzen, die Verkehrsströme intelligent zu lenken und die urbane Infrastruktur insgesamt zu steuern.

Ein Baustein des Erfolgs ist dabei der grenzübergreifende Austausch zwischen Praxis und Wissenschaft. Was lokal erprobt wurde und sich bewährt hat, verdient es, global diskutiert und eingesetzt zu werden. Für diesen internationalen Diskurs sorgen Formate wie die REAL-CORP-Konferenzen. Deshalb kooperiert das Land Nordrhein-Westfalen sehr gern bei der diesjährigen 25. Ausgabe – und das umso mehr, da der Kongress zum 150. Jubiläum der weltweit renommierten RWTH in Zusammenarbeit mit dem dortigen Institut für Städtebau in Aachen stattfindet.

Digitalisierung ist in diesem besonderen Jahr 2020 auch eine Herausforderung für die Veranstalter. Ich wünsche der virtuellen Ausgabe der REAL-CORP-Tagung ein interessiertes weltweites Publikum und allen Konferenzteilnehmerinnen und -teilnehmern erkenntnisreiche Tage, einen lebhaften Austausch und wertvolle Impulse für ihre Arbeit. Schließlich hoffe ich, dass Sie bald auch persönlich die Gelegenheit finden werden, Nordrhein-Westfalen und die ebenso traditionsreiche wie technologieaffine Stadt Aachen zu besuchen.

Ina SCHARRENBACH
Ministerin für Heimat, Kommunales, Bau und Gleichstellung des Landes Nordrhein-Westfalen

VORWORT

Ulrich Rüdiger

Rektor RWTH Aachen
Dr. rer. nat. Dr. h. c. mult., Universitätsprofessor

WELCOME to REAL CORP 2020, the 25th International Conference on Urban Planning, Regional Development, Information Society and Urban, Transport, and Environmental Technologies!

Seit über 150 Jahren wachsen die Stadt Aachen und die RWTH Aachen miteinander und arbeiten in vielen Bereichen sehr gut zusammen. Sie prägen sich dabei gegenseitig in ihrer Entwicklung.

Die RWTH Aachen hat sich im Zuge der Exzellenzinitiative in den letzten Jahren zu einer "Integrierten Interdisziplinären Hochschule für Wissenschaft und Technologie" entwickelt. Damit ist sowohl die Hochschule, als auch die Stadt als Wissenschaftsstandort für Menschen aus Deutschland und der ganzen Welt ein noch attraktiveres Ziel zum Studieren, Forschen und Leben geworden. Diese Entwicklungen und vielfältigen Einflüsse führen nicht nur innerhalb der Hochschule, sondern auch in Bezug auf die Transformation der Regionen, Städte und Quartiere zu immer neuen Anforderungen, die zusätzlich unseren Lebensstilen im 21. Jahrhundert gerecht werden müssen.

Ich freue mich sehr, dass dieses Jahr die 1. Aachener Städtebaukonferenz von der Fakultät für Architektur veranstaltet wird und damit diese großen gesellschaftlichen und räumlichen Herausforderungen thematisiert werden. Im Hinblick auf das Thema „Shaping Urban Change. Livable City Regions for the 21st Century“ werden zukunftsweisende Fragestellungen mit Expertinnen und Experten diskutiert werden können.

Dass die Konferenz aufgrund der Corona-Pandemie nicht wie geplant stattfinden kann, ist natürlich sehr schade, aber – ganz im Sinne der Wissenschaft – haben die Organisatorinnen und Organisatoren zielgerichtet nach alternativen Lösungswegen gesucht und die Konferenz um digitale Komponenten erweitert, damit dieses wichtige Thema ohne Verzögerung bearbeitet werden kann. Denn für uns als Wissenschaftsregion ist es wichtig, Transformationsprozesse anzuregen, mit dem Ziel Technologien, Innovationen und Wissen aus Forschung und Lehre in die Stadtplanung zu integrieren und gleichermaßen mit Blick auf die Stadtentwicklung die Universität zu gestalten.

Ich wünsche Ihnen angeregte Diskussionen und eine interessante Konferenz!

Mit freundlichen Grüßen
Univ.-Prof. Dr. rer. nat. Dr. h. c. mult. Ulrich RÜDIGER

1 ABSTRACT

Vor dem Hintergrund situationsgerechte Lösungen zu den großen Herausforderungen beispielsweise bezüglich der Klimakrise oder dem demografischen Wandel zu finden, stehen insbesondere mittelgroße und kleine Kommunen mit geringem Budget vor immer komplexeren Planungsaufgaben. Aufgrund der sich diverfizierenden Vielzahl an Informationen im Rahmen der fortschreitenden Digitalisierung gewinnt bei der Beantwortung von planerischen Fragestellung der Einsatz IT-gestützer Hilfsmittel an Bedeutung. Neben den oftmals nur durch Experten bedienbaren und in der Anschaffung kostspieligen Werkzeugen, wird jedoch aufgrund der unzureichenden Datenverfügbarkeit zur lokalen Situation eine aufwändige Datenerfassung benötigt. Einer integralen Planung folgend stellt die aus der umfänglichen Kenntnis der Situation, auch bezüglich des großmaßstäblichen Kontextes, erkannte Problemstellung eine fundamentale Vorrausetzung zum adäquaten Ansetzen zielgerechter Lösungskonzeptionen . Oftmals werden anstelle einer damit implizierten problemgerechten Zielplanung unreflektierte Quartierskonzepte und Maßnahmenbündel angegangen und in der Umsetzung dann notdürftig an die lokalen Gegebenheiten angepasst. Über frei verfügbare (bundesweite) Datenquellen stehen zwar Informationen zur lokalen Situation zu Verfügung, jedoch fehlen hierzu derzeit noch einfach zu bedienende Hilfsmittel.

Damit unterschiedliche Konzepte an verschiedenen Orte vergleichbar gemacht werden können, setzt im Rahmen von Forschungsprojekten eine Werkzeugentwicklung an, welche das Erstellen eigener Umfeldanalyse und Möglichkeiten des kommunalen Benchmarks unterstützt. Ein prototypisch umgesetztes, freiverfügbares Analysewerkzeug soll es den (technisch unversierte) kommunalen Akteuren ermöglichen zu ihren selbstständig aus den offenen Datenquellen zusammengestellten Datensätze grafische Aufbereitungen und Gegenüberstellungen anzufertigen.

Keywords: Dynamisch, grafische Auswertung, Umfeldanalyse, Benchmarking, Monitoringwerkzeuge, Indikatorenvergleich

2 EINLEITUNG

Durch globale Kontextfaktoren wie die Klimakrise getrieben, mit lokalen Entwicklungen wie dem demografischen Wandel konfrontiert und zugleich mit klammen Kassen ausgestattet steigt der Handlungsdruck auf die Kommunen sich an eine zukünftig stark veränderte Umwelt anpassen zu müssen.

Ein wesentlich bestimmender Faktor bei der Entwicklung situationsgerechter Konzepte besteht in der fundierten Kenntnis der lokalen Situation. Hier gilt es eine Vielzahl von verschiedenen Informationen aus verschiedensten Bereichen zu einem ganzheitlichen Bild der Situation zusammenzustellen, um auf Grundlage einer dadurch ermöglichten holistischen Sicht auf die bebaute Umwelt und die sie belebende Bevölkerung, die situationsgerechten Zielstellung erkennen zu können und entsprechende zukunftsweisenden Maßnahmen zu ergreifen. Dabei sieht sich die Stadtplanung angesichts der fortschreitenden Digitalisierung in unterschiedlichen Geschwindigkeiten in den verschiedenen Bereichen vor die Herausforderung gestellt, die richtigen zielgerechten IT-gestützten Hilfsmittel zur Verarbeitung der Informationsvielfalt einzusetzen. Hinzu kommt, dass sich diese Informationen stetig vor dem Hintergrund komplexer werdender Planungsaufgaben beispielsweise in den Handlungsfeldern einer energieeffizienten und nachhaltigen Quartiersentwicklung diversifizieren.

Zudem birgt eine jeweils situative, sich sehr heterogen darstellende Datenverfügbarkeit und -qualität bei der Anwendung der Tools oftmals große Unsicherheit. Dadurch wird auch die durch die IT-gestützen Werkzeuge designierten Hilfestellungen bezüglich der Lösungsqualität beieinträchtigt. Um diesem entgegenzuwirken wird ein (unverhältnismäßig) hoher Datenerfassungs- bzw. Datenaufbereitungsaufwand erforderlich. Gerade die auf Grundlage einer umfänglichen Kenntnis der gegebenen Situation sowie ihres großmaßstäblichen Kontextes erkannte Problemstellung stellt eine fundamentale Vorrausetzung zum adäquaten Ansetzen zielgerechter Lösungskonzeptionen im Sinne einer Integralen Planung dar (vgl. Dörner,

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

2003). Hierbei stehen insbesondere kleinere Kommunen vor dem Problem sich keine kostenintensiven und aufwändigen Datenerhebungen und -auswertungen von externer Hand leisten zu können, um somit ihrem Vorgehen eine problemorientierte Zielplanung voranstellen zu können. Des Weiteren mangelt es aufgrund der schmalen Personaldecke mit wenig divresifiziertem Fachpersonal in den Kommunen an eigenen Experten zur selbstständigen Handhabung der datentechnischen Grundlagen. Um nun diesen kleinen und mittelgroßen Kommunen trotz fehlender Fachexpertise ganzheitliche Situationsanalysen zu ermöglichen, fehlen derzeit noch Planungshilfsmittel, die bereichsübergreifende, komplexe Fragestellungen mittels frei verfügbaren Daten erleichtern. Dabei stehen diese Informationen zu den Kommunen in verschiedenen offen zugänglichen (bundesweiten) Datenbezugsquellen (vgl. beispielsweise Zensus-Daten oder Kommunaldaten der Bertelsmann Stiftung) zur freien Verfügung bereit.

In der Praxis fehlt es somit oftmals nicht generell an einer Datengrundlage, sondern an (IT-gestützten) Hilfsmitteln, die mit analytischen Methoden eine ungünstige Ausgangslage von lücken-, fehlerhaften oder nur aufwändig erfassbaren Daten zu überwinden helfen. Gerade diese Hilfestellung für eine ganzheitliche Bestandsanslyse zur Problemerfassung der vorhandenen Situation ist jedoch wichtig, da ohne sie die Gefahr besteht direkt mit dem oftmals unreflektierten Umsetzen von woanders bewährten Quartierskonzepten und Maßnahmenbündeln zu beginnen. Indem diese Ansätze jedoch für andere Orte entwickelt worden sind, können darauf aufbauende Planungen teilweise oder ganz am vorhandenen Bedarf vorbei gehen. Im Rahmen einer, im ungünstigsten Fall dann mittels „nachträglichen“ Anpassens auf eine lokale Situation bewerkstelligten Zielplanung kommt generell erschwerend eine einseitige Sicht der Planenden auf entweder urbanes Stadt- oder rurales Landleben hinzu, die einer sich im Wandel befindlichen Lebenswelt der Bevölkerung nicht mehr gerecht wird (Graf & von Both, 2019).

Um Potentiale von planungsmethodisch optimierten Vorgehensweisen vor dem Hintergrund eines Umgangs mit den offen verfügbaren Datengrundlagen aufzeigen zu können, werden in diesem Beitrag konkretisierte Problemstellungen aufgriffen, die im thematischen Fokus eines laufenden Verbundprojekt stehen. Bezugnehmend auf eine sich auch durch digitale Medien inzwischen angleichenden Lebenswelt der Bevölkerung, werden tradierte Planungsvorstellungen im Projekt mit dem Konstrukt einer Transformativen Zelle (TZ) zur Überwindung konträrer Planungsichten auf die Stadt bzw. das Land hinterfragt (ebd.). Von den verschiedenen Projektpartnern setzen im thematischen Projektrahmen an unterschiedlichen Orten Umsetzungskonzepte zu einer TZ an. Übergeordnete Fragestellungen zu den lokalen Randbedingungen der Umsetzungsorte bilden den Problemkontext auf dem in diesem Beitrag eingegangen wird. Zum einen stellt sich dabei die Frage nach der skalenübeergreifende Einordnung des Standorts in die Gesamtentwicklung des Umfelds und zum anderen ob und wie sich die in den unterschiedlichen (lokalspezifischen) Handlungsfeldern angesetzten Konzepte auf andere Orte übertragen lassen.

3 METHODIK

3.1 Zielstellung

Für die im Rahmen der Forschungsarbeit konkretisierte Problemstellung werden in diesem Beitrag eine entsprechende Lösung vorgestellt. Dabei bestand das Ziel darin ein IT-gestütztes Hilfsmittel zu entwickeln, dass die Planenen bei der Analysearbeit im Umgang mit den offenverfügbaren Datensätzen unterstützt. In einfach zu bedienenden Werkzeugen des Hilfsmittels soll es Planenden ermöglicht werden jeweils eine indikatorbasierte Analyse auf der von ihnen selbstverwalteten Datengrundlage durchzuführen und das Ergebnis anschaulich aufzubereiten. Durch eine selbstständige Erweiterung der Datensätze mit lokalspezifisch erhobenen Informationen soll generell dabei auch eine weitere Konkretisierung der Analysen ermöglicht werden. Vor dem Hintergrund der beiden im Forschungsprojektrahmen aufgezeigten Problemfälle sollen mit entsprechenden Werkzeugentwicklungen konkrete Hilfestellungen erstellt werden. Zum einen soll ein Werkzeug prototypisch entwickelt werden, das die Darstellung eines Aspekts der lokalen Situation im Kontext seiner zeitichen Entwicklung sowie im Bezug zu entsprechenden Ausprägungen im räumlich übergeordneten Kontext (Stadt, Kreis, Region, Land etc.) ermöglicht. Mit einem weiteren Werkzeug sollen zum anderen für ein Benchmark lokaler Aspekte im Vergleich zu deren Ausprägung in Orten mit ähnlichen Ausgangslagen ermöglicht werden.

3.2 Lösungsansatz

Gemäß der Zielstellung stellt sich der Planende zunächst für seine lokale Situation eine Datenbasis aus frei verfügbaren Daten zusammen. Den Ausgangspunkt hierfür bildet die Bertelsmann Stiftung mit ihren webbasiert, freizugänglichem Wegweiser Kommune als Datenbezugsquelle (Bertelsmann Stiftung, 2019). Hierbei handelt es sich um eine umfängliche Datensammlung thematisch kategorisierter Indikatoren für alle Kommunen[1] in Deutschland. Durch jährliche Erhebungen existieren hier bereits langjährige Datenhorizonte, auf die die Planer in frühen Projektphasen beim Erfassen der lokalen Situation zurückgreifen können. Besonders hervorzuheben sind erste Auswertungen zu Kommunen in Form von kommunalen Profilen sowie vereinfachte Prognoseinformationen. In langen Listen können Indikatoren zu bestimmten Themen zur eigenen nichtkommerziellen Verwertung bezogen werden. Durch die strukturiert abrufbaren Daten ist dem Planenden hierdurch bereits die Möglichkeit gegben die Zusammenstellung der Daten gemäß seiner Fragestellungen zu verändern und beispielsweise durch eigene erhobene Jahreswerte für einen Indikator anzupassen. Darüberhinaus kann er generell auch die Datenbasis nutzen um diese mit weiteren selbst erhobenen Daten bzw. Referenzwerte aus anderen Kommunen zu ergänzen.

Auf dieser selbstverwalteten Datenbasis können gängige Analysemethoden, wie beispielsweise ein interkommunales Benchmark, in einfach zu bedienenden, IT-gestützten Instrumenten aufgebaut werden. Der Planende kann damit dann problemorientiert bei der lokalspezifischen Grundlagenermittlung für die bedarfsgerechte Entwicklung von Stadtplanungskonzeptionen unterstützt werden.

Zum Beispiel beginnt ein strukturierte Vorgehen beim Aufbauen einer Analyse der lokalen Situation mit einer Thesenbildung zur Darstellung eines übergeordneten Sachverhalts. Als Grundlage hierzu liegen eine Vielzahl von Indikatoren zu einzelnen Sachverhalten in verschiedenen Themenfeldern eingeordnet vor. Jahresreihen dieser Indikatoren können bereits zweckgebundene Einzelaspekte aufzeigen wie eine temporale Entwicklung der Bevölkerungsanzahl einer Kommune. Durch Hinzunahme eines zweiten Indikators zur Bevölkerungdichte kann hierauf aufbauend nun beispielsweise die These aufgebaut werden, dass in der Beziehung der beiden Indikatoren ein Urbanisierungsgrad der Kommune aufgezeigt werden kann. Um für diese Art von Thesen des Nutzers ein entsprechendes Auswertungsdiagramm zu erstellen, werden die beiden Indikatorenwerte jeweils auf der X- und Y-Achse eines Diagramms aufgetragen und damit ein Relationswert der beiden Indikatoren angezeigt. Beim weiteren Aufbereiten der Diagrammdarstellung können die Planenden mit zwei Ansichts-Modi in der Verdeutlichung des von ihnen designierten Sachverhaltes unterstützt werden: Wie in Abbildung 1 dazu zum einen im ersten Anwendungsfall verdeutlicht, lassen sich die in Beziehung stehenden Indikatorenwerte einer Kommune für jeden Jahreswert als Entwicklungsgrafik darstellen. Zum anderen können die Relationswerte der beiden Indikatoren durch die Hinzunahme entsprechender Werte vom weiteren Kommunen für jeden Jaheswert in einem Benchmarkdiagramm vergleichend dargestellt werden (vgl. Anwendungsfall 2, Abbildung 1). Indem diese einzelnen jahresbezogenen Diagramme dann in einer Sequenz zusammengestellt werden, können sie in einer Abfolge als „dynamisches Benchmark“ betrachtet, wiederum den zeitlichen Verlauf des Aspekts im kommunalen Vergleich verdeutlichen.

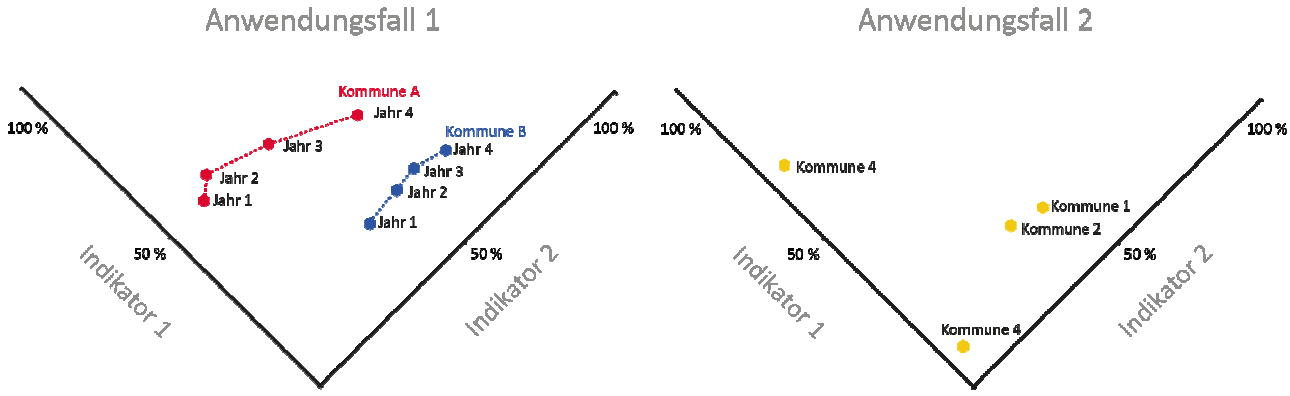

Abbildung 1: Anwendungsfälle einer indikatorbasierten grafischen Auswertung im Analysehilfsmittel

[1] > 5.000 Einwohner

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Der Lösungsansatz sieht eine als Desktop-Applikation angesetzte prototypische Implementierung einer Softwarelösung vor, die auf die durch die Planenden selbstverwaltete Datenbasis zugreift und sie beim (nachvollziehbaren) Ansetzen von Auswertungen der zusammengestellten Daten unterstützt. Für indikatorenbasierten Aspekte in ihren Analysen können die Planenden dabei jeweils die beiden oben beschriebenen Diagrammarten (Entwicklungs- bzw. Benchmarkdiagramm, vgl. Abbildung 1) mit dem Hilfsmittel erstellen. Sowohl als exportierte Bilddateien sowie auch auf dem Bildschirm dynamisch angezeigt, können sie die Diagramme dann in ihren Planungsprozessen weiterverwenden.

3.3 Entwicklungskontext

Die Entwicklung des im Weiteren vorgestellten prototypischen Analysehilfsmittels gliedert sich in zwei Stufen. Eine erste Version wurde in einem abgeschlossenen, vom Bildungsministerium (BMBF) in der Initiative Energieeffiziente Stadt geförderten Begleitforschungsprojekt (vgl. Rexroth & von Both, 2016) entwickelt. Den in einem BMBF-geförderten Wettbewerb teilnehmenden Kommunen diente es dabei beim Vergleich ihrer energetischen Stadtquartierskonzeptionen untereinander (Benchmark). In Abbildung 2 wird in einem Screenshot ein kommunales Benchmark exemplarisch dargestellt, das mit diesem Prototypen „Systemische Information und Analyse für die energieeffiziente Stadt“ (SIASG) erzeugt wurde.

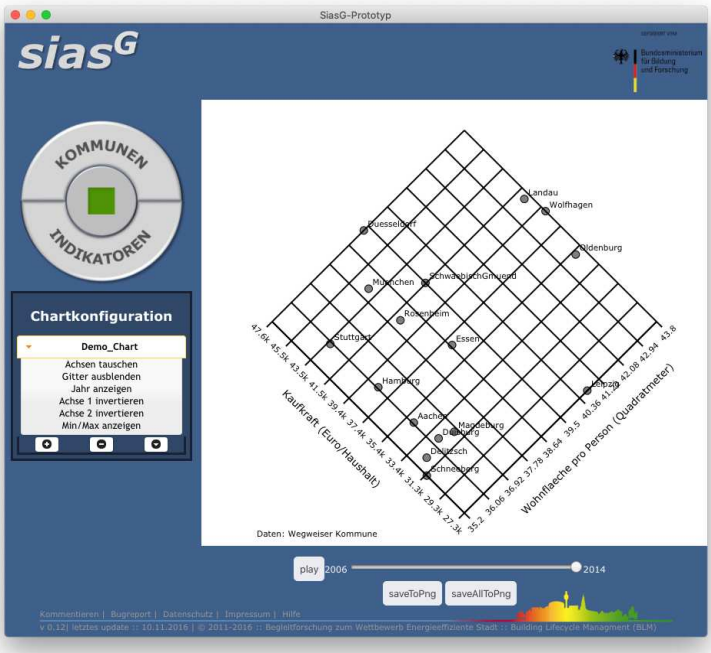

Abbildung 2: Prototyp zur grafischen Auswertung – Systemische Information und Analyse energieeffiziente Stadt (SIASG)

Eine auf dieser ersten Version des Werkzeugs aufbauende Weiterentwicklung des Prototyps „Systemische Analysen für Land und Stadt“ (SALSG) findet derzeit in einem laufenden Verbundprojekt statt, auf dessen Forschungskontext es angepasst wird. Dabei werden die bisher für die teilnehmenden Kommunen hinterlegten Informationen mit Möglichkeiten für die Anwender ersetzt, ihre eigenen Informationen in dem Werkzeug bearbeiten zu können.

4 UMSETZUNG

4.1 Technische Grundlagen und Methoden

4.1.1 Datengrundlage

Als Grundlage des Werzeugs dienen Daten mit Zeitreihen an soziodemografischen Indikatoren und weiteren Informtionen die jährlich im kommunalen Umfeld erhoben werden. Gerade mittelgroßen und kleinen Kommunen, für die eine Datenerhebung zu kostenaufwändig ist, bietet die Bertelsmann Stiftung mit dem Wegweiser Kommune (vgl. Bertelsmann Stiftung, 2019) unentgeltlich eine jährlich fortgeschriebene, umfängliche Datenbezugsquelle zu Informationen über die Kommunen in Deutschland.

Die Daten werden in Form einer Webseite zur Verfügung gestellt, in der sie strukturiert nach Kommunen bzw. Indikatoren in Zeitreihen angezeigt werden können. Darüber hinaus gibt es bereits erste Auswertungen in Form von vergleichbaren Kommunen-Steckbriefen oder kommunale Berichte zu größeren Kommunen. Ein einheitliches Dossierformat ermöglicht bezüglich der einbezogenen Indikatoren dabei einen Vergleich unter den verschiedenen Kommunen.

Um beispielsweise die soziale Lage einer bestimmten Kommune angezeigt zu bekommen, ermöglicht die Benutzerfläche des Wegweisers Kommune in drei Schritten die Auswahl geeigneter Indikatoren: Im ersten Schritt wird die Kommune bestimmt. Anschließend stehen mehrere Hauptthemen zur Verfügung. Unter dem Hautpthema „Ist-Zustand“ wird ein Analysethema wie beispielsweise „Soziale Lage“ ausgewählt. Der letzte Schritt ermöglicht es von einem Jahr bis hin zu allen erfassten Jahren den Zeitraum festzulegen. Alle in diesem Thema zusammengestellten Indikatoren werden im Hauptbereich aufgelistet und können auch einzeln dargestellt werden. In einer ersten Spalte mit dem Indikatorbezeichner können genauere Erhebungsinformationen eingesehen werden, gemäß dem gewählten Zeitraum schliessen daran für jedes Jahr weitere Spalten mit den entsprechenden Werten an. Bei einem einzelnen selektierten Indikator sind neben der tabellarischen Listung zudem einfache Auswertungen abrufbar, wie seine Entwicklung in der Zeitreihe. Bezugnehmend zum kommunalen Benchmark des im Beitrag vorgestellten Hilfsmittels (vgl. Kap. 3.2), können bis zu 10 weitere Vergleichskommunen ausgewählt werden. Dabei werden jeweils die Spalten zu den jährlichen Werten annotiert mit dem Kommunennamen aufgeführt.

Alle durch diese Schritte ausgewählten Datensätze zu einer Kommune können zur eigenen (nicht kommerziellen) Weiterverwertung in einem Tabellendokument exportiert werden. Dabei wird wie in der Oberfläche dargestellt in der ersten Spalte der Indikatorbezeichner aufgeführt und in den weiteren Spalten dann jeweils dazu ein entsprechender Jaheswert.

4.1.2 Technologiewahl und technische Aspekte

Herausforderungen bei der Prototypentwicklung lagen in einer plattformunabhängigen Gestaltung der Desktopanwendung sowie einer Wahrung der Erweiterbarkeit bzw. Migrationsmöglichkeit in eine Web-Applikation. Durch Gestaltung der Architektur nach dem Entwurfsmuster Model View Controller (MVC) zur Gestaltung von skalierbaren Benutzerschnittstellen, konnten diese technischen Zielstellungen im Prototyp umgesetzt werden. Die Umsetzung der Benutzeroberfläche in HTML basiert hierzu auf frei verfügbaren Modulen und Bibliotheken, die spätere Migration des Prototyps in eine serverbasierte Web-Anwendung erlauben. Das Open Source Framework AngularJS mit den darin veranlagten Komponenten zum Umsetzen des MVC-Entwurfsmusters ermöglichte es die Javascript-basierten Nutzerinteraktionen im Rahmen von HTML zielgerecht zu Implementierten. Zur Umsetzung dieser auch in einem herkömmlichen Webbrowser bezüglich Skalierbarkeit in eine Webanwendung bedienbare Programmlogik als plattformunabhängige Desktopanwendung wurde die Open-Source Bibliothek von Electron verwendet. Sie baut auf der plattformunabhängigen Browserkomponente Chromium auf und bedient sich daher des Rendering-Engine zur Darstellung der in HTML und CSS designten Oberfläche auf dem Bildschirm. Zudem nutzt Electron die in der JavaScript-Laufzeitumgebung (V8) laufende Implementierung von der umfänglichen Komponenten-Bibliothek Node.js. Letztere bietet eine Vielzahl an offenen Javascript Komponenten, auch bezüglich Interaktionen mit (lokalem) Betriebssystem und dient verschiedenen Bestandteilen der Software als Grundlage, beispielsweise der Abwicklung von Dateisystemzugriffen, oder dem Zusammenspiel von Datenmodell und Ansichten.

4.2 Beschreibung des Werkzeugs und seiner Anwendung

4.2.1 Datenkonfiguration (Nutzerdatenaufbereitung für den Anwendungskontext)

Das Werkzeug wird „leer“ ausgeliefert, d.h. im Prototyp sind keine eigenen kommunalen Daten enthalten. Die Nutzer müssen die aus offen verfügbaren Datenquellen beschafften bzw. (selbsterfassten) Datensätze selber in eine vorgesehene Ordnerstruktur auf ihrem Betriebssystem einpflegen. Vor dem ersten Start der Anwendung werden hierfür Datensätze des Wegweiser Kommune Informationssystems der Bertelsmann Stiftung unverändert heruntergeladen oder an deren Struktur angelehnt eigene Datensätze erzeugt. Dabei ist es wichtig alle Zeitreihen der Indikatoren jeweils in einem Tabellendokument pro Kommune abzulegen und die gleiche Inhaltsstruktur (vgl. Abbildung 4) beizubehalten.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Eine übersichtliche Beschreibung der verschiedenen Stränge zur Datenaufbereitung, damit die Daten im Prototyp verwendet werden können, ist in den untenstehenden in BPMN abgebildeten Prozess (siehe Abbildung 3) dargestellt. Standardmäßig können die vorhandenen Datensätze des Wegweisers heruntergeladen und direkt verwendet werden. Dabei können die Nutzer jeweils einzeln bzw. gebündelt zu den Hauptthemen die Datensätze zu einer Kommune beziehen und in einem Tabellendokument die für ihre Analysen bedeutsamen Indikatoren zusammenführen. Darüberhinaus kann in einem ergänzenden Datenaufbereitungsstrang dieses kommunenspezifische Dokument um weitere, selbsterhobene bzw. aus anderen Datenbezugsquellen bezogene Indikatoren sowie entsprechende Jahreswerte erweitert werden. Prinzipiell können auch eigene Datenblätter zu Gebietskörperschaften neu angelegt werden, wie beispielsweise zu einer Kommune, weitere Stadtteile mit detaillierteren oder der Kreis bzw. die Region mit gemittelten Indikatorenwerten.

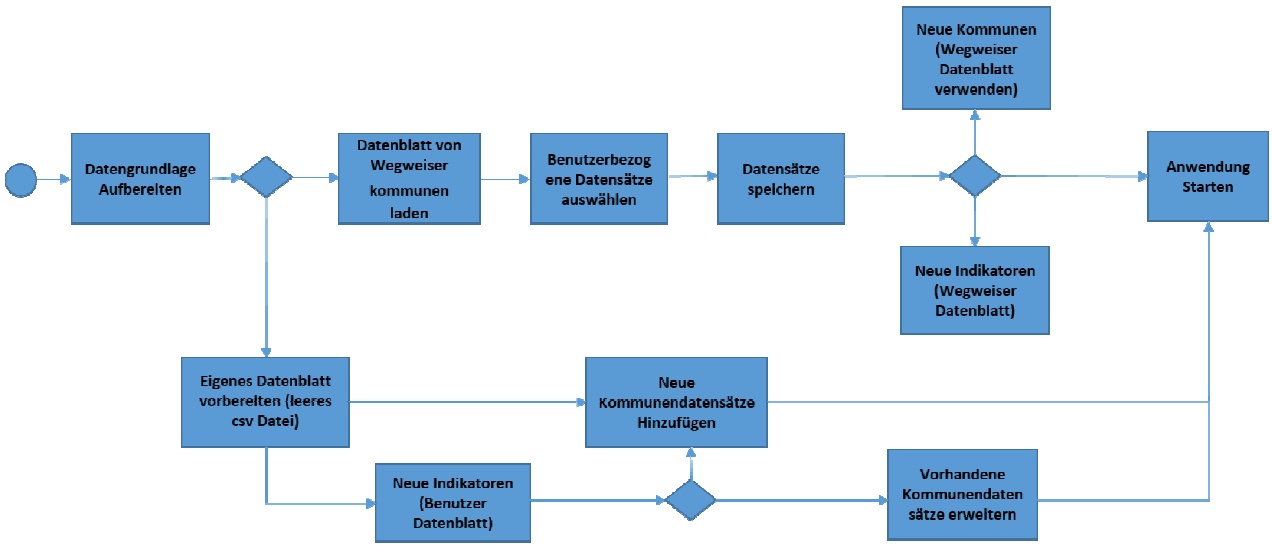

Abbildung 3: Prozessbeschreibung zur Datenaufbereitung der Kommunen

In Abbildung 4 wird ein Beispiel eines Tabellendokuments dargestellt, in dem auszugsweise Indikatoren des Wegweiser Haupthemas Demographischer Wandel sowie zwei eigene (rot markierte) Musterindikatoren die obligatorische inhaltliche Struktur der einzelnen Datensätze veranschaulichen. Neben dem dargestellten Hinzufügen neuer Indikatoren können auch nur Jahreswerte für bereits vorhandene Indikatoren eingepflegt werden.

Abbildung 4: Auszug einer (benutzerspezifisch angepassten) CSV-Datei der Bertelsmann Daten zu Aachen

Alle Daten die jeweils für eine Gebietseinheit auf die sich die beinhaltenen Indikatoren beziehen in einem eigenen Tabellendokument angelegt sind können von dem Prototyp berückichtigt werden. Damit bedeutungsvolle interkommunale Benchmarks bzw. Vergleiche zu lokalen Situationen in der Software aufbereitet werden können ist beim Aufbau der eigenen Datenbasis auf das Vorhandensein der gleichen Indikatoren respektive der gleichen Jahreswerte in den einzelnen Tabellendokumenten der gegenüberzustellenden Gebietseinheiten zu achten.

Alle benutzerspezifischen Daten werden generell auf dem Computer im Benutzerverzeichnis in einem Ordner „Data“ als Comma-Separated-Values (CSV) Tabellendokumente abgelegt bzw. erstellt und bearbeitet. Gemäß folgender Namenskonvention werden dabei die einzelnen Dokumente für das Einlesen in den Prototyp bezeichnet, damit aus den bedeutungsvollen Dateinamen die Metadaten zu den beinhalteten Datensätzen interpretiert werden können. Der Dateiname wird hierbei jeweils mit einem Unterstrich („_“)

getrennt zusammengestellt aus dem Namen der Gebietseinheit (Kommune usw.) optional gefolgt einer Spezifizierung der Daten, beispielsweise zum Anzeigen der Quelle und abschliessend ergänzt mit dem Zeitraum in Form der Jahre(sspanne) der beinhaltenen Indikatorenwerte. Eine Bezeichnung des Beispieldatensatzes der Kommune Achen mit Indikatorenwerten zwischen 2011 und 2013 könnte somit „Aachen_Musterdaten_2006-2018.CSV“ lauten. Mittels zwei entsprechender Musterdateien werden die für eine bedeutungsvolle Anwendung des Prototyps zumindest benötigten Daten für den Nutzer veranschaulicht. Darin sind jeweils zwei Indikatoren mit jeweils zwei verschiedenen Jahreswerten als Muster angelegt, die den Umfang benötigter Daten darstellen, damit alle designierten Programmfunktionen angewendet werden können.

4.2.2 Konzepte zur Benutzerführung

Vor der Beschreibung der einzelnen Ansichten und darin angesiedelten Nutzerinteraktionen werden im Folgenden die Grundkonzepte der Bedienoberfläche des Prototyps erläutert. Die Benutzeroberfläche ist dabei, wie in Abbildung 5 abgebildet, in drei Funktionsbereiche gegliedert:

(1) Das „Steuerrad“ (links oben) aktiviert die Zugriffe auf die Teilfunktionen der Anwendung. Diese werden im Hauptfenster angezeigt.

(2) Das Verwaltungsfenster (links unten) ermöglicht es, kontextbezogene Einstellungen zu treffen oder diese zu verwalten.

(3) Das Hauptfenster (rechts) zeigt die aktuelle Teilfunktion an, beispielsweise die anpassbaren Konfigurationseinstellungen vom Benutzer zur Kommunen- bzw. Indikatorenauswahl, oder die Ergebnisse/Animation des Benchmarkingergebnisses.

Zur Gewährleistung aller erforderlichen (auf einander aufbauenden) Konfigurationen – Projekt auswählen, Kommune(n) auswählen, Indikatoren auswählen – bevor den Anwenderinnen die Anzeige eines entsprechenden Ergebnisses ermöglicht wird, ist erst nach dem erfolgreichen Durchlauf der einzelnen Einstellungen in den Detailkonfigurationsansichten das zentrale Steuerrad-Element mittels Abspielsymbol gekenzeichnet und zur Navigation in die Ergebnisansicht freigeschalten. Wenn bereits entsprechende „vorkonfigurierte“ Projekte vorhandenen sind kann über dieses zentrale Element auch „abgekürzt“ in einen darin konfigurierten Analysefall gesprungen werden (vgl. Kap. 4.2.3).

Abbildung 5: Oberflächeneinteilung und Steuerungselemente

4.2.3 Projektverwaltung (Start- und Projektansicht)

Beim Starten des Prototyps wird im Hauptfenster eine Willkommens-Meldung angezeigt (Abbildung 3) und der Benutzer befindet sich damit bereits in der Projektverwaltungsansicht In dieser Ansicht wird im Verwaltungsfenster eine Liste alle verfügbaren Projekte (vgl. Abbildung 3) angezeigt. Ein Musterprojekt ist standardmäßig bereits angelegt (vgl. Musterdaten in Kap. 4.2.1). In der Projektliste kann ein Projekt zur Bearbeitung ausgewählt werden und wird als aktuelle Selektion hervorgehoben (fett und orange unterlegt) in der Liste dargestellt. Durch die unterhalb des Fensters befindlichen Schaltflächen können Projekte angelegt, dupliziert und umbenannt, oder auch gelöscht werden. Neben dem Bezeichner können einem Projekt in

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

dieser Ansicht eine Beschreibung zugeordnet werden. Zu Austausch- bzw. Archivierungszwecken können die Projekte in die Liste ex- bzw. importiert werden, dazu werden die Projektmetadaten zusammen mit der Datenbasis in einer komprimierten Datei verpackt.

Vor der Auswahl eines Projektes sind die Schaltflächen des Steuerrades nicht freigeschalten (ausgegraut). Bestimmt durch den Stand der Detailkonfigurationen in einem selektierten Projekt werden dann die Steuerad-Elemente freigeschalten. Dabei beinhaltene Konfigurationsmöglichkeiten (im Projekt gespeicherte Einstellungen sowohl in der Kommunen- als auch der Indikatorkonfiguration; vgl. Kap. 4.2.4 bzw. Kap. 4.2.5), die wiederum den Konfigurationsstand des selektierten Projekts bestimmen können jeweils einem der folgenden drei Fälle zugeordnet werden:

(a) Es existiert jeweils nur eine Einstellung zu der Kommunen- sowie zu der Indikatorauswahl, daher kann über das zentrale Steuerrad-Element direkt zur Ergebnisansicht mit der aus der Kombination der beiden Einstellung erstellten Analysegrafik navigiert werden.

(b) Es existieren drei oder mehr gespeicherte Einstellungen, dabei jeweils mindestens eine Einstellung zu der Kommunen- sowie zu der Indikatorauswahl, durch Betätigen des zentralen Steuerrad-Elements werden in einem Kontextmenu alle möglichen Kombination der beiden Einstellungsmöglichkeiten zur Navigation in eine entsprechende Ergebnisansicht präsentiert.

(c) Existiert keine Einstellung oder nur einseitig – entweder in der Kommunen- oder der Indikatorkonfigurtion – dann ist das zentrale Steuerrad-Element nicht navigierbar (ausgegraut) und es müssen zunächst die Detailkonfigurationen druchgeführt bzw. vervollständigt werden.

Wenn beispielsweise ein (neuangelegtes) unvollständig konfiguriertes Projekt in der Projektliste selektiert wird (vgl. Fall 3) kann ein Analyseergebnnis erst angezeigt werden, wenn die erforderlichen Einstellungen zur Auswahl von mindestens einer Kommune (vgl. Kap. 4.2.4) sowie von mindestens zwei Indikatoren (vgl. Kap. 4.2.5) über die entsprechend freigeschaltenen Schaltflächen des zentralen Steuerrads. Prinzipiell kann dabei beliebig zwischen allen drei Konfigurationeansichten des Prototyps gewechselt werden, alle darin jeweils gemachten Änderungen sind direkt wirksam und entsprechend geänderte Projekte bzw. Einstellungen lokal abgespeichert.

4.2.4 Auswahl der Kommune(n) (Kommunenkonfigurationsansicht)

Durch das Betätigen der Schaltfläche „Kommunen“ wechseln die Anwender in die Kommunenkonfiguration, diese Ansicht wird durch das (gelb) hervorgehobene Steuerrad-Element angezeigt (vgl. Abbildung 6).

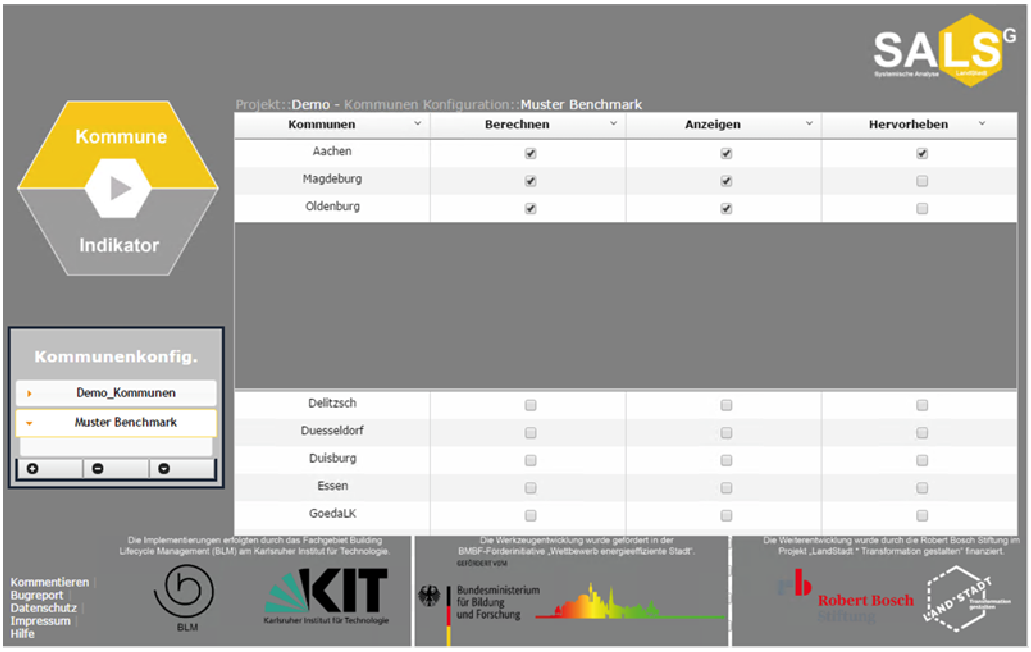

Abbildung 6: Auszug aus der Kommunenansicht

Sind im selektierten Projekt bereits Einstellungen, wie beispielsweise eine Auswahl von zwei zu vergleichenden Kommunen, in der Konfiguration abgelegt, werden diese im Verwaltungsfenster gelistet und

können direkt als ein erster Teil der Konfiguration einer intendierten Auswertung selektiert werden. Mit der Selektion einer Kommuneneinstellung in der Auswahlliste, ist sie bezüglich einer aktuell zu konfigurierenden Auswertungsgrafik aktiviert, d.h. wenn bereits eine Einstellung in der Indikatorkonfiguration aktiviert wurde (vgl. Kap. 4.2.5) kann direkt über das nun freigeschaltene Steuerrad-Element in die Ergebnisansicht gewechselt werden. Durch die weiteren Schaltflächen + und – unterhalb der Auswahlliste können neue Einstellungen hinzugefügt bzw. Selektierte gelöscht werden. Im Hauptfeld der Konfigurationsansicht werden für jede in der Auswahlliste selektierte Einstellung rechts alle in den Datensätzen verfügbaren Kommunen gelistet, die vom Anwender zusammengestellt werden können. Die eigene Zusammenstellung wird dabei in der oberen Hälfte der Listung (Abbildung 6) angezeigt. Neben einer Checkbox „Berechnen“ zum Hinzufügen in die Zusammenstellung, sind jeder Kommune weitere Checkboxen bezüglich ihrer grafischen Darstellung in der Auswertungsgrafik zugeordnet. So können die Werte Kommune generell über die Checkbox „Anzeigen“ ein und ausgeblendet werden oder gegenüber anderen Werten mit der Checkbox „Hervorheben“ farblich markiert werden. Eine Mehrfachauswahl ermöglicht den Anwendern eine individuelle Gestaltung der in der Einstellung zusammengestellten Kommunen für die grafische Auswertung.

4.2.5 Auswahl der Indikatoren (Indikatorkonfigurationsansicht)

Durch das Betätigen der Schaltfläche „Indikatoren“ wechseln die Anwender in die Indikatorenkonfiguration, durch das (gelb) hervorgehobene Steuerrad-Element wird dieser Wechsel den Anwendern angezeigt (vgl. Abbildung 7). Analog zur Kommunenkonfiguration werden gegebenfalls im selektierten Projekt bereits vorhandene Einstellungen, in denen jeweils zwei Indikatoren zusammengestellt abgelegt wurden, im Verwaltungsfenster gelistet und können direkt als ein zweiter Teil der Konfiguration einer intendierten Auswertung selektiert werden.

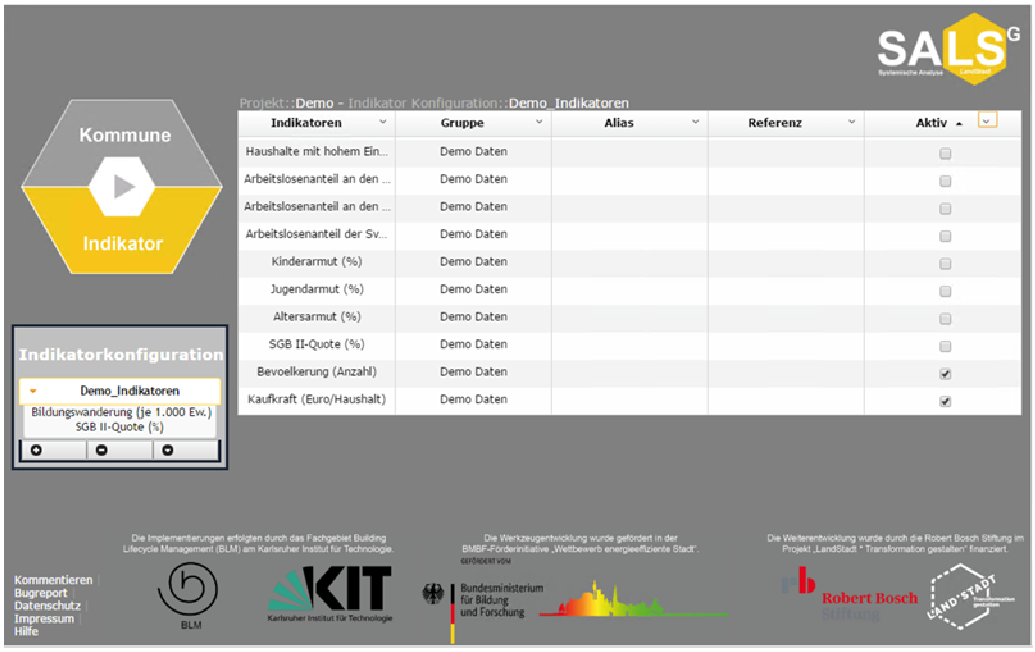

Abbildung 7: Auszug aus der Indikatorenansicht

Somit kann bei gegebener aktiver Einstellung in der Kommunenkonfiguration mit der Selektionen einer Indikatoreneinstellung in der Auswahlliste direkt über das nun freigeschaltene Steuerrad-Element in die Ergebnisansicht (vgl. Kap. 0) gewechselt werden. Zum Erstellen bzw. Entfernen von Einstellungen stehen entsprechende Schaltflächen unterhalb der Auswahlliste bereit. Zur jeweils selektierten Einstellung werden im Hauptfenster tabellarisch alle in den Datensätzen vorhandenen Indikatoren angezeigt. Für die Auswertung sind vom Anwender darin dann zwei Indikatoren zusammenzustellen, in dem die entsprechende Checkbox „Aktiv“ angehakt und somit in der Einstellung abgelegt wird.

4.2.6 Auswertung und Ergebnisse anzeigen (Chartansicht)

Wenn eine Auswertung vollständig durch das Aktivieren sowohl einer Kommunen- wie auch einer Indikatoreneinstellung in den Konfigurationsansichten konfiguriert ist, wird die zentrale Schaltfläche im

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Steuerrad freigeschalten und als „Abspiel“ Symbol dargestellt (vgl. Abbildung 7). Darüber kann in den Ergebnisansicht (vgl. Abbildung 8) gewechselt werden. Im Hautbereich wird das um 45 Grad gedrehte Diagramm angezeigt, bei dem jeweils ein Indikator die X-Achse und einem Indikator die Y-Achse zugewiesen ist. Die Darstellung kann durch verschiedene Anzeigeoptionen im Verwaltungsfenster justiert werden. Generell kann dabei zwischen den beiden Ansichtsmodi eines Eintwicklungs- bzw. Benchmarkdiagramms (vgl. Kap. 3.2) ausgewählt werden. Zudem können beispielsweise die dargestellten Indikatorenwerte im Diagramm invertiert werden, wobei die hohen Werte zum Achsenschnittpunkt hin ausgerichtet werden. Äquivalent zu den Einstellungen in den Konfigurationsansichten können für ein konfiguriertes Auswertungsdiagram jeweils zusammengestellte Ansichtsoptionen in verschiedenen Einstellungen zur Darstellung des Charts angelegt, gelöscht, umbenannt bzw. ex- und importiert werden.

Während die ganze Zeitreihe im Entwicklungmodus im Chart angezeigt wird, können im Benchmarkmodus mittels eines Schiebereglers unterhalb des Diagramms die einzelnen Jahreswerte im Diagramm dargestellt werden. Darüber hinaus ermöglicht eine Schaltfläche „play“ ein dynamisches Benchmark zu vergleichender Kommunen, in dem die einzelnen Jahreswerte nacheinander dadurch in einer Animation abgespielt werden können. In einen nach dem Projekt benannten Ordner im Nutzerverzeichnis können sowohl alle Einzelgrafiken der Animation wie auch jede einzeln navigierte Diagrammansicht als Bilddatei im PNG Format gespeichert werden.

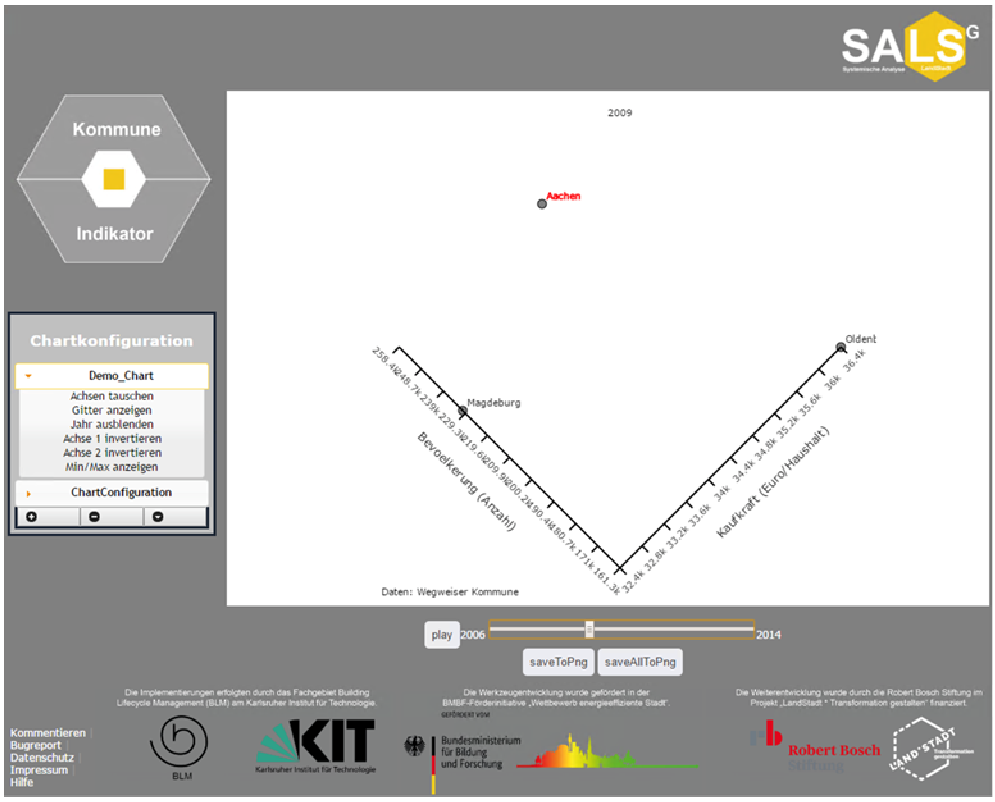

Abbildung 8: Auszug aus der Analyseansicht

5 ZUSAMMENFASSUNG

Im Beitrag wird ein einfach zu bedienendes IT-gestütztes Hilfsmittel vorgestellt, das Kommunen unterstützen soll sich an den offen verfügbaren Datenquellen beim Analysieren ihrer lokalen Situation bedienen zu können. Im Rahmen von zwei Forschungsprojekten wurde eine prototypische plattformunabhängige Software entwickelt und frei zur Verfügung gestellt, mit der sich die Anwender auf Basis ihrer selbstverwalteten Datensätze eigene Auswertungsdiagramme für ihre Kontextanalysen zusammenstellen können. Neben dem Aufbereiten von jeweils zwei in Beziehung gesetzen Indikatoren entlang der vorhandenen Jahreswerte zur Verdeutlichung einer Entwicklung, können auch unter Hinzunahme der Werte weiterer Kommune interkommunale Vergleiche angestellt werden. Indem diese jeweils für die Jahreswerte in einer Sequenz abgespielt werden können wird zudem ein „dynamisches“ Benchmark durch das Werkzeug

ermöglicht. Für Weiterverwendung in der Planung können alle erzeugten Diagramme als Bilddateien exportiert werden.

1 ABSTRACT

The research project called Smart Through Gender+ aims to support a gender+ appropriate urban planning and investigates on how new GIS based spatial planning tools can assist analysing the available data. In this context, gender groups are not only determined by sex, but by further factors which are considered to shape a person's urban routines.[1] Those groups are referred to as gender+ groups. For the case study area of Linz, a medium sized city in Austria, data from different sources like official statistics (Statistics Austria), Open Government Data (OGD), OpenStreetMap (OSM), Foursquare and TomTom have been evaluated. The focus is on data about infrastructure, services and facilities that are crucial for daily routines and the everyday life patterns of certain gender+ groups. The analysis is centred upon the principle residence of the citizens. This data is used to correlate supply and demand, deficits and potentials.

Based on the "city for all" approach, different gender+ groups and their specific spatial demands were identified in the course of the research project. This paper demonstrates the creation of gender+ specific supply and demand maps. For increased readability and comparability, a unique key performance indicator (KPI) was developed, which evaluates the appropriateness of the urban space to the needs of a specific gender+ group. This KPI set is a combination of spatial, infrastructural and demographic features, the classification is based on median values.

The resulting maps 1) express the current situation highlighting especially areas where the current infrastructure offer, and the available functions and facilities show need for improvement and 2) expel areas which possess the potential for an increased demand due to an already existing infrastructure for a specific gender+ group. Generally speaking, the resulting maps facilitate planning decisions within given spatial circumstances, which might range from easily adjustable services to fixed, immovable infrastructure.

The paper further discusses the different data sources and analysis methods, as well as the workflow of creating the maps of the current situation. The data basis as well as generalisation and simplification – both in terms of map creation and formation of gender+ groups – is critically reviewed. It finally concludes with the potential involvement of the demand and supply maps to display and validate future demographic development scenarios, as well as to support accompanying urban planning decisions. Decisively based on open data the developed tool shall be applicable to further Austrian cities, providing planners with a first overview of hotspot areas concerning gender+ appropriate design of a given city.

Keywords: Demographic Change, GIS Analyses, Urban planning tools, Open Data, Gender appropriate urban planning

2 INTRODUCTION

Cities are facing a fast change in their population, their needs and thus the requirements and demands. Social change processes and the global trend towards urbanization, as well as the current migration pressures on European cities are increasingly posing a major challenge to respond to the processes of change in urban planning. Although gender issues are considered important in some cities, they are often disregarded in planning practice due to the many other issues and the time and money spent on spatial research (especially in smaller and medium-sized cities). Cities always have been areas wherein different user groups, males, females, young and old, as well as different ethnic groups lived – and all of whom have different needs for urban functions. The current trend of migration even increases the requirement to cope with the different demands of citizens and to understand, which infrastructure and functions of a city have to be provided at which location. In this context, gender groups are not only determined by sex, but by further factors which are considered to shape a person's urban routines. Those groups are referred to as gender+ groups in this paper.

[1] such as age, household size, employment and country of origin

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Furthermore, the role of urban planning and urban planners in shaping cities and regions changes increasingly as new data sources allow a more detailed insight in the spatial distribution of functions and forms of cities. Since the 1970s, an increasing consideration of gender-specific aspects in planning theory and practice has become apparent (Damyanovic and Zibell 2013). Since the gender mainstreaming strategy was anchored in the Amsterdam Treaty, there has also been an increased implementation of this strategy and thus of gender-specific aspects in urban planning. Some cities e.g. Berlin, Vienna have published guidelines on the integration of gender issues in urban planning and development (Stadt Wien, 2013). Only four of the 12 bigger cities in Austria refer to the gender mainstreaming strategy, use gender-disaggregated data or point out the different demands of women and men (Reinwald et al., 2016).

Digital tools for the analysis of socio-spatial structures and for the simulation of measures and their effects are increasingly used in urban planning. These tools though lack the integration of gender and group-specific aspects. Gender-sensitive urban planning is, as one of the basic principles, dependent on gender-specific disaggregated data.

3 SMTG+ PROJECT AND CASE STUDY LINZ

The project "SmartThroughGender+" (SMTG+) develops solutions for this, it investigates on how new GIS based spatial planning tools can assist analysing the available data. Traditional planning tools, such as local development concepts, have difficulty coping with the rapid changes and aligning goals and measures with long review periods. "SmartThroughGender+" aims in integrating gender+ aspects into a toolset to support urban planning. The overall objective of the project is a Proof of Concept if this toolset consisting of (quantitative) digital analysis and simulation tools as well as (qualitative) instruments from urban and landscape planning, taking into account gender+ specific requirements, enables to support gender+ sensitive urban planning. Thus, on the basis of a case study in the city of Linz (Austria), it examines based on commonly available data if and how indicators and characteristics can be developed to enable a (partially standardized) "rapid assessment" of social and spatial structures while taking the gender+ approach into account. SMTG+ develops quantitative tools on different spatial resolutions. One is developed at the overall level and a cell resolution of 250m*250m for the entire city to investigate “hot spots”, which possess an above average demand for gender+ sensitive urban planning. This quantitative tool is based on statistical data from the national statistic agency (Statistic Austria) and Open Government Data (OGD) and sources like OpenStreetMap (OSM), Foursquare and TomTom. The tool is implemented as a web application using R-Shiny. For a district, which was chosen based on the results of a GIS analysis and stakeholder judgement, a quantitative tool on the level of building blocks will be developed using Rhinoceros3D/Grasshopper and a parametric modelling concept. In order to validate, test and clarify the results at the overall level, a qualitative analysis is carried out at district level in which participatory statements are examined and proposals for measures are worked out (combination bottom-up and top-down). This qualitative analysis will also be combined on district level with the quantitative parametric design tool later. The project lasts till Mai 2021, thus in this paper we will focus on the already developed method for the GIS analyses at the overall (entire city) level and the first results and findings of the implementation into an interactive web application.

4 DATA SOURCES AND EVALUATION OF USE

In order to be able to carry out quantitative analyses at overall (entire city) level, different data sources were examined. The focus is on commonly available data to easily transfer the methodology to other cities. A good availability and standardised form of the data sets is essential for the automated processing and analysis of the data. In addition to the availability of the data covering a wide area, the relevance of the data and the implementation of updates is an essential requirement. Data sets which show the development in cities over a period of several years prove to be particularly helpful. In the presented project, demographic data and location data on selected uses were used for the analyses.

For the demographic information on the population the data of the national statistical agency (Statistics Austria) were used in a cell resolution of 250m*250m for the calculations. Here there is a wide range of different categories (family, household, population structure, ...), which represent the population structure on a grid available throughout Austria. In the analysis presented, data on age, gender, ethnicity, household size and marital status are examined. This information is available as bundled packages and can be purchased commercially on individually selected regions. The principle residence is used for the evaluation of

population distribution and accessibility of the daily infrastructure. The availability of everyday facilities close to the workplace is therefore not represented. The data source Statistics Austria has proved to be very suitable according to the demographic data for the application in the project and the transfer of the tool to other Austrian cities.

Location data was used to check the availability and accessibility of daily local supply. The following data sources were tested for their usability: TomTom, OpenStreetMap [OSM] and Open Government Data [OGD]. Location data is available in different geometrical forms [points, polygons] and therefore the usability of data depends on the usage. The supply of daily infrastructure (e.g. shops, education, social infrastructure) can be expressed geographically by points of interest [POI]. However, the sufficient supply of green spaces requires the outlines (polygons, areas) to include the size of the parks in the calculation.

For the analysis of points of interest, comparisons were made between different data sources. The different classification schemes within the data sets form a challenge for counting and comparing characteristics (Hochmair and Zielstra 2013). For the project the TomTom data was bought as points (POIs) data set and the road network as lines for the overall city level. The POIs are available for the overall city of Linz in 2018 with 5571 points and in 2019 with 5667 points. The structure of the data is organized by PACKNAME, in by LABELNAME and by SUBNAME as a clear description of the point information. By applying filters, selected uses from POIs can be included in the evaluation. This means the data is described in the first level (Package) Eating & Drinking, in the second level (Labelname) Café or Pub which is on the third level (Subname) differentiated in Café, Coffee Shop, Pub or Empty.

PACKNAME	LABELNAME	SUBNAME	COUNT
Eating & Drinking	Café or Pub	Café	46
Eating & Drinking	Café or Pub	Coffee Shop	3
Eating & Drinking	Café or Pub	Pub	20
Eating & Drinking	Café or Pub	Empty	40

Table 1: Example on Structure of TomTom data

It was determined that not all POIs contain information in the SUBNAME, this affects that filtering POIs in the third level can cause a loss of data (POI). The percentage distribution of POIs on the PACKAGES also shows that the focus is on business (34.3%) and shopping (31.3%). The necessary basic health care is represented by 10.3% of the POIs and the food & drink category by 9.8%.

The advantage of the open source dataset of OpenStreetMap [OSM] is, a worldwide availability of data. However, the data is created by a user community in a different level of detail and is not validated by the providing company like TomTom. Hence the inclusion of this OSM POIs in the analyses can be beneficial in some applications.

The amount of pharmacies in Linz can be well compared among the different data sources. The lower Figure 1 shows the distribution of pharmacies in Open Government Data, OpenStreetMap and TomTom of the currently available datasets.

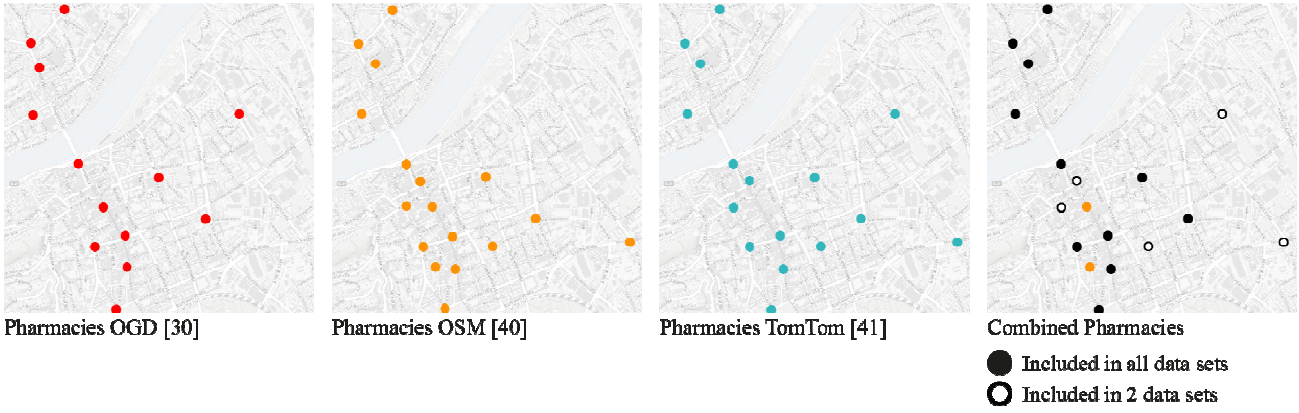

Fig. 1: Distribution of Pharmacies [POI] in Linz – Open Government Data, OpenStreetMap & TomTom © AIT

A comparison of the data sets showed that not only the location of the point data varies, but also the number of POIs in the urban area. For the general accessibility in a 250m raster the geographically exact location on

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

a few meters variance is negligible. However, the completeness of the data sets is an essential quality criterion. This insight raises the need for validation of the data within the research project which as a necessary step for a representative statement of the analyses. A detailed documentation of the processing and integration steps must be done in order to enable an optimized work when transferring the method.

The analysis of the polygons (e.g. green areas and open spaces) was based on the official zoning data by Open Government Data [OGD]. The dataset contains the polygons by function and therefore provides information about the area coverage of urban green areas for the population. For the calculation of the supply of open spaces, not only the distance but also the size, type and quality of the open spaces are relevant.

5 GENDER+ SPECIFIC SUPPLY AND DEMAND

The main idea is to combine the demand based on the spatial distribution of the different gender+ groups, with their needs regarding infrastructure as well as green and open spaces distribution. This means a combination of three factors so-called scores. A demographic score, an infrastructure score and a spatial score (green and open space score). All together -the combination of three single scores- was integrated to the so-called gender+ score, a unique key performance indicator (KPI) to investigate how the demand and supply matches Figure 2.

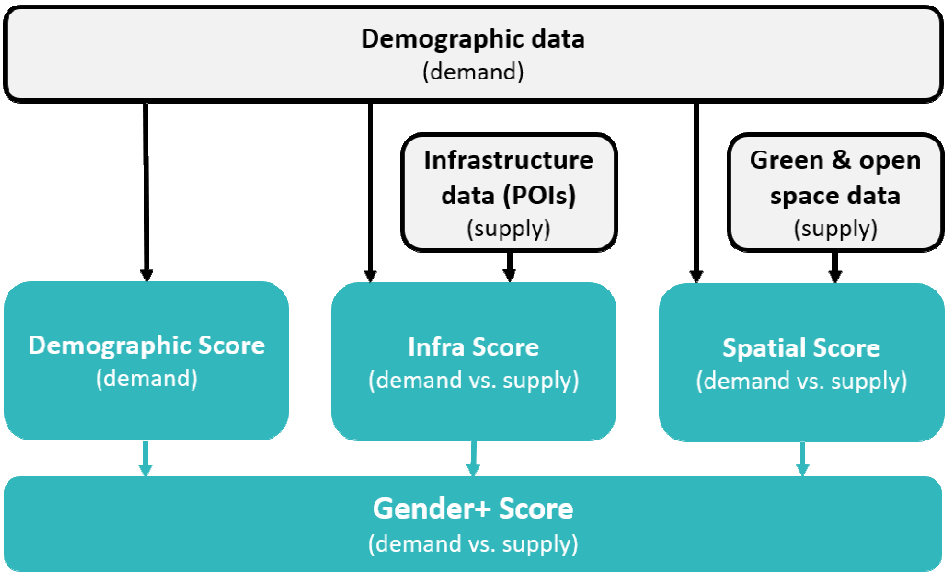

Fig. 2: Gender+ score schemata © AIT

First step to analyse gender+ specific supply and demand was to create the gender+ specific groups. This was established based on gender experience from the projects, desktop research and the available data. The following table shows the chosen gender+ groups for the analysis at the overall city level.

Gender+ Group Name	Sub-groups	Comments
Unemployed	male, female	Source: Statistik Austria
Persons 70+	male, female	Source: Statistik Austria
Childrens 0-9	male, female	Source: Statistik Austria, age groups available in 5-year steps (0-4, 5-9, 10-14, 15-19,…)

Table 2: Investigated Gender+ groups

All these groups have their own set of requirements to fulfil their needs regarding all day infrastructure, mobility, security, health, leisure equipment etc. Which does not mean that there are no common needs for all, like open spaces or food shops, but with different weights in their daily life.

The second step was to explore these different needs for the gender+ groups regarding infrastructure and green and open space distribution. This step included searching for available spatial data to derive the single scores. The third step was to develop methods to derive the single scores and to combine them into a so-called Gender+ Score.

In this paper we focus exemplarily on one important group and show how this was done, namely for the gender+ group children females 0-9 years. The demographic data from statistic shows individual numbers of children which were classified into three quantiles visualized with lower case letters of “a”, “b”, “c”, as can be seen in Figure 3.

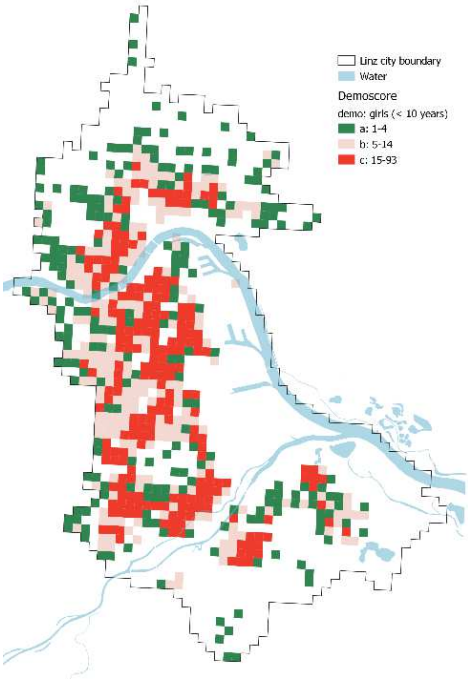

Fig. 3: Demographic score gender+ group female children 0-9 years © AIT

Regarding the infrastructure score a list of factors was found as important to be in close distance to the demand of the specific gender+ group. We used data from several sources mainly TomTom and OGD to calculate Euclidian distance maps to the individual factors called Points of Interests (POIs). First results have shown that due to the difference in the spatial distribution of some of the factors weights have to be used not to create biased maps. The following table shows the list of POIs as well as default weight factors chosen, to create the map depicted in Figure 5.

POI category	**weight factor**
Hort	0.7
Youth centre	0.3
Playground	0.8
Kindergarten	1
Park	0.8
Day sursery	0.5
Library	0.2
Music school	0.5
School	1

Table 3: Gender+ specific POIs and default weight factors, ©AIT

Similar as it was done for the demographic score where we categorised the euclidian distances to combined weighted infrastructure into three classes using quantiles. This time we used upper case letters “A”, “B”, “C”. The following Figure 4 shows the resulting possible combinations of the demographic and infra scores.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

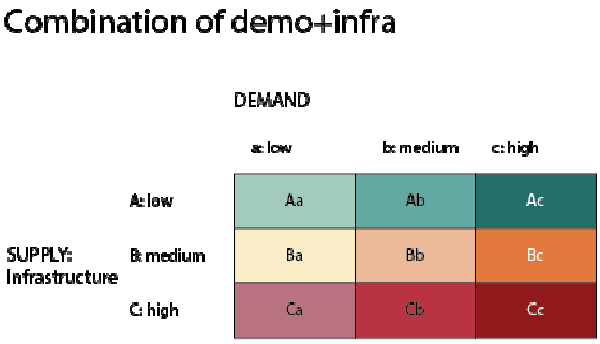

Fig. 4: Possible combinations of demographic and infrastructure score classes © AIT

This allows to understand for each class it's cause, e.g., "Ca" as low demand (few girls living in the given cell) and high supply of the relevant social infrastructure, as can be seen in Figure 5.

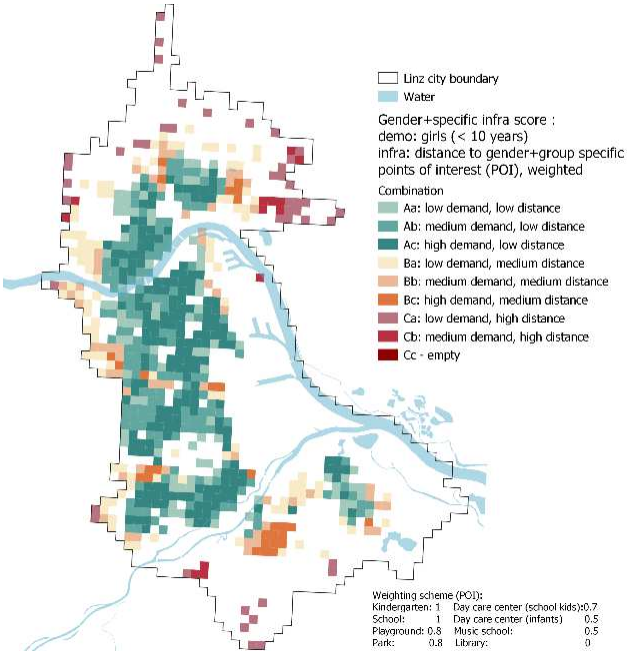

Fig. 5: Gender+ specific INFRASCORE (female children 0-9 years) © AIT

For the gender+ group childrens 0-9 also a spatial score (green and open space score) was calculated distinguishing between different sizes of green spaces. The categories were classified according to their size. For each category a distance was defined as the maximal acceptable distance based on expert judgement and former studies. The following table shows the chosen size and default maximal acceptable distance for the green space categories.

Green space category	**Size**	**Maximal acceptable distances**
Neighbourhood	<1 ha	250m
Residential area	1-3 ha	500m
District: small greenery	3-10 ha	1,000m
District: big greenery	10-50 ha	1,500m
City region	>50 ha	6,000m

Table 4: Gender+ specific POIs and default weight factors, (Wien and Magistratsabteilung 18 2015)

The calculated spatial score is thus a combination of the different green space categories and therefore a well supplied location would be one if all categories are reachable within the maximal acceptable distances. The first analyses showed that a simple counting does not achieve an informative result as for example the big green space in the case study area was accessible within all locations (250m*250m) raster cells in Linz. And furthermore, if for example a green space of 40ha would be in a distance of 1,750m it would be accounted as

not acceptable (>1500m), but 250m is only a minor deviation compared to 1500m. Taking the same transgression into account for the smallest green space, the neighbourhood category, this green space would be twice as far away as it is aimed for. To avoid this a method has been developed named inaccessibility transgression. This method calculates for each green space category the percentage of inaccessibility compared to the maximal acceptable distance. Only transgressions are taken into account. If the closest green space of the given category is within the maximum acceptable distance, the percentage will be 0. The following Figure 6 shows a schematic representation of this method.

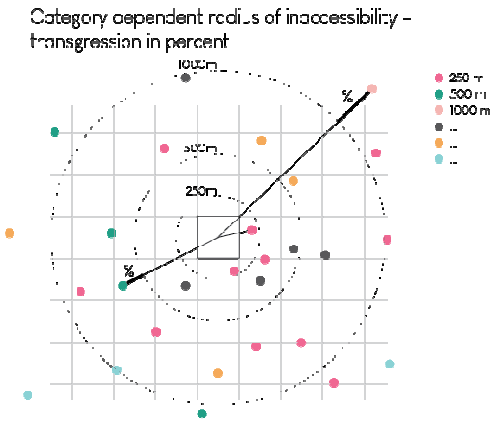

Fig. 6: Inaccessibility transgression © AIT

The calculated inaccessibility transgression was classified in the same way as the demo and infra scores using quantiles into three classes. To combine the demographic score with the spatial score the following combinations were used (Figure 7).

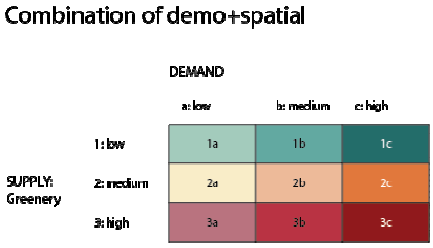

Fig.7: Possible combinations of demo and spatial score classes © AIT

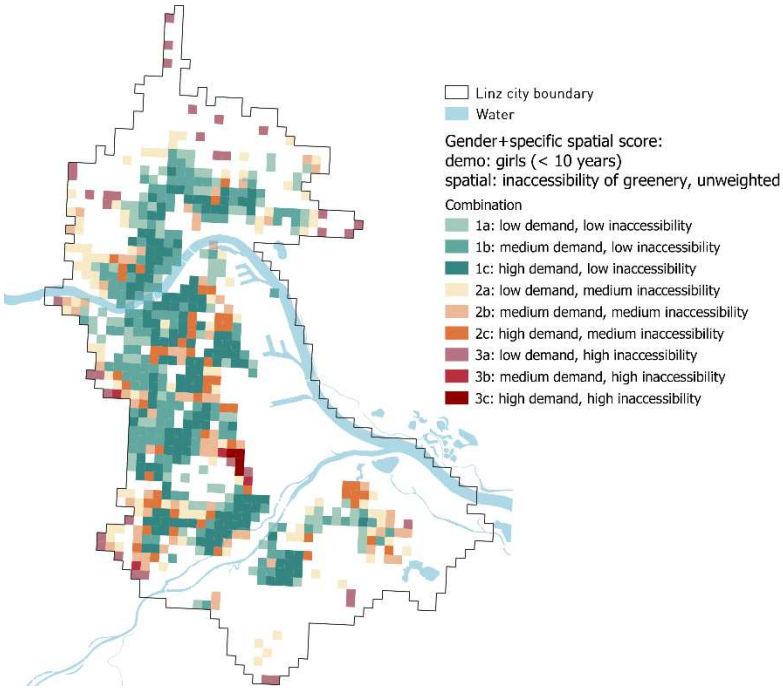

Fig. 8: Gender+ specific SPATIAL SCORE (female children 0-9 years) © AIT

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The gender+ specific spatial score in Figure 7 shows areas with high demand and low inaccessibility, meaning well supplied areas but also with a high demand and thus bear no high potential to increase the specific gender+ group there. The map also enables to find areas currently not appropriately supplied with access to the green infrastructure (classes “3c”and “3b”) as well as areas with a high potential for further increase of gender+ specific demand (i.e. in this case more females 0-9 year).

Last but not least, the above described scores have been combined to the Gender+ Score. The combination of the three criteria would give 27 different gender+ score classes, which would result in a very complex map (Figure 9 left). To simplify the visualisation and identify the “hot spots” we concentrated on the extreme values (Figure 9 middle). An additional category “0” was introduced as an indicator for areas with currently no demand (no specific gender+ population). This means the demand category exists of 4 categories “a”, “b”, “c“, “0”. So, the final possible combinations are 12 (Figure 9 right).

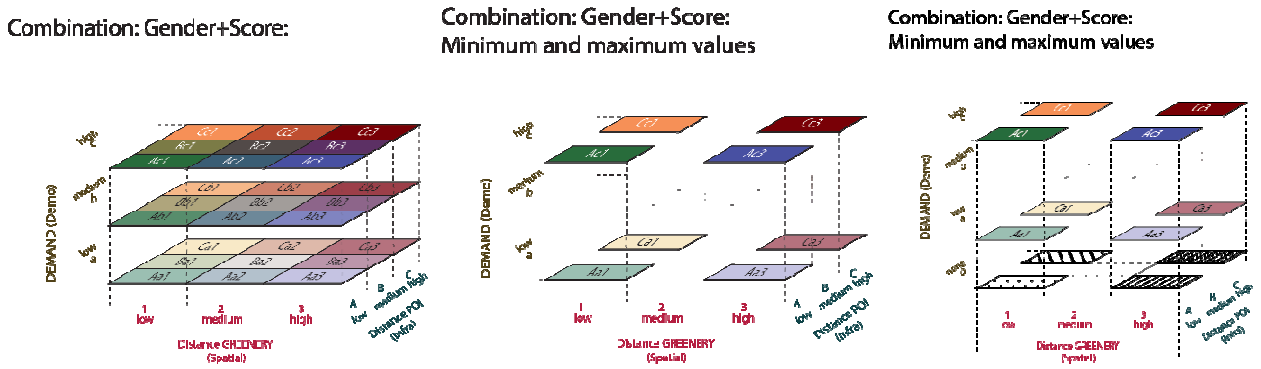

Fig. 9: Possible combinations GENDER+ SCORE (female children 0-9 years) © AIT

For the above chosen default values of the POI weights for the infrastructure score (Table 3) and green space types and maximal acceptable distances (Table 4) the following specific gender+ score map was calculated. This map (Figure 10) contains a lot of information depicting areas where demand and supply match “Ac1” (dark green), areas where a low demand but high supply indicate that a demand increase is easy to manage “Aa1” (light green). The same map can be used to find areas where new demand (females < 10yr) would find the infrastructure and green space they need “A01” (doted areas), and on the other hand areas where the current situation for these gender+ group seems to be very bad “C03”.

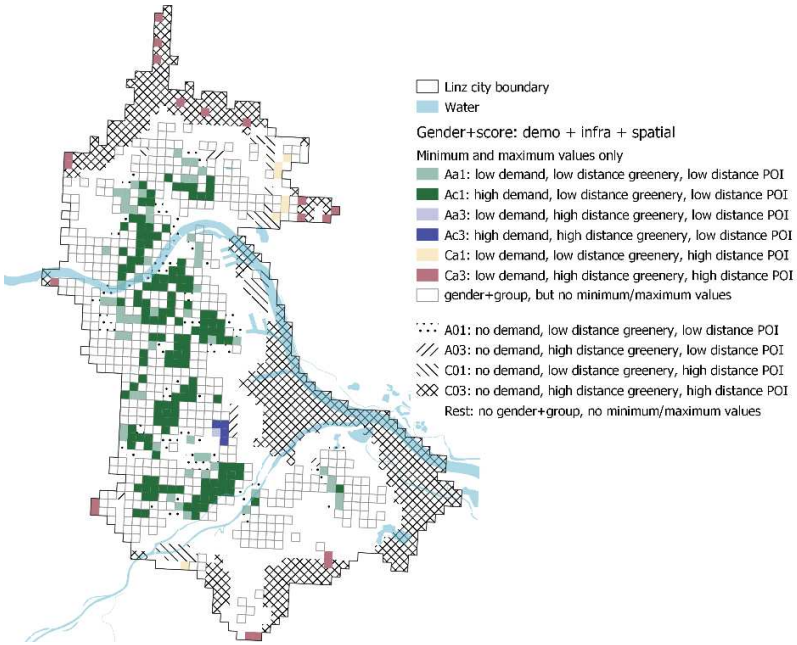

Fig. 10: Possible combinations GENDER+ SCORE (female children 0-9 years) © AIT

6 DEVELOPMENT OF A DECISSION SUPPORT PLANNING TOOL

The section 5 demonstrates that it is a high effort and a complex procedure to create these demand and supply maps and furthermore some parameters influence the results significantly as the weight and green

space sizes etc. Additonaly, it is very difficult to define the "correct" values which shall be used. The aim of SMTG+ is to show as a proof of concept that an interactive simulations tool could help in several aspects. Firstly to reduce the effort to create this kind of maps, and secondly, to use them together with local experts from the city in co-creation workshops. The idea is to develop a decission support planning tool, which can perform the same or at least in a very similar way as GIS analysis tools and create the above discussed maps. As a first concept, we developed a web based application which uses the spatial data analysis capacity of R (Muenchow n.d.), (Lovelace et al., n.d.). To create the interactive web application Shiny was used, an R package that enables to build interactive web apps with less effort straight from R (R-Studio n.d.; Chang et al. 2017; Gebetsroither-Geringer, Stollnberger, and Peters-Anders 2018). The development of the interactive web application showed that the GIS analysis can be performed using R. The user interface (sliders in Figure 11 right image) enables to interactively choose the weights for the infrastructure (Table 3). The calculation of a new map needs less than half a minute using a standard notebook. This is a huge improvement compared to calculating all the necessary steps one by one in a starndard GIS program as QGIS.

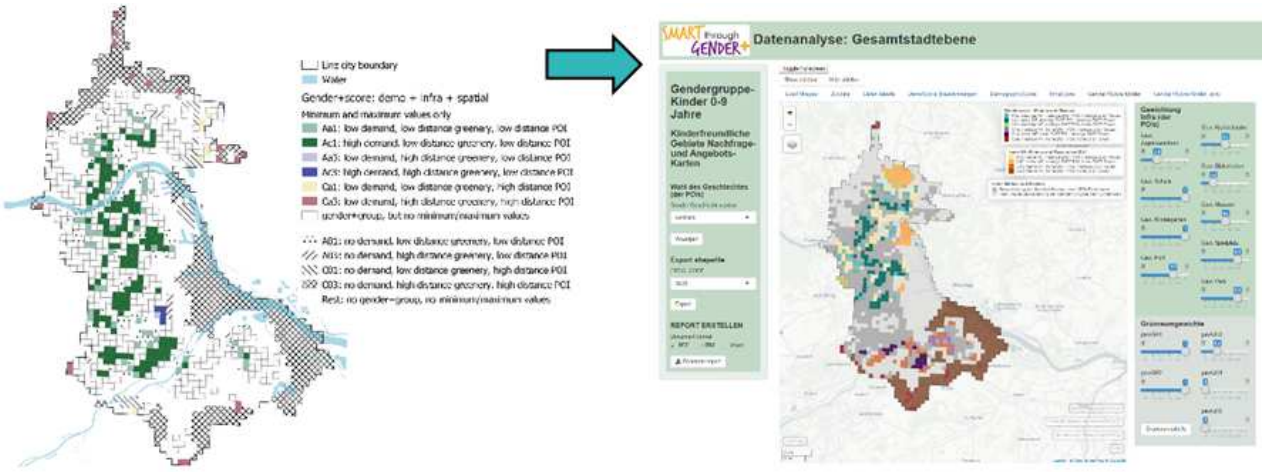

Fig. 11: Interactive web application - implementation of the Gender+ SCORE (female children 0-9 years) with R-Shiny © AIT

Furthermore, the developed application shows the single score maps at the same time, and zooming synchronously shows details on all maps.

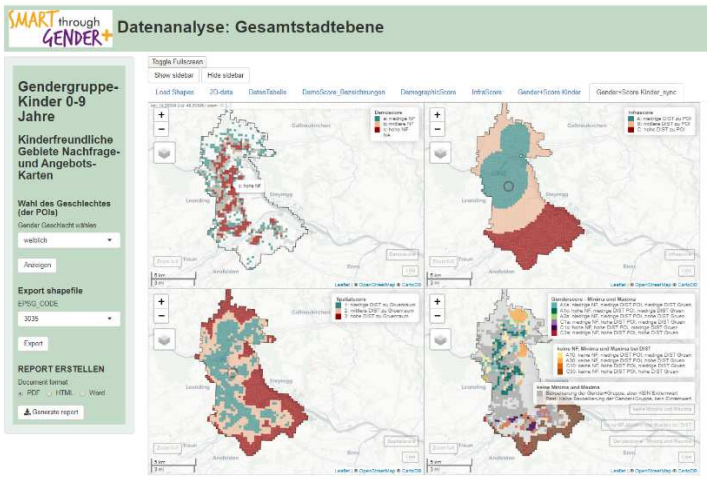

Fig. 12: Single synced maps - implementation of the Gender+ SCORE (female children 0-9 years) with R-Shiny © AIT

7 RESULTS DISCUSSION AND OUTLOOK

The result of the presented methodology is a proof of concept of a web application for the quantitative evaluation of the current situation regarding gender+ specific demand and supply on the overall (entire city) level. The dynamic evaluation and change of input data sets enables a flexible working mode, intended for planners in practice. This high flexibility is important, since it should be possible to create and evaluate different results depending on the input parameters as the weights, or discussed green space sizes. Furthermore, driven by the need to update the analysis with newer or more accurate data sets. This enables to

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

monitor the changes easily e.g., every 5 years with demand data from the statistic or new supply data from different sources. The application for other cities within Austria is possible without major adjustments by using standardized data sets. The application to other European cities is also considered possible through the use of open source data. While the development of a userfriendly web-application is considered as a possible next step in the future, it is this not covered by the project Smart Through Gender+ and its proof of concept analysis.

(Univ.-Prof. Aglaée Degros, 145 Institut für Städtebau TU Graz, a.degros@tugraz.at)

1 ABSTRACT

Urban regions are changing at all levels. Technological and demographic change poses major challenges for urban planning and regional development. Evaluation from the report "Europe's demographic future" from 2017, prepared by the Berlin Institute for Population and Development, illustrates the demographic development of the population 65+ by 2050. According to this, an increase of up to 55% of the population over 65 in Europe is forecast by 2050. Independence and the associated opportunity for a self-determined, autonomous life in old age is the wish of the aging population and is often accompanied by a changed form of living. But how can this predicted increasing demand and the associated range of infrastructure and services be implemented and managed in urban areas? In order to identify the parameters and necessary framework conditions that influence the development of an age-friendly, smart city district, this paper deals with the comparison of seven European smart city districts and their offers in relation to their aging population, for autonomy and flexibility also in old age. Modern forms of housing, shared flats, mixed concepts of senior and students, where the collective is lived, are reality. Flexibility of use plays an important role here. Common spaces, accessibility at all levels, good public transport connections and an environment with the best infrastructure are indicators of self-determination even in old age. A case study of seven selected European Smart City districts focusing on "Living in old age" will be analysed and evaluated here. The selected European Smart City districts: „Malmö BO01“, „Stockholm - Hammarby Sjöstad“, „Vienna Seestadt Aspern“, „Hamburg – HafenCity“, „Helsinki – Kalasatama“, „ Helsinki – Jätkäsaari „ and „Copenhagen – Nordhavn”. Here, the ratio of offers for older people to registered residents +65 is analysed and compared: „Vienna Seestadt Aspern“, with 6.348 inhabitants and a population density of 2.645 inhabitants per km², has 2.39% inhabitants in the category +65, despite multiple offers, although various assemblies on the construction site D13 „Aspern Die Seestadt Wiens“ advertise with a focus on communal living. „Hamburg HafenCity“, with an average age of 35,7 years and a population density of 1.893 inhabitants per km², has a population +65 of 9,2%. The percentage of one-person households is 37,6%. Here, intergenerational communal housing solutions can benefit from one another and form synergies. Another positive aspect in this district is the medical infrastructure, which with 13 established medical facilities, including a pharmacy, forms a good basis for an independent life in old age. The infrastructure and the necessary services are available in many districts. Society is currently undergoing a rethink, and the population is also willing to accept these social offers. The percentage of the resident population +65 is still manageable in Smart City districts, but the result is that they are still relatively young. However, the population will change in the future and in 2050 there will be more old people than young people, even those currently under 65 will follow the demographic change with the desire to age autonomously and independently.

Keywords: ageing population, Smart City districts, autonomous, flexibility, districts

2 INTRODUCTION

Smart City is the challenge of the new generation of the city. Digitalization is driving social change. The analysed target group 65+, too, is discovering the digital world and its numerous possibilities to make life easier in old age, more and more for itself. In the future, it will be easier for older people to live in their own homes for as long as possible and to participate in social life in a self-determined way. Although older people attach great importance to self-determination, people often have to make themselves dependent against their will. The older people get, the more time they spend in their home. With this reduced radius, the demands on the apartment also changes and the need for comfort and security increases. My thesis on this is: Old people prefer to live autonomously and longer in a Smart City District than in rural areas, because they can manage their everyday life there independently and therefore do not have to seek outside help from a nursing home. Accessibility, networking in old age and an appropriate infrastructure in the immediate vicinity are considered important factors for senior living. There are now many alternative forms of living, such as intergenerational living for seniors and students. Alternative concepts are the future here. Today's best agers

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

do not want to live in the home, but rather self-determined in associations that offer a social life. Therefore, the following part deals with the analysis of seven European Smart City Districts in relation to the population living in them, their percentage 65+ and the offer for independent living in old age per district.

3 SMART CITY

The term Smart City is the development of future-oriented urban planning programmes and strategies, in the form of creative networking, as well as innovative integration of different areas of a city. Its intelligent structure and the associated infrastructure overcome the urban challenges of the city and operate 24 hours a day, seven days a week. There are various interpretations and interpretations worldwide. Innovative smart city concepts include technical, social, economic and ecological developments. It offers its residents an energy-efficient and low-emission city with a high quality of life and minimal resource consumption.[1] The use of information and communication technologies, which promise a change in cities as systems and as a society, can only lead to smart city development in combination with other factors. In order to bring about this change in living conditions, smartness must be thought through in terms of innovative ability, ecological sustainability and quality of life. Participative processes of participation and the integration of social aspects of urban society are essential here, because smart cities are committed to sustainable and integrated urban development at all levels in order to improve living conditions in cities.[2]

4 DEMOGRAPHIC CHANGE

Demographic change is changing European society. The world's lowest birth rate contrasts with increased life expectancy. Demographic change is increasing, with the increase in single households and increased mobility, an increasing number of people in need of care. Due to this demographic development, the aging population and its holistic area of life, from economy to architecture, is being brought into focus, because in our affluent society you not only live longer, you also age more slowly. The reasons for higher life expectancy are growing prosperity, advances in medicine, hygiene and health care, and accident prevention.[3]

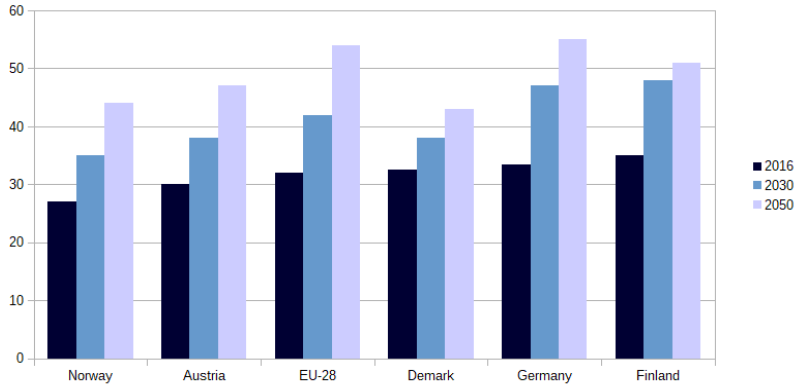

Fig. 1 Europe's demographic future - Percentage over 65 years old

The graphic illustrates the evaluation from the report "Europe's demographic future" from 2017, prepared by the Berlin Institute for Population and Development. In this study, the demographic development of the population 65+ is forecast by 2050. According to this, by 2030 more than 40% of the population in Europe will be over 65 years old. In 2050, an increase of over 65-year-olds in Europe's population is forecast with an average of up to 55%. This share of the population is expected to be 44% in Norway and Denmark in 2050, 49% in Austria and Finland and 55% in Germany. The calendar age will lose more and more meaning, because the population has two age values, so to speak. A value based on the year of birth and one based on actual skills and behaviour. One of the greatest challenges of the future will be to keep the aging population, economically and socially, efficient.[4]

[4] Hergott 2012, 10-11.

5 LIVING IN OLD AGE

Participation is a social phenomenon based on relationships with other people. It is an important factor in physical self-determination and medical health. This aspect also has a high impact, in the areas of housing and social integration, in relation to the satisfaction of the residents of a neighbourhood. It is also an important indicator in the case of supportive digitalization in order to be able to lead a certain lifestyle, because older people want actively designed leisure time in order to maintain physical and mental fitness as well as social contacts. The technical assistance systems are in a process of constant further development and are becoming increasingly important. These systems are used in nursing to support older people and those in need of care, as they allow them to stay in their own home for longer. The desire to be able to live autonomously in your own apartment for as long as possible often goes hand in hand with a change in living arrangements.[5]

5.1 Living in a district

Independent living in a familiar environment can be best achieved in a district even in old age, through participation and mutual help. A district is a social space and describes the individual radius of action, the extent of which is variable, and promotes quality of life. The radius of action is a dynamic process and is made up of the available offers and individual skills in everyday life. To do this, one is faced with the question of what skills are required to use the available offer. The radius of action can be expanded by the social space offered in a quarter, in the form of one's own apartment and the regularly used public space. Activities and interactions of everyday life take place here. The advancing digitalisation is already having an impact on networking in the district. In this context, older people have a local connection and digitalization in the district can become a concrete problem solver in everyday life. Neighbourhoods and social-spatial networking at the district level are essential in order to receive help when needed, because support from the surrounding area improves living together, reduces the need for help and increases the quality of life.[6]

5.2 Survey Target group

In order to better understand the target group 65+, a survey of 63 people aged 65+ was carried out in Austria and Germany. 34% of those questioned form the 65-69 year olds. 70-74 year olds are 33%. The age groups 75-79 and 80-84 each make up 14%. The age group 90 - 94 make up 5%. For this purpose, questions were asked in the area of digitalization, infrastructure and mobility, in terms of habit and relevance, and the following findings were obtained: Basic tenor: The older population 65+ is afraid of change. 67% find nursing robots as not necessary and 5% find nursing robots as very important. The emergency bracelet, on the other hand, was rated as very important by 81%. Many do not have a PC, but a smartphone. Whats App is used by 62% and the mobile phone by 86% every day. 76% have never used Facebook. The target group rarely orders online but goes shopping regularly. 33% go shopping daily and 57% weekly. 67% have never ordered anything online. Small-scale infrastructures and businesses must be preserved! Public space is of great importance for 66%. Barrier-free accessibility as a human right. 95% find that public spaces should ne barrier-free. Short distances are particularly important. 62% of the respondents walk up to 2 km on foot. Short distances to medical aid are very important for 76%. 66% find short routes to shopping very important and 34% find short routes to green spaces very important. Social infrastructure in the neighbourhood is important. Networking in the neighbourhood has a significant impact on housing satisfaction and is an important quality feature. Neighbourhood relationships were rated as particularly important by 71%. It is important to be used. 86% find it very important to be needed.

6 ANALYSED SMART CITY DISTRICTS

6.1 Smart City districts

In old age, one's own home is the centre of life. However, many apartments are not suitable for the elderly. That is why many older people, at age 65+, are considering changing their living situation. Parameters for selecting the new living situation are not only aspects of accessibility in the form of levels and thresholds, but also short distances and social aspects, such as a good neighbourhood network. That's why some move to a smart city district. A case study of seven selected European Smart City neighbourhoods focusing on "Living in old age" will be analysed and evaluated here. The selected European Smart City districts: "Malmö BO01", "Stockholm - Hammarby Sjöstad", "Vienna - Aspern", "Hamburg - HafenCity", "Helsinki - Kalasatama", " Helsinki - Jätkäsaari " and „Copenhagen – Nordhavn". The districts were selected based on "Mapping Smart Cities in the EU"[7] and in the Smart City publication "Technical Tours Smart Cities 2014-2018".[8] All seven considered Smart City districts were selected according to the indicators of sustainability and innovative strength in the area of urban and district development and considered and defined as a Smart City project based on an already implemented project.

	population	0 - 64	>65	%	ha
Malmö - BO01/ Västra Hamnen	10203	8945	1258	12,33	175
Stockholm - Hammarby Sjöstad	18902	16564	2338	12,36	110
Vienna - Seestadt Aspern	6.348	6196	152	2,39	240
Hamburg - HafenCity	4.592	4168	42–4	9,20	157
Helsinki - Kalasatama	2910	2559	351	12,06	175
Helsinki - Jätkäsaari	6901	6432	478	6,92	68,5
Copenhagen - Nordhavn	2896	2781	115	4,00	55,4

Table 1: The selected European Smart City districts. (population 65+, population and district size)

[7] Cave u.a. 2014, 180-198.
[8] BMVIT 2020, 19-20.

6.1.1 Malmö - BO01/ Västra Hamnen

The project start of Bo01 - Västra Hamnen in Malmö was in 2001, through the Bo01 architectural exhibition. Since then, an internationally known example of sustainable urban development has established itself here. The Bo01 quarter is Sweden's first climate-neutral district. Malmö - BO01 / Västra Hamnen, has a very high number of the considered target group 65+ with 12.3%. The population of the district is 10203, of which 1258 are 65+. The population density is 5830 people per km².[9] Pedestrian zones, room sequences of different sizes, wind-protected inner streets and extensive urban spaces refer to the human scale. Västra Hamnen, as a residential and office town, has eight kilometres of shoreline with swimming areas, green areas and beach promenades with many beautiful parks. Pedestrians and bicycles have priority, so bus stops have been set up within a radius of 300 m from the residential buildings. High priority is given to public space as a lifeline and meeting point. The Västra Hamnen project pursues the goal of an urban district that covers all areas of life around the focus of diverse living and training. The mix focuses on affordable social sustainability. MKB Senior Accommodation is a house in Västra Hamnen for people aged 55 and over, it offers regular activities for residents and cafes for the elderly living there. Attendo Västra Varvsgatan senior accommodation also offers 53 apartments on three floors with a courtyard, terraces and balconies.

6.1.2 Stockholm - Hammarby sjöstad

Hammarby sjöstad on the southern outskirts of Stockholm, has 12.4% of the considered target group 65+. The population of the district is 18902 people. 2338 of them are 65+. The population density is 17,184 people per km².[10] Hammarby Sjöstad was planned for a balanced mix of rental and condominiums. The district's rainwater is collected and the waste is transported through an underground suction system. The focus is on public transport, in the form of light rail, bus and ferry, as well as bicycle and foot traffic. The green space concept provides 25m² of free space per apartment. All green areas are interconnected. Stockholm pays strict attention to standardized dimensions and materials in the area of barrier-free accessibility, such as the inclination of the streets, non-slip materials or the lowering of the curb. The ground floor zone of the building offers space for shops and public services such as a health centre. Hammarby sjöstad has its own apartments for customers aged 55 and over, which must also be sold to them. Homes for older people who need medical care are called Seniorgården. There are gyms for seniors and regular senior meetings in a cafe. In addition, a caretaker service for small-scale repairs in everyday life is offered throughout the city of Stockholm for seniors.

6.1.3 Vienna – Seestadt Aspern

The Seesatdt Aspern master plan places great emphasis on public space in the context of smart development processes, participation and inclusion. The Urban Lakeside is young because more than half of the urban residents are between 19 and 39 years old. At 2.4%, Seesatdt Aspern currently has a small number of the target group 65+ considered. The population of the district is 6,348. 152 of these residents are 65+. The population density is 2,645 people per km².[11] An important point in the design of public spaces is accessibility. Thus, for example, all sidewalks are made in sufficient width and angle. The assemblies in Seestadt Aspern are very concerned about a mixed life. "MISCHA" offers communal living in response to demographic developments. In addition to „MISCHA“, there is also a dormitory for senior citizens. "Yella Yella" works with overarching concepts such as childcare for neighbours. "LiSA" - nine living spaces for older people who want to live in a community and are interested in integrating into a home community. "Gesiba" - offers 36 manageable apartments especially for seniors. "House of Life" is a cross-generational, barrier-free housing project that relies on neighbourhood help. There is good public transport links by bus and subway. A high-quality open space - with more than 30 business locations, as well as pharmacies, doctors, banks is located directly at the „Seepark“.

6.1.4 Hamburg - HafenCity

The HafenCity has an average age of 35.7 years and, at 9.2%, has a relatively high number of the target group 65+ considered. The population of the district is 4,592, of which 424 are 65+. The population density

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

is 5830 people per km².[12] The future-proof urban structure of HafenCity shows a delicate, inclusive mix of uses from social infrastructure, such as work, living and educational and leisure facilities with a large public ground floor zone. Accessibility and social meeting places as well as networks and associations are intended to strengthen participation here. The proportion of single-person households is 37.6%. Here, cross-generational municipal living solutions can benefit from each other and create synergies. Another positive aspect in this district is the medical infrastructure, which, with 13 established medical facilities, including a pharmacy, forms a good basis for independent living in old age. The area division in HafenCity is 24% traffic areas, 31% building floor areas and 25% public open spaces, here a distinction is made between "green open spaces" and "blue open spaces". 41 accessible senior apartments have been rented by the „Martha Foundation“, in the middle of HafenCity with a view of the harbour, since summer 2009 with a common room and additional services such as emergency calls and caretaker services.

6.1.5 Helsinki - Kalasatama

Kalasatama is Helsinki's Smart City model area and, at 12.1%, has a very high number of the target group 65+ considered. The population of the district is 2910, of which 351 are 65+. The population density is 1663 people per km².[13] The water edge with the promenade is 5 km long and the metro station is 7 minutes from the centre. There are common rooms and rooms for temporary use in the buildings. The offer in public space consists of social infrastructure such as a health centre. The focus is on foot and bike connections. A large number of the street blocks consist of different residential buildings, which are arranged around a collectively used courtyard. Special forms of living such as senior citizens' communities are also offered here. Kotisatama is a barrier-free low-energy house with condominiums for 85 residents 48+ and offers senior citizens a new type of living facility, which is partly based on the collective help of neighbours. There are also common rooms such as a sauna and roof terrace with a garden, workshop and kitchen. “Kalasatama is an innovation laboratory, so every third inhabitant has already participated in a survey.

6.1.6 Helsinki - Jätkäsaari

Helsinki - Jätkäsaari has 6.9% of the target group 65+ considered. The district has 6901 residents, 478 of whom are 65+. The population density is 5949 people per km².[14] The blocks of flats in the area are usually 7-8 stories high and there are large and sheltered courtyards between the blocks. Jätkäsaari as a test site for intelligent mobility solutions, is a district that is characterized by a variety of wide services, shops, a park with a total area of 2.4 hectares, a dense tram network and well-developed bicycle and pedestrian paths. City Village CO-10 is a startup for sustainable development. The “generation block” is a developed concept for multi-generation residential construction. The concept unites people of all ages and offers a variety of urban living options.

6.1.7 Copenhagen - Nordhavn

Copenhagen - Nordhavn has 4% of the target group 65+ considered. The population of the district is 2,896, of whom 115 are 65+. The population density is 5830 people per km².[15] Nordhavn is planned as a green district on many levels. Water is the subject of the redesign of the port area. The concept of public space and urban planning is under the water, above the water and on the water. Temporary projects increase activity in the port area. The area is 600m from the Nordhavn train station. The prioritization is based on cycling. There is even a bicycle highway for this. The district consists of a mixed use of public and private facilities for a lively, varied district and active ground floor zones. HOLO operates autonomous buses for senior citizens in the district. The development plan is designed with a special focus on public spaces. The district consists of small residential units for singles, the elderly and medium-sized houses.

6.2 District advertising strategy

A Smart City district has many advantages for “living in old age”. In order to transport them and attract the 65+ target group, these advantages, such as vicinity to shops and green, networking, and collective living solutions must also be advertised and illustrated accordingly. For this, the respective official Smart City

Table 2: district advertising strategy (0 = not advertised, 1 = minimally advertised, 2 = advertised, 3 = heavily advertised)

7 CONCLUSION

Smart City districts are still very young districts, which is why it can be concluded that the population in the districts will change due to increasing demographic change. The key words are integration and networking. It is about social networks, barriers and participation of the residents through active involvement. Smart city districts are good places to age autonomously, as the results of the target group surveyed reflect (Fig. 2: Core data of the respondent's target group 65 +). It can be derived from the survey that the desires of the aging population go hand in hand with the advantages offered by a Smart City district. Smart City districts would meet the demands of the aging population of interaction and self-determination. The percentage of the resident population 65+ is between 2% and 12% in the analysed Smart City districts. In the EU, the population of the 65+ group had already been just over 30% in 2016 (Fig. 1 Europe's demographic future). Thus, the population 65+ in the analysed Smart City districts is 18% to 28% lower than the European average of 2016 and thus strongly underrepresented. It can be concluded from the analysis that there are differences in the implementation and theming of the seven Smart City districts analysed in relation to the aging population. In order to be able to analyse these measures and focal points in depth in the analysed Smart City districts, a field study would be necessary to take up the feeling of the residents and the real offer for the participation of older people in the district. Even if these analysed districts, as the evaluations of the advertising strategy (Table 2) make visible, currently rarely advertise with qualities for living in old age, the age of the population in the district will change in the future.

1 ABSTRACT

In recent years, big data has been extensively applied in urban planning and design area. However, its wider application is constrained by the data acquisition approach. Accordingly, many efforts have been made to accurately find and solve urban problems by mining legal open source internet data, which gradually becomes a hot topic among urban researchers. In this context, this study applies the Gaode OPEN API in the urban real-time traffic circle construction and fire-fighting facility planning evaluation taking Nanjing as example. First, a batch processing model is established on the basis of Gaode OPEN API, including automatic acquisition of real-time traffic data in the study area and extraction of average vehicle speed of all the roads during specified time period. It found that speed involves division of the whole Nanjing City into several characteristic zones. Then, a case study is conducted to construct the urban real-time traffic circle through python language and Arcgis software based on existing fire-fighting facilities. In the end, through a subsequent evaluation, it is found that the existing fire-fighting facility planning has a stark regional difference between urban central area and suburban area, which shows a low coverage rate of 22% and 39% for respond time of 6min and 8min respectively. This study provides an integrated approach for acquisition and processing of Gaode data, mining of its space-time features, and application in the planning evaluation practice. This approach demonstrates the advantages of streaming features and distributed processing of big data, effectively utilizes the real-time characteristics of big data in the emergency facility planning, and is expected to broaden ideas for data acquisition.

Keywords: Gaode OPEN API, fire-fighting facility planning evalation, Nanjing, China, real-time traffic circle

2 BACKGROUND

In recent years, the growing number of public emergency causes great losses to society. Especially for emergency events like fire disaster, require rescue workers get to the scene with least delay possible and take action immediately. Low treatment efficiency could turn general emergencies into serious public incidents or major catastrophic accidents. Additionally, the growth of urban traffic volume and vehicle out-driving ratio which results from the improvement of urbanization process and socioeconomic status, brings serious traffic congestion. Consequently, the commuting time of fire fighting trucks gets delayed, so that the emergency respond time is affected. Traditional emergency facility siting is static and determined, which is calculated on the basis of existing road network and specified vehicle speed. However, the traditional analogy method is considered to be unconvincing and imprecise since its neglects on the influence of the actual traffic capacity on commuting time. Therefore, it is believed that real-time big data could help making more accurate evaluation of fire station service quality and efficiency, which contributes to sophisticated emergency facility siting: making sure the emergency service could arrive at designated position within required time so as to ensure the safety of life, property and urban operation. Based on the above, this article tries to analyze the real-time traffic data of Gaode API, establish real-time traffic circle by Python and Arcgis. Taking fire station in Nanjing as example, following the logic of “intelligent extraction of real-time traffic data – establishment of real-time traffic circle – evaluation of fire station planning”, this article explores the flow characteristic of big data and the application of distributed processing in urban planning practice, in order to provide reference and basis for similar study and project. Moreover, this essay will help EU countries where the inspire regulations are responsible for obligatory generation of huge amounts of free open governmental datasets.

3 INTELLIGENT EXTRACTION AND PROCESSING OF TRAFFIC BIG DATA BASED ON OPEN API

3.1 Introduction of Gaode OPEN API

Big data has became growing important in urban study area during the past few years. Due to the restriction of data acquisition, the research value of OPEN API (application programmers interface, the interface code that makes internet connection between two websites or databases) on big data acquisition, technology broaden and urban ecosystem receives increasing attention. Gaode open platform is the leading LBS service provider in China, which possesses advanced data fusion technique and massive data handling capacity. In the meantime, it also provides development kits both on the web terminal and mobile terminal to the public. Developers achieve functions including map display, map labeling, position search through recall development kits or API interface. API open the gate of open resource data for data demanders in internet and big data ear. The existing web service includes geocoding & inverse geocoding, route planning, POI search, input tip, batch request interface, administrative region enquiry, static map, IP positioning, coordinate transformation, weather query, road extraction, traffic situation, etc. According to the ten billion level daily average location requests and related actions, it is convincing that the data acquired from Gaode open platform could reflect the population flow, regional heat, behavioral preference and traffic characteristic in real world effectively.

Traffic situation is one category of the HTTP interface, which responds traffic inquiry according to the input content. Massive original data with spatial position and time scale could be achieved from Gaode open platform through data acquisition from a database which is established on floating car data and travel data of over seven hundred million users, and covers 40 cities including Nanjing. Before using, it is essential to apply for a Gaode API account and key. Then, traffic situation data can be achieved for designated rectangle, roundness or roadway (it is confirmed by test that the maximum side length of rectangle is 0.6 longitude/latitude degree). Besides, there is daily restriction for total volume and utilization frequency. There are detailed technical specifications for data acquisition with spatial information through Open API wed interface both in China and other country. Some studies have introduced APIs of online map developers such as Google Map or Baidu Map to estimate travel time[1-3], recently Zhou et al. [4] and Xi et al. [5] use online map API to obtain data on the dynamic population distribution and variation in transit time due to different transportation modes. In this way, researchers can make use of the dynamically updated transport network data and the routing rules maintained by map developers to obtain a reliable estimation of travel time. In the previous prediction of travel distance, Euclidean distance is often used to represent the spatial connection between geographical entities[6-7], and some researches also calculate the transportation cost by dividing the grid[8-9]. The road network distance[10-11] can be used to build a complete network, but it often takes a lot of time to carry out topology analysis, integrity check and manual correction. Besides, the existing handling method are tedious in general. Moreover, there is few detailed description for acquiring traffic situation of designated area by merging units and automatic data collection in different time scale.

This study proposes to extract real-time traffic data using a Gaode Open API-based streaming processing method(Fig.1). Given the rectangular-shaped data extraction scope, this study first divides the urban area into several rectangular units according to their longitudes and latitudes, and then extracts the original traffic information of each unit through the traffic data acquisition program, which is subsequently archived in the database. After that, units are merged to form the actual regional road network, followed by pre-processing of the original data and linking them with the effective road condition information. Meanwhile, timers are set for multiple periods of multiple consecutive days to automatically acquire the road condition data, which are then intelligently processed in batch. In this case, urban traffic data within a specified time range are successfully acquired, and the processed information table can be automatically matched to the urban road network for related processing and time-space analysis. The presented approach fully considers flow characteristics of the Gaode data, which is a branch of open source big data, and achieves higher efficiency than the currently used more complicated manual traffic data crawling method.

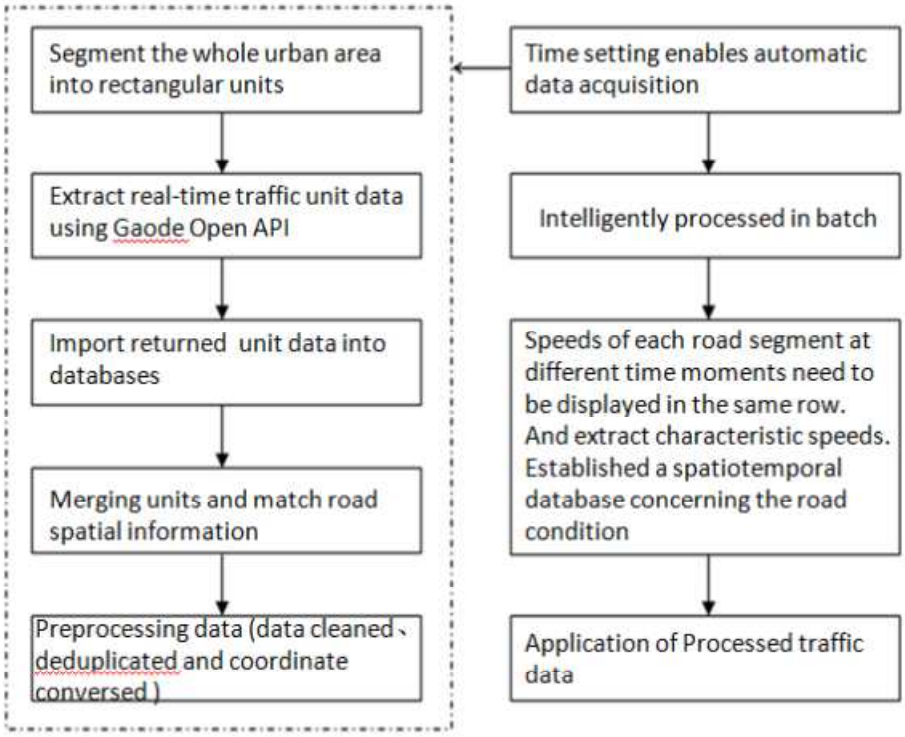

Fig. 1: Gaode Open API-based automatic processing method.

3.2 Intelligent traffic data extraction

3.2.1 Request diameter settings

Both data acquisition and processing are implemented using the Python language. The obtained data includes the real-time traffic speed and congestion status of the Nanjing City provided by Gaode Map, with a time range from May 28, 2019 to June 10, 2019 and a data acquisition spacing of 1 hour. Request parameters for traffic situation data acquisition in the rectangular units are input through the web service traffic situation API, including user permission identification, query road level, return data format, callback function, longitude and latitude coordinate pairs of top-left and top-right vertices of the rectangle unit to be queried (Table 1). The maximum distance in the rectangular unit to be queried should not exceed 10 km. Accordingly, the whole urban area of the Nanjing City is segmented into 230 rectangular units (0.06°by 0.06° for each unit). Before this, the latitude and longitude coordinates of top-left and top-right vertices of each unit need to be converted to Gaode coordinates from WGS84 counterparts(Fig.3 and Fig.4).

3.2.2 Data format analysis

Returned data objects include the result status value, the request status, the request status code, and the traffic situation information. Specifically, the traffic situation information includes road condition overview, road condition evaluation, and road information, and the road information includes road name, road condition, direction description, driving direction, speed, sign code for a certain road segment, and road coordinate set. Critical information such as road name, road segment code, road status, road speed and road point coordinate set is obtained and archived, accompanied by recording of the real-time acquisition time. Each rectangular unit contains several roads, and a certain road with its specific name consists of several road segments. In order to avoid repeated acquisition of road segments across units, this study assigns global codes (Row_ID) to road segments in a certain order during the data archiving. In this case, the overall road traffic situation is stored in the road condition information table, while the spatial point coordinate set is stored in the spatial point table. Data in both tables are linked to the corresponding Row_ID. In order to facilitate recognition of Chinese road names, input parameters and output data encoding of the interface are unified as UTF-8. The sracpying function is defined to loop through coordinates of top-left and top-right vertices of each rectangular unit, accompanied by data acquisition in order.

Parameter	Meaning	The rule description
key	user permission identification	users applies for the Web service API type KEY on the Gaode Map website
level	road level	specify the meaning of the following values for the road class: 1：highway 2：expressway 3：auxiliary-road of the expressway 4：main road 5：other road 6：anonymous road
output	format type of returned data	optional type：JSON,XML
callback	callback function	The callback value is the name of the user-defined function, which is valid only if output=JSON
rectangle	a rectangular area is queried	top-left and top-right vertices of each rectangular unit; The diagonal of the rectangle shall not exceed 10 km

Table 1: Request parameters through the web service traffic situation API

Name		Meaning	The rule description
Rdstatus		result status value	0：request failed；1：request suceed
trafficinfo	Rdname	road name	
	RdOrgin	original of the road segment's name	
	RdDest	destination of the road segment's name	
	Rdstatus	road condition	0：unknown 1：clear 2：slowdown 3：congest
	Rdspeed	speed	
	RdPx;RdPy	road coordinate set	format：x1,y1;x2,y2

Table 2: Return parameters through the web service traffic situation API

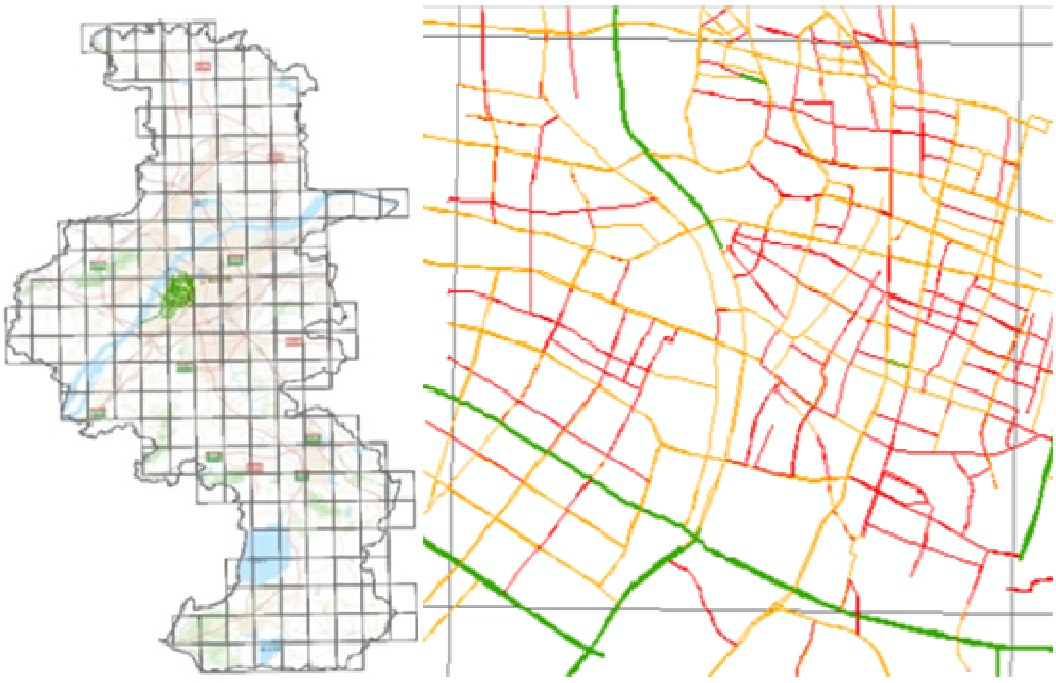

Fig. 3: Schematic diagram of the segmentation unit segmented units(left); Fig.4.Schematic diagram of the independent units(right)

3.2.3 Data cleaning and deduplication

In order to enhance accuracy and clarity of traffic information, data in the tables are processed using the Pandas library of Python, including merging of all units at the same time, deduplication of overlapping road segments after merging, and conversion of the coordinate system. All the merging processes are implemented while calling the sracpying function. After data of all units are obtained, the drop_duplicates function is called to delete the duplicate objects through filtering road names and road segment codes.

3.2.4 Batch data spatialization

Cleaned traffic data are implemented with coordinate conversion to the same coordinate system as the digital map. In this way, the information that is simply stored in the data table is spatialized. During data processing, the primary key pairs for regional traffic Shapefile files at different time moments, consisting of globally coded Row_ID, road name, and road segment code, are converted into hash values. In other words, the primary key pairs are converted into non-Chinese-character primary keys. These hash values are used as associated values to combine road condition characteristics of the same road at different time moments, resulting in spatial polyline objects with attributes such as hash values, road congestionstates, transit speeds, and time of data acquisition. Each Row_ID corresponds to a road polygon object and several latitude and longitude point pairs. In this context, the roads can have data concerning both spatial attributes and road conditions.

3.2.5 Timer setting

Above procedures are shown in the left part of Figure X. In order to obtain real-time traffic data for multiple days in Nanjing City, these procedures need to be repeated multiple times. Using automated means to ensure continuous operation can reduce a lot of manpower and improve data acquisition accuracy. Accordingly, a main_funtion function is defined to comprehensively package abovementioned procedures including user request sending, data acquisition, and data processing. Meanwhile, a timer is set using the threading library of Python. Specifically, the function is automatically run at intervals of 1 hour (3600 seconds) for 14 consecutive days, which enables automatic data acquisition, data pre-processing, and storage of the road condition data in readable shapefile format.

3.2.6 Establishment and use of spatiotemporal road condition database

Eventually, a spatiotemporal database concerning the road condition of Nanjing City is established, which consists of multiple shapfile files that document spatial road conditions at each hour (e.g. 7:00, 8:00, etc.) and one table that includes congestion and speed record of each road segment at all hours. In general, speeds of each road segmental different time moments need to be displayed in the same row. After transpositions of rows and columns, there should be theoretically a total of 336 (14 days * 24 hours) columns of speed features, which are excessively too many. It has been previously demonstrated that there are certain rules for residents' urban travel behavior, and thus there must be a lot of redundancy in road speed data for multiple periods of many days. Accordingly, the characteristic speeds related to the research purpose are extracted through principal component analysis to reduce speed data dimensionality of each road segment at all time moments. And characteristic speeds that are of interests are taken as the representative speeds of the road segment.

3.3 Modeling approaches of real-time traffic circle

On ArcGIS platform, running topology processes including intersection interruption, interface connection in the shapfile-format road network document, then a grid data set could be established as the real-time traffic circle model. Based on the real-time traffic circle model of Nanjing city, taking the location of emergency station as start point, and transit time as impedance, this study works out the coverage of emergency service within specified time. Thus, the real-time traffic circle could be evaluated by the road length and cover area with its scope. Through multi-plan trial and amendment, it could be suggested that stations with overlapped coverage area should be abolished or relocated, or new station should be built in the shadow area. Overall, this study helps optimizing the layout of emergency infrastructure. Specifically, it aims at reducing the overlapped coverage area of different stations, and improving the coverage rate especially in high risk regions.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The nature of real-time traffic model is to seek the service area of any position using Network Analyst which is a extended module of ArcGIS. As a matter of fact, it is a route solution program based on Dijkstra which is considered as a classical algorithm that solve the unisource shortest path finding in weighted graph. In order to find the shortest path from the initial position s to the target position d, this study originate a meeting point set S of which the shortest path to s is calculated by Dijkstra algorithm. Afterwards, meeting point with shortest estimated value would be searched repeatedly and be added to the set S. Meanwhile, the shortest estimated value of those adjacent points not included in the set S are being updated continuously. The algorithm will be executed until all expected meeting points get added to the set S. This study use the model as a refined stimulation that reflects the emergency response of related facilities in the research area, so as to lay the foundation of service area division. Basically, a traffic network model consists of road segment and road junction. Road segment is the edge feature of road network, which is expressed as segmental arc in ARC/INFO. Its attributes include normal average vehicle speed, average congestion speed, transit time, road length, etc. Road junctions is expressed as nodes in ARC/INFO, associated with the turn table, it could stimulate real-time road condition including waiting time during red light, no straight through, no left turn, elevated through, etc.

The steps are as follows: construct the road network framework with every road segment as an edge; set turn attribute, intersection attribute to establish connectivity; assign the value of length, vehicle speed and transit time to the road network according to the element attribute list. Finally, a feature dataset of all meeting points is generated. The existing road network is derived from Gaode open platform, and calculated with real-time average transit speed. Meanwhile, the planning road network is taken from “Overall urban planning of Nanjing” to the sub-arterial road level in principle, and partially access road if necessary. Vehicle speed using in the calculation is extracted from the real-time data considering different directions.

4 THE APPLICATION OF API BASED REAL-TIME TRAFFIC CIRCLE MODEL IN THE EVALUATION OF FIRE STATION LAYOUT

4.1 Gaode open API based real-time traffic status analysis in Nanjing

The vehicle speed extracted from Gaode API model is based on real-time traffic status, which is affected by holidays and festivals, fatal traffic accident and rush hour. Considering that emergency facility study more focus on the stable traffic connection and transit time between the facility and demand point, it is essential to evaluate the variability and stability of the transit time extracted from Gaode API model at different time. Therefore, this study acquires the two-week vehicle speed data from 28th, May, 2019 to 10th, June, 2019 as sample, and obtains the hourly average vehicle speed after data analysis. Compared the vehicle speed data of the two week, it can be seen from the covariance calculation result that the two average speed curves are highly matched, with a correlation coefficient of 0.973 (Figure.5). It confirms that the data is representative.

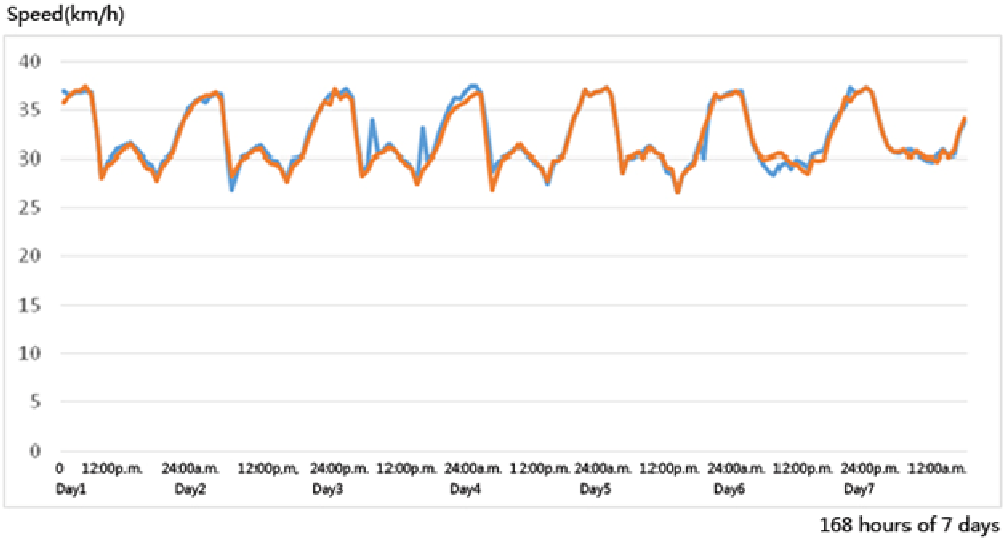

Figure 5: Comparison of average speeds (May 28 - June 10, 2019)

4.2 The space-time characteristics of road network during traffic congestion in Nanjing urban region

According to the Web API data, road condition spatial information has two characteristics: congested condition and driving speed. Taking the data from 28th, May, 2019 to 10th, June, 2019 as sample, the study carries on the statistics. The congested condition is divided into three level according to the congestion delay index1: clear (congestion delay index equal or less than 1.5), slowdown (congestion delay index between 1.5 and 1.8) and congested (congestion delay index equal or greater than 1.8). The statistics of all urban road data in Nanjing shows that the speed range of "clear" condition is [20, 120 km/h] with Eigen value of 35 km/h; the speed range of "slowdown" condition is [10, 50 km/h] with Eigen value of 20 km/h; the speed range of "congested" condition is [5, 25 km/h] with Eigen value of 10 km/h. It is calculated that the daily congestion delay index in Nanjing is 1.55 with the average vehicle speed of 28.29km/h. And for rush hours, the congestion delay index reaches 1.81 with the average vehicle speed drops to 24.21 km/h. The calculation result above can be corroborated with data from the official report of traffic management department. Thus it can be seen that traffic congestion has been a chronic disease of Nanjing city.

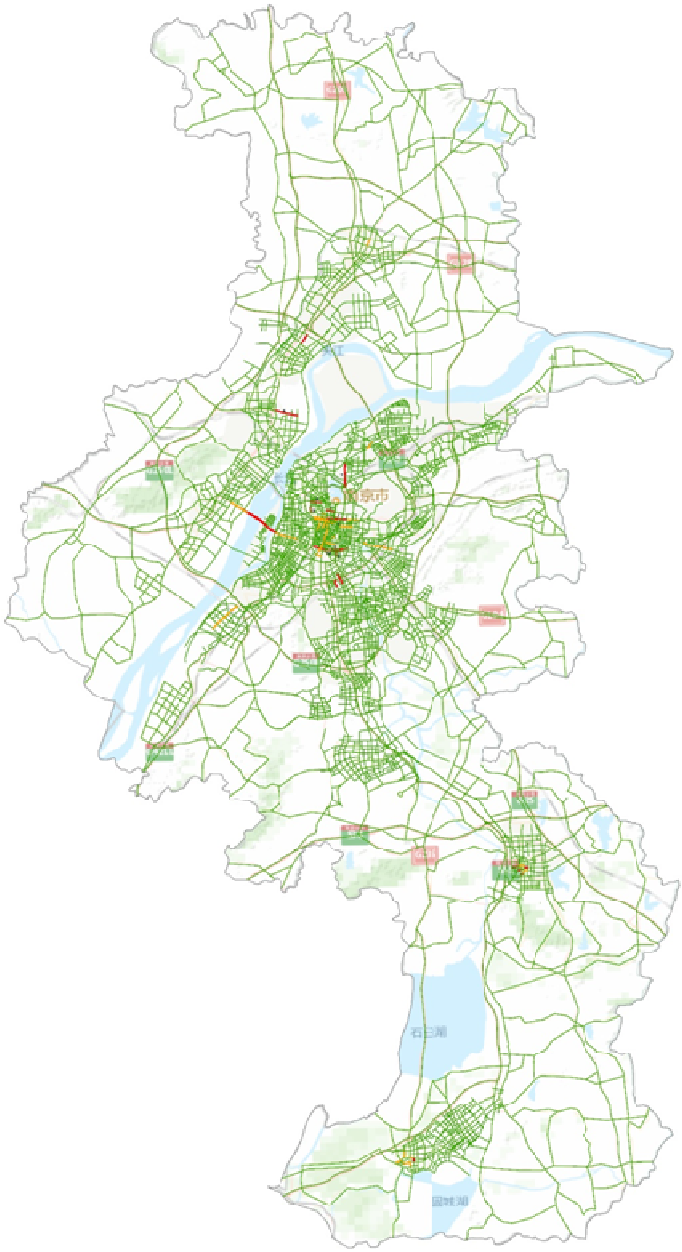

Figure 6: Road value of Nanjing City

The visualization result indicates that it is evidently more congested in Nanjing central urban area than in surrounding rural area. Specific to the district level, and focusing on the morning and evening rush hours. It suggests that Qinhuai District is the most congested area. Attributed to the traffic congestion, Qinhuai city

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

dwellers spend twice as long travelling time compared with that in free flow condition. The congested condition is gradually improved from the center to the edge. According to the distribution characteristics of the two-week data, this study defines the road segment with average vehicle speed equal or less than 20 km/h as congested segment, the road segment with average vehicle speed between 21to 35 km/h as slowdown segment, and the road segment with average vehicle speed equal or over 36 km/h as clear segment. Taking a statistics of average vehicle speed on the 11 administrative districts of Nanjing respectively, it can be found that in the coral area of Nanjing central urban area including Qinhuai, Gulou, Xuanwu, Jianye district and their conterminous area, there is a continuous peaking traffic situation emerges in non-late-night hours while there are still a few road segments display slowdown situation during late night. In another word, within the coral area mentioned above and its 5 km extended scope, the traffic situation could be described as widespread “slowdown” with partially “clear”.

To be specific, the first circle with the core location facing outward: from Xuanwu District to Qixia district, Qinhuai district to Yuhuadai district, Qinhuai district to Jiangning district, and Jianye to Pukou district, all have major input and output roads bearing a large amount of transit traffic, causing time-division congestion. Similiarly, Hexi district is characterized with slow traffic as well, especially Hengshan Road, Fuchunjiang East Street and Yurun Street. Above all, Yuhuatai district has more prominent congestion. For transition area: The junction of Qixia and Xuanwu district starts from Hongshan Road, reaches Keyan Road in the north, and reaches Huadian East Road in the west, which is the characteristic congested area of the whole city. For surburb area: Lishui district, Liuhe district and Gaochun district shows that most of the road are unblocked with a small part of the central urban streets and main transit roads has more prominent congestion.

Through the two-week traffic data, 24 full-time data are automatically obtained every day. The average speed of the road is calculated and the congested road section is evaluated by the extreme value and average value of the road speed (Figure.6). In addition to the unknown state of the road, the original data is formatted to the effective road, and the average data availability reaches 89.8%. Considering that the traffic speed is limited by the road grade, the road with low traffic speed cannot be simply classified as congested state, so this paper retains two dimensions of average speed and congested state for comprehensive analysis. According to the analysis, the overall traffic situation shows the commuting characteristics of a single center in the city, spread to the transition area and many small centers in the suburb area; the characteristic congested sections in each jurisdiction are obvious; and the congested periods are also obvious (Figure 7).

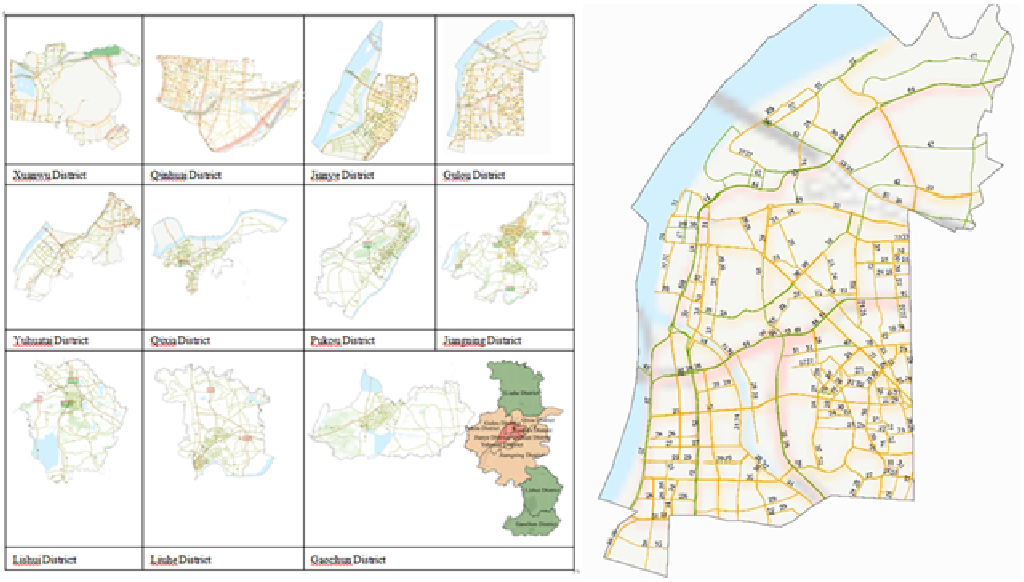

Figure 7: Average speed diagram of different districts (Top line for central area; the middle line for transition area; the end line for suburb area, the figure on the right is an example of a map of the Qinhuai region)

Urban real-time circles model integrate the two dimensions of time and space, which generally refer to the space range that can be reached within a certain time from the central location. In addition, it is a direct reflection of the ability of the transportation infrastructure to guide, support and secure urban and regional development [12]. The traffic circle can be used to assess the spatial scope of facilities and services.

Traditional traffic circle measurement methods are often carried out by simulating the speed of traffic [13-15]. However, it lacks the measurement of people's actual decision on behaviors and congestion in different parts of the city in real situation, thus it cannot mirror the influencing factors in real traffic congestion. Besides, there is no better way to quantify and extract those factors for explanation. In light of this, the article combines the real-time traffic conditions provided by the Gaode API, and applies Python and Arcgis software to extract and construct the real-time traffic circle. In other words, it divides the vehicle circle based on the speed of each road acquired from the Internet's open data to evaluate the coverage of the current service facilities.

4.2.1 Determination of evaluation index system

The traffic circle generated by the real-time traffic conditions can run through the entire process in the practice of emergency facilities planning. this study divides it into three stages: assessment of service scope of current facilities, mid-term location selection model to assist decision-making, and later facility optimization and verification. This article focuses on the application in the first stage. Namely, it divides the travel circle based on the speed of each road acquired from the Internet's open data to evaluate the coverage of the current service facilities. After extracting the current vehicle speed of each road in Nanjing, accurate real-time traffic circle analysis on the current facilities could be performed, corresponding to the arrival time of various emergency facilities, and choose different times to analyze the current traffic circle. In accordance with different levels in prevention, control and service requirements of fire stations, real-time circles including 2-4-6-8mins are set for comprehensive analysisc(Figure.8). Taking the linear coverage of fire stations as an example, the analysis of the current coverage of fire stations in the city of the actual road network speed reveals that, based on the area of the city, the overall service area coverage of fire stations is 16%. There are many blind areas in the Nanjing city, of which the core of the main urban area covers a continuous range, the surrounding jurisdictions mainly cover the central urban area. The lack of stations has become the main cause of large blind areas. Within 8 minutes, the maximum distance that can be visited by each fire station is 12435 meters, the minimum distance is 1085 meters, and the average service distance is 5125 meters. Besides, the service distance of the main urban area is smaller than the surrounding jurisdictions. The coverage of the 8-minute station almost coincides with the high-risk area, but there is still a large gap to meet the national regulatory requirements of "the fire brigade shall reach its descending edge within 5 minutes after receiving an active command". It shows a low coverage rate of 22% and 39% for respond time of 6min and 8min respectively.

4.2.2 Evaluation of current fire service coverage characteristics

The fire stations are rather independent and the 2-min fire service scale does not overlap. In the central urban area with high road density, service scope is distributed in plane shape, radiating from every fire station along the road network. While in the rural area with low road density, service scope is distributed in line with the shape of narrow belt, and the length-width ratio is pretty unbalanced. Vehicle traffic speed and road network density are the primary influencing factors, so that the 2-min fire service can cover 100% of the high fire risk area. The 4-min fire service scale are found partially overlapped. In the remote urban areas with high traffic speed, the patches become more diffuse, and the CONTAG rises. In the main urban area with high site density, the patches are even more diffuse, but connectivity increases which begins to show continuous characteristics. Thus in 4 minutes, the service scope is influenced by the road network density, the station density and the traffic speed, in which the impact of the traffic speed continues to increase. Compared with 4-min service scope, 6-min service scope is partially overlapped in remote urban area if more stations set and road network density offered. In the middle and north of Hexi, in the border area of Xuanwu, Gulou, Jianye and Qinhuai, and those 5km range, fire service is fully covered. The layout of road density is still narrow as a belt. Namely in 6 minutes, station density is the primary factor, while the influence of road density is reduced by traffic speed. In 8 minutes, except that Gaochun and Lishui are too far away from other fire stations and little stations in southern Jiangning, the service coverage shows connectivity between and inside jurisdictions, but far behind the demand of high fire risk area. The blindness would clearly reflect that high traffic speed cannot make up for the lack of fire station. In other words, unless the full travel time of fire fighting truck increases by a large span rather than 2-min staged rise (eg. 15 mins), the current fire service blind area cannot be effectively filled. In order to reduce the influence of traffic speed, the density of fire station plays a vital role (Fig.9.and Table 3).

5 CONCLUSION

The purpose of this study is to provide a method of automatically acquiring and processing data using internet open data represented by Gaode open platform through the streaming and distributed processing features. This method restores the authenticity of data, and provides a practical method for the application of big data in urban planning discipline. Compared with traditional methods, it is perspective to establish a real-time traffic circle based on Gaode data. Besides, with the help of various government departments, it has been successful implemented into the emergency facility planning of Nanjing city, which helps proving its feasibility in practice. Speaking of the creativity, this study not only makes up the shortage of ignoring traffic condition in traditional emergency facility planning, but also expands thought for similar planning by reviewing the application of traffic circle. However, there are still some imperfections in this paper that need to be further supplemented in the future: firstly, the accuracy of data analysis is on hourly level which could be further divided in to minute level for more details.

Approaches of Flexible Spatial Planning to Sustainable Cities

Antonia Stratmann

(MSc. Antonia Stratmann, RWTH Aachen University, Faculty for Architecture, Department for Urban Design, Graduated School For Sustainable Energy Systems in Neighbourhoods, stratmann@staedtebau.rwth-aachen.de)

1 ABSTRACT

This paper is a literature review of approaches of flexibility in spatial planning. It is about key elements which provide a flexible spatial planning to sustainable cities.

Spatial planning plays a decisive role in the implementation of sustainable adaptation measures and in ensuring the climate stability of spatial developments. Because urban structures have an impact on energy consumption and pollution, depending on how a building, park or square is designed.

In order to explore this issue, the paper first underscore the current environmental challenges and combines them with current challenges in spatial planning to point out the need of flexible spatial planning; second, explains why flexibility is necessary and which advantages it brings for sustainable city planning; third gives an overview of existing approaches in the literature. Next it provides the key flexibility elements analyzed from literature review. In conclusion the paper presents eight key elements which provides flexibility in spatial planning: Planning rules and norms, Programs and Concepts, Organization, Experiments, Control and Limits, Utilization structures, Spatial Planner and Time.

Keywords: space, cities, sustainability, spatial planning, flexibility

2 CURRENT ENVIRONMENTAL CHALLENGES AND THE IMPACT OF CITIES

Different strategies and concepts developt in countries and regions to set targets to sustainable city planning and designingto meet environmental targets and social needs. Because we do not know exactly what constitutes the environmental challenges and its consequences, it is stressed, that opportunities should be explored which are flexible and adaptive (van Buuren et al. 2013).

The term flexibility in spatial planning is not uniform defined yet. Cattlin (2017) points out that there is a definitional problem of flexibility: “if we lack of a common idea of what flexibility consists of, or who or what can be flexible, or over what kind of timescales we mean spaces to be flexible, we are talking about different things.” (Cattlin 2017, p.1). In literature terms like adaptable, flexible, adjustable, agile, customizable or adapt-flexible are used. For this reason, it is necessary to find out whether the terms are used simultaneously or whether they are different terms with different meanings. Perhaps it is not even necessary to define flexibility uniformly. Because this may contradict the term flexibility per se. However, it makes sense not to talk past each other when it comes to the approach. For this reason, it is assumed that flexibility in spatial planning is “a change in the system and making the possibility of obtaining new conditions, needs, and frameworks” (Ardeshiri et al. 2016, p.83-84). If the definition is transfered to urban development, flexibility for spatial planning must achieve the following: spatial structures must be able to adapt to changing circumstances, new uses and also social requirements.Thus, in a next step, flexibility can also be integrated in the planning of cities.

Figure 1 shows the main current challenges in urban development to sustainability: resource scarcity, environmental pollution, urbanization, sealing and soil compaction. Cities are responsible for 2/3 of the worlds emissions, thereby they account for only three percent of the surface area. But there is a rethinking in society, they are calling for sustainable solutions and products that adapt to viable (King and Trübstein 2019). Social and political pressure bring about change: it is about more sustainable solutions that influence spatial planning and are influenced the other way round by it. These include, for example, electrification in the transport sector, sector coupling, the generation of sustainable energy, emission-free mobility, green areas and, last but not least, the structures of the built city.

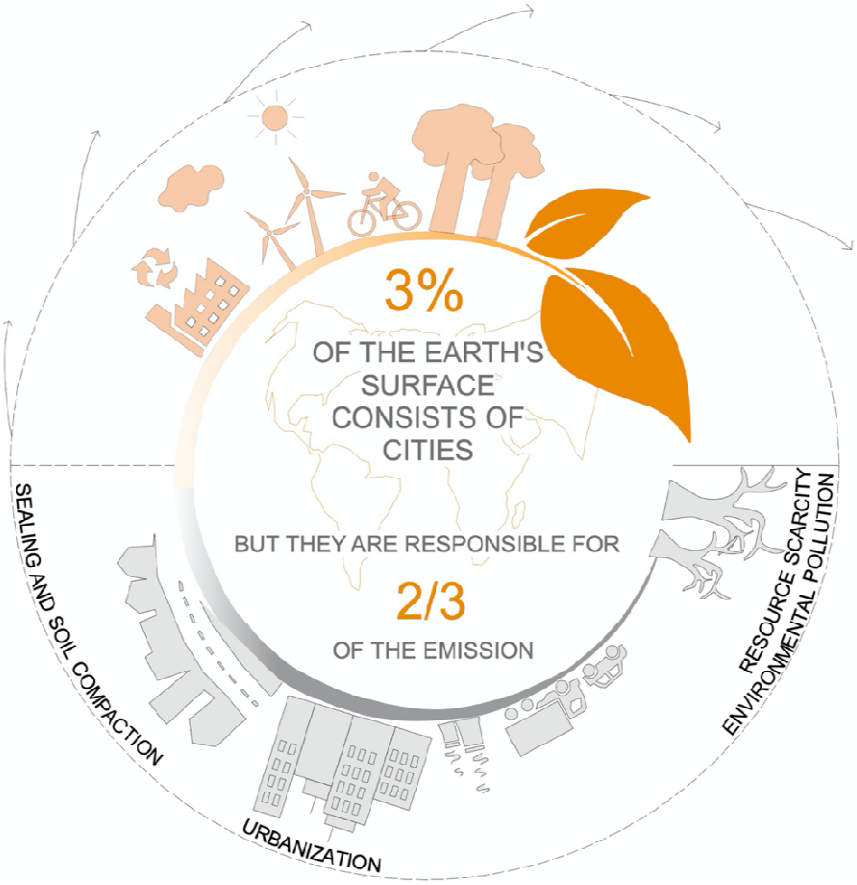

Figure 1 Indicators of climate change and urban development: rethinking in politics and society (own figure according to Stratmann 2019, p.1)

The United Nation recognised the link and interaction between sustainability and cities and therefore developed goals and targets to promote the sustainable development of cities. According to the Sustainable Development Goals (SDGs) one promote Sustainable Cities and Communities (Nr. 11). One of the idicators to achieve this target is the ratio of land consumption rate to population growth rate (United Nations 2020). The goals are not only quantificabile but also qualifiable, because sustainability challenges are different everywhere. It has not only to depend on geographical conditions, but also on social and economic conditions.

3 METHODICAL PROCEDURE AND OBJECTIVES

The aim is to filter out and summarize the key elements for flexibility in spatial planning from literature. In this way a common understanding of the planning approach of flexibility can be created and this can also be understood as a planning tool for the future of sustainable cities.

Designing cities with uncertainty and with gaps of knowledge means to develop innovative approaches (Zandvoort et al. 2019). The current challenges can be met by flexible approaches in spatial planning, as “the use of flexibility in designing projects is becoming increasingly common” (Geltner and Neufville 2012). As well van Buuren et al. (2013) called for an adaptive approach where flexibility is central. Based on these facts, it is necessary to take a closer look at the existing approaches to flexible spatial planning and to compile the most important principles to set an understanding.

New solutions must be found to meet the growing pressure for more sustainable cities. Due to the high decisive influence of spatial planning, the approaches already found in the literature are analysed and linked more closely. In the following, the research design is posed and the methodological approach of the work is explained. As a process-based dynamic planning tool, flexibility creates an adaptable planning basis.

In order to achieve this goal, it is necessary in the first step to understand why the approach requires closer examination. The already presented problem shows that due to the increasing pressure for sustainability in order to survive climate crises etc. and to offer society an adequate living space in cities, new approaches to spatial planning are taken.

Figure 2 schematically shows the procedure of literature research and analysis. First of all, an overview of existing approaches to flexibility in spatial city planning has been provided. To select significant flexibility approaches a national (germany) and international literature review was taken. Next followed by a brief analysis of key elements involved in each approach. After filter out the key elements a connection between the elements and sustainable spatial planning is created. At the end the impacts on sustainable city planning and the inferences are presented.

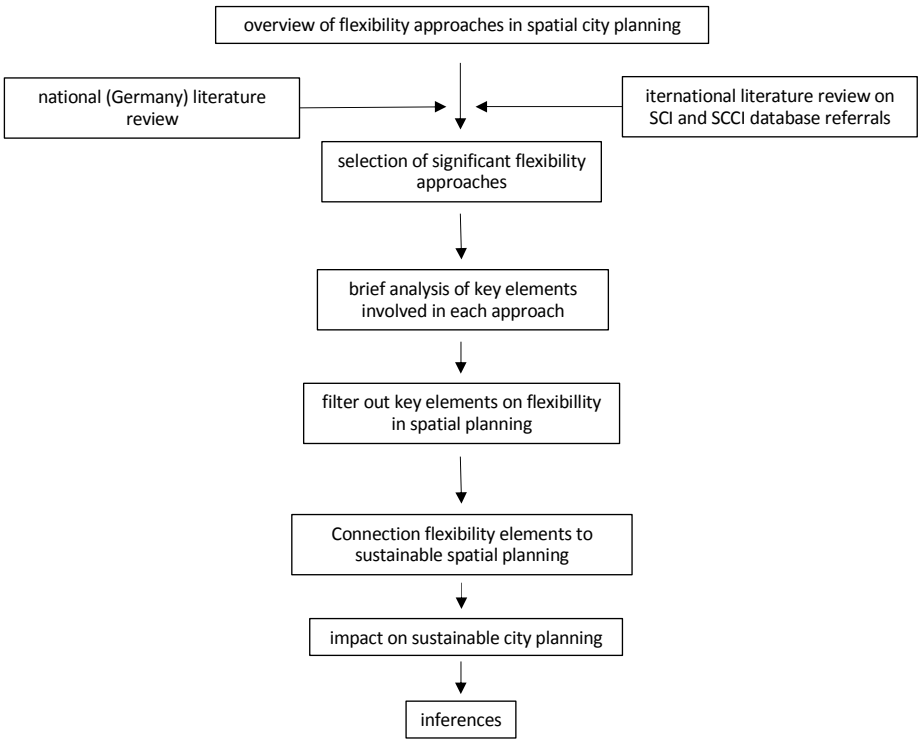

Figure 2 Methodological flow chart

The outline of the paper is: First the paper establishes a connection between current challenges in climate and environmental challenges and current urban development problems. This leads to the conclusion why the approach of flexibility can make a positive contribution to reducing the negative consequences of these challenges. Second, an overview on the methodical procedure on the literature review is given. Next the necessarity and advantages of the approaches of flexibility are explained. Various approaches of flexibility are taken up simultaneously. Next the paper provides the key flexibility elements analyzed from literature review. In conclusion the paper presents the key elements which provides flexibility in spatial planning

4 WHY DEALING WITH FLEXIBILITY IN SPATIAL PLANNING?

Summarizing it is seen that flexibility in spatial planning is justified in order to meet sustainable goals in city planning. There are a lot of different arguments promoting the idea of flexibility. Besides social and economic reasons, the ecological benefits play an important role. Next the advanteges and also critical points are given.

Flexible spatial planning brings diverse chances to urbanism (Costa et al. 2014). Cozzolino summarize arguments of different authors (Alfasi; Buitelaar; Cozzolino; Moroni; Rauws) towards the essential role of flexibility in the city: “if we recognize the essential role of spontaneity and flexibility in the city functioning (i.e., its creative role for innovation, the importance of localized knowledge, the need for perpetual adjustment and improvements of the build environment, and on) we cannot regulate the city in order to obtain or preserve the specific and predetermindes social-spatial configurations as we would or desire” (Cozzolino 2018, p. 16). More flexibility mitigate adverse effects of uncertainty (Zandvoort et al. 2019) and shortcomings of planning (Carr and Dionisio 2017). Because we do not know the future, agile approaches, like flexibility, fits into that we do not know the final result (Aurigi 2016). This brings design for unsheduled uses (Carr and Dionisio 2017). Moreover, it is possible that flexibility reduce resistance against further uses we do not know yet (Carr and Dionisio 2017). Because “adaptive landscape designs are important for heding

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

against the negative consequences of long-term commitments" (Zandvoort et al. 2019, p. 21). As well, flexibility supports short-term measures, while keeping options open on the long-term (Zandvoort et al. 2019).

Flexibility offers great opportunities to reduce resource consumption. Because multi usage is possible, less space is needed. Thus, the resource soil can be used sparingly (Geltner and Neufville 2012; Stiftung et al. 2003). For this reason "flexible […] land use represents efficient land use. This also serves to ensure the conservation of resources and sustainability in urban development" (Stratmann 2019, p. 69). Flexibility can reduce natural and unnatural damages (Ardeshiri et al. 2016), e.g. in times of climate change, when it is necessary to design more adaptable and flexible (BBSR 2016). In times of unforeseeable natural events, areas can be used both as public space for societies and as space for e.g. flooding events. By reuseing space and materials a much smaller carbon foodprint is given (Godwin 2018). One of the most commonly used defintion which links flexibility with climate change points out: "the adjustment in natural or human systems in response to actual or expected climatic stimuli or their diem, which moderates harm or exploits benefical opportunities" (IPCC 2007, p.7). Flexible public space contributes to ecological sustainable cities, because it is adaptable for different uses, users and in different times and it consume less ground, because usage can happen in parallel and/or side by side and offers hybrid space organizations (Stratmann 2019).

Likewise, flexibility offers great opportunities in social aspects. Flexibility provides potentials to society and achieves requirements and goals of peoples needs (Ardeshiri et al. 2016). As also mentioned by Ardeshiri et al. "in effect, it should be stressed that flexibility searches for selection arrays against needs" (2016). In view of the ever more rapidly changing demand needs, flexible spatial planning can be combined with faster implementation (King and Trübstein 2019). To put it briefly: flexibility is demand-oriented.

On the one hand there are a lot of reasons to design flexible in spatial planning. But on the other hand there are a few arguments which call the approach into question. Carr and Dionisio explain "that flexible spaces may provoke a greater level of NIMBYism (Not In My Backyard) than convential land uses" (2017, p. 76). As well there is a risk of inferior re-use and less security of planning (Stiftung et al. 2003; Gifford 1994).

5 KEY ELEMENTS OF FLEXIBILITY IN SPATIAL PLANNING

In summary there are some repeated elements in literature which welcome flexibility in spatial planning. For this reason it is assumed that there is a consensus on these elements in literature. Therefore it can be assumed that flexibility depends mainly on the eight elements identified. The identified key elements are: Planning rules and norms, Programs and Concepts, Organization, Experiments, Control and Limits, Utilization strucutres, Spatial Planner and Time.

To find out key elements in flexibility approaches, an analyse was taken. A total of 16 approaches to the issue have been examined more closely. The approaches have been filtered through national (Germany) and international literature research and do not necessarily explicitly include the approach of flexibility but implicitly. Nevertheless, there are already approaches in the literature that have specifically addressed the issue of flexibility. This spectrum of authors and also the way the term is dealt with highlight the key elements of flexibility through its diversity and at the same time uniformity. The analysis has been carried out qualitatively and is not regarded as conclusive. In the end, once the recurring elements have been included, it is possible to determine on a quantitative level which elements have been mentioned particularly frequently. From this it is concluded that the frequently mentioned elements are central elements of flexibility in spatial planning. Below the key elements are listed and discribed in their impacts to flexibility in spatial planning.

Planning rules and norms: Rules ensure that flexibility is reduced quickly and easily and thus takes away the possibility of adapting. For this reason, it is necessary to make the way rules and norms are written and deployed flexible. Rules must be established that allow flexibility in spatial planning. This includes not only the flexibility of the standards among themselves, but also the context of the content. There should be flexibility in the rules of use in spatial planning. Conversely, the space itself should also be able to provide differences in rules. Without enough space for flexibility in planning rules, there is no flexibility in spatial planning. Any regulation should be minimal, for maximum flexibility. (Aliyha and Aulia 2019; Carr and Dionisio 2017; Cozzolino 2018; King and Trübstein 2019; Rauws 2015; Van Buuren et al. 2013)

Programs and Concepts: Traditional urban development plans and concepts have been drawn up without flexibility and are completed in their spatial and functional system. But flexible concepts have to be established which convey the concept and the handling of adaptability and flexibility in spatial planning. The concepts must be flexible so that the plans and measures developed and implemented on them become flexible. Flexibility must be conceptually anchored in order to be applicable. Flexible concepts can help planners to design the future. The aim is to create long-term plans and concepts that can be flexible adapted in short-term. (BMBVBS 2013; Cozzolino 2018; Fainstein et al. 2018; Lotto and Di Morelli Popolo 2015; Rauws 2015; Reicher 2014; Zandvoort 2019; Zikovic et al. 2014)

Organization: The management, institutional context and the planning process itselfs, has to become flexible, summerized to the term organization. To get flexibility in spatial planning, flexibility has to be managed. There has to be a manager, who is responsible for flexibility. The involvement of institutions play a role to establish flexibility in spatial planning. For more flexibility in spatial planning, the institutional design must become more flexible. Institutions must not be rigid, but do welcome flexible participation. If the planning processes do welcome and change to flexibility. (Aurigi 2016; Friedman 1997; Van Buuren et al. 2013)

Experiments: Flexibility can provide spaces that are suitable for experiments and pilot projects. This creates new opportunities and possibilities in urban planning: new solutions can be found through flexible space, which are effective and valuable. There are spaces for new ideas and solutions that can be try out without having to commit to them. Therefore, flexibility is also experimental, apart from the fact that the approach is innovative and experimental in itself. Therefore, flexibility in spatial planning brings spaces for unpredictable, improvised and ephemeral uses. (Carr and Dionisio 2017; Hetzberger 2014; Lewis and Schwindeller 2014; Van Buuren et al. 2013)

Control and Limits: Flexibility is strongly influenced in spatial planning by control and limits. On the one hand, it can be said that the more the city is controlled and planned from above, the less flexibility. On the other hand, it can be said that a lack of control and limits can have a negative influence on flexibility. Therefore the degree of control and limits plays a decisive role in the flexibility of spatial planning. (Cozzolino 2018; Friedman 1997; Lotto and Di Morelli Popolo 2015; Zikovic et al. 2014)

Utilization structures: The current utilization structures are called into question by flexibility. Flexible space and utilization structures must be created multifunctional, but do not claim to be fitted to all uses. The build environment and inventory must be flexible, offering space for other uses and users. Structural elements must be flexible and the utilization structure must be flexible for unsheduled uses. (BMVBS 2013; Carr and Dionisio 2017; Hetzberger 2014; King and Trübstein 2019; Lotto and Di Morelli Popolo 2015)

Spatial Planner: If planners do not fulfil the task of flexible planning, there can not be flexibility in spatial planning. Planners must be more sensitive to needs in order to be able to react more flexible to changes. The way planners understand their task influences flexibility. Relevant suggestions from society should also be sought for this. A flexible space makes it unnecessary for planners to intervene at a later stage. (Carr and Dionisio 2017; Cozzolino 2018; Fainstein et al. 2018; Friedman 1997; Lotto and Di Morelli Popolo 2015; Rauws 2015; Zandvoort 2019)

Time: The time frame of flexibility plays a crucial role, because flexibility creates the possibility to adapt to the physical and social world over time. Because there is always uncertainty about future uses and the requirements change over time. It is therefore important to draw up plans and concepts that are designed for the long term, but can always act in the short term. Changes have to be accepted in different time periods, only then flexibility can succeed. Sufficient space must be left for the time factor, because planning processes can often only be regulated over time. (Cozzolino 2018; Fainstein et al. 2018; Hetzberger 2014; Lewis and Schwindeller 2014; Lotto and Di Morelli Popolo 2015; Rauws 2015; Reicher 2014; Zandvoort 2019)

The combined eight key elements influence the flexibility of spatial planning to varying degrees. The degree of flexibility in spatial planning depends on how many elements are used and the value of these elements accoring to the conditions and case study. How to measure and determine the degree of flexibility on a qualitative and/or quantitative level and whether this is even necessary to achieve the goal of a sustainable city has not yet been considered.

6 CONCLUSION: FLEXIBILITY TO SUSTAINABLE CITIES

As outline before, the spatial planning approach of flexibility influence the possibility to achieve sustainable cities. Flexibility is called a designing tool to reach sustainable spatial planning. The approach of flexibility is to see as a process which influence spatial planning as much as spatial planning influence flexibility. In conclusion in literature there are different terms of flexibility but in case they usually mean the same circumstance and there are many overlapping requirements and elements for flexible planning in the analyised approaches.

By analysing the key elements of flexibility it is possible to create a common understanding of flexibility in spatial planning. Without the knowledge of the approach of flexibility and its elements it is not possible to establish the approach and create an international understanding. The eight elements illustrate the complexity of the influence of spatial planning on the flexibility of a city. Not only the built, the physical structures (such as the elements Urbanization structures), but also the temporal course, element time, the organization and last but not least one of the strongest elements: the social influence of Spatial Planner. Looking at the elements, it is obvious that they need and influence each other in order to create the goal of flexible and thus sustainable cities. Without the Spatial Planner no new planning rules and norms can be established. Without concepts and plans, Spatial Planner cannot be guided by them. Without the organization, the approach cannot be executed. Without the temporal consideration, no experiments can be conducted, which in turn require control and limits. These relationships can be elaborated further and it becomes very clear that the elements are closely related and interrelated. All together, as well as each one individually, contributes to the planning and design of a sustainable city.

The field of flexibility is large and certainly includes more than the eight elements presented in this paper. Furthermore, it is debatable whether these elements are representative, how far their influence is. Therefore, a closer (also spatial) investigation is needed in further steps.

1 ABSTRACT

Bei Baumkontrollen werden sogenannte Baumkataster angelegt, in denen Informationen über in einem bestimmten Bereich befindliche Bäume dokumentiert werden. In ihnen wird unter anderem die Gestalt der Bäume durch die Parametern Baumhöhe, Baumkronendurchmesser und Baumkronenumfang beschrieben. Im Rahmen dieses Beitrages wird ein in Python entwickeltes Analyse- und Transformationswerkzeug vorgestellt, welches erlaubt, Baumdaten in unterschiedlicher, strukturierter Form (CSV, XML) einzulesen, tabellarisch darzustellen und zu analysieren. Weiterhin ermöglicht es, aus den Gestalt beschreibenden Daten ein 3D-Modell abzuleiten und dieses im standardisierten Datenformat CityGML unter Verwendung des Vegetation-Moduls als geometrisches 3D Modell mit den vorhandenen Sachdaten zu exportieren.

Keywords: Digitalisierung, CityGML, 3D, Baumkataster, Python

2 EINLEITUNG

Im Rahmen der Verkehrssicherungspflicht ist diejenige Person, die Verfügungsgewalt über ein Grundstück ausübt, dazu verpflichtet sicherzustellen, dass von den auf dem Grundstück befindlichen Bäumen keine Gefahren ausgehen. Daraus resultiert, dass Bäume im öffentlichen Raum in regelmäßigen Kontrollen auf Standsicherheit und Beschädigungen überprüft werden müssen.

Dabei werden sogenannte Baumkataster angelegt, um der Dokumentationspflicht nachzukommen, in denen neben einer Bewertung jedes Baumes auf einem Grundstück dessen genaue Lage sowie Metadaten erfasst werden. Einige dieser Metadaten beschreiben den Baum in seiner Gestalt, z.B. die Baumhöhe, der Stammdurchmesser oder der Baumkronendurchmesser.

Die Daten eines Baumkatasters lassen sich abgesehen von der Dokumentation aber auch noch für andere Einsatzgebiete nutzen. Aus den erfassten Parametern lässt sich die Gestalt der Bäume in parametrisierter Form beschreiben und damit für die Visualisierung oder für Simulationsberechnungen einsetzen. In einer Abschattungsanalyse kann beispielsweiße der Schatten berechnet werden, der von einem Baum auf ein Gebäude geworfen wird. Diese Informationen können für eine Solarpotentialanalyse oder für thermische Gebäudesimulationen genutzt werden. Um solche Berechnungen durchführen zu können ist ein digitales dreidimensionales Modell der Bäume notwendig. Viele Softwarelösungen zum Verwalten solcher Baumkataster unterstützen einen Export dahingehend jedoch nicht. Das am Campus Nord des KIT eingesetzte Programmsystem Arbokat® unterstützt beispielsweiße lediglich einen Export in die Formate CSV, PDF, KML, Shapefile und INGRADAweb, sodass die Entwicklung eines Werkzeuges, welches aus den Baumkatasterdaten dreidimensionale Geometrien ableitet und diese im standardisierten CityGML-Format exportiert, notwendig ist.

3 GRUNDLAGEN

3.1 Baumkataster

Ein Baumkataster ist ein raumbezogenes Verzeichnis, in dem Informationen zu Bäumen innerhalb eines bestimmten Gebietes erfasst sind (Stadt Stuttgart, 2020). Ein solches Gebiet kann zum Beispiel ein einzelnes Grundstück sein, aber auch ein gesamtes Stadtgebiet umfassen. Sie werden zu Dokumentationszwecken regelmäßig stattfindender Baumkontrollen angelegt. Solche Kontrollen müssen regelmäßig von sowohl öffentlichen als auch privaten Grundbesitzern stattfinden, die Verkehr eröffnen oder auf einem Grundstück zulassen. Der Grund hierfür ist, dass ein Baumbesitzer der Verkehrssicherungspflicht nachzukommen muss, die er gegenüber Dritten hat (Wessolly und Erb, 2014). Bei diesen Baumkontrollen wird der Zustand des Baumes erfasst und bewertet, um beispielsweise Sach- und Personenschäden durch baumkrankheitsbedingte Sturmschäden zu vermeiden. Im Jahr 2004 hat die Forschungsgesellschaft Landschaftsentwicklung Landschaftsbau e.V. (FLL) erstmals die Anforderungen an Baumkontrollen in den Baumkontrollrichtlinien

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

normiert. Diese Baumkontrollrichtlinien der FLL wurden über gerichtliche Urteile dem aktuellen Stand der Technik der Baumkontrolle zugeordnet. Mittlerweile wurden die Baumkontrollrichtlinien überarbeitet, sodass diese seit 2010 in einer neuen, aktualisierten Fassung zur Verfügung stehen (Forschungsgesellschaft Landschaftsentwicklung Landschaftsbau e.V., 2010). Während dieser Baumkontrollen werden Daten über die untersuchten Bäume erfasst, wie z.B. der Gesundheitszustand, der Standort, die Höhe, der Stammdurchmesser oder der Baumkronendurchmesser.

Alle während der Baumkontrolle erfassten Daten werden danach zu Dokumentationszwecken im Baumkataster festgehalten. In ihnen werden also neben Daten zum Gesundheitszustand des Baumes und Standortinformationen und auch Daten über die Gestalt des Baumes festgehalten.

Es existieren einige Software-Programme, um die Erstellung und Verwaltung eines digitalen Baumkatasters zu erleichtern. Die am Campus Nord des KIT verwendete Software zur Erstellung und Verwaltung des digitalen Baumkatasters heißt Arbokat® und wird von der Firma iNovaGIS und dem Sachverständigenbüro Peter Klug konzipiert und entwickelt. Dabei werden alle in den Baumkontrollrichtlinien der FLL festgelegten Kriterien berücksichtigt (iNovaGIS, 2016).

3.2 CityGML

Das Datenformat City Geography Markup Language (CityGML) ist das Datenmodell, in das das Baumkataster überführt werden soll. Es ist ein semantisches Datenmodell zum Speichern und Austauschen digitaler dreidimensionaler (3D) Stadtmodelle (Gröger et al. 2012).

Das CityGML-Datenmodell wird seit 2002 von der Special Interest Group 3D (SIG 3D) entwickelt. Die Arbeitsgemeinschaft besteht aus mehr als 70 Firmen, Gemeinden und Forschungseinrichtungen. Ziel ist, ein standardisiertes Datenformat zum Speichern von 3D-Stadtmodellen zu schaffen, um den Austausch von Stadtmodellen zu erleichtern (Kolbe, 2009). Im Jahr 2008 wurde das CityGML-Datenformat (damals in der Version 1.0.0) auch vom Open Geospatial Consirtium als Standard (OGC) anerkannt. Aktuell liegt CityGML in der Version 2.0.0 vor und wird von vielen Städten weltweit (z.B. Berlin, München, Paris, Monaco, Istanbul, Doha) dazu verwendet, 3D-Stadtmodelle bereitzustellen (Gröger et al. 2012).

CityGML verbindet dabei eine geometrische Modellierung von Städten mit einer semantischen Modellierung. Das bedeutet, dass ein Stadtmodell im CityGML-Format sich nicht nur zur Visualisierung einer Stadt eignet, da nicht nur eine geometrische Repräsentation von einzelnen Objekten einer Stadt vorliegt, sondern dabei die einzelnen Objekte auch klassifiziert und aggregiert werden können, sowie mit verschiedenen, das Objekt näher beschreibenden, Attributen versehen werden können. Eine solche semantische Modellierung ermöglicht in Kombination mit der geometrischen Modellierung weitreichende Analysen (Gröger et al. 2012).

Das CityGML-Format ist modular aufgebaut. Es besteht aus dem zwingend erforderlichen Core-Modul sowie aus thematisch gegliederten Erweiterungs-Modulen. Das Core-Modul umfasst alle dem Datenmodell zugrundeliegenden Konzepte und Komponenten, die von jedem der Erweiterungsmodule genutzt werden. Mit den thematisch voneinander abgegrenzten Erweiterungsmodulen findet dann die eigentliche Modellierung der Objekte einer Stadt statt. Das Stadtmodell besteht dann aus der Gesamtheit der einzeln modellierten Objekte. In CityGML 2.0 existieren Erweiterungsmodule für z.B. Gebäude, Brücken und Stadtmöbelierung. Es existiert außerdem ein Modul für Vegetation, welches im Folgenden genauer vorgestellt wird (Gröger et al. 2012).

Unterschieden werden im Vegetation-Modul zwei verschiedene Klassen von Vegetation. Während die Klasse PlantCover dazu verwendet wird, eine größere Ansammlung von Vegetation zu modellieren wie z.B. eine Wiese oder einen Wald, können über die Klasse SolitaryVegetationObject einzelne Vegetations-Objekte beschrieben werden wie z.B. einzelne Bäume, Sträucher oder Büsche. Beide Klassen erben von der abstrakten Klasse _VegetationObject, die wiederum von der abstrakten Klasse _CityObject des Core-Moduls erbt. Abbildung 1 zeigt das UML-Klassendiagramm des CityGML-Vegetation-Moduls.

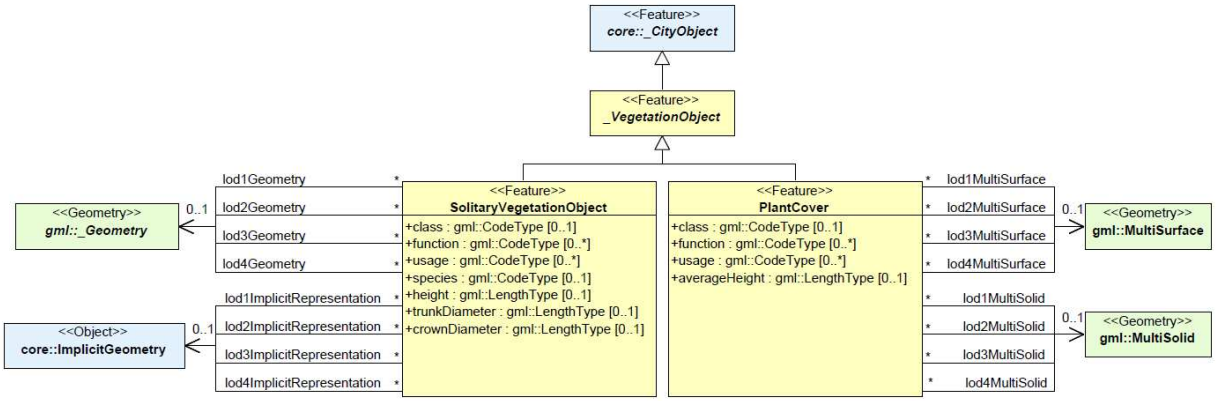

Abbildung 1: UML-Klassendiagramm des CityGML Vegetation-Moduls (Gröger et al. 2012)

Ein Objekt der Klasse PlantCover besitzt die Attribute class, welches die Vegetationsgruppe beschreibt, der das PlantCover-Objekt angehört. Die Attribute function und usage beschreiben den angedachten und tatsächlichen Zweck eines Objektes. Zudem besitzt die Klasse PlantCover das Attribut averageHeight, in dem die durchschnittliche Höhe der Vegetationsgruppe gespeichert wird (Gröger et al. 2012).

Auch ein Objekt der Klasse SolitaryVegetationObject hat die Attribute function und usage, die hier die gleiche Verwendung haben. Das Attribut class wird bei SolitaryVegetationObject jedoch dazu verwendet, um das Vegetations-Object genauer zu klassifizieren (z.B. Baum, Busch, Gras). Ein Objekt der Klasse SolitaryVegetationObject besitzt außerdem das Attribut species, in welchem der botanische Fachname der Spezies (z.B. Abies alba für Weißtanne) als CodeType gespeichert ist. Das bedeutet, dass jeder Baumspezies über eine sogenannte Codelist ein Zahlencode zugeordnet ist, und nur dieser Zahlencode im CityGML-Stadtmodell gespeichert wird (Gröger et al. 2012). Diese Codelist ist in der CityGML-Spezifikation definiert, sodass die verwendeten Codes programmunabhängig interpretiert werden können.

Des Weiteren besitzt die Klasse SolitaryVegetationObject einige Attribute zur parametrisierten Beschreibung der Geometrie. So kann im Attribut height die Höhe des Vegetations-Objektes gespeichert werden, im Attribut trunkDiameter der Durchmesser des Baumstammes (falls das modellierte Objekt ein Baum ist) und im Attribut crownDiameter der Durchmesser der Baumkrone. Alle Attribute der Klassen PlantCover und SolitaryVegetationObject sind jedoch optional und nicht zwingend erforderlich, was auch die Modellierung sehr flexibel macht. So können z.B. mit der Klasse SolitaryVegetationObject Bäume als auch Sträucher und Büsche modellieren, obwohl z.B. das Attribut trunkDiameter bei Büschen nicht sinnvoll einzusetzen ist. Es macht aber auch dann eine thematische Modellierung möglich, wenn nicht alle Attribute eines Vegetation-Objektes erfasst sind oder erfasst werden können. Weiterhin ist es möglich, jedem Objekt der Klasse _CityObject eine beliebige Anzahl frei definierbarer Attribute hinzuzufügen, sogenannte Generic Attributes, um eine thematische Modellierung über Attribute zu ermöglichen die nicht vom Datenmodell vorgesehen sind (Gröger et al. 2012).

Zur Visualisierung der Vegetation sowie zur Durchführung geometrischer Analysen ist es außerdem möglich, jedem Objekt der Klasse PlantCover und SolitaryVegetationObject Geometrien im Level-Of-Detail (LOD) 1 bis LOD4 zuzuweisen (Gröger et al. 2012).

4 ANALYSE

In diesem Kapitel werden zunächst die Ausgangsdaten, die im CSV-Format vorliegen, analysiert. Anschließend wird untersucht, welche Anforderungen an das zu erstellende Softwarewerkzeug gestellt werden

4.1 Baumdaten im CSV-Format

Das am KIT Campus Nord zur Verwaltung eines digitalen Baumkatasters verwendete Programmsystem Arbokat® unterstützt einen Export der Baumdaten in das Datenformat Comma Seperated Values (CSV) (iNovaGIS, o.D.). Dabei handelt es sich um eine Textdatei zur Speicherung strukturierter Daten, die sich aufgrund der Einfachheit des Datenformats leicht automatisiert verarbeiten lässt.

Die von Arbokat® generierte CSV-Datei enthält alle im Baumkataster gespeicherten Bäume. Jede Zeile der Datei enthält dabei die Informationen für je einen Baum. Innerhalb einer Zeile stehen, durch Semikolons

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

voneinander getrennt, verschiedene Attribute, die den Baum näher in seinem Standort, seiner Gestalt und seinem Gesundheitszustand beschreiben. Um die einzelnen Baumattribute interpretieren zu können stehen in der ersten Zeile der CSV-Datei die Namen der Attribute. Für die Erstellung eines dreidimensionalen Baumkatasters sowohl als geometrisches als auch als parametrisiertes Modell im CityGML-Format sind dabei die folgenden Informationen wichtig, die in der CSV-Datei gespeichert sind:

- Genaue Position des Baumes: Rechts- und Hochwert im Referenzsystem Gauß-Krüger-Zone-3
- Lateinischer Name der Baumart
- Gestalt des Baumes: Baumhöhe, Baumkronendurchmesser, Stammumfang

Auffällig ist, dass den Bäumen in der CSV-Datei keine ID zugewiesen ist, über die ein Baum identifiziert werden könnte. Es existiert lediglich eine Baumnummer, die jedoch mehrfach vergeben wurde. Allerdings ist jedem Baum ein Bereich zugewiesen ist, in dem er steht und bei näherer Betrachtung fällt auf, dass die Baumnummer innerhalb eines Bereiches eindeutig ist. Somit ist es möglich, einen Baum anhand einer Kombination aus Bereichsnummer und Baumnummer eindeutig im gesamten Datensatz zu identifizieren.

4.2 Anforderungen an das Programm

Im Allgemeinen soll das in Python geschriebene Programm Baumdaten verschiedener Datenformate einlesen und verarbeiten können. Die Daten sollen analysiert, validiert und aus ihnen ein parametrisches als auch geometrisches Baummodell generiert werden können. Dieses soll im CityGML-Format exportiert werden können. Diese allgemeinen Anforderungen, die im Folgenden konkretisiert werden, legen die Rahmenbedingungen für die Entwicklung des Programms fest.

- Einlesen der Baumdaten: Das Programm soll Baumdaten in zweierlei Datenformaten einlesen und verarbeiten können. Es soll Baumdaten im CSV- als auch im XML-Format einlesen, verarbeiten und interpretieren können. Dabei soll eine gewisse Flexibilität beim Einlesen der Daten hinsichtlich ihrer Modellierung im jeweiligen Datenformat möglich sein.
- Graphische Benutzeroberfläche: Das Programm soll zur vereinfachten Bedienbarkeit über eine graphische Benutzeroberfläche verfügen. In ihr sollen die eingelesenen Baumdaten tabellarisch angezeigt werden, damit der Benutzer sich einen Überblick über den Datensatz verschaffen kann. Über die Benutzeroberfläche sollen alle Funktionen des Programms aufgerufen werden können.
- Analyse der Daten: Die eingelesenen Daten sollen analysiert werden können, damit der Benutzer sich einen Überblick über die Qualität der Daten schaffen kann. Die Daten sollen sowohl nach ihrer ID als auch nach ihrer Position auf Duplikate überprüft werden können. Weiterhin soll eine Validierung der Gestalt beschreibenden Parameter der Bäume stattfinden.
- Ableitung einer Referenzhöhe: Da in Baumkatastern häufig keine Referenzhöhen zu den Bäumen gespeichert sind, diese aber für weitere Analysen wichtig ist, soll es eine Möglichkeit geben, für jeden Baum im Datensatz eine Referenzhöhe aus einem DGM abzuleiten. Diese soll in der Datenstruktur gespeichert und bei der Weiterverarbeitung der Daten zu berücksichtigt werden.
- Export in das CityGML-Datenformat: Das Programm soll die Möglichkeit bieten, das Baumkataster im standardisierten, semantischen Datenformat CityGML unter Verwendung des Vegetation-Moduls zu exportieren. Dabei soll ein parametrisiertes als auch ein geometrisches Modell des Baumes erstellt und exportiert werden.

5 KONZEPT UND IMPLEMENTIERUNG

In diesem Kapitel soll zunächst das theoritische Konzept, auf welches das Softwarewerkzeug aufbaut, vorgestellt werden. Im Anschluss wird kurz auf die technische Umsetzung dieses Konzeptes eingegangen.

5.1 Konzept

Den Ablauf des entwickelten Programmes zeigt in schematischer Darstellung der Programmablaufplan in Abbildung 2. Es ist möglich, sowohl CSV- als auch XML-Dateien zu interpretieren und in eine räumliche Datenbank, die als interne Datenstruktur fungiert, zu überführen. Von dort aus werden die Daten in der GUI angezeigt, können analysiert, mit Höheninformationen angereichert und ins CityGML-Format exportiert werden.

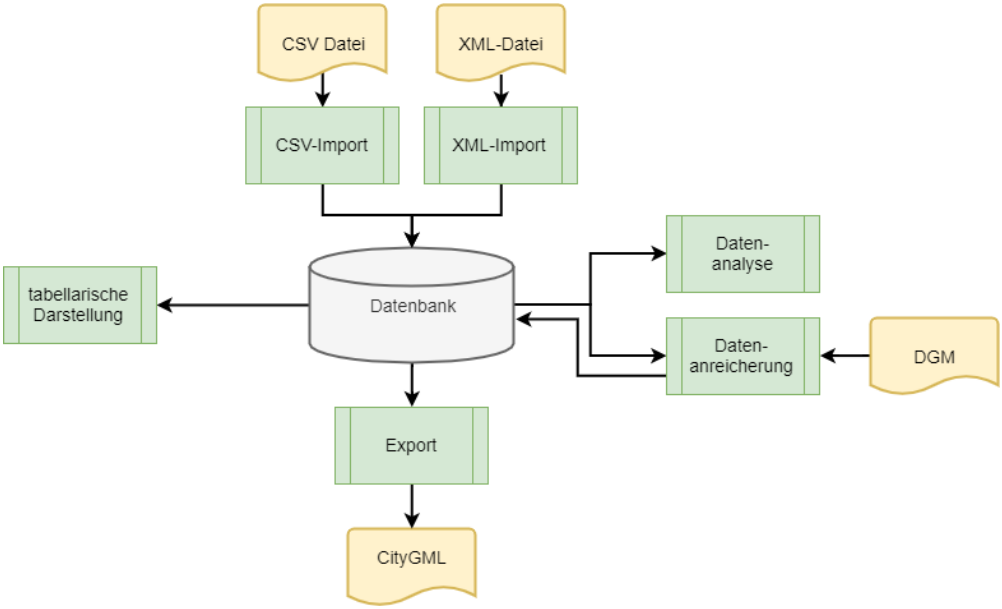

Abbildung 2: Programmablaufplan (eigene Darstellung)

Während der tabellarischen Anzeige der Daten hat der Benutzer die Möglichkeit, die Reihenfolge der Tabellenspalten anzupassen sowie einzelne Tabellenspalten ein- und auszublenden. Weiterhin hat er die Möglichkeit, die Spaltenwerte auf- und absteigend zu sortieren, um so einen besseren Überblick über die Daten erhalten zu können.

Während der Datenanalyse ist es möglich, die Daten auf zweierlei Arten auf Duplikate zu untersuchen. Einerseits wird dazu die ID des Datensatzes untersucht, wobei ein Duplikat potentiell dann vorliegt, wenn eine ID mehrmals im Datensatz vergeben wurde. Andererseits ist es möglich, den Datensatz auf Duplikate zu untersuchen, indem die Position eines Baumes betrachtet wird. Ist der Abstand zweier Bäume des Datensatzes geringer als ein zuvor vom Benutzer eingestellter Schwellwert, handelt es sich potentiell um ein Duplikat. Werden Duplikate festgestellt hat der Benutzer die Möglichkeit, die Duplikate von einem späteren Export ins CityGML-Datenformat auszuschließen.

Eine weitere Analysemöglichkeit der Daten ist die Validierung der Gestalt beschreibenden Baumparameter (Baumhöhe, Stammdurchmesser, Baumkronendurchmesser). Dafür sind verschiedene Kriterien implementiert, anhand der die Validität der Parameter geprüft werden kann. Bäume werden als ungültig eingestuft, wenn folgende Kriterien verletzt werden:

- Es existiert ein Wert für Baumhöhe, Stammdurchmesser und Baumkronendurchmesser
- Die Werte für Baumhöhe, Stammdurchmesser und Baumkronendurchmesser sind größer als null
- Der Stammdurchmesser ist größer als der Baumkronendurchmesser
- Der Baumkronendurchmesser ist größer als die Baumhöhe
- Der Stammdurchmesser ist größer als die Baumhöhe

Für jeden als invalide eingestuften Baum wird dem Nutzer anschließend in einer kurzen Meldung auf der Benutzeroberfläche die ID des ungültigen Baumes ausgegeben, sowie eine kurze Erklärung, warum diese invalide ist. Beim späteren Export der Daten ins CityGML-Datenformat werden die als invalide eingestuften Bäume zwar als parametrisiertes Modell exportiert, jedoch nicht als geometrisches, da für sie kein geometrisches Modell erzeugt werden kann.

Bei der Datenanreicherung ist es möglich, die vorhandenen Baumdaten mit weiteren Informationen anzureichern, um die vorhandenen Daten entweder um weitere Informationen zu erweitern oder um vorhandene Informationen zu verbessern. Es ist dabei möglich, eine Referenzhöhe für jeden Baum aus einem digitalen Geländemodell (DGM) abzuleiten oder eine einheitliche Referenzhöhe für jeden Baum festzulegen, falls dem Nutzer kein DGM vorliegt (was aber nur in flachen Gebieten sinnvoll sein kann).

Zur Ableitung der Referenzhöhe wird in einem ersten Schritt das digitale Geländemodell in die räumliche Datenbank importiert. Jeder Höhenreferenzpunkt des DGMs entspricht dabei einer Zeile einer neu

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

angelegten Tabelle. Diese Tabelle hat die Lage des Höhenreferenzpunktes als 2D-Geometrie gespeichert, die Höhe als numerisches Attribut. In einem zweiten Schritt wird zunächst für jeden Baum untersucht, ob er innerhalb der konvexen Hülle aller Referenzpunkte liegt. Ist das nicht der Fall, kann zu diesem Baum keine Referenzhöhe aus diesem DGM abgeleitet werden, da zur Position des Baumes keine Höheninformationen im DGM vorliegen und keine Extrapolation der Höhe erfolgen soll. Liegt der Baum aber innerhalb der Konvexen Hülle, werden die vier Höhenreferenzpunkte, die dem Baum am nächsten liegen, extrahiert. Zwischen ihnen wird anschließend mit der Inverse-Distance-Weighting-Methode interpoliert, um die Referenzhöhe des Baumes zu bestimmen. Dabei handelt es sich um eine gewichtete Mittelwertbildung, wobei räumlich näher liegende Datenwerte stärker gewichtet werden als weiter entfernte Datenwerte (Bill, 2016)

Beim Export des Baumkatasters in das CityGML-Format wird jeder Baum, der im Baumkataster vorhanden ist, als SolitaryVegetationObject ins Stadtmodell exportiert. Dabei wird einerseits ein parametrisiertes Baummodell erstellt und exportiert. Der Nutzer trifft dazu vor dem Export eine Zuordnung über die GUI, in welcher er die Baumattribute des programminternen Datenmodells in der Datenbank den Attributen der CityGML-Klasse SolitaryVegetationObject zuordnet. Andererseits wird auch ein geometrisches Baummodell erstellt und exportiert, das aus den Gestalt beschreibenden Baumparametern errechnet wird. Der Nutzer hat dabei die Möglichkeit, den verschiedenen LODs unterschiedliche geometrische Baummodelle zuzuweisen. Diese geometrischen Baummodelle unterscheiden sich erheblich in ihrer Komplexität. Je nach Komplexität der Geometrie wird dabei nach Laub- oder Nadelbaum differenziert und unterschiedliche Geometrien generiert. Alle möglichen Arten der Baumgeometriemodelle, die der Nutzer den LODs zuweisen kann, sind im Folgenden nach aufsteigender Geometriekomplexität geordnet aufgelistet:

- Linie (Abbildung 3a): Es wird an der Position jedes Baumes eine senkrecht im Raum stehende Linie generiert. Der Anfangspunkt der Linie liegt dabei auf Höhe der Erdoberfläche, der Endpunkt auf Höhe der Baumhöhe über der Erdoberfläche.
- Zylinder (Abbildung 3b): Es wird an der Position jedes Baumes ein senkrecht auf Höhe der Erdoberfläche stehender Zylinder generiert. Die Höhe des Zylinders entspricht dabei der Höhe des Baumes, der Durchmesser des Zylinders entspricht dem Durchmesser der Baumkrone.
- (texturiertes) Rechteck (Abbildung 3c): Ein (texturiertes) Rechteck im Raum wird auf Höhe der Erdoberfläche an der Position jedes Baumes generiert. Die Höhe des Rechtecks entspricht der Höhe des Baumes, die Breite entspricht dem Baumkronendurchmesser. Auf Wunsch des Nutzers können pro Baum mehrere, sich in der Mitte überkreuzende Rechtecke generiert werden, um die Sichtbarkeit auf das Baummodell aus verschiedenen Blickwinkeln zu ermöglichen.
- Kontur beschreibende Polygone (Abbildung 3d): Es werden Polygone generiert, die die Kontur des Baumes beschreiben. Diese Polygone überkreuzen sich in der Mitte, um die Sichtbarkeit auf das Baummodell aus verschiedenen Blickwinkeln zu ermöglichen.
- Stark vereinfachte Baumgeometrie (Abbildung 3e): Zur Repräsentation des Baumstammes wird ein Quader generiert. Länge und Breite dieses Quaders entsprechen dem Stammdurchmesser. Für die Baumkrone eines Laubbaumes wird ein Würfel oberhalb des Quaders generiert, für Nadelbäume eine vierseitige Pyramide. Sowohl bei Quader als auch bei Pyramide entsprechen deren Längen und Breiten dem Baumkronendurchmesser. Die Summe der Höhen von Quader und Würfel bzw. Quader und Pyramide entspricht der Höhe des Baumes.
- Vereinfachte Baumgeometrie (Abbildung 3f): Zur Repräsentation des Baumstammes wird ein Zylinder auf Höhe der Erdoberfläche generiert. Dessen Durchmesser entspricht dem Stammdurchmesser. Für die Baumkrone eines Laubbaumes wird eine Kugel, für Nadelbäume ein Kegel oberhalb des Zylinders generiert. Kugeldurchmesser bzw. Kegelgrundflächendurchmesser entsprechen dem Baumkronenradius. Die Summe von Zylinderhöhe und Kugeldurchmesser bzw. Kegelhöhe entspricht der Baumhöhe.

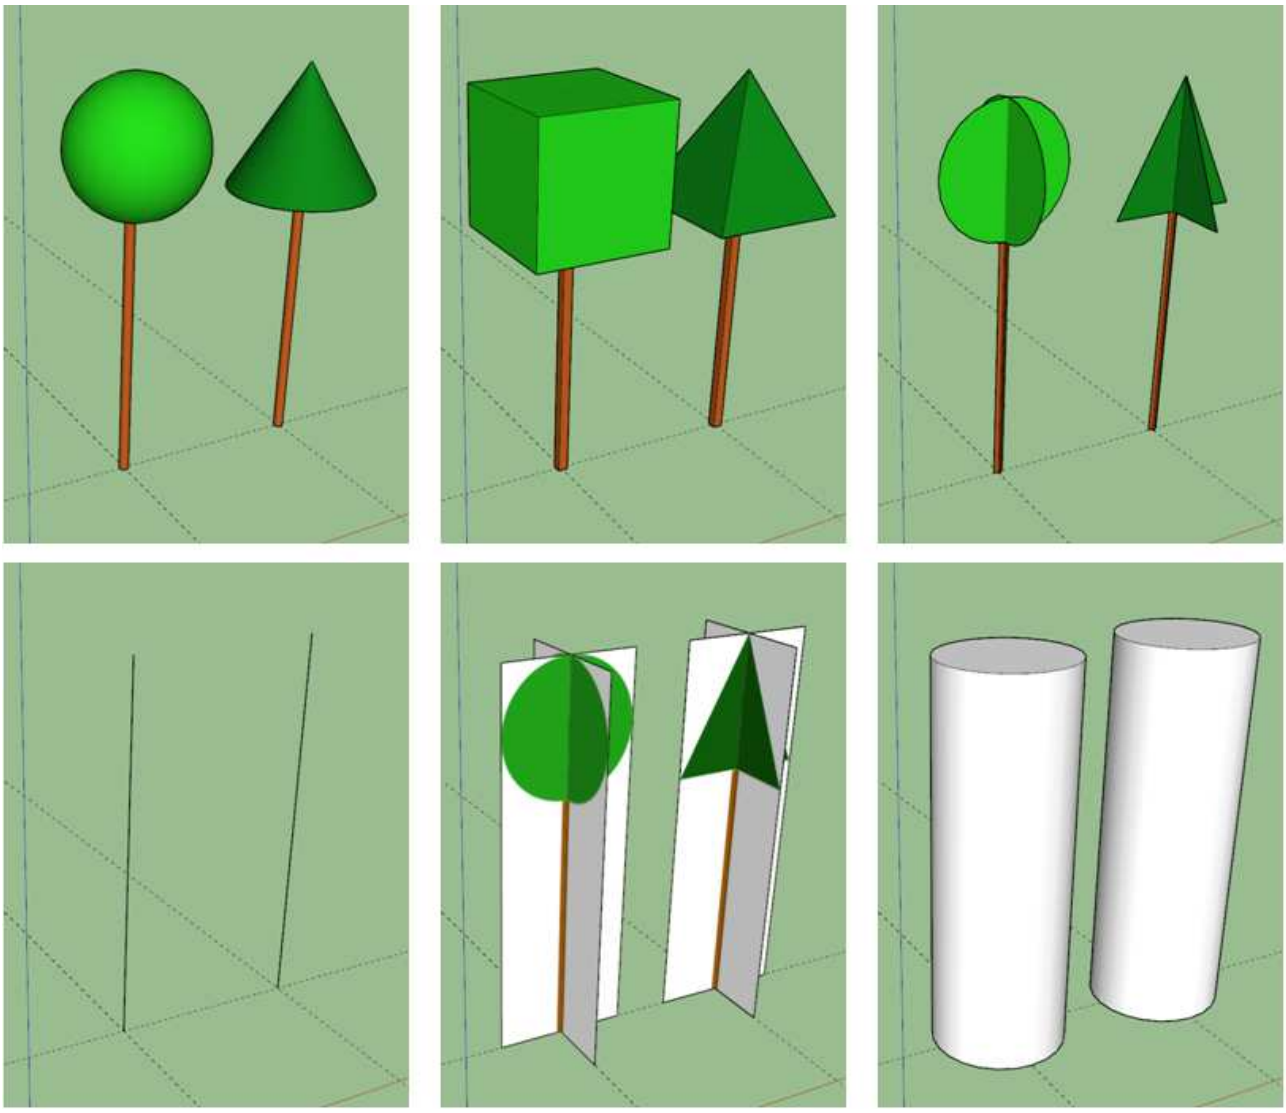

Abbildung 3a-f: Die zu erzeugenden Geometrien in den verschiedenen Detaillierungsgraden für Laub- und Nadelbäume (eigene Darstellungen)

Da das von CityGML verwendete Geometriemodell nur ebene und keine gekrümmten Flächen zulässt (Gröger et al. 2012), müssen Kugel-, Zylinder- und Kegeloberflächen durch Kombination von Polygonen angenähert werden. Der Benutzer kann dabei die Genauigkeit dieser Annäherung bestimmen, wobei die Komplexität der Geometrien mit steigender Annäherungsgenauigkeit ebenfalls zunimmt, da zu einer Steigerung der Genauigkeit die Anzahl der Flächen zunimmt.

5.2 Implementierung

In diesem Abschnitt wird kurz dargelegt, wie das zuvor vorgestellte Konzept technisch umgesetzt wird. Zur Implementierung des hier vorgestellten Programmes wird die Programmiersprache Python der Version 3 verwendet.

Als Datenbank, die zur Verwaltung des internen Datenmodells genutzt wird, kommt SQLite zum Einsatz. Bei SQLite handelt es sich um ein frei verfügbares SQL-Datenbanksystem, und hat den Vorteil, dass keine Serverarchitektur benötigt wird sondern die komplette Datenbank als seine Datei auf der Festplatte gespeichert ist (SQLite, 2020a). Unterstützung für SQLite-Datenbanken ist direkt in die Python-Standardbibliothek implementiert (Python Software Foundation, 2020), somit sind keine zusätzlichen Softwarebibliotheken nötig, um SQLite-Funktionalität in einem Python-Programm nutzen zu können. In dieser Anwendung verwendet SQLite zusätzlich die Erweiterung SpatiaLite, eine quelloffene Programmbibliothek, die SQLite um Funktionalitäten einer räumlichen Datenbank erweitert (Furieri, 2020).

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Die graphische Benutzeroberfläche wird mit der Bibliothek wxPython realisiert. Der Programmcode für eine Standardbenutzeroberfläche wird dazu mit dem Programm wxFormBuilder automatisiert generiert. Diese Standardbenutzeroberfläche wird dann durch eigenen Code ergänzt und angepasst.

Da die im Baumkataster vergebenen Baumnummern lediglich innerhalb eines Bereiches eindeutig sind, ist es möglich, eine ID aus einer Kombination der Bereichsnummer und der Baumnummer zu generieren. Dem Nutzer wird also beim Import der Daten die Möglichkeit gegeben, zwei Spalten auszuwählen, die dann miteinander durch einen Unterstrich verbunden werden. Hat ein Baum in Bereich 04 beispielsweiße die Baumnummer 4394, wird daraus die ID 04_4394 generiert. Diese ID wird in einer neuen Spalte IAI_TreeID in der Datenbank gespeichert. Da bei der weiteren Benutzung des Programmes häufig auf einzelne Bäume in der Datenbank zugegriffen werden muss, wird aus Gründen der Effizienz ein Index für die Spalte IAI_TreeID generiert.

Für den Fall, dass in den eingelesenen Daten keine ID vorhanden ist, ist es außerdem möglich, die von SQLite automatisiert generierte ROWID als ID zu verwenden. Es handelt sich dabei um eine Integer-Zahl, die automatisiert von SQLite vergeben wird, über die jede Zeile in einer Datenbanktabelle angesprochen werden kann (SQLite, 2020b).

Im Datenansichtsfenster des Programms werden nach dem Einleseprozess die Daten aller Bäume tabellarisch angezeigt, wie Abbildung 4 zeigt. Vom Programm automatisiert generierte Spalten (wie z.B. die der ID) werden dabei mit gelber Farbe hinterlegt um dem Nutzer anzuzeigen, dass diese Spalte nicht dem Baumkataster entstammt.

Abbildung 4: Datenansichtsfenster des Programmes unter Windows 8.1 mit tabellarischer Anzeige der Baumdaten des KIT Campus Nord (eigene Darstellung)

Über einen Rechtsklick auf eine Spaltenüberschrift hat der Benutzer die Möglichkeit, die Tabelle nach dieser Spalte auf- oder absteigend zu sortieren oder diese Spalte auszublenden. Außerdem kann er per Drag-and-Drop die Reihenfolge der Spalten verändern. Über das Hauptmenü können alle wichtigen Funktionen des Programmes aufgerufen werden, wie z.B. das Einlesen einer Datei mit Baumdaten, den Export eines Datensatzes als CityGML, die Analyse der Daten und die Erweiterung der Daten. Zum jetzigen Zeitpunkt ist lediglich ein CityGML-Export des parametrisierten Baummodells möglich, Generierung und Export eines geometrischen Baummodells ist noch nicht möglich.

6 FAZIT UND AUSBLICK

Wie in diesem Beitrag gezeigt wurde, wird mit diesem Programm ein Werkzeug geschaffen, das es ermöglicht, strukturierte, nicht-standardisierte Baumdaten in das standardisierte, semantische Datenmodell CityGML zu überführen. Da das Datenformat der OGC-Standard für 3D-Stadtmodelle ist, kann es von vielen Programmen eingelesen und weiterverarbeitet werden. Es stellt also das Bindeglied zwischen Programmen zur Baumkatasterverwaltung und Programmen der Visualisierung und Analyse von Stadtmodellen dar.

Im weiteren Verlauf der Entwicklung dieses Programmes soll zunächst der Export der 3D-Baumgeometrien in den verschiedenen LODs realisiert werden. Der Nutzer soll außerdem auswählen können, ob weitere

Attribute, die zwar im Baumkataster erfasst aber nicht von der CityGML-Klasse SolitaryVegetationObject abgebildet werden können, als generische Attribute ins Datenmodell eingefügt werden sollen. Es sollen außerdem weitere Funktionen zur Anreicherung der Baumdaten implementiert werden. So soll es möglich sein, die im Baumkataster gespeicherte Baumhöhe mithilfe eines Laserscanning-Datensatzes aus einer Befliegung des Geländes zu verifizieren. Um realitätsgetreuere 3D-Modelle der Bäume zu erstellen, ist es außerdem notwendig die Höhe des Laubansatzes des Baumes zu kennen. Diese wird allerdings bei den Baumkontrollen häufig nicht erfasst und ist daher nicht im Baumkataster gespeichert. Daher soll untersucht werden, ob es möglich ist, diese ebenfalls aus den Laserscanning-Daten der Befliegung abzuleiten.

1 ABSTRACT

This paper presents a comprehensive overview about methods and practice cases regarding behavioural change initiatives towards sustainable mobility triggered by nudging techniques. “Nudges refer to purposeful changes in the choice architecture that influence peoples' behaviour by making changes in the environment that guide and enable individuals to make choices almost automatically. This can be done by simplifying the information provided or by offering default choices in a way that facilitates socially desirable decisions. Thus, nudges do not try to change one's value system or increase information provision. Instead they focus on enabling behaviours and private decisions that are beneficial for society and usually in the individual's long-term interests, as well.” Lehner et al. (2016). Four types of tools are part of nudging: 1) simplification and framing of information, 2) changes to the physical environment, 3) changes to the default policy, and 4) the use of social norms. The objective of nudging originally is to promote certain behaviour, which is beneficial for individuals as well as the society and increases the effectiveness of policy. All these techniques are well known, successful and applied in many areas such as for super markets selling their products or in politics campaigning for the next elections. Surprisingly, such techniques are less known in the field of mobility aiming at leading people towards a more sustainable behaviour. Nevertheless, isolated activities were successfully applied already as pilot actions.

Regarding 1): Simplification and framing mean that information is made more straightforward. It fits the information processing capabilities and decision-making processes of the target group because not only the amount or accessibility of provided information matters, but also how the information is presented. Therefore, it matters how the situation/nudge is presented or with what words. E.g. people in a rush will try to reduce complexity regarding the information they use to make a decision. As examples in the area of sustainable mobility information about public transport such as time tables need to be visible and easily understandable, e.g. not only at the bus stops, but at public places, restaurants, hotels, working places as well, ideally online screens with departures. Nudging through changes in physical environment is well known, for example in placement of preferred products in shelves in supermarkets. Good examples are to place sustainable mobility options with a higher priorisation on a homepage and leaflet, or to put the bus stop area closer at a destination as the car park. Defaults are set standards, which determine the result as long as the addressed person does not take action and insist in making changes, e.g.: “print double sided copy” as standard instead of “print single pages” at a printer. An example in the area of sustainable mobility can be the strategy, if one asks in a tourism office or at the hotel reception, how to reach a specific destination, he/she get explained how to reach by means of public transport or bicycle and not by car instead of. Social norms are a strong force that influence human behaviour. However, social norms can influence human behaviour if they are salient and visible for the target group. Examples are announcements such as “in our company already xx km were cycled this month for commuting with the bicycle already, saving xx CO2 emissions at the same time” which are send out to the employees in the course of an active mobility campaign in a company.

Keywords: Intervention, Behaviour change , Sustainable Mobility, Nudging, Tools

2 INTRODUCTION

Within the project SMACKER - funded under the Interreg Central Europe programme - mobility issues related to peripheral and rural areas, and main barriers are assessed and addressed by providing solutions that draw on the best international know-how. SMACKER promotes demand-responsive transport services to connect local and regional systems to main transport corridors and nodes such as the TEN-T network: soft measures (e.g. behaviour change campaigns) and hard measures (e.g. mobility service pilots) are used to identify and promote eco-friendly solutions for public transport in rural and peripheral areas to achieve more liveable and sustainable environments, better accessibility for the population to main corridors and better

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

feeder services. SMACKER also encourages the use of new transport services through motivating and incentivizing campaigns (Batiajew et al. 2019). The direct beneficiaries of the actions are residents, commuters and tourists. This paper presents a comprehensive overview about methods regarding behavioural change initiatives based on nudging techniques. This overview will allow to identify suiting methods for supporting the implementation of new mobility offers or promote existing, but underused supplies of sustainable transport. In the first part of this paper a definition about nudging is given and the target groups of the methods are described. Different channels for the communication of the nudging methods are explained as well as potential points of contact, which may act as entry point for the introduction of a nudging method. In the second part a comprehensive overview presents all the methods and an overview is given.

3 THE CONCEPT OF NUDGING

3.1 Definition

“Nudges refer to purposeful changes in the choice architecture that influence peoples' behaviour by making changes in the environment that guide and enable individuals to make choices almost automatically. This can be done by simplifying the information provided or by offering default choices in a way that facilitates socially desirable decisions. Thus, nudges do not try to change one's value system or increase information provision; instead they focus on enabling behaviours and private decisions that are beneficial for society and usually in the individual's long-term interests, as well.” Lehner et al. (2016) based on Thaler and Sunstein (2008). According to Lehner et al (2016) these four types of tools are part of nudging: 1) simplification and framing of information, 2) changes to the physical environment, 3) changes to the default policy, and 4) the use of social norms. Regarding 1): Simplification and framing mean that information is made more straightforward. It fits the information processing capabilities and decision-making processes of the target group because not only the amount or accessibility of provided information matters, but also how the information is presented (Lehner et al. 2016). Therefore, it matters how the situation/nudge is presented or with what words (Lehner et al. 2016). E. g. people in a rush will try to reduce complexity regarding the information they use to make a decision. Nudging through changes in physical environment is well known, for example in placement of preferred products in shelves. Defaults are set standards, which determine the result as long as the addressed person does not take action and insist in making changes, e. g.: “print double sided copy” as standard instead of “print single pages”. According to Lehner et al. (2016) social norms are “a strong force that influence human behaviour”. However, social norms can influence human behaviour if they are salient and visible for the target group (Chialdini and Goldstein 2004). The objective of nudging originally is to promote certain behaviour, which is beneficial for individuals as well as the society and increases the effectiveness of policy (Thaler and Sunstein, 2008 in Lehner et al. 2016).

3.2 Target groups

Target groups relevant for nudging towards the use of flexible transport are residents, commuters and visitors (tourists) of a specific region, which may need to be addressed in different ways and through different channels. Residents are very open for interventions in regard to their mobility choice, if changes in their individual stages of life take place, like starting at a new school or workplace, relocation of the place of residence, the household size is extended (e. g. children were born), the household size was decreased (e. g. grown up children were leaving the household, divorce), medical reasons, which implicate the need to change mobility patterns. These framework conditions often cause the reflection of usual activity patterns and the need to adapt individual behaviour. Each new stage of life offers the possibility to nudge residents towards the use of sustainable mobility. Mobility patterns of commuters are highly repetitive and thus have a high potential to provoke sustainable behaviour. In particular, employees that change their work place are open to new mobility options due to changed framework conditions. Contrary to this, tourists usually do not have habitual trips at their holiday destination. They often have to find their way themselves in a new area, thus, they are open for mobility options offered (especially, if they do not have their car available at the holiday destination). Addressing tourists offers a high potential to nudge towards sustainable mobility and could stimulate them to rethink their mobility at home as well.

3.3 Channels of communication

This chapter includes a description of channels which can be used as starting point for nudging. These channels describe ideas how to get in contact with the target groups. At first there is an alternative to directly contact your target group or indirectly via a third party. Direct ways of contact are direct written information paper based or electronic. This includes sending an information letter and a registration postcard for further information to potential participants by post or email. An alternative, but more costly are direct face-to-face information. One can get in touch with potential participants directly on local events or by creating an own event, knocking on the door, at public meeting points etc. A third alternative are direct phone contact and getting in touch with potential participants directly by phone. But usually, telephone lists are outdated or incomplete and there are some legal restrictions. So there need to be a strategy established to collect the phone numbers, either via direct contacts or via mail (which usually includes the agreement to contact these persons via telephone).

Indirect ways of contact means to include a trustful third party to convey the nudgings, ideally local stakeholders, employees in contact with the envisaged target group or any other multiplier or role model who is getting into direct contact with the target group. If these persons play a main role in the campaign, they need to be prepared and trained for this task. Not to let others do too much work, sending an information letter/ email and/or face-to-face contact from such persons could be a door opener (by creating a friendly background for the direct contact with the participants) and then get in direct contact with the target groups. Other indirect channels (but only supporting a more interactive campaign) can be the usage of info boards, which can provide relevant information for the target group in different settings, (preferably local) radio or TV providing relevant information for the target groups, so many potential participants can be reached. Ideally the messages are not reduced on advertisement jingles only but embedded in infotainment sections of the programme, e.g. interviews or editorial contributions.

4 NUDGING INTERVENTIONS FOR SUSTAINABLE MOBILITY

The different types of action and intervention are described below. All of these were already carried out in different target areas, reference is given in each chapter.

4.1 Mobility stand on local or regional event

At regular local events (e.g. farmer's market) a mobility stand provides general explanation of sustainable transport modes and in detail the following question get answered: How to get the information I need, e. g. in the case of flexible transport offers in the area: How to get a bus picking me up? How much will the using of (flexible) PT cost for the customer? The information is provided by trained staff for individual dialogs and consultation but also via infofolders and other information material to take away. Specific information for commuters, pupils etc. can be provided. An example is the Verkehrsverbund Rhein Sieg, Germany, see www.vrs.de/fileadmin/Dateien/downloadcenter/VRSundNVR_gemeinsam_fuer_die_Region_2014.pdf.

4.2 Self-organized event about sustainable local mobility

Self-organized events about sustainable local mobility supported by the municipality or the PT/mobility provider take place. Presentation and discussions about local PT provide information and insights. Contrary to measure 3.1, an additional task is to motivate people to visit the event by including an attractive program for this event (e.g. games, demonstrations of vehicles, presentations, discussion rounds etc.). A location needs to be organised: An accessible site within the municipality, e.g. municipal office. Often the municipalities or local organisations (social clubs, health care centres, schools, homes for elderly and similar) can offer relevant infrastructure. Depending on the target group, daytime, duration and kind of day need to be arranged, ideally a date which is not favouring a specific group. Trained staff from a mobility agency or PT/mobility provider or project partner need to provide adequate presentations, depending on the target group. It is important, how the invitations to the event will be sent out. Often the municipalities can assist because they are owning relevant address lists (if not selective, excluding some groups of citizens), but also can publish the event in their media or at their homepages. Additionally, local media can be contacted to report about the event. Prepare layout and contents of the presentation. When sending out an invitation letter, participants can be asked for the most important information they want to hear. This can be a valuable input, if preparing the presentations. Typical topics to be presented are: Understanding the operation times, maps of

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

area of operation, tariff information (specific and general), how to book or modify a trip (if flexible system is in operation), how the local bike sharing system works, the bicycle infrastructure in the area etc. Hand out material should be provided for the event. Gaming elements, lotteries, the presentation of vehicles and test rides or other mobility related demonstrations can accompany the event. An example of this action is the Project Midas, see https://ec.europa.eu/energy/intelligent/ projects/en/projects/midas.

4.3 Presentations at periodic local meetings, establishment of a local mobility forum

Open periodic discussion rounds/open meetings about important local concerns in the municipality (or within a bigger company) provide a good platform where topics about sustainable local mobility are attached. Target groups get addresses by the local municipality. This could be either a regular meeting series, where all topics residents are concerned with, are included or periodic meetings with a focus on mobility within the municipality (or within a bigger company). A regular meeting is chosen, which guarantees an "open" characteristic, so that no citizens are excluded in these events and various issues are discussed. Local stakeholders/multipliers should be included in the meetings attracting citizens/employees to attend. An example of this action are the partner regions of the SMACKER project, see https://www.interreg-central.eu/Content.Node/SMACKER.html.

4.4 Empowering pupils to use public transport

Trained staff presents threats of car usage and highlights alternatives in schools. Pupils learn how to use PT, biking or even walking including the legal situation. If possible, try out activities are provided in cooperation with the transport providers. Discussions with pupils about e. g. daily mobility patterns in a playful way shall encourage the process of reflexion. Schools need to be contacted to provide time and space for the event (directors and teachers, where the activity could be integrated in the courses). In case, try out activities are planned, local transport providers need to be contacted as well. If there exists an initiative for sustainable behaviour already (e.g. Fridays for Future), representatives of this initiatives within the school can be integrated in the activities. Trained staff needs to provide a presentation, which is well tailored for the target group (preferably children in primary school or young children in high school due to openness for new mobility options and the need to establish new daily mobility routines). Information material is a must have to bring, to provide information not only for the pupils but also for their parents. Gaming elements could support the usage of public transport (e.g. traffic snake game, where classes are compared with regard to their sustainable mobility). An example of this action is the Staffordshire County Council case study, see https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/575323/ Home_to_school_travel_and_transport_guidance.pdf.

4.5 Mobility managers in companies, institutions or other organisations

Work places or organisations like schools, tourist accommodations set up a representative, who is a contact person to provide help for individual mobility concerns but also to provide information about alternatives to car usage in general (e. g. through presentations or include aspects in newsletters). Preferably, this representative acts as a role model (uses PT or the bicycle for way to work), but actively contacts the employees to put sustainable mobility on the agenda within the company or organisation. Furthermore, organisations implement a bonus system, which encourages the usage of PT and active transport modes. Work places and organisations need to be contacted and empowered to highlight the importance of the action. Benefits need to be pointed out and the work places and organisations need to be supported by developing and implementing a strategy for mobility management. Information material and options of concrete actions (job ticket, commuter lottery for sustainable mobility) need to be provided for the representative to forward these actions within the companies or organisations. An example of this action is the Travel Smart Initiative in Singapore http://viajeoplus.eu/wp-content/uploads/sites/4/2015/11/ Viajeo_PPT_Travel-Smart-LTA.pdf.

4.6 Guided PT, walking or cycling tour per target group

This event takes the target groups on a tour. The tour can be combined with (small) touristic events. If focusing on PT, timetables, tariffs and ticketing are explained and tested, as well as safety rules. The tours are designed for specific target groups like elderly people, pupils, parents and commuters so attention is drawn to specific needs of the target group, e. g. usage of PT by wheelchair or walking frame for elderly

people. This event can either be attached to an existing local event (e. g. farmers market) or established on its own. Either way, trained staff needs to be found and information for the target group needs to be prepared. Potential points of contact are the following: schools, local municipality, at home, work places, doctors, participation at local events, self-organized events, club associations and radio. If the event is established on its own, a meeting point needs to be organised per target group. Club associations or local municipality and schools can provide sensible meeting points. An example of this action is an initiative in Münster, Germany, see www.stadtwerke-muenster.de/privatkunden/busverkehr/kundenservice/bustraining/vorschulkinder.html.

4.7 Personal mobility assistants for elderly people at major transport interchanges

This measure involves the provision of a personal assistance service at major public transport interchanges. The measure will help older citizens to travel independently and increase the attractiveness of PT for older people. Project staff should be located at one or two public transport interchange points for certain time slots. A group of young, trained persons are positioned ready to help older people at the bus and tram stops at public transport interchanges. These staff help older people to enter and to exit buses and trams, based on previously defined rules and advice. They can also provide information about PT connections and bus and tram schedules and assist with the use of ticket vending machines or apps. Assistants are available e. g. in the morning, every day from Monday to Friday. In order to be properly recognized, they should wear colourful jackets or T-shirts with logos (ideally provided by the local PT/mobility provider). They should also have special ID-cards that are kept visible. The idea is not only to help older people directly, but also to raise awareness among others and to encourage travellers to assist each other. As a result, it is expected that more and more younger people will help older people to enter and leave the vehicles, provide information about available connections, and help with ticket purchase, etc. Potential points of contact, which inform the target group about this service can be: Local municipality, at home, doctors, local events, self-organized events, radio, TV, club associations. An example of this action provides the AENEAS project, Krakow Poland, see http://www.eltis.org/resources/videos/krakow-assistance-service-older-people-major-public-transport-interchanges.

4.8 "Car-free day"/EU Mobility week

The EUROPEAN MOBILITYWEEK campaign provides the perfect opportunity to present sustainable mobility alternatives to local residents and to explain the challenges that cities and regions are facing. By taking part, towns and regions can showcase the benefits of cleaner transport choices and make progress towards better mobility in Europe. Local authorities are strongly encouraged to use the week to test new transport measures and get feedback from the public. It is also an excellent opportunity for local stakeholders to get together and discuss the different aspects of mobility and air quality, find innovative solutions to reduce car-use and transport emissions, and test new technologies and planning measures. (see http://www.mobilityweek.eu/the-campaign/). Interested towns and regions register for the European mobility week. Every European mobility week uses a special topic, which is the theme of the week throughout Europe (e. g. "Safe Walking and Cycling" for 2019). Participating towns can either organize activities, which promote public transport, cycling and walking and other forms of sustainable mobility or can implement permanent measures during this week. Finally yet importantly, towns can carry out a "Car free day", preferably on "World car-free day". The chosen activities are promoted through all points of contact. Depending on the chosen activities, different cooperation partners needs to be contacted. An example of this action is the city of Igoumenitsa (Greece), which is the winner of the EUROPEAN MOBILITY WEEK Award 2017 for smaller municipalities, see http://www.mobilityweek.eu/fileadmin/user_upload/materials/participation_resources/2018/2018%20EMW%20Best%20Practice%20Guide%20LR.pdf.

4.9 Public transport try-out activities (free PT test ticket etc.)

With this measure, potential public transport users get in contact with the public transport system either for the whole trip or in combination with other feeder systems (incl. flexible transport). With the free try-out ticket there is no financial risk for the user (e. g. that she/he did not purchase the correct ticket). Nevertheless, the persons receiving a try out ticket for public transport should be contacted again after the usage of the try out ticket asking them to report (and discuss) their experience made. At least a return ticket should be offered to test a trip to a destination within a pre-defined area. If budgetary resources are available or a sponsor can be found, full day or weekly tickets would increase the attractiveness of the measure. This

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

measure can be accompanied by a social media campaign, encouraging people, who try out PT the first time, to "post" a picture or similar at social media, about their experience travelling with public transport. This measure can also be extended to other sustainable modes of transport. An example of this action was carried out in the city of Salzburg, Austria, where 20.000 test tickets were distributed, https://salzburg-verkehr.at/pa_file/presseinformation-testticket-gewinnspiel-vom-testfahrer-zum-gewinner/?download=650983d5b3b7919354a5fb32fe5a1968.

4.10 "Trips for Trash" & other local charity activities

Free PT tickets are exchanged for recyclable materials like plastic bottles and paper (e. g. one ticket per 5 kg plastic waste). The measure can be extended to other charity activities too, where credits can be earned for obtaining a public transport ticket (like assisting senior citizens, doing voluntary community work etc.). Information about PT is given as well at point of exchange credits/waste against the public transport ticket. Depending on the format, companies need to be contacted to create an incentive (e. g. waste collection, social institutions etc.) A place for the exchange needs to be organised, the local municipality can probably help to find a suitable place or take over this task. In case no trash is returned and instead other social efforts are supported, these need to be proven (e. g. via notification). In case trash is returned, it is necessary to provide suitable containers for the trash. The local waste collection company or the municipality can provide these. An example of this action is carried out in the is the city of Rome, see Trips of Trash, https://www.thelocal.it/20190725/you-can-now-trade-plastic-bottles-for-metro-tickets-in-rome?fbclid=IwAR3-H5vWt_OCwAcpSnaiCkHesFAKu9Gau0Zz5TMuZ85WcllY-E-SVH2o-sk or the city of Almada (Portugal), see Trips for Trash, http://www.epomm.eu/old_website/study_sheet.phtml?sprache=en&study_id=2887.

4.11 With PT/bicycle/on foot to work/school competition with lottery

A competition with lottery is set up with a competitive character, in which people are acknowledged if using sustainable modes of transport on a specific day or can collect "kilometres" or "points/kilometre" travelled by sustainable modes and have the chance to win prizes, which, at best, encourage further travelling with sustainable modes (e. g. high quality rain jackets, umbrella etc.). Potential participants (pupils, employees) need to be contacted, e. g. via schools or work places. A website and/or app is created to give the opportunity that participants can record their travelled kilometres and with this create a basis for the lottery. Prizes of the lottery can be contributed by local PT/mobility provider or local municipality. Alternatively, to the collection of mileage approach a randomly selected day can be the reference day and all registered players win or are in the drawing of the lottery, who used sustainable modes of transport that day. Examples of this action are the "Austria cycles" initiative in Austria, https://www.radelt.at/, the LOVE TO RIDE activity, https://www.lovetoride.net/global?locale=de-DE or the Travel Smart Initiative, Singapore, http://viajeoplus.eu/wp-content/uploads/sites/4/2015/11/Viajeo_PPT_Travel-Smart-LTA.pdf.

4.12 Bonus mile programme for PT

Kilometres travelled by PT are collected via smartphone or social media and get rewarded with discounts at local shops or other goodies. Ideally, the bonus mile programme is accompanied by a social media campaign: e. g. a winner is selected each week/month etc. and gets honoured on (social) media. In principle the system works as any other customer loyalty program, e. g. of telephone companies, supermarkets etc. Potential participants (e. g. pupils and employees) need to be contacted through all points of contact, but especially via work places. Participants will register themselves to start to collect, e. g. by downloading an app or receiving a booklet. An app is created to give the opportunity that participants can record their travelled kilometres with PT and create a basis for the discounts in local shops. As low tech alternative a booklet (for stamps) or sticker album can be used, where conductors or bus drivers (in rural areas with less crowded buses advisable only) confirm the usage. If electronic ticketing system is in use (e. g. electronic check-in and checkout), this technology may be used for the recording as well. Interested local shops, museums, pubs or other potential cooperation partners need to be contacted, for preparing discounts or little presents ready to offer to the participants or other goodies need to be purchased. The handing over process needs to be defined. Selected winners, who enjoy using social media can be encouraged to post about being selected on social media. Therefore moderation of the activities need to be clarified (host of social media). Potential followers and participants need to be contacted. Examples of this action are the Bella Mossa

campaign, Bologna, Italy, https://www.bellamossa.it/ or the Better Points campaign, Wroclaw, Poland, https://www.wroclaw.pl/wroclawskie-wyzwanie-mobilnosc.

4.13 Gamification for sustainable modes

The use of sustainable modes and the collection of "kilometres" or "points/kilometres" is implemented with a playful approach. In this approach the use of sustainable modes is encouraged by visualizing the user's scores allowing the user to reach different levels, collecting "trophies", geocaching etc. (e. g. comparable to "Pokemon Go"). Progress bars, which show the amount of CO2 or money saved by using sustainable modes shall further encourage the behaviour. An app with gamification needs to be developed. Therefore, guidelines about the goal of the app and target groups need to be clarified. A system, how to record the mileage need to be included in this app, possibly using interfaces with other tools such as electronic ticketing. Maybe responders in the buses are needed (e. g. blue tooth or nfc) to confirm the usage. In case, winners are selected, similar to measure 3.12, awards need to be organised and the handing over procedure need to be specified, preferably accompanied with a (social) media campaigning. Examples of this action are Bolzano in South Tirol, Italy https://www.masstransitmag.com/technology/press-release/12270742/onyx-beacon-gamification-in-public-transportation-passengers-quit-using-own-vehicles-and-participate-in-ecological-competition-based-on-kilometers-of-bus-travel-measured-by-onyx-beacons or the Viaggia Trento e Rovereto Play&Go, Trentino, Italy, https://www.smartcommunitylab.it/apps/viaggia-trento-e-rovereto-playgo/.

4.14 Use of social media to make sustainable modes visible

Sustainable modes will be visible in social media through its users by putting pictures and stories on the social media page e.g. of the regional/local public transport operator, etc. or at the users´ page themselves, e. g. by using a specific #hashtag. Cooperation with regional media (e. g. online magazines or print) may be a further option. Participating people can get rewarded and encouraged to join social media challenges. Moderation of the activities needs to be clarified (host of social media). Potential followers and participants need to be contacted. If foreseen, awards need to be organised for competition, e. g. for the best pictures etc. Rewards can be based on number of shares or likes. Ideally, the campaign gets recognition in regional media as well. Therefore regional media needs to be contacted. Examples of this action are the Youth Alpine Interrail initiative, see http://yoalin.org/challenges/, https://www.instagram.com/p/BwRO2OmAMF-/ and http://yoalin.org/do-the-yoaling/ or the Austrian federal railways ÖBB, see http://blog.oebb.at/schaumalraus-macht-mal-gemuetlich/ and https://www.facebook.com/unsereOEBB/posts/ fotowettbewerb-wir-rufen-unter-dem-motto-175-jahre-eisenbahn-alle-hobbyfotografi/248421711927148/.

4.15 "Thank you" – Incentives for current users of sustainable transport modes

Current users of sustainable transport modes receive a little present (like coffee, cake, flowers etc.) e. g. before or after leaving the PT or at the cycle path to show appreciation for the persons effort to actually use sustainable transport modes. PT or mobility providers or the local municipality need to be contacted, to request interest in this measure. If these institutions show interest, they can support the measure by providing staff for the distribution of the presents or sponsor such items. Points of distribution should be chosen carefully: e. g. PT interchanges, (touristic) destinations or in the PT vehicle or cycle paths itself. Activities can be done at any day, but typically to select a specific day, e. g. a jubilee of the bus line concerned, a modification or upgrading of a line or the time table, in the course of events such as the European mobility week or local events, etc. Alternatively the beginning of a typical season, e. g. school start, semester start of the university etc. can be selected as well, if the target group is defined as pupils or students. An example of this action is the Bike breakfast, Bologna, Italy, see http://salvaiciclisti.bologna.it/bike-breakfast.

4.16 Entertainment event at PT

Stand-up entertainers perform for current PT users in the PT vehicle in an unexpected way (e.g. little concerts, circus, "pub quiz" etc.), preferably at off peak time like in the evening. Alternatively interested people can participate at a "surprise ride" with PT, where they use PT on a certain day and time and PT takes them to interesting sites. An example of this action is the Verkéiersverbond Luxembourg, https://www.mobiliteit.lu/de/uber-uns/verkeiersverbond/ or the so called Staukonzert in Salzburg, Austria, see https://www.fraeuleinflora.at/salzburg/fraeulein-flora-staukonzert/.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

4.17 Customized information packages on paper about selected topics

Interested people order customized information packages on paper in which they are interested, e. g.: ticket purchase, usage of flexible transport, receive individual time table information online & offline, PT network map or cycling network map. In a first step, they receive an order form, where they select the required documents. Some of these can be tailor made as the foot path to the next PT stop, an individual time table of their specific trip demand, an orientation map of their place of residence, a calculation of the ticket costs for their individual travel needs etc. Based on this feedback (via online form, paper form or telephone contact), the people only receive the information, which is relevant to them and do not have the burden of researching this information by themselves. An example of this action is the project SmartMove, see http://www.smartmove-project.eu/.

4.18 Welcome kit - information packages for new residents about sustainable mobility

Providing comprehensive information regarding the range of PT options/sustainable mobility available in the region/neighbourhood for new residents. A welcome kit info package will be sent individually to new residents in the area. The main objective is to inform new residents and take advantage of the change in personal life to foster the use of sustainable mobility. The target group can be accessed during the handing over the keys of a new housing development (in cooperation with the developers) or with a cooperation with other institutions like cable tv providers, water or energy providers as they know about new residents even in exisiting buildings. An example of this action is carried out in the Portuguese city of Almada, see https://www.eltis.org/discover/case-studies/new-residents-mobility-welcome-kit-almada-portugal.

4.19 Folder for specific target groups such as commuters/tourists/elderly persons/pupils

Creation of a folder, which promotes and informs about special tickets or other offers for different target groups (tickets for: commuters, tourists, elderly persons, pupils). The folder(s) will be available at all points of contacts, to reach each target group. An example of this action is the VOR – Youth ticket folder in the Eastern region of Austria, www.vor.at/fileadmin/CONTENT/Downloads/Folder/Infofolder/Jugendticket_Flyer_2019-20.pdf.

4.20 Sustainable mobility guidebook with comprehensive information for sustainable mobility of a whole region

A comprehensive guidebook including information about public transport, taxi, cycling, walking, vehicle sharing, ride sharing, taxies, micro mobility community and hiking bus offers etc. is put together. This measure aims at improving people´s mobility through the provision of information and guidance all in one. Occasionally, by sending in a reply-card, further information material can be obtained free of charge (e. g. customized PT information). Another option is to include touristic or other practical information about the region as well. The guidebook should be additionally available at important points, e. g. touristic destinations, transport nodes, in the buses at the driver, travel agencies, etc. Mobility guidance on the phone is delivered as well if requested. An example of this action is the Lungau Tälerbus, Austria, see http://www.taelerbus.at/.

4.21 Salient implementation of PT information on webpages of destinations

Work places, tourist accommodations, municipalities, tourist destinations etc. offer salient implementation of PT information on webpages. “Arrival” with PT is displayed. The nearest PT station and an interface for journey planning regarding national, regional and local PT is implemented. Where possible, the option to make a booking for PT on the webpage itself (e.g. webpage of a tourist accommodation) is provided, to offer an easy booking experience. Links to other local mobility options like flexible PT, bike/car-sharing systems, bike/car rental, etc. are displayed, too. This section should be found easily at the start page of any web pages of organizations creating transport demand. Priority should be given to sustainable modes in the web design and order of link lists. An expert should be available to support and train the organisations how to implement these information at their webpages. An example of this action is the tourist association Tyrol, Austria, see https://www.tyrol.com/good-to-know/arrival/by-train#anchor-anker-journey-planner.

4.22 Eco-labelling of organisations supporting sustainable mobility

An eco-label about sustainable mobility for municipalities and tourist accommodations highlights the efforts of the municipalities and tourist accommodations regarding sustainable mobility. Participating organisations provide the following information on the webpage and on-site: e. g. booking options for PT, information about PT (time tables etc.) before and during the stay of tourists etc. Other criteria regarding sustainable mobility are possible, e.g. offer bicycles for the guests or cooperating with a bike renting system. Participating entities receive their eco-label at a media-effective ceremony. The ceremony also can be part of a social media campaign forwarded by local municipality, tourist associations etc. It is important, criteria to receive an eco-label can be influenced by the organisation itself, e.g. if talking about hotels, pt information at the rooms available, trained staff at the recption, a poster with the time table etc. An example of this action is the Stars for mobility initiative in Tyrol, Austria, https://www.klimabuendnis.at/tiroler_mobilitaetssterne.

4.23 Time table and other information as APP for mobile devices

Provision of a journey planner, time tables, reservations and real-time information and if further development is wanted, the inclusion of payment and booking etc. via one App for PT and all other transport modes (like car-sharing, taxi etc.). An example of this action is the Whim APP in Finland, see https:// helpcenter.whimapp.com/hc/en-us/articles/115003538029-Whim-and-the-Mobility-as-a-Service-concept.

4.24 Making public transport and other sustainable mobility visible on public places and places were people meet and likely need mobility supply

This measure can be manifold, e. g. basic information on public transport such as a network map & phone number for flexible transport on coasters at bars, at tickets for concerts, museum tickets etc. This measure shall inform potential customers about the offer, especially to present an alternative to car usage. The idea is, to be visible at places were people have time to receive such information und a big group of people can be reached. Special flyers or giveaways can be produced and distributed at places where people meet or stay, such as in waiting rooms of doctors or other social services, administrative offices etc. At these places explanations videos about how PT works are also an option. QR-Codes on flyer or at public places can link to explanation videos, flyers etc. An example of this action is the coasters as ticket for PT in Hamburg, Germany, see https://www.horizont.net/marketing/nachrichten/eins-noch.-aber-dann-ist-bus-wie-die-hvv-und-astra-ein-bisschen-bvg-magie-nach-hamburg-holen-174343.

4.25 Training events for multipliers

Staff with contact to residents, pupils, employees or tourists, acts as a “multiplier” and participate in training events to be able to provide the necessary knowledge in upcoming situations. The following jobs can be seen as “multiplier”: teacher, hotel receptionists, PT drivers, staff at tourist destinations etc. These persons are the contact persons, with which people of the target group can directly communicate and therefore can provide highly relevant information about sustainable mobility. This measure can be accompanied by a (social) media campaign, in which the “multipliers” post about their engagement and at its best, also act as role models and post this as well. An example of this action is the mobility manager training in Tyrol, Austria, see https://www.tirol2050.at/de/geschichten-des-gelingens/mobilitaetscoach/.

4.26 Provision of sustainable mobility related information for touristic destinations at public places or where tourists meet

Information for touristic attractions (like information boards or signposts for hiking, cycling etc.) also provide information about the next PT station, operating times of PT, links to relevant APPS and e. g. phone number for booking flexible transport (for cyclists the options for bicycle transport as well). Recommended hiking routes and bicycle routes in info folders (and at the sites itself) are created in a non-circular way so the usage of a car becomes less attractive. Information about next PT station and time tables need to be provided with the information about recommended routes in any case and were accessible (web, boards, flyers etc.). An example of this action is the presentation of different hiking routes in Styria, Austria, see https://www.verbundlinie.at/freizeit1/freizeit/wanderfolder.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

4.27 Mobility packages for tourists

At origin: The idea is that tourists receive a package about sustainable mobility at the tourist destination before they start their travel and therefore can decide whether travelling by car is an appropriate choice or if sustainable transport modes might offer an acceptable or even a better option. Therefore, tourists receive a package directly after their booking with detailed information about sustainable mobility at the travel destination, including e. g. luggage transport, pickup service from PT etc. At destination: An information package is displayed in each room and/or at the reception desk of the tourist accommodation. In these mobility packages, tourists can find detailed information about all local sustainable mobility options. If possible, free tickets for PT are provided for the tourists, as well (included in the room price). An example of this action is the Lungau Tälerbus in Salzburg, Austria, see http://www.taelerbus.at/.

5 CONCLUSIONS

The options choosing appropriate measures nudging residents, tourists or commuters towards the use of sustainable mobility are manifold. There is a big variety of options available. All of them were implemented already in different places and environments and have proven succesful applications. Ideally - based on a complete offer of sustainable modes without any gaps in a region - these various activities accompany this integrated offer and motivate people to behave in a sustainable way. Because of the ongoing discussion due to the obvious climate crises, the majority of people are especially open to these topics and are willing to use sustainable modes in principle. In particular, if the information is easily accessible, the targeted persons would feel a social norm to use sustainable modes and to receive positive feedback when using sustainable modes, and that will break the ice. Additionally, if most of the measures described above can be implemented within the region on a permanent level, the effect will be stronger compared to single and isolated activities, because residents, commuters or tourists would be confronted with sustainable mobility on a daily basis.

Between Urban Transformation and Everyday Practices – Participation and Co-Production in the City of Tarija, Bolivia

Fabio Bayro-Kaiser

(Fabio Bayro-Kaiser, RWTH Aachen University, Chair and Institute for Urban Design, Wüllnerstraße 5b, 52062 Aachen, Germany; bayrokaiser@staedtebau.rwth-aachen.de)

1 ABSTRACT

By 2050, around two-thirds of the global population will live in an urban environment. Urban growth is currently prevailing in the developing world, and in this context informality is seen as a general mode of urbanisation. The patterns of growth vary regionally, and the resultant urban fabric is expected to become more complex in various world regions in the years to come. In addition, not only are many regions facing dramatic and unforeseeable changes in the environment, but non-renewable resources are also becoming increasingly scarce; thus, concerns regarding sustainable and resilient development have been internationally voiced. Therefore, understanding and managing urban growth has become of general concern to a wider public.

In particular in the Global South, a dichotomy between formal and informal urbanisation has prevailed that has hindered a sustainable and resilient development in various ways. What comes to mind, here, is the often-used image of a São Paolo favela segregated from the city's wealthier neighbourhoods—a common phenomenon in many cities of the developing world. Against this background, many efforts have taken a more social and political approach in order to overcome this dichotomy and, thus, to promote more inclusive development—a cities for all approach. At the core of these approaches are co-ordination and communication between top-down and bottom-up approaches, the reduction of tensions between formally and informally developed urban areas, and modes of participation and co-production that consider local action as well as long-term and large-scale effects. However, what does participation and co-production mean and which are the framing conditions under which they can be implemented? The paper pursues these questions for the medium-sized City in Tarija, Bolivia, where a massive urban expansion has overwhelmed formal planning instruments in recent years. Moreover, it aims to contribute with practical experiences to the conference on how social segregation in fast growing city regions could be overcome.

The paper describes Tarija's urban expansion from a historical perspective and identifies critical environmental as well as social challenges as well as the shaping dynamics. Furthermore, the literature and development plans review is enhanced by semi-structured interviews and by two transdisciplinary workshops that where held in 2018, in the city of Tarija, in the framework of a real-world laboratory. This paper argues that urbanisation as it transpired in Tarija was highly inefficient and that the main benefactors were land traffickers, which has promoted the formal/informal dichotomy even further. The paper discusses three main points to tackle this issue. First, it identifies an institutional gap between the central and local government, which is considered the main cause for this formal/informal dichotomy. Second, it proposes the real-world laboratory as a more dynamic and adaptive instrument for urban development than formal planning, as well as a mediator between top-down and bottom-up approaches. And third, it discusses the framing conditions under which informally developed urban areas could be further developed.

Keywords: adaptive urbanism, informal settlements, Latin America, Urbanisation, real-world laboratory

2 INTRODUCTION

By 2050, around two-thirds of the global population will live in an urban environment. Urban growth is currently prevailing in the developing world, and in this context informality is seen as a general mode of urbanisation (Roy 2005). The patterns of growth vary regionally, however, and the resultant urban fabric is expected to become more complex in various world regions in the years to come. Not only are many regions facing dramatic and unforeseeable changes in the environment, but non-renewable resources are also becoming increasingly scarce; thus, concerns regarding sustainable and resilient development have been internationally voiced (UN-Habitat 2014 & 2017, WBGU 2016). As a consequence, understanding and managing urban growth has become of general concern to a wider public.

Latin American rates of urbanisation are among the highest in the world, and it is expected that the region's cities will continue to grow (UN-WUP 2018). The increasing social inequality and environmental damage

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

following this trend have been identified and widely discussed (Butterworth 1981, Angotti 1995, Hall/Pfeiffer 2000, Rodgers et al 2012), especially at UN-Habitat III in Quito in 2016. What comes to mind, here, is the often-used image of a São Paolo favela segregated from the city's wealthier neighbourhoods – a common phenomenon in many cities of the developing world. In this context, two points of view are commonly discussed: one of crisis and misery, and one of heroism; both, however, contemplate informality as fundamentally separated from formality (Roy 2005, p. 148). For instance, spatially the informal city is differentiated as the urban poor build their own city with no regards to existing formal planning and regulatory frameworks. Furthermore, the urban poor are excluded from trading their assets in the formal sector, which also strengthens this fundamental separation. Challenging this dichotomy of formality and informality, Roy argues that urban informality can be seen as a series of transactions that connect different economies and spaces to one another – an organising logic – and that learning from emerging solutions should be of particular interest to urban studies (ibid.).

Likewise, McGuirk (2014) argues for a 'learning from approach' and, in the latest research, discusses radical solutions in Latin American cities that address rapid urbanisation and resource scarcity with approaches that are both more social and political; approaches that question the modes of modernist planning that have dramatically shaped Latin American cities until recently. With a 'needles instead of scalpels' approach, urban informality has been addressed in various ways (McGurik 2014, p. 14f); for instance, the transformation of the cities of Bogota and Medellin in Colombia. Two aspects were key to this development: firstly, civic education programmes for rehabilitation of the public realm, as introduced by the Mayor of Bogota, Antanas Mockus; secondly, innovative mobility concepts that allowed for the creation of social relations through the linkage of the informal city with the formal city (McGurik 2014). In particular, Alejandro Aravena's approach to social housing in Chile has been much discussed. He proposed an open-ended approach that provided families with half of a house, leaving the other half to be built according to their means and within a defined structural framework; moreover, where public money should be spent was co-decided (Aravena/Iacobelli 2016). At the core of these approaches are co-ordination and communication between top-down and bottom-up approaches, the reduction of tensions between formal and informal urban areas, and modes of co-production that consider local action as well as long-term and large-scale effects (McGuirk 2014, Aravena/Iacobelli 2016, Brillembourg/Klumpner 2019, Forman/Cruz 2019).

The paper operates on the premise that there are uncertain and manifold outcomes to planning. As such, planning should not be thought of as absolute, but rather as an open process of discovery – but under which framework could such a discovery process be operationalised? Three points are relevant to address this. Firstly, cities need to be thought of as a process where decisions are made along the way involving manifold perspectives as well as sustainable and resilient development (WBGU 2016). Secondly, local actions and long-term and large-scale effects need to be considered together (McGuirk 2014, Aravena/Iacobelli 2016, Moroni/Cozzolino 2019, Krebs and Tomaselli 2019). Thirdly, urban studies could learn from on-site and problem-solving experiences (Roy 2005). These aspects are put into relation with the urban expansion of the city of Tarija in Bolivia, which is described from a historical perspective in Section 3. In doing so, this paper identifies a contested situation between spaces within formality and spaces within informality in Tarija (Section 4). In this context, the paper sees overcoming this dilemma as a central challenge and, as such, proposes a more adaptive framework for Tarija in Section 5 based on a transdiscplinary approach.

Thie paper argues that urbanisation as it transpired in Tarija was highly inefficient and that the main benefactors were land traffickers, which has promoted the formal/informal dichotomy even further. The paper discusses three main points to tackle this issue. First, it identifies an institutional gap between the central and local government, which is the main cause for this formal/informal dichotomy. Second, it proposes the real-world laboratory as a more adaptive instrument for urban development with a mediator role between top-down and bottom-up approaches than formal planning. And third, it discusses the framing conditions under which informally developed urban areas could be further developed.

3 URBAN GROWTH IN THE CITY OF TARIJA, BOLIVIA

The city of Tarija is located in a valley in the south of Bolivia, about 1,850 metres above sea level, in an area that is defined by the South American Andean Mountains. Founded in 1574, the city alongside the Guadalquivir River was a strategic location for the expansion of the Spanish Empire towards the south. The city's urban layout and expansion followed a traditional grid-iron urbanism, with a north-south and east-west

orientation of its streets, typical to monocentric Latin American cities. This development can be better understood from three periods of time: the colonial, from 1574 to 1825; the republican, from 1825 until 1952; and the modern, from 1952 onwards (Lea Plaza Dorado et al 2003, Trigo O'Connor d'Arlach 2017, de Mesa Figueroa et al 1998).

During colonial and republican times, city development was framed by the Spanish semi-feudal regime. Commodities were produced in rural areas and traded in the city, and housing and political participation in the city was mainly reserved for aristocrats and wealthy members of society. In 1825, Bolivia proclaimed its independence from Spain and became a republic; however, the semi-feudal regime continued to define society as in colonial times (Trigo O'Connor d'Arlach 2017). Indigenous and farmers' communities lived and worked in haciendas in rural areas, with no right to own property (Larson 2017). Urban growth was low in terms of the surface area the city covered; in terms of population and built structure, however, the city became denser as the plots were subdivided due to growing families and migration (Lea Plaza Dorado et al 2003). In the early 1930s, this dynamic was slightly disrupted by an increase in migration triggered by the discovery of oil in the southern region of Gran Chaco. The new neighbourhoods with lower population densities that emerged around the city's centre (GAMT 2008) are now considered as the formal city as they concur, to a certain degree, with zoning plans and building codes.

In 1952, Bolivia saw great transformations in citizenship, political participation, land distribution, and state control of the national economy and natural resources (Vargas Gamboa 2016, Urioste 2012). Furthermore, the right to vote was universalised, which gave women and indigenous and farmers' communities a new role in society. After the agrarian reform in 1953, everyone was able to own property. Moreover, the state provided fiscal land to families as non-transferable and indivisible private property (Urioste 2012). However, over time these large properties were either sold to developers at low prices or sub-divided by the families themselves. Particularly during the dictatorial military regimens of the 1970s and early 1980s and the neoliberal governments in the early 1990s, land with no arable value from indigenous and farmers' communities was freely distributed to political supporters and foreign investors. This led to the establishment of a land market that freely operated on rural territory with few governmental constraints (Urioste 2012, pp. 61-64). A lucrative business developed for those who re-sold land they had acquired from the state for free or for very little money. Moreover, in the mid 1990s, the election of a neoliberal government led to the closure of state-owned mines in the city of Potosí. As a consequence, thousands of unemployed miners migrated in search of new economic opportunities. This, combined with the discovery of natural gas reserves in the Department of Tarija, led to a pattern of heavy migration towards the city of Tarija. As a result, the existing regulatory frameworks and municipal capacities were overwhelmed by the influx and the compact structure of Tarija collapsed (PNUD 2015, GAMT 2008 & 2016, GADT 2015, Vargas Gamboa 2014).

In 2006, a socialist government, represented by Evo Morales, assumed office, and since then Bolivia has seen profound socio-political changes (Lazar 2013). Furthermore, Bolivia was termed a pluri-national state in 2007 with 34 indigenous nations (Estado Plurinacional de Bolivia 2007). Of particular relevance to urbanisation in Bolivia were shifts in policy addressing land ownership and housing as they reacted to the great demand mentioned above. A revised agrarian reform was promulgated to tackle neoliberal decisions and corruption from previous periods; now the state had the capacity to secure land for indigenous communities and to expropriate unproductive lands so as to avoid land speculation (Urioste 2012, p. 64). Moreover, the construction of social housing was intensified and accessible financing systems were developed (AEVIVIENDA 2019). Further, the state, through its Ministry for Development Planning, promulgated the law N° 247, which addresses regularisation of land tenure in urban environments and the right to adequate housing (Ministerio de Planificación del Desarrollo 2012).The law did not only apply to urban environments, however, and settlements and squatters outside the urban radius could also legalise tenure after demonstrating five years of permanent residency (ibid., p. 7). In consequence, municipal zoning plans experienced modifications and urban radiuses were expanded several times, but the monocentric structure remained. Furthermore, legalisation processes led to heavy discussions. For instance, urbanisation of the municipal park 'Las Barrancas' in Tarija, after being squatted for more than five years, was heavily criticised by the general public (El Periódico 2019). It was seen as an invasion of public and private land and counterproductive to development, which remains a general discussion up to now and often carries a discriminatory tone. However, a critical issue is missing in this point of view: the main benefactors of shifts in policy were land speculators and land traffickers, as people who previously did not have the resources to

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

buy land could afford it now and rural land could be transformed into urban without having infrastructure or being envisioned as such (Vargas Gamboa 2014).

It was during this period that Tarija grew the most in terms of covered surface area, and its expansion was primarily shaped by land speculation and with little institutional control (Bayro-Kaiser, forthcoming). This has had critical effects on the natural environment, as land speculation has deprived the city of valuable natural land and bodies of water, and biodiversity has been destroyed in the process. As Figure 1 shows, the emerging surroundings are approximately four times larger than the actual consolidated city. These emerging surroundings are, nowadays, considered as informal settlements. In conclusion, analysing urban expansion in Tarija from a historical perspective has shown the tension between the formal and informal city, and that the spaces in between are contested. Moreover, through the analysis it can be visualised that the city of Tarija is predominately informal and that formal planning and regulatory frameworks played a minor role in the recent expansions.

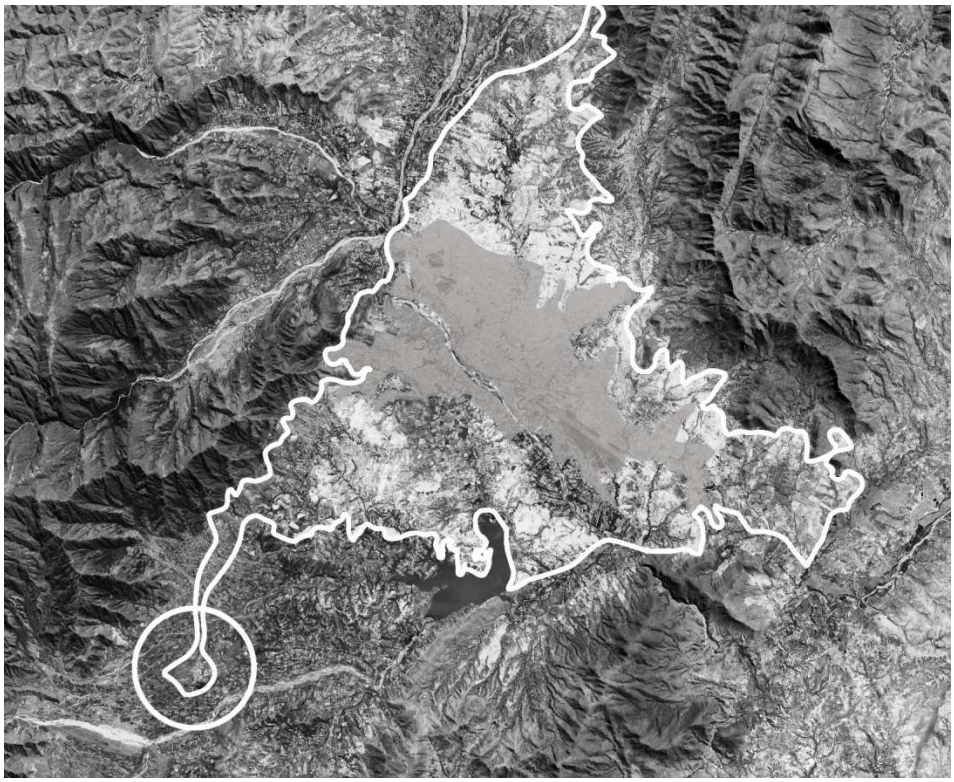

Figure 1: The consolidated city of Tarija, urban expansion, and localisation of the community of San Andres. Source: DigitalGlobe 2019 (edited)

The year 2025 marks the bicentennial of Bolivia's founding. For this occasion, the Ministry of Autonomy of the Pluri-national State of Bolivia proposes a patriotic agenda with thirteen pillars for development towards a dignified and sovereign Bolivia, based on international agreements on sustainable development. The Ministry, moreover, has identified the role of each level of government for the operationalisation of these pillars (Ministerio de Autonomías Estado Plurinacional de Bolivia 2014, p. 13-14). At the centre of this agenda is the promotion of an inclusive, participative, and democratic society and nation – without discrimination, racism, hatred, or division. Furthermore, the agenda proposes an inclusive and strategic collaboration between the four levels of government: central, departmental, municipal, and native indigenous peasants. In particular, the key role of the autonomous territorial entity (ETA) in achieving such goals is stressed. The pillars range from the eradication of extreme poverty through universal provision of basic infrastructure, the right to adequate housing, and the protection of the natural environment. It is under this scheme that Tarija is to be further developed and, thus, existing planning and regulatory frameworks ought to be reformed accordingly.

4 BETWEEN URBAN TRANSFORMATION AND EVERYDAY PRACTICES

In Tarija, two realities clash: the formal, which is within the urban radius, and the informal, which has emerged outside of the urban radius. Furthermore, there is no institution responsible for the spaces in-

between the urban and the rural. The central government attends to the needs of the rural dwellers, whereas the municipal government only to those within the urban radius. As a consequence, people who bought a parcel of land in the informal market lack formal property titles and are unable to develop their habitat in a formal manner; thus, dwellers of these contested spaces find themselves between constitutionality and illegality (Vargas Gamboa 2016). The approach of the local government has been to modify zoning plans and impose building codes, i.e., to expand the urban radius in order to legalise tenure. However, building codes do not concur with existing practices of construction and, in this respect, are outdated; this also hinders the process of legalisation. Moreover, issues such as infrastructure and liveable environment are rarely discussed. The stages of development are visualised in Figure 2. From the city centre towards the periphery, development has mainly happened on a self-organised and incremental basis, i.e., in an informal manner. This development does not have the scale or complexity of cities such as Sao Paolo or Mexico City, but it concurs with the perspectives initially discussed (see Introduction). A fundamental separation between the formal and the informal city can be observed in Tarija, and this has been underpinned by associations of informality with disorder, poverty, criminality, and vulnerability by the general public (El Pais 2013 & 2019, El Períodico 2019). Furthermore, planning in Tarija has mainly followed a top-down approach of imposing formality through the restructuring of existing settlements in order to include them in municipal zoning plans (Bayro-Kaiser, forthcoming).

Figure 2: Different stages of self-organised and incremental development can be found in the informally developed areas from the centre towards the periphery. Source: Author

In this contested situation, a desired and undesired situation is constructed: from an informal perspective, the formal is desired as it is the solution to everything that is wrong (especially infrastructure), and from a formal perspective, the informal is undesired as it risks everything that has been solved (disorder, criminality, and land encroachment, among others). This binary point of view, however, hinders addressing the complexity of urban expansion and, in turn, development. Moreover, this critical construction often leads to the social and spatial segregation of the informal city and, thereby, to the closure of the formal city from the emerging surroundings – a situation of contestation that can be observed in many cities around the world. Following this reflexion, a central question arises: what does participation and co-production mean and which are the framing conditions under which they can be implemented?

5 CITIES FOR ALL THROUGH TRANSDISCIPLINARITY

This research draws its findings from a real-world laboratory approach in the city of Tarija initiated in 2018 – the Real-World Laboratory: San Andrés and surroundings. This approach was proposed as framework to understand and manage urban growth in Tarija and was developed in collaboration with the UAJMS University of Tarija, the Municipal Government of Tarija, and the RWTH Aachen University. As such, it opened the planning discussion to manifold perspectives by gathering researchers from academia and actors from practice and civil society, and has had a co-ordinating role between formal institutions and informal organisations and initiatives in Tarija. It aims to reform existing planning and regulatory frameworks in Tarija to be more open to what is on offer in informal areas and, also, to raise awareness within the general public regarding sustainable and resilient urban growth. Here, resilience is understood as a precondition for sustainable development and as being able to respond to changing conditions, both reactively and proactively (Bott et al 2019, p. 13f); thus, openness, responsiveness, and the ability to learn and to adapt are central to this approach. It focuses, in particular, on San Andres Road, which connects the urban centre with the rural community of San Andres (see Figure 1), and addresses neighbourhood, city, and regional development in Tarija. This initiative is at its infancy and, therefore, the discussion presented here cannot be seen as concluded and, instead, should be seen as a contribution to more open discussions around development in

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)

cities facing similar challenges. The results of two experimental and transdisciplinary workshops held in 2018 will be discussed in this section.

Figure 3: Housing on top of a ravine. A situation of vulnerability and environmental damage produced by uncontrolled urban expansion shaped by land speculation. Source: Author

Within the laboratory's first year of operation, two transdisciplinary workshops were held. They raised questions of regional, city, and neighbourhood scale addressing issues such as infrastructure, mobility, housing, public space, and natural environment. The workshops were visited by researchers and students from the collaborating universities, representatives from the municipal government, representatives from the farmers and the neighbourhood associations, practitioners from various disciplines, and the general public. In particular, the dialogue between the municipal government and citizen-driven initiatives was of importance. During the workshops, input on the status-quo of urbanisation in Tarija was given by institutional actors, which was then discussed based on on-site surveys as well as residents' testimonies and participation. As described in Section 2, urban expansion in the city of Tarija is shaped by land speculation, which has been out of control for the last three decades and has thus deprived the city of valuable natural land. Furthermore, urbanisation has destroyed important water bodies and biodiversity has suffered greatly. This is, thus, a highly inefficient way of achieving urbanisation. In response, two overall goals were formulated: firstly, restoration and preservation of vital water-bodies and the region's biodiversity, and, secondly, spatial and social integration of the informal city. To achieve this, transformative actions and everyday-life practices have to be negotiated on various spatial scales and levels.

Additional effort was put into round tables, where the overall goals were intensively discussed and the strategies and instruments needed to achieve them were elaborated. To be more specific, a multi-scale model for development was proposed in which the real-world laboratory plays a central and mediator role on the city level (see Table 1). The inclusion of manifold perspectives is possible when the regional, city, and neighbourhood development is considered together. Moreover, various fields of action were identified. In this particular context, there are five: development, biodiversity, mobility, inclusion, infrastructure, and densification. They all have to be thought in accordance to national, regional and local development and zoning plans; however, plans need to be updated and, thereby, become more adaptive to unforeseeable changes. Besides development and zoning plans, (revised) urban codes and co-production are important instruments. They allow, firstly, for a relational production of habitat and, secondly, a learning process. The discussions concluded with an ambitious agenda combining local actions and long-term and large-scale effects.

The need for housing and the promotion of low-density development in Tarija created favourable conditions for a profitable land market; therefore, actors involved in land speculation and development have promoted this type of model. The laboratory, which challenges this model, puts tackling land speculation on the agenda of the local governments. In doing so, it proposes densification and adaptation of existing structures as a

more economical and sustainable way of achieving urbanisation. It is, however, important to consider site-specific circumstances, and trade-offs between institutions, actors, and future dwellers. The co-operation of national, regional and municipal governments, and indigenous and farmers' organisations is fundamental to this approach. Moreover, first experiences have shown great acceptance by the public, as different actors were able to stress their concerns and to participate in discussions previously unreachable to them. However, two risks were identified. Firstly, corruption and client-politics are a common thing and they hinder inclusive and community-based development. Secondly, land speculation, which promotes individual interests over the common good has severely damaged vital water bodies and biodiversity and has been an attractive business in Bolivia. Therefore, creating an institution with the necessary legal competences to address contested spaces and capable of mediating between top-down and bottom-up approaches is proposed; and as such, the real-world laboratory will continue to play a crucial advisory role.

	Strategies	**Instruments**	**Agenda**
Region	Sustainable and resilient development Restoring and preserving bio-diversity Regional connectivity Inclusive urban communities Infrastructure and basic services Densification	National and regional development plans and zoning plans	Lively and healthy environment
City		Municipal development plans and zoning plans Urban codes **Real-world laboratory**	Inclusion of the informal city Tackling land speculation and land traffickers Dialogue between national, regional and municipal governments
Neighbourhood		Neighbourhood development plans Co-production	(Re)development of leftover spaces (Re)naturalisation of eroded land Attractive public spaces and walkability Mixed-use and new typologies

6 CONCLUSION

The formal/informal dilemma outlined in Section 4 is a consequence of an institutional gap: the central government manages the rural land and the local government manages the urban areas; thus, the contested spaces cannot be developed and an undesired situation is produced. This has had severe effects on the natural environment and has produced discrimination within society towards newcomers. The paper argues that in order to sustainably develop the city of Tarija, and cities that face similar challenges, it is crucial to overcome this dilemma and that municipal planning and regulatory frameworks should be reformed towards a more-integrated approach (as presented in Table 1). In particular, development should be looked at from various spatial scales and levels, transformative actions should be considered, and everyday-life practices included as well. This is essential for promoting an open city discourse, and underscores the importance of a median between top-down and bottom-up approaches. So far, this has not been achieved institutionally in Tarija and this initiative remains an informal instrument. As such, however, it is more responsive and capable of producing knowledge in the short-term. Therefore, it has been anchored in teaching and research activities at the local university where, we believe, it will contribute more efficiently to structural changes in local institutions as well as in the general public opinion towards informal urbanisation. Both dimensions are important when thinking about a more adaptive urbanism. Above all, the promoted transdisciplinary discussions and transparency have dramatically changed the mindset around development in Tarija, which has set off a new dynamic. In the future, different perspectives will have to be integrated, the natural environment will have to play a role, and development plans will have to be socialised before being operationalised. This means, development will have to be negotiated on various spatial scales and levels, but also how knowledge—that sustains our actions—is produced and acquired needs to be discussed.

1 ABSTRACT

Minerals play an important role for the European economy, hence the secure and sustainable supply of minerals is of political importance for the EU and its Member States (MS). Despite the fact that Europe has a potential for minerals development, access to minerals is, however, influenced by different stakeholder interests, often reflected in competing forms of land-use and institutional complexity of two policy streams of minerals and land use planning. Recent public sector responses in EU MS introduce new instruments such as safeguarding or protection of minerals deposits or valorisation schemes for minerals development, both aiming to bridge the two policy streams. However, there are significant challenges for governments and public administrations on all levels to achieve the effective integration of the two policy streams: Institutional and administrative fragmentation, unclear roles and duties, coordination deficiencies between levels of governance (departmentalism) or lack of willingness or ability to collaborate (Endl, 2017; Gugerell, 2019).

Thus, our research identifies different approaches to policy integration of minerals and land use planning policy based on a qualitative analysis of 12 case studies from 11 different EU MS. Against this background, the article conceptualises and analyses policy integration with regards to: 1) instruments for horizontal and vertical integration; 2) degree of integration - full versus partial integration (e.g. for horizontal integration: considering integration ex-ante/in the design versus ex-post/during implementation); 3) which aspects of horizontal or vertical policy integration are outlined (e.g. protection of deposits or design of land use plans); and 4) the capacity and willingness for policy integration by different actors.

The results indicate two central characteristics for policy integration: (i) the mix of different types of instruments for horizontal and vertical integration and (ii) capacity of the involved actors. Across the 12 case studies we identified a mix of regulatory, economic or informative instruments, national strategies/ policy guidelines across horizontal as well as vertical policy integration. However, we recognised a trend across all 11 countries: instruments that signify full integration of minerals and land use planning on both horizontal and vertical levels; the application of soft rather than coercive instruments; and a prevalence for instruments in the form of planning tools and/or maps with the objective of enhancing knowledge of potential land use, mitigate land use conflicts and/or integrating minerals into land use planning processes.

Our research shows that across 11 countries policy instruments are assembled to policy mixes for integrating minerals and land use planning policy combining regulatory, economic (fiscal) tools, (national) strategies and guidelines and information-based instruments. In the specific context of instruments for minerals planning (e.g. multi-criteria assessment, safeguarding) the results indicate that in order to support the integration of land-use and mineral policy, instruments should be adapted to the land-use planning system and a good fit with the actual processes on the lower level of implementation (local and regional). Moreover, the results illustrated that willingness and capacity of actors play a crucial role for policy integration and implementation. Against this backdrop, more centralised public administration can more readily support lower levels to manage policy challenges: they can support lower levels by providing expertise, capacity building activities and create platforms where the different policy sectors can meet. Conversely, in decentralised systems and systems where policy design and implementation are dispersed among different levels of government the willingness to collaborate between higher and lower levels of government is important to support later policy implementation.

Keywords: Policy instruments, Mineral policy, policy integration, Mineral resources, Land-use planning

2 INTRODUCTION

European economies are dependent on the secure and stable supply of raw materials and minerals. The access to raw materials for sectors such as the construction, chemicals, automotive, aerospace, machinery and equipment are estimated to be connected to the existence of 30 million job opportunities in Europe (European Commission, 2013). Import dependency and the need for minerals (including Critical Raw Materials, CRMs) for the transition to cleaner technology are necessitating a coherent and comprehensive minerals policy framework in the EU and EU Member States (MS) (Dooley, & Leddin, 2005; Tiess, 2010; Thomashausen et al. 2018, Fraser Institute, 2018).

A national policy framework can either enable or hamper the development of sustainable mineral production. Due to the cross- spatial, temporal, and sectoral nature of mineral- and raw material production, minerals policy constitutes a particularly "wicked" policy problem (Endl, 2017). Defined as intractable, ill-structured, fragmented and contested a wicked policy problem resists standard approaches to problem solving (Daviter, 2019). The governance of wicked problems constitutes an administrative challenge too complex to be tackled by prevalent sectoral silo thinking and specialisation (Daviter, 2019). Avoiding silo-thinking and engaging in coherent policy approaches, is particularly relevant in the context of land-use planning (LUP) and mineral policy for achieving access to and protecting minerals resources, managing the contested nature of exploitation and exploring new approaches for integrated policy design and implementation. Up until today, there are significant challenges for public administration on all levels to achieve the effective integration of the two policy streams: Institutional and administrative fragmentation, unclear roles and duties, coordination deficiencies between levels of governance (departmentalism) or lack of willingness or ability to collaborate (Endl, 2017; Gugerell, 2019). The paper gives an overview about concrete examples of EU Member State policy instruments for integrated minerals and LUP policy and their design and implementation experiences in order to address above-mentioned challenges.

3 BACKGROUND

3.1 Mineral resources in mineral and land use planning policy

Several EU MS have established more strategic policy approaches to secure minerals supply from primary sources. However, public disapproval, incoherence with other policy areas and lack of business incentives constitute barriers and challenges to ensuring effective policies and implementation (Everingham et al., 2013, Moffat & Zhang, 2014). Governing the secure and sustainable supply of minerals from primary production faces particularly "wicked" dynamics. Minerals policies need to address various factors such as multiple stakeholder interests, competing land-use interests, as well as conflicting agendas and objectives. Hence, studies focusing on governance of wicked policy problems often focus on the need for government coordination and/or collaborative governance to challenge existing patterns of sectoral responsibilities (Askim et al., 2009; Christensen & Laegreid, 2007, 2008; Flynn et al., 2011; Kavanagh & Richards, 2001; Bryson et al., 2006; Ferlie et al., 2011; Weber & Khademian, 2008).

The complexity of minerals policy-making warrants the consideration and application of different policy- and decision-making instruments; voluntary, regulatory and strategic, whilst recognising stakeholder and public interests (Clausen & McAllister, 2001). Nevertheless, studies on resource governance often tend to focus on the effectiveness of a single policy instrument rather than underlying factors of policy governance for managing the complex dynamics of primary mineral production (Söderholm, 2015; Endl, 2017). Hence, this paper explores the notion of a more integrated and comprehensive approach to minerals policy which addresses the instruments for horizontal and vertical policy integration; as well as degrees, aspects and capacity of such integration in the 14 EU MS case studies, thereby extending research on minerals- and land use policy integration beyond 'environmental trade-offs' to recognise inclusion of present (and future) socioeconomic and political needs in society.

Overall, LUP deals with assessments of potential land-use options serving the demands and needs of communities while managing natural resources of that option. These natural resources cover, for example, water(sheds) (Boschet and Rambonilaza, 2015), forests and agriculture (Ayambire et al., 2019; Gosnell et al., 2011), ecosystem services (Grêt-Regamey et al., 2017) or mineral resources (Bax et al., 2019; Lopes et al., 2018). Against this backdrop, LUP systems (i.e. instruments and processes) are expected to manage competing demands (e.g. nature protection, residential, agriculture (Gałaś, 2017; Mitchell et al., 2004;

Mitchell, 2016) and integrate them into the socio-spatial context (Gustafsson and Scurrah, 2019; Roth and Howie, 2015).

The current literature on land-use planning and mineral resources largely investigates valuation of mineral resources for LUP decision making (EUROMINES, 2011), modelling of decision support tools (e.g. for Strategic Environmental Assessments) considering different social, environmental and economic aspects (Lechner et al., 2017; Ustaoglu et al., 2018) and LUP instruments (e.g. Gustafsson and Scurrah, 2019). Altough research on linking or integrating mineral resources into LUP policies exists (Baker and Hendy, 2005; Roth and Howie, 2015; Wagner et al., 2006; Wrighton et al., 2014), there is no comprehensive overview that provides a more nuanced picture on different approaches in EU Member States. This article address this gap by looking into 11 EU MS and their setup of policy instruments covering a wide range of different aspects of minerals and LUP policy and outlining their success in integrating these two policy streams.

3.2 Forms of policy Integration - horizontal, vertical, diagonal

Policy integration can be understood as "the replacement of specific elements of existing policy 'mixes' or 'regimes' – the goals and objectives and calibrations of existing policy tools and goals – by a new policy mix, in the expectation of avoiding the counterproductive or sub-optimal policy outcomes that arise from treating interrelated policy regimes and components in isolation from one another"(Rayner and Howlett, 2009, p.99).

Policy integration can take place at different moments and/or periods of the policy cycle: either in the policy design and –development process, implementation, evaluation or in the re-design or update of a policy (Kivimaa and Mickwitz, 2006). Prior research advocates that the policy design and decision-making phase might be better suited for policy integration than later stages of the cycle, such as implementation (Jordan and Lenschow, 2010a; Uittenbroek et al., 2013). Two lines of arguments are supporting that consideration: a) early integration efforts are assisting the consideration of other actors/stakeholders' interests and policy objectives in the policy design and the development of implementation actions and measures; b) administrative procedures and routines of other administrative units might differ and thus sufficient time for coordination and administrative and pre-information is needed. However, the implementation phase and implementation actions and measures are the ones where the actual impact of integrated policies is created (Kohlhoff et al., 2016).

Horizontal policy integration is often understood as pertaining to organisational and institutional interactions across distinct sectors or, the extent to which a central authority has developed a comprehensive cross-sectoral strategy (Di Gregorio et al., 2017; Lafferty and Hovden, 2003). Horizontal policy integration can thus be seen in converging two (or more) policy streams to obtain a coherent approach, as policy streams with conflicting goals and objectives may undermine long-term alignment of overarching objectives across sectors (Nilsson, 2005). Horizontal policy integration is particularly addressed as paramount in 'naturally' cross-sectoral topics such as environmental- or climate policy (Di Gregorio et al., 2017; Jordan and Lenschow, 2010; Nilsson, 2005; Lafferty and Hovden, 2003) but also for minerals and raw materials policy (Endl, 2017; Clausen and Mcallister, 2001). Vertical policy integration, on the other hand, takes place among different levels and hierarchies across political administrative levels and/or territories (Endl, 2017). Hence, vertical policy integration involves actors from different levels of government such as, for example, national ministries, regional authorities and local governments, thereby increasing the need for capacity within and between such actors to achieve integration. Vertical policy integration can involve processes of devolving responsibility to local levels, and can foster coherency, consistency and learning between different levels of government (Nilsson, 2005). When the coordination efforts are crossing policy streams and administrative level, one speaks of diagonal policy integration: such cases can become apparent in strongly decentralised or federal systems, where setting the policy goals and their implementation is dispersed over different levels of government and policy sectors. Steurer and Clar (Steurer and Clar, 2015) are stressing, that, in such settings early agreements and commitment between the different administrative levels and the actors responsible for implementation are crucial in policy design and goal setting.

3.3 Enabling factors of policy integration: tools, capacity and willingness

In order to be effective in terms of delivering policy goals, policy integration is subject to the availability of tools, and the capacity and willingness of public institutions to employ these tools. With regards to tools, we will mainly draw on EPI (Environmental Policy Integration) research done by Runhaar (2016), which has a long tradition and has produced a strong body of knowledge on policy integration. Runhaar (2016) distinguishes four types of integration tools:

(1) Regulatory tools (restricting/allowing certain options, actions and behaviour),

(2) Information tools (steer by providing information and guidance)

(3) Economic tools (e.g. change cost-to-benefit ratios)

(4) Organisational tools (organisational conditions such as capacity/willingness, procedures, etc.)

Regulatory tools are regulating choices: Runhaar (2016) also introduces regulatory tools relying on interactive governance modes (e.g. voluntary agreements, covenants). Voluntary agreements are criticised for their limited capacity to unfold implementation and integration pressure, due to too much flexibility and ambiguity (room for interpretation), lack of enforcement mechanisms, limited compensation measures (Glasbergen, 1998; Wu et al., 2018).

Information and voluntary tools are considered to drive behaviour through learning and grants of the addressed audience with a large freedom of discretion and freedom to act on the provided information. Voluntary usage of indicators (such as environmental indicators) is challenging in practice, due to language asymmetries (e.g. planners/policy makers) or insufficient involvement of planners (or other end-users) in the indicator development, which subsequently results in limited, fragmented or no application later on (Brown, 2003) or a mismatch between indicator scale and user-needs (Graymore et al., 2008).

Typical incentive structures are economic tools. Economic tools are supporting integration by either setting financial incentives, rewards or punishments. They are on the interface of top-down steering and voluntary behaviour: they might be put in place by higher levels of administration or government but depend on the voluntary behaviour (by contracting) of the involved actors and stakeholder. In EPI different studies have shown the effectiveness of market-based tools: their effectiveness depends on the financial reward and the enforcement power and possible trade-offs with other policy objectives and issues. EEA emphasises that economic tools should only be one part of a broader package and toolset that steers policy integration (EEA, 2005).

Organisational tools are stressing the importance of organisational structure and organisational practises, as well as the establishment of partnerships and networks that are supporting integration in different stages of the policy cycle. However, also those partnerships are assessed critically by stressing that they "seem to solve some problems but also create new ones". Partnerships and networks are long-term voluntary engagements that need trust building efforts and the willingness to share duties and responsibilities (Klijn and Koppenjan, 2016).

Capacity and willingness are key for effective policy integration (Fleurke and Hulst, 2006; Wu et al., 2018; Zuidema, 2016). Capacity (ability) refers to an organisation's or unit's capacity to perform certain tasks and objectives. Prud'homme (Prud'homme, 1995) explains that it cannot be assumed that (local) units are in command of all technical and managerial expertise and skills to perform certain tasks. This observation is important considering mining and mineral extraction is a very specific and technically sophisticated topic. Zuidema (Zuidema, 2016) is emphasising so called 'economies of scale' where larger (e.g. central government) units might have greater resources or the ability to attract and/or allocate resources to handle broad and complex policy issues. Ostrom (Ostrom, 2015) is noticing the importance of the central government to support local (and regional) authorities to handle and overcome possible challenges and hindrances.

4 METHODS

In our paper we screened a total of 16 case studies originally compiled via two MINLAND Horizon 2020 project reports for evidence of integrated minerals and LUP policy approaches (Luodes et al., 2019; Endl et al., 2019). Complementary information on case studies was retrieved from additional sources, such as summaries and minutes from MinLand Local Workshops and descriptive policy networks (Gugerell, 2019).

As a result the authors identified a total of 12 MINLAND cases that described 13 policy tools dealing with different aspects of minerals and LUP policy, and addressing different phases in the policy cycle. The identified policy instrument types are listed in the table below.

Policy tool	**Regulatory:** demanding compliance equally, steering predictability of governmental decisions (rule of law) and often followed by sanctions for non-compliance.
	Economic or fiscal: designed to encourage investments into exploration and access to raw materials, e.g. tax rebates for research activities (prospecting and exploration)
	National strategies/ policy guidelines: proposing a framework and/or identifying suggested criteria for consideration of minerals in e.g. land use planning
	Information-based: maps, data and tools to be utilised (on a voluntary or regulated basis) for the integration of minerals/land-use plans.

Table 1: Policy tool types differentiated for analysis.

Drawing insights from the literature review on policy integration and respective challenges dealt within minerals and LUP policy, the authors set up the following analytical framework where distinctions were made between 'low degree' and 'high degree' of integration efforts and potential:

	Degree of integration		
Vertical Policy Integration	**Low:** national voluntary or non-mandatory tools addressing minerals (often related to safeguarding objectives)	**Capacity for policy integration**	**Technical capacity** is referring to content-specific knowledge and skills, existence of other supportive policies (e.g. project subsidies, rewards, regulatory instruments)
	High: considers of minerals in land-use planning (input into land use planning originates from other levels of governance)		
Horizontal Policy Integration	**Low:** Land-use (or mineral) issues integrated into minerals (or land-use) planning documents, primarily in ex-post or in the implementation stage		**Managerial expertise** is referring to sufficient expertise regarding integrated policy approaches and/or expertise and skills for collaboration and working across departmental and governmental organisational borders
	High: considers minerals in preparation or design stage of land-use plans/ zoning documents or considers land-use planning in minerals planning documents.		

Table 2: Analysis framework for forms of policy integration, degree of integration and capacity.

The distinction between 'low' and 'high' degree of integration efforts was based on emprical findings from the cases, as well as evidence from the literature on minerals- and LUP policy integration. 'Low degree' in the vertical level hence refers to the existence of a tool with the intention to include e.g. minerals safeguarding into land use plans, whereas a 'high degree' is evidence of actual consideration (and inclusion) in the design and development phase of land-use planning. Similarly, with regards to horizontal integration again 'low degree' was used to describe practices of integrating mineral aspects into land-use (or vice versa) ex-post or in the implementation stage, rather than considering integration on a preparation or design phase, which was then deemed to display 'high degrees' of integration efforts and practices.

5 RESULTS

5.1 Policy instruments for minerals and land-use policy integration

12 MINLAND casess were assessed for horizontal and vertical mineral and land-use policy integration. Furthermore, following the framework of policy instrument type, instruments for vertical and horizontal policy integration were grouped according to: (i) strategies and regulatory instruments, or; (ii) informative policy instruments.

5.1.1 Vertical policy integration instruments

In Finland and Ireland mineral interests outlined in the national guidelines and planning frameworks directly fed into regional and local planning documents, thereby indicating high vertical integration. In Sweden, the regional level (municipalities) preside over the discretion to weigh the 'areas of national' interests (defined through horizontal/sectorial integration) with their regional land-use objectives, thereby signalling this as a low (and flexible) degree of vertical integration. See table 3 below for an overview.

Country	Policy Tools	Aspect of Vertical Policy Integration	Degree of integration
Finland	National land use guidelines stipulate policy streams and strategic goals (including mining and deposits) in a centralised approach.	Top-down implementation in the regions – although regions can contribute to goals and objectives through setting their own priorities.	High
Ireland	Planning and Development Act complemented by a National Planning Framework (addresses objectives of minerals policy horizontally on a national level).	Top-down regulatory framework: general objectives are translated into regional and county level land-use plans.	High
Sweden	System of 'national interests' (horizontal/sectorial) definition of land-use interests and objectives.	Local levels responsible for land-use plans, system of 'national interests' can be weighed (partial vertical integration) on a local level and chief mining inspectorate or national levels can be involved if conflict arises.	Low

Table 3: Vertical policy integration in strategies and regulatory instruments.

The informative and voluntary tools by Austria, Portugal and Spain are all subject to challenges of vertical integration as they are designed on a national level but with the intention to support minerals policy (and safeguarding) integration in local and regional land-use plans of federal or decentralised systems. All cases discussed the need for coordination and communication between national and regional/local levels of government in achieving 'uptake' and integration of the tools on lower levels of government. A specific challenge that was brought up in the cases was the need to involve regional/local authorities already in the design-process of instruments as this would ensure 'ownership' and thus, willingness to integrate the tool or outcomes thereof in regional/local land-use plans. Two more MINLAND cases addressed the design and implementation of an informative policy tool (from a national to a regional level), similar to the cases outlined above. The tool from Greece was implemented in a centralised (top-down) manner, thereby, ensuring integration into spatial plans. In Norway the case study showed that the integration of the land-use management tool was successful in the county of Nordland (high integration).The pilot will now be extended to other municipalities and regions (no integration currently known). See table 4 for an overview.

Country	Policy tools	Aspect of Vertical Policy Integration	Degree of integration
Greece	National level policy tool for safeguarding the exploitation of primary aggregates – focus on framework applied for delineation of conflict free (land-use) aggregates extraction areas	Top-down implementation of national safeguarding policy (aggregates) in regional/local land use planning (spatial plans).	High
Norway	National land-use management tool with the objective of mediating potential land-use conflicts and safeguarding mineral resources of possible current and future value	Responsibility of planning lies with municipal council and regional authorities. Nordland case used as a pilot; the instrument contributed to increased awareness of mineral safeguarding on all levels of governance and is set to be implemented in all municipals and regions	High
Austria	Austrian Raw Materials Plan (ARMP). Soft-policy informative tool designed on a national level to avoid land-use conflicts and ensure mineral safeguarding	Local levels responsible for land-use plans – consultations between different levels occur in the form of checks and balances, review of the proposed plan on regional level and partly on national level if related to responsible department.	Low
Portugal	National voluntary instrument (land use planning methodology for mineral resources – LUP-MR)	Municipalities responsible for land-use planning, some have used the sub-categories of land proposed by the LUP-MR. National authorities approach municipalities not adopting the LUP-MR in an effort to increase understanding of the importance of minerals safeguarding	Low
Spain	National informative and voluntary instrument of mining-environmental planning map intended to be used as a starting point of defining mineral and mining strategies in regional land-use plans.	Challenges of vertical integration in a decentralised system where regional levels are responsible for land-use plans. Implementation met with challenges and is yet to be seen	Low

Table 4: Vertical policy integration in informative instruments.

5.1.2 Horizontal Policy Integration instruments

Regulation, strategies, informative instruments (land use planning or zoning) were most common instruments for horizontal policy integration during the implementation phase. Mineral issues integrated at a design stage (of land-use planning or a policy) were considered to signal a high degree of horizontal integration. Other instruments where minerals issues were considered (more ad-hoc) in the implementation stage were considered as evidence for low degree of integration. The information in table 5 outlines

strategies and regulatory policies that address horizontal integration of minerals resources in land-use policy (or vice versa) and the different aspects thereof.

Country	Policy Tools	Aspect of Horizontal Policy Integration	Degree of integration
Finland	Regional development strategies	Preparation phase of regional land use plans considers minerals exploitation via regional development strategies; consultation is conducted and regional strategy zoning updated/proposed.	High
Finland	Flexible zoning plans	Land use planning processes allows for re-evaluation of land use zoning according to development possibilities; e.g. re-evaluation can be conducted based on company plans for exploitation	High
Sweden	System of 'national interests'	National interests determined through sectorial integration – minerals and other land use interests determined through mechanisms of horizontal integration (respective authorities and actors involved).	High
Norway	Planning and Building Act (National)	Revised to include mineral resources as a specific topic (design) in the Norwegian land use legislation, mineral resources must be considered in the land use planning process.	High
Italy	Regional land-use and minerals strategy / municipality mining plan	Mapping geological heritage, flora and fauna with the intention of modifying the current planning instrument to consider e.g. touristic possibility of geological heritage.	High
Ireland	Planning and Development Act complemented by a National Planning Framework 2040	One policy objective of the national planning framework addresses 'rural development through the sustainable and economically viability of extractive industries, bio-economy and accelerating other sectors whilst protecting the natural landscape and cultural heritage. *The case still indicates that the integration of minerals policy in land-use planning appear modest.*	Low

Table 5: Horizontal policy integration in strategies and regulatory instruments.

Our results indicate that some countries cover instruments that weigh different land-use interests in the design phase of the policy on different levels of government: for example, whereas in Italy this was done on a regional level, in Sweden it was on a national level. Some cases also showed evidence that mineral resources have been integrated to a high (Norway), or low degree (Ireland). Finland also included an aspect of having flexible zoning plans that allowed for 'reformulated' strategies and land-use processes if new deposits were discovered (thereby integrating minerals into land-use plans in a flexible and on-demand basis). The cases, thus, indicated that horizontal integration of minerals and land-use planning represent different shapes and forms and can occur on different levels of government.

Similar to the section on vertical integration was the prevalence of informative policy instruments for horizontal integration. As outlined above, these instruments were characterised by a varying degree of vertical integration success in the different EU MS. Utilising a high degree of horizontal integration as pertaining to integration in the design of the policy instrument, the majority of informative instruments were considered to achieve a high degree as they often accounted for different land-use and societal interests already in their design phase. In one case, the informative instrument integrated aspects of already existing policy streams to achieve coherency and compliance, this was considered as low instead of a high degree of integration (Austria).

Country	Policy Tools	Aspect of Horizontal Policy Integration	Degree of integration
Greece	National Policy for Minerals Safeguarding (Quarrying Areas).	Designed for vertical integration into regional spatial plans this policy tool considers minimisation of environmental footprint, the national spatial strategy, socioeconomic factors and protection of archaeological and cultural heritage.	High
Spain	National mining-environmental mapping	Early phases of environmental land use assessment: territorial analysis factoring in environmental inventory, exploitable resources, cultural heritage, and visible impacts on landscape.	High
Portugal	Land use planning methodology for mineral resources (LUP-MR)	LUP-MR refers to the practice applied by the mining authority when contributing to Land Use Planning review processes of municipal land use plans. Full-integration of minerals safeguarding into land-use plan processes on a national level but modest implementation on sub-levels of government (vertical).	High
Austria	Austrian Raw Materials Strategy and Austrian Mineral Resources Plan	Coordinating parts and components of other policies such as Land-Use and Nature Protection into a Raw Materials Plan.	Low

Table 6: Horizontal policy integration in informative instruments.

5.2 Capacity for policy integration

Technical and managerial capacities are necessary to support and perform coordination and policy integration. Technical capacity is referring to content-specific knowledge and skills, existence of other supportive policies (e.g. project subsidies, rewards, regulatory instruments). Managerial expertise is referring to sufficient expertise regarding integrated policy approaches and/or expertise and skills for collaboration and working across departmental and governmental organisational borders.

Our data on policy tools illustrate a differentiated perception regarding ability and capacities of involved actors, covering the entire scale from perceived low to high capacity. While respondents with geological and/or mining background consider LUP technical capacity in general rather low (e.g. Spain, Finland, Norway). On the other hand, MINLAND project meetings are illustrating a rather modest LUP knowledge (objectives, approaches, tools etc.) from many involved actors affiliated with geology or mining. This situation emphasises the importance of projects like MINLAND, to establish platforms for capacity building, knowledge sharing and as meeting space for involved parties.

Our results indicated that the availability of data for GIS and the necessary skills and knowledge for the integration of provided GIS data into LUP practise was prevalent in the planning departments and LUP authorities (see table 7 below) for most countries: GIS applications are standard applications in GIS practice, hence suitable interfaces and low-threshold download options with the necessary data provide a suitable base for LUP activities and support the integration of mineral resources in LUP practise (e.g. Austria).

Country	GIS tools and skills
Portugal	GIS tools assisting planners, all data in GIS systems
Austria	GIS processing tools are in full use, interface
Greece	Sufficient expertise and tools
Sweden	GIS data sharing
Italy	Specific data base is existing, assisting the mining and LUP
Finland	Each organisation relies on their GIS resources
Hungary	Data provided for GIS applications & National or Regional Development and Spatial Planning Information

Table 7: Technical skills for GIS and Information Systems for mineral resources and LUP, outlined in the MINLAND case studies

Among the abovementioned countries there are, however, differences regarding the general availability to mining experts and/or geologists in public administration and for immediate availability for LUP authorities: while in some cases geologists are available in public administration on regional or provincial level (e.g. Austria/Styria/Tyrol) in other cases they are not (e.g. Poland). Minerals, quarrying and mining is considered a delicate topic with very specific questions, which cannot be covered in house but experts are needed. The MINLAND cases show, that for authorities it is not always possible to have an expert on site, but it becomes clear that they either collaborate with experts or with geological surveys to tackle specific and complex questions they cannot cover by themselves (e.g. Ireland, Spain, Sweden).

6 CONCLUSION

Our paper indicates that in EU Member States a diversity of policy tools are assembled into policy mixes combining regulatory, economic (fiscal) tools, (national) strategies and guidelines and information-based instruments. One challenge of introducing new policy tools is their evalution in the context of the existing policy regime, and how the different tools work and fuction together. Existing research (e.g. Howlett and del Rio, 2015; Rayner et al., 2017) points out, that the mere adding or replacing of policy tools can result in a situation in which the policy tool and/or the entire policy mix cannot unfold its expected performance and/or can lead to underperformance and inefficiencies (e.g. resource expenditure).

The tools addressing vertical integration indicate the importance of coordination and communication between different levels of government. This is of high importance in decentralised and federal systems where involvement of lower levels of government early on in the design of tools were mentioned as key to ensure integration and implementation (e.g. Norway, Spain). It was apparent that a high degree of vertical integration was more prevalent in centralised systems where regulatory tools demanded integration of objectives or goals in lower levels of government planning. Interesting to note is the mandate of local

authorities to prioritise (Sweden) or identify own pathways toward realising national goals and objectives (Finland), which also gives flexibility of prioritising local interests and may increase legitimacy and ownership of policy and responsibility over connected challenges (Nilsson, 2005).

Our results on horizontal (sectorial) integration most commonly outline nationally developed policy tools with the intention of integrating mineral resources into land-use planning. However, there appears to be a deficit in vertical integration of such tools in systems where regional and local levels of governments have land-use planning mandates, as seen in the examples from Portugal and Austria. This suggests that although a high degree of integration can occur on a horizontal level, challenges remain to successfully achieve vertical integration in such systems. As seen from literature on policy integration, this again strengthens the notion that both dimensions of horizontal and vertical mechanisms are needed to achieve 'full policy integration' (Jacob and Volkery, 2004).

Capacity for policy integration plays a crucial role for effective policy implementation and delivery, which should be considered in both policy design and its translation into policy instruments. As regards the capacity of public authorities for policy integration, MINLAND cases indicate that for particular questions experts are needed to advise public authorities. Support, exchange and capacity building is considered particularly important for municipalities and regions which have no long tradition as an industry player and where public authorities and public administration were not engaged with mining earlier (e.g. cases Spain, Austria/Styria). Aligning with Zuidema (2016) and Ostrom (2015) we can see that the support of the central government or higher levels of government are needed to provide such resources and that smaller units (e.g. regions, municipalities) often do not have the capacities to utilise such resources (e.g. hired geologist). The cases of Sweden and Austria show that geological surveys provide support. For example, the Swedish Geological Survey provides particular support for the industry. Hence, it is important to note, that for advising public administration unbiased consultancy is required, apart from lobbying activities of industry, since LUP is expected to weigh, value and integrate various needs, expectations and policy streams.

Building a Common Platform: Integrative and Territorial Approach to Planning Cultural Heritage within the Framework of the Spatial Plan of the Republic of Serbia 2021-2035

Ana Niković, Božidar Manić

(Dr Ana Niković, DipEngArch, Institute of Architecture and Urban & Spatial Planning of Serbia, Belgrade, 73/II Bulevar kralja Aleksandra St., anan@iaus.ac.rs)
(Dr Božidar Manić, DipEngArch, Institute of Architecture and Urban & Spatial Planning of Serbia, Belgrade, 73/II Bulevar kralja Aleksandra St., bozam@iaus.ac.rs)

1 ABSTRACT

In accordance with international documents, European regulations and standards, recent documents of spatial and urban planning in Serbia promote the objectives of an integrative and territorial approach for the protection and planning of cultural heritage. This is intended as a cross-institutional, cross-sectoral approach and extending the scope of the protection of single monuments to wider spatial entities. Institutional and legal frameworks of the cultural heritage protection and planning have not yet been harmonised with international recommendations and do not support achieving these goals. Cultural Property Law (1994) is still in force and does not recognise the categories of cultural landscape (although the European Landscape Convention was ratified in Serbia in 2011) and of urban landscape (as the UNESCO's Recommendation on the Historic Urban Landscape from 2011 has not been ratified yet, although the scientific and professional community has been acquainted with it). In accordance with the current law, single monuments dominate the structure of the Central Registry of immovable cultural properties. Considering that registration is not legally binding, there is a lack of additional research to recognise the architectural and urban heritage that is not under institutional protection. This has resulted in the decline of valuable buildings and ensembles, including entire urban settlements that represent important constituents of the cultural and urban identity of Serbia. Furthermore, Reports on the Implementation of the Spatial Plan of the Republic of Serbia from 2010 point to an unequal spatial distribution of registered cultural goods, which is not related to the factual cultural and historical importance of certain areas, but to the degree of economic development and the activity of certain regional protection services. This sets an additional task for the planning documents on enhanced urban protection measures in these areas. The preparation of the Spatial Plan of the Republic of Serbia 2021-2035 is underway, which affirms that cultural heritage is a resource of sustainable development as well as of national, regional and urban identity as one of the general objectives of spatial development. This paper is a summary of an initial analysis of the draft plan. It indicates the need to establish a common platform for the protection, planning and sustainable use of cultural heritage in Serbia. This platform should act on three main levels, firstly gathering data on cultural properties; secondly compounding all formal and informal documents relating to cultural heritage, especially s regards its spatial dimension; and last but not least, inolving a wide range of participants in the protection, planning and management of cultural heritage.

Keywords: Spatial plan of the Republic of Serbia, protection, planning, use, cultural heritage, sustainable development, spatial dimension

2 INTRODUCTION

In accordance with international documents, European regulations and standards, recent spatial and urban planning documents in Serbia promote the objectives of an integrative and territorial approach to the protection and planning of cultural heritage. Such a cross-institutional, cross-sectoral approach extends extening the scope of the protection of individual monuments to wider spatial entities. Servian institutional and legal frameworks of cultural heritage protection and planning have not yet been harmonised with international recommendations and do not support achieving these goals. Cultural Property Law (1994) is still in force and does not recognise the categories of cultural landscape (although the European Landscape Convention was ratified in Serbia in 2011) and of urban landscape (as UNESCO's Recommendation on the Historic Urban Landscape from 2011 has not been ratified yet, although scientific and professional community has been acquainted with it). In accordance with the existing law, individual monuments dominate the structure of the Central Registry of immovable cultural properties (Republic Institute for the Protection of Cultural Monuments of Serbia, 2017). Considering that this is not legally binding, there is a lack of additional research to recognise the architectural and urban heritage that is not under institutional protection which would be needed to review the boundaries of cultural properties and protect the adjacent units. This situation has resulted in the decline of valuable buildings and units, including entire urban

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

settlements that represent important constituents of the cultural and urban identity of Serbia. Furthermore, Reports on the Implementation of the 2010 Spatial Plan of the Republic of Serbia point to an unequal spatial distribution of registered cultural goods, which is not related to the factual cultural and historical importance of certain areas, but to the degree of economic development and the activity of certain regional protection services. This sets an additional task for the planning documents to enhance urban protection measures in these areas. The preparation of the 2021-2035 Spatial Plan of the Republic of Serbia is underway, which affirms the cultural heritage as a resource of sustainable development as well as of national, regional and urban identity as one of the general objectives of spatial development. This paper presents the results of one of the initial analyses of the draft plan. It indicates the need to establish a common platform for the protection, planning and sustainable use of cultural heritage in Serbia. This platform should act at three main levels; firstly gathering data on cultural properties; secondly compounding all formal and informal documents relating to cultural heritage, especially its spatial dimension; and last but not least, involving a wide range of participants in the protection, planning and management of cultural heritage.

In accordance with the contemporary debate on the conservation and planning of cultural heritage, sustainability is one of the common denominators of conservation and urban planning. However, there is a lack of a balanced and holistic approach to managing development and focusing on sustainability. In doing so, conservation would be a major componeont, not an 'elitist niche', and conservationists would be important stakeholders in the planning and decision-making process (Chakravarty, 2017). This problem is particularly obvious in developing countries (Steinberg, 1996). In addition, it is important to note that neglecting the spatial dimension of cultural heritage in terms of character and place identity remains a global problem, mostly due to institutional and sectoral division that has negative spatial effects (Samuels, 2010; Bienstman, 2011).

The paper primarily points to the relationship between the international and national frameworks for the protection, planning and use of cultural heritage and to the existing capacities for reviewing the spatial dimension of cultural heritage in current spatial development policies and strategies of the Republic of Serbia (RS). It then presents strategic planning of cultural heritage in Serbia in the spatial plan instrument. Particular attention is given to the treatment of cultural heritage in planning documents that are adopted in accordance with higher order plans and their strategic goals, whose implementation directly affects changes in space.

3 THE RELATIONSHIP OF THE INTERNATIONAL AND NATIONAL FRAMEWORK FOR THE PROTECTION, PLANNING AND USE OF CULTURAL HERITAGE

3.1 Current international guidelines and trends

The following international charters in the field of the protection of cultural heritage have been ratified in Serbia: Convention Concerning the Protection of the World Cultural and Natural Heritage (UNESCO,1972, ratified in 1974); Convention for the Protection of the Architectural Heritage of Europe-Granada (Council of Europe, 1985, ratifed in 1991), European Convention on the Protection of the Archaeological Heritage (Council of Europe, 1992, ratified in 2009), Convention on the Value of Cultural Heritage for Society (Faro Convention, Council of Europe, 2005, ratified in 2010); European Landscape Convention (Council of Europe, 2000, ratified in 2011).

3.2 Current development policies and strategies

The map of strategically important public policy documents of the RS (available on the website of the Government of the RS, the Public Policy Secretariat) includes various planning areas. There are still no documents in the field of culture (the Draft Strategy for the Development of Culture of the RS from 2019-2029 is in process). In the field of urbanism, spatial planning and construction, the Sustainable and Integrated Urban Development Strategy of the Republic of Serbia until 2030 was adopted, in which the theme of protection and planning of cultural heritage was addressed within the framework of urban settlements, with the overall goal of improved and harmonised quality of urban organisation and accessibility of urban space.

3.2.1 Policy of Cultural Heritage Development

The Strategy for the Development of Culture of the RS 2019 - 2029 defines three priorities: personnel development (education, digitalisation, development of creative industries); infrastructure development (development of new and reconstruction of existing objects and spaces in the function of culture, improvement of the conditions of protection of cultural heritage, information and communication infrastructure, physical relations and networking with digital technologies); and European integration and international cooperation (participation in EU programmes and projects, conformation to international standards). The Strategy points to the need to improve the legislative framework in the field of protection of immovable cultural heritage and aligning it with the international charters in the field of cultural heritage protection that have been ratified in Serbia so far.

The Sustainable and Integrated Urban Development Strategy of the Republic of Serbia until 2030 is a public policy document, addressing the topic of protection and planning of cultural heritage within the framework of urban settlements, and defining the overall goal as improved and harmonised quality of organisation and accessibility of urban space. Development policy is in line with the binding policies and documents of the United Nations and the European Union.

3.2.2 Spatial aspect of the policy of cultural heritage development

The Strategy for the Development of Culture of the RS 2019 - 2029 suggests the digitalisation of heritage, a cross-sectoral approach, stronger partnership between administrative and professional institutions for the protection of cultural heritage and urban and spatial planning, in particular by adopting management plans for certain types of cultural heritage and enacting spatial plans for certain types of immovable cultural property. The strategy indicates that due to incomplete decentralisation and a non-unified system of protection services, the immovable cultural heritage in the RS is in an unequal position, i.e. it depends on the financial and personnel capacities of individual institutes and municipalities, which differ significantly and are insufficient in many cases.

In accordance with the spatial dimension of the Sustainable and Integrated Urban Development Strategy of the Republic of Serbia until 2030, priority areas of urban intervention have been identified, linking identified development problems with concrete locations thus directing local integrated urban development strategies to priority funding projects. Spatial units with cultural and architectural heritage and important reference points of cultural and historical development of urban settlements and groups of urban settlements were singled out, due to the need to extend the subject of protection and the notion of cultural heritage. The following interventions are proposed: rehabilitation and revitalisation of buildings and architectural heritage units, an integrative approach to the protection of cultural property and urban protection of buildings and entities which are not under institutional protection, especially from the second half of the 20th century, adaptation of architectural heritage facilities to modern requirements, such as energy efficiency. Measures to achieve the objectives of the Strategy are combined and applied to: urban reconstruction of central urban areas; urban regeneration of parts of urban settlements exposed to devastating processes; reactivation and development of brownfield zones, complexes and sites with industrial heritage; protection of buildings and units which are not protected as cultural assets; more efficient use of units with underutilised structures; landscaping and preservation of public spaces; and use of renewable energy sources.

4 STRATEGIC PLANNING OF CULTURAL HERITAGE IN SERBIA THROUGH THE SPATIAL PLAN INSTRUMENT

The planning system in Serbia has similar procedures as in most countries with a comprehensive planning approach and the principle of hierarchical integration of different spatial plans - from a larger scope of spatial plans to a smaller scope of urban plans. The Spatial Plan Instrument is a strategic document defining the goals and principles of spatial development of larger spatial units. In particular, it defines the planning units of common spatial and developmental features, for which smaller scope planning documents will be adopted (typological classification of areas), as well as the spatial development of transport and infrastructure systems of general importance. Prior to the Spatial Plan currently under development, the 1996 and 2010 Spatial Plans of the RS were adopted.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

4.1 Key objectives, planning solutions and priorities for development in the field of cultural heritage protection in the previous Spatial Plans of the RS

In the 1996 Spatial Plan of the RS, besides preserving material remains of different cultures developed on Serbian ground, the emphasis is on the importance of preserving national identity through strengthening awareness of cultural heritage and the importance of continuity in the development and use of immovable cultural assets, through their reintegration into the contemporary context of life. The protection of immovable cultural property is considered an integral part of the development of society, and cultural heritage is considered an activator of the development of various activities that can have economic effects. The protection includes not only registered immovable cultural property, but also a heritage which was not included in the regime of protection, especially complexes, objects and places from 19th and 20th centuries. This implies a revaluation of cultural heritage and an even territorial presence of protection.

In the 2010 Spatial Plan of the RS, the development of cultural identity and territorial recognition and the promotion and protection of natural and cultural heritage as a development resource is one of the general principles of Serbia's spatial development, which forms also part of other general principles: sustainability, territorial cohesion, formation and strengthening of networks of cities and towns that can provide development of complementary functions and public-private partnerships. Cultural heritage is subject to protection, regulation and use (controlled and sustainable) in accordance with European regulations and conservation standards and is treated integrally with natural heritage and landscape protection. An integrative territorial approach implies further systematisation of cultural heritage and the development of networks of natural entities and cultural landscapes that are protected or have special values.

4.2 Basic concept of spatial development in the field of cultural heritage protection in the previous Spatial Plans of the RS

The 1996 Spatial Plan of the RS provides planning protection measures for three types of areas: protected urban structures and urban environments, rural architecture and sites, and archeological sites. This classification corresponds to the categories of immovable cultural property in the system of valorisation of the protection services and in that sense facilitates implementation. It is important that the previous 1996 Protection Plan of the RS suggests additional explorations of the territory of the RS in order to fully record cultural assets, especially in large spatial units such as e.g. the valleys of large rivers (Danube, Morava, Ibar), etc. Also, additional research is needed to review the protected environment of cultural property to include other spaces relevant to the experience and presentation of the property. Given the uneven distribution of cultural property on the territory of the Republic, greater attention is suggested regarding planning protection in areas of poorer heritage. Important advances in the field of planning protection under the previous 1996 Spatial Plan of the RS relate to the importance of identifying and delimiting a territory into parts that have homogeneous features, according to certain criteria. This further enables the planning of settlements by historical and topographical units in the way they were created. Particular emphasis is given to the importance of harmonising transport and infrastructural corridors with cultural heritage zones, as well as ensuring the accessibility of cultural monuments located in hard-to-reach sites (medieval and early antique fortifications).

The 2010 Spatial Plan of the RS introduces an integrative territorial approach to the protection of cultural and natural heritage and landscapes, in accordance with European standards of protection. This implies the introduction and definition of cultural areas, which will then be divided into zones with varying degrees of protection and treatment of cultural heritage. Priority cultural areas have been identified that should receive special treatment, regardless of their status within the protection services. Although this approach contributes greatly to the recognition of cultural heritage as a resource for sustainable development, the problem remains of a legal and institutional framework of protection that is still inconsistent with contemporary conservation approaches, which raises the question of the possibility of implementing planning recommendations. In accordance with the general principle of territorial cohesion, the division of the territory of Serbia into 7 large spatial units with their particular geographical, historical, functional and cultural characteristics is relevant for the planned protection of cultural heritage. In addition, the previous 2010 Spatial Plan of the RS identifies three development directions whose development would incite spatial integration and functional connectivity of regional entities. Particularly recognisable are the key characteristic entities and objects/

They are: urban centres, points of intersection of important corridors, objects of cultural and natural heritage, objects of social infrastructure, symbols of statehood.

4.3 Assessment of the realisation of the concept of spatial development in the field of cultural heritage protection

The reports on the implementation of the Spatial Plan of the RS (2011, 2012, 2013, 2014 and 2016) show the state of spatial development indicators of the RS, realisation of priority strategic projects from the Spatial Plan of the RS and the spatial planning documentation, based on which the assessment is given of the status of spatial development of the RS. Indicators are the number of protected cultural assets in the area (source: the Republic Institute for the Protection of Cultural Monuments of Serbia) and the number of immovable cultural assets enjoying prior protection (source: regional institutes for the protection of cultural monuments), according to legally defined categories and degree of protection.

The Report on the Implementation of the 2010 Spatial Plan of the RS (2015) estimates that there are significant differences in the number of protected cultural assets between administrative districts and that, in general, the number of cultural assets is increasing, whereas trends of disparity and spatial cohesion are stable. The number of cultural heritage sites and integral entities under previous protection is declining, whereas long-standing value trends are stable. It is pointed out that, in order to gain a better understanding and a more reliable assessment of the realisation of this indicator, additional spatial development criteria should be provided in the future. The largest number of recorded cultural assets is concentrated in the Belgrade and Vojvodina regions (the Danube Region), which are the most economically developed, while the sites on the World Heritage List are concentrated in other regions (south, east, west).

There is a constant increase in the number of recorded and declared cultural property, whereas the number of cultural property under previous protection is in stagnation or declining. This is a consequence of the slow process of declaring property, as well as the uneven methodology of record keeping in all protection services. There is a need for additional reconnaissance of the terrain. For spatial development, the property enjoying prior protection must be treated in the same way as the protected cultural property. Conversely, the preparation of spatial plans should include the recording of cultural assets, whereas planning documents that are directly implemented (urban planning, special purpose spatial plans and spatial plans of local self-government units) should define the rules of regulation and construction.

The following strategic priorities are defined in the sub-area of Protection and Sustainable Use of Cultural Heritage: arrangement, presentation and management of Roman sites in Niš and Mediana; development of national and regional "cultural pathways"; development and adoption of management plans for cultural property on the World Heritage List; preparation of nomination files and management plans for cultural property on the preliminary UNESCO World Heritage List; drafting the Strategy for the Development of Culture of the RS; revision of the status of identified immovable cultural property and compliance with applicable legislation; preparation of an analysis of the condition of industrial heritage facilities (complexes) for the purpose of defining criteria for industrial heritage valuation in order to determine the protection measures for industrial facilities (complexes) in the RS; identification of characteristic authentic types of rural settlements in all regions of the RS; elaboration of protection proposals for five selected types of the most preserved authentic rural entities with monumental features.

5 CULTURAL HERITAGE TREATMENT IN PLANNING DOCUMENTS

Planning documents incorporate data on protected cultural property and conditions for their preservation together with instruments for their preservation. Planning is based on the results of the work of the protection service which classifies cultural assets in the territory of the RS into 4 types of monuments: spatial cultural-historical units; cultural monuments; archeological sites and landmarks; and objects under previous protection. The regime of space protection, the instruments of protection, the size of the protected space, etc. is determined based on valorisation.

5.1 Regional spatial plans

In regional spatial plans, the area of cultural heritage protection represents a structural part of the integral protection of space and environment. The concept of protection and improvement of the environment is based on the projection of spatial development, which is harmonised with the specific regional character of

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

the landscape and the physical structure of the settlements in the territory of the plan; promotion, protection and sustainable use of declared natural and cultural heritage (landscapes and natural and cultural values in settlements), their integration in space (local, regional, national ecological and cultural networks), and strengthening and promoting the existing and creating new values in the spaces in which the value of landscapes and ambient of settlements is of particular importance for the development (tourist, cultural areas) that represent the part of international networks and border areas. The regional spatial plan is implemented by elaboration of planning solutions and spatial plans of the special purpose areas, spatial plans of local self-government units, urban plans and sectoral plans and programmes in accordance with the law, respecting the principle of horizontal and vertical connection.

Cultural heritage in the higher order plans, especially in the spatial plan of the RS, is unequally distributed on the territory of the Republic (See Fig.1 in: Niković and Manić, 2018). The lower order plans lack the results of additional research in the planning process that would predict urban protection for valuable objects and entities that are not subject to institutional protection and possess architectural, urban, historical, ambient and other values.

5.2 Spatial plans of special purpose areas and spatial planning in local self-governments

In addition to 9 regional and municipal spatial plans, several special purpose spatial plans for cultural landscapes (Bač), archeological sites (Viminacium) and areas with outstanding natural features and cultural and historical heritage (Sremski Karlovci, Radan, Ovčar-Kablar Gorge) were adopted.

In the spatial plans of the areas of special purpose, the concept of spatial development is based on the determination of measures for the protection of cultural property in accordance with the data of the competent protection services, as well as on the designation of the protective zone of cultural assets in accordance with detailed reconnaissance in the field. The most common developmental conflicts are the uncontrolled construction of protected areas and urban sprawl that disrupts the existing compact settlement structures.

5.3 Spatial planning in local governments

The spatial plans of the local government units mainly incorporate data obtained from the competent protection services and provide an overview of the cultural assets in the scope of the plan, together with protection measures. The protection zone of immovable cultural property generally coincides with the boundary established by the competent protection service, although it often does not cover other areas of importance for the experience and presentation of the property.

6 GENERAL ASSESSMENT OF THE SPATIAL DEVELOPMENT OF CULTURAL HERITAGE IN SERBIA

In Serbia, as in most developing countries, there is a problem of inconsistency of the institutional and legal framework with international recommendations, despite the existence of favorable preconditions for the improvement of the already developed system of protection. Cultural heritage still includes primarily individual monuments that dominate in number the structure of registered cultural assets. In this context, buildings of vernacular architecture, industrial heritage, modern architecture and valuable ambient units are not usually subject to conservation and restoration programmes, although they have significant architectural, urban, civilizational values and/or represent important reference points of cultural and historical development.

On the one hand, the current approach to the valorisation of the created structure leads to the neglect of the environment of the protected entities, and very often to the degradation of ambient entities, especially by illegal construction, which is a distinct problem in urban development in Serbia. On the other hand, we have the problem of decaying urban settlements and valuable examples of architecture that are not recognised through institutional protection, plans and strategies. These problems must be addressed by applying an integrative and territorial approach to cultural heritage planning.

STRENGTHS (advantages)	**WEAKNESSES (disadvantages)**
• Rich cultural heritage and cultural diversity • Urban settlements with specific typological characteristics • Recognizable architectural typologies • Developed system of the protection of cultural property • Trend of steady increase of the number of protected cultural assets in the Central Register of ICP (immovable cultural property) • Programs to encourage the preservation of old crafts • Serbia's representation in programs and projects for the rehabilitation of the architectural and archeological heritage of Southeastern Europe, under the patronage of the Council of Europe and the European Commission • The project "Digitalization of immovable cultural heritage" – Ministry of Culture and Information and Serbian Academy of Sciences and Arts has started • Several international charters in the field of cultural heritage protection have been ratified • International cultural cooperation proclaiming Novi Sad the European Capital of Culture for 2021; participation of Belgrade, Novi Sad, Sremska Mitrovica and Smederevo in EU program for culture - Creative Europe	• Insufficiently developed database on cultural assets • Non-alignment of the institutional and legal framework for the protection of cultural heritage with international recommendations, conventions and ratified charters • Long-lasting processes for the declaration of cultural property, especially those under prior protection • Insufficient cooperation of the professions involved in cultural heritage protection, planning and management - lacking practical guides and methodologies • Inadequate treatment of immovable cultural property in planning documents - lack of contextual analysis and valuation of the building stock and spatial verification of individual sites • Directing funds intended for the maintenance of cultural monuments primarily to the technical protection and maintenance, without emphasizing the elaboration of development programs and projects that would contribute to the integration of cultural monuments in the environment and contemporary life • The typology of urban structure is not sufficiently recognized through planning documents • Declining urban settlements that represent important reference points of Serbia's cultural and historical past - especially smaller ones, in less economically developed parts of the country • Decay of valuable examples of urban architecture types (especially buildings and urban units from the other half of the 20th century and Industrial heritage) • Inadequate funding for heritage protection, cultural infrastructure, cultural programs and projects • Insufficient capacity of the cultural heritage protection service • Underdeveloped interpretation, animation and mediation at the immovable cultural heritage sites and cultural institutions • Low level of citizen participation
OPPORTUNITIES (chances, potentials)	**THREATS (risks)**
• The availability of digital technologies to integrate cultural property data into a single, central database • Awareness of the scientific and professional public on the importance of culture and the protection of cultural heritage • Liaison between educational institutions and institutions dealing with the protection and planning of cultural heritage; creative educational programs for raising awareness of cultural heritage from the earliest age • Diversification of the financing system and ensuring greater involvement of the private sector, public-private partnerships, donations and funds from various European and international programs and funds (greater representation of urban settlements in the EU program for Culture - Creative Europe, etc.) • Strengthening urban identity based on cultural diversity • Realization of projects in culture and heritage protection in individual and groups of urban settlements and their rural environment - projects in the Danube area, wine routes, roads of Roman rulers, etc. • Development of cultural tourism and urban tourist destinations with cultural heritage offering cultural content and natural heritage in the destination • Development of promotion of cultural heritage sites, programs and projects in culture • Encouraging the development of old crafts • Promoting good practice examples • Active participation of citizens, cultural and artistic societies and representative associations in decision making on cultural development and heritage protection • Development of international cultural cooperation • Improvement of cultural heritage management instruments	• The system of protection of immovable cultural heritage is decentralized in an incomplete manner - it does not allow for a uniform approach to the protection of heritage in accordance with the cultural and historical significance of particular areas • Sectoral approach to the protection and planning of cultural heritage • Insufficient cooperation between protection and planning institutions and insufficient awareness of the need of modernizing protection and planning procedures • Decay of valuable objects and entities • Economic underdevelopment of areas with important cultural potential • In urban development planning and management procedures, insufficient recognition and differentiation of important features of urban structure that represent elements of their identity and potential for development • New typologies that violate the identity of urban settlements due to the dominance of investors' economic interests - partial construction, illegal construction, etc. • The unresolved issue of improving funding for heritage protection, cultural infrastructure, cultural programs and projects

Table 1: SWOT analysis of the spatial development of immovable cultural heritage in Serbia – prepared for the Sustainable and Integrated Urban Development Strategy of the Republic of Serbia until 2030 (by authors)

7 GENERAL OBJECTIVES, PRINCIPLES AND CONCEPTS OF SPATIAL DEVELOPMENT OF CULTURAL HERITAGE IN THE 2021-2035 SPATIAL PLAN OF THE RS

The overall objective of spatial development in the field of protection and planning of cultural heritage is to affirm cultural heritage as a resource for sustainable development and a factor of national, regional and urban identity. The principles of spatial development in the field of protection and planning of cultural heritage are:

- Integrative approach to the protection and planning of cultural heritage: cultural heritage consists not only of individual monuments and registered cultural assets, but also of objects of vernacular

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

architecture, industrial heritage, modern architecture and valuable ambient units, including the levels of the cultural area and cultural landscape;

- Harmonisation with international regulations: Serbia's cultural heritage is part of the international cultural heritage and, accordingly, protection and planning must be in accordance with international recommendations and standards;
- Sustainability: continued use of facilities that enjoy the status of cultural property saves resources and energy;
- Cultural heritage is a resource for sustainable development and a significant impetus to the development of urban settlements in Serbia, becoming a benchmark on tourist routes and contributing to the economic development of the community;
- Active public participation: the planning process takes place through a continuous dialogue between professionals and residents / users of the space;
- Respect for the context is the basis for improving the planning methodology in protected areas and in protected cultural assets; valorisation criteria must be applied to the overall physical structure in the environment of cultural property for the purposes of determining the precise protection zone;
- Digitalisation of cultural heritage for the purpose of more fruitful interdisciplinary cooperation, creation of a digital platform with a database and a map of cultural goods and cultural areas, with the possibility of filtering the database according to different attributes of cultural goods; in this way it is possible to assess the harmonised distribution of cultural property in the territory of Serbia and, through planned protection, to further affirm the lower category heritage in economically less developed areas, which in Serbia represent areas with rich culture and history (e.g. southern and eastern Serbia);
- Promotion and presentation of cultural heritage: national, regional and local identities are enhanced by raising awareness of cultural heritage and the responsibility of local and regional communities to their environment;
- Territorial approach to heritage conservation: cultural heritage is an integral part of broader spatial units to which it belongs, together with their ecological and landscape values, which imposes the need for integrated spatial management and development of holistic strategies and coordinated actions of all participants involved in urban development processes of contemporary cities in accordance with international documents dealing with the sustainable development of modern cities.
- Public-private partnership.

The expected effects of implementing an integrative and territorial approach to the protection and planning of heritage are:

- Connecting institutions through digitalisation of cultural heritage, better cooperation and awareness, transparency and visibility of cultural assets that are protected, in the process of protection or proposed for protection;
- Formation of networks and sub-networks, cultural routes and cultural areas through a territorial approach, which opens the possibility for project financing, special programmes (especially cultural tourism) for the regeneration and revitalisation of certain areas, which creates economic effects;
- Recognition of architectural and urban heritage and their inclusion in planning and institutional protection in accordance with the most recent international recommendations and charters;
- Strengthening of national, regional and urban identity as an important lever for sustainable development - increase of tourist appeal and consequently economic effects;
- Inclusion of Serbia in international cultural routes recognising its cultural potential, especially as part of its international cultural heritage.

8 CONCLUSION

Integrative approach, territorialisation and digitalisation were the 3 key topics of the principles of spatial development of Serbia in the field of protection and planning of cultural heritage. They are related to charters and recommendations adopted at European level since the adoption of the previous spatial plan (2010), primarily the UNESCO Recommendation on the Historic Urban Landscape 2011 and the Territorial Agenda of the European Union 2011.

The principle of an integrative approach to the protection and planning of cultural heritage is in line with the first topic. Therefore, not only individual monuments and registered cultural assets are included in cultural heritage, but also objects of vernacular architecture, industrial heritage, Modern architecture and valuable ambient units, including the levels of the cultural area and cultural landscape. Respect for context represents the basis for advanced planning methodology in protected areas and in protected cultural assets. In order to determine precisely the protection zone, valorisation criteria must be applied to the overall physical structure in the environment of cultural property.

The principle of a territorial approach to heritage conservation is in line with the second topic: cultural heritage is an integral part of the wider spatial units to which it belongs, together with their ecological and landscape values, which imposes the need for integrated space management and the development of holistic strategies and coordinated actions of all participants involved in urban development processes of modern cities in accordance with international documents dealing with the sustainable development of modern cities.

The principle of digitalisation of cultural heritage is in line with the third topic. For the purpose of more fruitful interdisciplinary cooperation a digital platform is suggested with a database and a map of cultural goods and cultural areas, with the possibility of filtering the database by different attributes of cultural goods. In this way, it is possible to assess the uniformity of distribution of cultural assets in the territory of Serbia and, through planned protection, to further affirm the lower category heritage in economically less developed areas, which in Serbia represent areas with rich culture and history (e.g. southern and eastern Serbia).

The access analysis of the drafting of the new 2021-2035 Spatial Plan of the RS indicates the need of a common platform for the protection, planning and sustainable use of cultural heritage. This platform should operate on three levels, first linking data on cultural property; second, all formal and informal documents relating to cultural heritage, and above all its spatial dimension; and last but not least, a wide range of participants engaged in the protection, planning and management of cultural heritage.

Campus Development of the IDEA League Universities

Hanna Potulski

(MSc. Hanna Potulski, RWTH Aachen, Faculty of Architecture, Chair of Urban Design, Institute of Urban Design and European Urbanism, Wüllnerstraße 5b, 52062 Aachen, potulski@staedtebau.rwth-aachen.de)

1 ABSTRACT

The university campus – for centuries an important urban building block and also in our future cities of tomorrow: it is impossible to imagine life without it. But what does modern campus planning look like in a re-mixing city of tomorrow and what concepts are being followed to integrate the university campus in the 21st century and to adapt it to digitalization and networking and develop it further?

What concepts can be derived from networks, such as strategic alliances like the IDEA League, an association of five leading technical universities in Europe? How do these universities help to shape our European cities, what urban development ideas do they follow and how can they serve as a motor for urban development?

Based on the IDEA-League partners: Delft University of Technology (Netherlands), ETH Zurich (Switzerland), RWTH Aachen University (Germany), Chalmers University of Technology (Sweden) and the University Politecnico di Milano (Italy), these research questions will be examined and analysed in detail with the aim of developing a design guideline for campus development.

Based on current plannings, such as the campus redesign in Milan by Renzo Piano, the Science City at the ETH Zurich and the RWTH Aachen extensions Campus Melaten and Campus West, first results of the analysis are presented below. Important aspects that will also form the first cornerstones of the design handbook are the “24-student campus”, “outdoor space” and the “recreational area”.

Keywords: IDEA League Universities, campus development, redesign, future cities, urban development

2 INTRODUCTION

What exactly is meant when we talk about “Future Cities”, “Re-Mixing the City: Concepts and Perspectives for Mixed Use in Future Cities?” (REAL CORP 2020) What are the uses, the building blocks, the contents that put together such a future city?

Especially in Aachen, one of the most important and largest urban building blocks is the university, namely the RWTH Aachen University. Campus development and planning is not only in Aachen a current topic of urban development. Universities are growing, student numbers are increasing and more and more people are deciding to study after school. Society is increasingly transforming itself into a knowledge society.

Growth, digitalization and new media have an impact on the teaching units of the universities and force them to adapt and change again and again, regardless of their sometimes centuries-long traditions, such as the RWTH Aachen University, which is celebrating its 150th anniversary this year. Universities are thus involved in constant processes of change, which not only affect aspects of content or the further development of curricula, but are also physically manifested in the expansion of campus areas in the urban space. Despite digitalization, the physical presence of the universities remains untouched, current surveys show that demand for student learning jobs and places to stay at the universities is constantly growing, and that digitalization itself requires increasing space. This is because servers and technical infrastructures also require university buildings, and despite the fact that more and more lectures are available on the Internet, new research clusters and university departments are being developed and built.

Not only are new research areas increasingly emerging, but digitalization also leads to ever new networks. University departments and research institutions are combining forces in an interdisciplinary way, even beyond national borders. One example is the IDEA League, an association of the leading European technical universities. Technical and scientific exchange, which is currently already taking place in the field of traditional engineering subjects, also represents a great potential to be used on an architectural level.

All of these five universities have faculties of architecture and the question that now arises is how these renowned universities can help to shape their home towns and cities and thus be a motor for urban development? Can this network be used to develop guiding principles for urban development and what goals can be identified and how can future urban planning benefit from the knowledge gained?

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)

In summary, the objective is to analyse the aforementioned research questions in more detail with regard to the IDEA League locations and to derive guiding principles from them as to how future campus development should be designed. In this process, we will take a closer look at how campus development and urban development concepts of the European university network of the IDEA League work and how they can be mutually dependent on each other to develop future design principles and concepts.

This goal is to be achieved by analyzing the existing literature and planning documents, by on-site research and interviews with planners, in order to be able to map the developments and active planning in the field of campus development.

3 CAMPUS DEVELOPMENT

By definition, the campus is the site, the field on which the university with its entire number of faculties is housed, but how does one develop such a campus area in terms of urban planning today?

From historical sources, universities have developed in urban locations with an exposed location of their main building (Kruschwitz 2011: 218). The inner-city connection between university and city was not only identity-forming for university life but also for the entire city.

However, the question that now arises is, how can these same old inner-city universities develop in the future and what will future university development models and campuses look like?

The IBA Heidelberg is running from 2012 to 2022 under the heading “Knowledge Creates City”. The IBA is concerned precisely with the question of how university and city and the associated development work together.

But where exactly is the campus development going? Today the campus is no longer just the former field - it is much more the outdoor space around the individual university buildings that is gaining in importance. The public outdoor space is increasingly becoming a place for living and working through digitalisation and mobile user terminals.

On the one hand, our teaching is also becoming increasingly digitalized, with lectures being retrievable and traceable from the Internet. The time students spend on campus is being reduced, but at the same time a contrary development can be observed, with students increasingly visiting study and work rooms on campus to meet and let ideas grow through chance encounters. The world is becoming increasingly networked, the campus of tomorrow will be different from the mere place where knowledge is absorbed, but what does this mean in terms of urban planning and architecture, how can one learn from such networks there as well?

These campus development analyses are to be examined and executed on the basis of five leading technical, European universities, which have joined together to form the IDEA League University Network.

4 THE IDEA LEAGUE UNIVERSITIES

4.1 The Idea of the IDEA League

The IDEA League is a strategic alliance of currently five leading European universities, which pursue the goal of representing Europe as a leading technology and innovation location worldwide. The five research-oriented partner universities have a high international reputation and educate future generations of engineers.

The title of the IDEA League goes back to the names of the four founding universities. These include Imperial College London (United Kingdom), Delft University of Technology (Netherlands), ETH Zurich (Switzerland) and RWTH Aachen University (Germany). In addition, ParisTech (France) joined the league in 2006. Imperial College London and ParisTech have already left this network and were replaced in 2014 by Chalmers University of Technology (Sweden) and the University Politecnico di Milano (Italy) in 2016.

For Imperial College London, the reasons for leaving the alliance were financial, and for ParisTech, the reorganization into Université Paris-Saclay (UPS). (Schlaefli 2014)

The League is an alliance whose name “IDEA” stands for its basic attitude, namely to act less out of lobbistic, political interests and more with the motivation of a common exchange of ideas. (Schlaefli 2014)

In addition to the function of the best possible European representation, the network aims to link research and teaching and to promote technological exchange and knowledge sharing between leading European

technical universities. Through exchange programs and summer schools, for example, students and scientists in many fields of study come together to network the universities.

4.2 Urban Development in the European Context

Especially in the field of architecture and urban planning, however, very little discourse takes place in the context of the IDEA League, which means that the potential of different urban development ideas and concepts within the university network is not exploited. Especially with regard to the urban development planning of the campus areas in the individual IDEA League cities, synergies could be used and strategies could be exchanged and thus mutual inspiration and learning could take place.

What role do urban planners play in these development strategies and which actors work together in these campus development processes?

The intention is not only to achieve a functioning campus planning, but also to create a “livable city” in which there are no urban parallel societies between university and city society. The aim is to create a “city for all” that integrates knowledge into the city and thus allows the public welfare of an interlocking and multi-layered urban society to be experienced.

Furthermore, it is not only the spatial integration of the university into the city that must work, but also a social integration is crucial. The university must not see itself as an elitist, difficult-to-access urban component, but rather it must be accessible at various levels, to all social classes, in order to be able to integrate itself really actively into the city structure. Recent efforts such as children's universities, summer schools or the concept of study courses for senior citizens contribute precisely to such an opening of the university and create integration and networking with the city. Due to the subliminal use of the university in the everyday life of the non-university urban population, a natural and true integration of the university into the urban fabric is achieved.

This aspect also leads to the fact that the urban fringes of university campuses, which often show hard urban breaks, begin to intertwine with the usual urban fabric, because the campus areas are then also used by the entire urban population. A prerequisite for this, however, is that the university understands and designs the areas around its research buildings as atmospheric outdoor spaces and recreational areas of the city and does not see them as purely functional, as a park or a rubbish dump. The integration of gastronomy, sales and recreational areas, as an extension of the urban mix of uses, especially at the edges of the campus, will allow the campus to be successfully linked to the city.

4.3 Future Campus

“The identity of a city cannot be measured” (Reicher 2019: 27), but it is particularly the interplay of the individual city components that makes up the identity of a city. A university is also one of these city building blocks and the example of the five IDEA League universities shows how campus planning and development can be thought of in very different ways in connection with the city.

How do these five differently sized cities of the League deal with the challenge of campus development and how can a university influence an entire region or metropolis?

The examples of Aachen, Zurich or Delft show how globally identity-giving for the entire city are their universities, whereas Milan or Gothenburg are not necessarily known primarily through them.

However, the connecting element of these five universities is that they are constantly growing and also have to expand spatially, resulting in five very different campus development systems, which are to be analysed and compared.

A campus development is currently taking place in Milan. Milan is not only known for its university, but increasingly sees itself as a city of science, and the Politecnico di Milano with its inner-city locations the Campus Leonardo and the younger Campus Bovisa shall be complemented by the Renzo Piano Campus. The Renzo Piano Campus will be created by redesigning the campus areas along the Via Bonardi. The decisive design element is to connect the individual solitary university buildings by means of new buildings and to open up the intermediate areas, the exterior space by means of intensive greenery. This will create a liveable campus and a completely new urban area of knowledge.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

What exactly is the so-called “Science City” (Schmitt 2004: 3) as propagated by the ETH Zurich as a campus and urban development system and what exactly is the implementation of this idea of a sustainable city district that includes knowledge locations?

In 2010, the new ETH Zurich Hönggerberg campus was awarded the European Science Culture Prize. This campus area, located on the outskirts of the city just outside the city centre, is aimed to become the new flagship of ETH Zurich as "Science City". As an expansion opportunity for the university, which is actually located in the city centre, an attempt was made to directly shape the aspect of the stay on the campus through its location in a former natural recreation area, through living and sports facilities.

In the same way, the example of RWTH Aachen University also raises the question of how campus development clusters in Aachen West or Aachen Melaten function detached from the innercity campus.

RWTH Aachen University is a constantly growing group of new faculties and comprised 32,240 students in the winter semester 2010/2011, which has now increased to 45,628 students in the current winter semester 2019/2020. (RWTH Aachen University 2020)

Particularly in so-called university cities such as Aachen, the university is the largest employer and closely interwoven with the city. But campus expansions are increasingly being relocated to peripheral locations, which means that the city loses the positive influence of demographic change and thus also part of its identity as a university city.

Another question that can be derived from this aspect is the question of if a university in its function as an economic real estate player and employer would not have to intervene much more strongly with its campus development in the context of urban development in order to do justice to its identity-forming role?

An example of this would be the campus developments at RWTH Aachen University. With its newly built research clusters on the Melaten campus, the university has moved away from Aachen city centre. But RWTH Aachen University is continuing to expand, and in June 2018 it purchased the Aachen West area, a disused railway area at Aachen’s Westbahnhof station. The university now has the opportunity to build a completely new campus in the link between the original inner-city Mitte campus and the new Melaten campus, and to build a new piece of the city as a developer, so to speak.

RWTH Aachen University will thus not only become one of the largest research campuses in Europe, but will also have the opportunity to connect its campus areas. In contrast to the campus development in the Melaten area, the goal was once again defined: not only to create more university and research clusters that are completely empty at night as on the Melaten campus, but also to revitalize the west campus with housing, shops, restaurants and cultural offerings. The question that now arises is whether RWTH Aachen University will be able to create the so-called 24-hour campus and if it creates an integrated new urban quarter with the campus.

Furthermore, the question arises if an integrated urban district is created when living on the campus is only planned for students or university members. On the one hand, this would create a ghettoising, planning definition, while on the other hand, it would help to tackle the acute housing shortage for students. However, in view of the prospect of the Re-Mixing City, an attractive residential area should be created on campus for all parts of the city’s population to ensure that this part of the city is not only busy during the semester.

5 CONCLUSION

In summary, the first results of the campus analysis in Milan, Zurich and Aachen show the aspect of a re-mixing city. An essential component of a functioning, high-quality campus structure is the integration of mixed use. City and campus development must be thought and developed together so that they are positively interlinked. The campus must be designed like a piece of quality city and not like a collection of faculty buildings that seem abandoned at night.

The often mentioned and demanded 24-hour campus is based on exactly this model of mixed use. It is especially the main attraction of living that leads to a 24-hour revitalization of a campus area. A positive side-effect of the residential use is a public transport connection that must be guaranteed 365 days a year, whereby learning rooms and, for example, sports facilities on the campus are also well connected at weekends.

Through a connection with gastronomy, utilities and cultural offers, living on the university campus itself becomes an attractive area of public life and is included in the urban space.

This makes it clear that living is the guarantee for a 24-hour lively quarter and that this aspect should be taken into account in new campus developments or extensions. Regardless of whether it is an inner-city campus area or a spin-off, the remixing city aspect is essential for a qualitative atmosphere on the campus. From an inner-city point of view, the campus must be seen as a piece of the city and try to develop it further in a peripheral location, otherwise industrial area-like structures will be created and the homogeneity of the campus landscape will break up urban structures or prevent them from being created. It is precisely this homogeneity of a single use that is responsible for the creation of a ghost campus, where after the end of lectures and on weekends areas lie fallow and the potential of urban building blocks is not used.

This aspect leads to a further analysis result, the residence areas. As banal and simple as this aspect may seem, it is also decisive. The aim is to increase the quality of life on the campus. Because it is precisely the intermediate areas between the lecture hall and the seminar rooms that allow time for creativity to develop and create space for encounters. It is about creating a campus where people like to be in the city and even spend their free time. Because this is the breeding ground for new ideas, initiatives and start-ups. Various studies show that boredom promotes creativity and how important it is in the development of children to awaken their own creative will and fantasies. Large corporations have also taken this insight on board and create consciously atmospheric lounges and areas to stimulate their employees' idea development through brief relaxation phases. The campus therefore needs areas where people like to get bored and simply linger. Today's working time models are becoming more and more flexible and longer, so places to relax on the campus are essential, and it is also essential to offer catering in the later evening hours. It is not acceptable that elitist research is carried out on the university campuses of today and that new research clusters are constantly being created, but that the essential infrastructural aspects of daily needs do not grow with them.

This aspect also leads to the third result of the analysis, the external space / interspace. What may have been simple pathways or traffic areas in the past is now used much more naturally as outdoor space. Public places, but also open staircases are becoming meeting places and recreational areas in public urban space. The outside space is getting prominent. Since working and learning is no longer limited to libraries or power connections due to the progressing technology, this is now possible on the entire campus and especially in the outdoor areas. Some university campuses have managed to create and secure atmospheric outdoor spaces or even green spaces, but many campuses are an accumulation of different solitaires from different decades. The challenge now is to combine them into an atmospheric campus by upgrading the exterior and intermediate areas and creating recreational spaces.

These initial results of the analysis will serve as basic building blocks for the design guidelines and will provide a more in-depth analysis of how the different university cities deal with these issues. Country-specific planning ideas and approaches on the urban planning level will be considered and worked out in further steps in order to create a design guideline for inner-city campus development as an objective and imlication of research.

1 ABSTRACT

Sustainable campus development has gained the attention of several policymakers and urban planners within the past decades with different campuses across the world claiming to be sustainable or have adopted initiatives of becoming sustainable. The different tools for assessing sustainability in higher education cannot be utilised in all institutions across the globe due to factors such as regional variation. This paper established and formalised a systematic approach to comprehensively review sustainability indicators identified in 13 campus sustainability assessment tools. Thereafter, Twitter social media and an online big data analysis tool were utilised in selecting environmental-based sustainability indicators for higher educational institutions in Nigeria. The rise in the use of social media amongst tertiary institution stakeholders ensures that a better understanding of environmental challenges can be derived from the perspectives of these stakeholders. The findings from the comprehensive review of the selected 13 tools reveal that there are variations in the sets of their sustainability indicators and selection process. None of the tools have compatible indicators for campus sustainability appraisal and none of the tools utilised social media and big data technology to arrive at the adopted set of indicators for their appraisal framework, threshold, and rating. We identified energy, environment, transport, infrastructure, waste, and water as the major categories for sustainability indicators in Nigeria. The current research gap identified from literature strongly justifies the purpose of this study that setup sustainability indicators that are peculiar to tertiary institutions in Nigeria that will bring about an appraisal framework and also give room for campuses to compare their sustainability performance and interchange of standard practices.

Keywords: Elastic stack, Campus sustainability, Social media data, Nigeria, Sustainability indicators

2 INTRODUCTION

For several decades, campus sustainability appraisal (CSA) has been identified as a paramount initiative in different academic disciplines such as urban planning, urban design, environmental design, landscape architecture, social sciences, and others. Research on CSA differs based on methodology, aim, objectives, nature of the study and the local conditions of the location where it is being carried out. Different researchers in academic fields have an interest in multiple aspects of CSA, therefore its implementation has been initiated, conceived and measured differently over time. While some scholars are interested in the appraisal of sustainability courses in tertiary institutions' curriculum, research, scholarships, and campus operations; others are paying attention to sustainability accounting and outreach to the larger society. According to Sonetti et al. (2016), CSA “have been used for more than a decade, as tools for identifying best practices, communicating goals and experiences, and measuring progress towards achieving the concept of a sustainable campus” p.2. A sustainable university is defined by Velazquez (2006) as ‘‘a higher educational institution, as a whole or as a part, that addresses, involves and promotes, on a regional or a global level, the minimisation of negative environmental, economic, societal, and health effects generated in the use of their resources in order to fulfil its functions of teaching, research, outreach and partnership, and stewardship in ways to help society make the transition to sustainable lifestyles“p.30.

Different scholars at university, non-governmental, country-level in addition to the United Nations Environment Programme (UNEP) have established toolkits, ratings, models, frameworks for CSA as a tool to evaluate the level of environmental, social, economic and institutional sustainability in higher educational institutions (HEI) campuses. In such an appraisal, the first task is usually the identification of the various dimensions and attributes of the CSA in HEIs settings. In general, the CSA attributes are categorised into main criteria, sub-criteria, and indicators. The hierarchy and number of CSA criteria and indicators specified and addressed in different tools are numerous and differ from framework to framework. However, despite various definitions of CSA, a larger percentage of researchers in the area of campus sustainability tend to

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

always conduct their studies with the approach that the CSA framework is multidimensional. They also agree that CSA tools have subjective and objective attributes and that these should serve as the foundation of CSA as a whole.

CSA studies in HEI campuses have been driven by the United Nations Environment Programme, Education for Sustainability Development Innovations Programmes for Universities in Africa (Lotz-sisitka 2013) and many more. This trans-continental, extensive development and utilisation makes the CSA an effective, useful and practical approach of measuring and rating the impact of campus developmental and sustainability policies. As a result, CSA can be referred to as a pragmatic tool that gives a broad base of information for HEIs authorities, administrators, campus planners, and local policymakers. For instance, the outputs of CSA exercise can be utilised by HEIs policymakers to evaluate the accomplishment of their policies and action plans. The appraisal of sustainability at the HEI level can also be perceived as a way of monitoring changes in HEI stakeholders' view of the level of importance for improving campus life and direction for future development in developing nations like Nigeria.

Nigeria is a country located in West Africa with huge crude oil and gas reservoirs and is among the countries with the highest Gross Domestic Product (GDP) in Africa. The country was transformed from an underdeveloped sub-Saharan African country to a powerhouse in Africa mostly due to huge revenue from the sales of crude oil. The spontaneous development of university campuses to meet the demand of the huge population of the country and the migration of people from the hinterland to the urban centre for the acquisition of higher education degrees had led to the difficulties of initiating and implementing new and adequate facilities and infrastructure. These challenges have been creating some significant impacts on the people residing within these HEI campuses and their environs. Urban planners and government officials have been formulating plans and policies to curb these challenges without any significant improvement leading to the need for CSA research. In approaching these challenges, there is a need for the establishment of an assessment tool/framework for the appraisal of campus environmental development within the HEI campuses in Nigeria with a corresponding policy manual on campus environmental sustainability. To achieve these enormous tasks, there is a need for setting up sustainable appraisal indicators that are in line with the situation on campuses within Nigeria.

Despite the high investment in planning, designing and establishment of HEI campus across the geopolitical zones in Nigeria, there is an absence of metrics to appraise the environmental sustainability of these campuses for adequate quality of life. A comprehensive review of the literature reveals that studies using social media data and or big data analysis tool to ascertain the peculiar sustainability indicators of the region where CSA techniques are being implemented has not been conducted before. Despite the focus of some of the targets of the Sustainable Development Goals (SDGs) on information and communication technology (ICT), it can be observed that this has not been fully implemented. This study utilised a technology-driven (open-source software and social media data) methodology that bridges the gaps in existing research and produces an outcome that has the potential of ensuring liveable campuses and cities for all. The findings of this study are also very useful for all professionals in the built environment as well as researchers in the area of sustainable and green campus planning. It will also serve as the foundation for studies, projects, and research on CSA in Nigeria HEI campuses.

3 LITERATURE REVIEW

3.1 Social media Data and Campus Sustainability Appraisal Research

The social media has completely changed the way people communicate within the last decade. Different social media platform provides a huge volume of information which has led to a new field of research known as big data. Researchers are now relying on a large amount of data from various social media channels to conduct social science projects rather than wasting huge financial cost and time on ethnographic trips, questionnaire survey or interviews. This is because the social media is currently the most preferred means of communication which do not restrict the users the expression of their feelings within their comfort zones and available time, unlike conventional survey and interview that will require that the interviewer book an appointment with the interviewees or encroach on their privacy and busy schedule. At present, virtually everyone with access to the internet has at least a social media platform for interacting with family and friends, colleagues, groups, news channels, organisations, politicians and institutions administrators.

Moreover, social media is now gradually eliminating the print media, television channels, and other media channels. There are currently more than 2.82 billion of the world population with internet service on social media making social media one of the highest means of communication and sharing of online information (Pitrov and Krejˇ 2019). The increase in the use of social media can also be related to the wireless internet connection to tablets and smartphones which are easy to move around and easily accessible unlike laptops, personal computers, and desktop computers. The connection of the internet to different devices is no more a daunting challenge in the current age and time in most developed and developing countries of the world.

The social media is now transforming communication from physical (face to face) interaction to virtual interaction on different electronic gadgets. The dramatic decrease in the price of electronic gadgets and a corresponding increase in the performance of software/hardware, wireless connection, computer processing unit and application that is being witnessed across the globe have given rise to the concept of social media big data analytics and artificial intelligence. This has also led to the implementation of projects in various fields like transportation, e-tourism, e-commerce and construction and environment. Presently the huge volume of social media data mined by different researchers, analytic companies and institutions are much easier to clean, filtered and interpreted in different cloud storage environments to bring about new services or approaches to conduction business or designing transportation route, etc. These new discoveries emanating from the use of data from social media is opening new commercial, investment, sustainable planning and construction opportunities. The era of experiencing difficulties with the storage of a huge volume of social media is gone as there are several cloud storage environments that can be utilised for free or via the payment of subscription fees. Now, the vital aspect of the social media big data research is the development of models, framework or logical approach towards efficient utilisation of the data to bring out excellent outcomes.

In the nearest future, there is a high tendency for the adoption of social media data in several fields will escalate. A comprehensive review of literature on tools and framework for the assessment of sustainability in HEIs across the globe reviews that the utilisation of social media data is lagging. Studies conducted by Carpenter et. al., (2016) and Hamid et. al., (2017) recommended the promotion and the awareness of social media roles in sustainability in higher education. This study seeks to bridge this gap identified in the existing literature and advanced the studies of environmental sustainability in Nigeria higher education with the incorporation of social media data. Currently, there are several conferences, workshops, and seminars on several social media research outcomes. Although, there are difficulties with the use of social media data for conducting different types of research, the most prominent one is the trade-off between privacy and utility. The difficulties of accessibility and privacy were eliminated in this study by obtaining a Twitter developer account application as well as the use of a Python 3 library in addition to a complementary codes/command lines for accessing old Twitter data.

3.2 Elastic Stack for Campus Sustainability Appraisal Research

The three powerful online open-source software for a huge volume of data analysis from single or multiple sources which are (i) Elasticsearch, (ii) Logstash and (iii) Kibana are jointly referred to as Elastic Stack. Each can work independently but more reliable and efficient when incorporated together. The Elastic stack is designed to work as a software as a service but it can also be used on other premises/platforms (Bajer 2017). The first plugin-based which is known as Logstash is designed to mine different or single data source in the form of HTTP API, CSV file, etc. once or simultaneously; and thereafter, to modify and transfer the data to other software, devices or plugin-based features (Bajer 2017). The mining and transformation of data takes place usually in a three-phase process of (a) inputs (b) filters and (c) outputs. In most cases, the filtered data are shipped to Elasticsearch despite having the power of sending the processed data to other database or analytics algorithms. The second which is called an Elasticsearch performs simple and or complex search operations such as query in newline delimited JSON, statistical and CRUD (create, retrieve, update and delete) operations. The third powerful tool called Kibana is a visualisation internet-based platform for analysing, searching and viewing data that are contained in Elasticsearch assemblage.

In summary, Logstash can be referred to as a collecting and parsing tool; Elasticsearch, a storage, and searching tool while Kibana is a visualising tool. A fourth product known as Beat has been recently added to the stack. A comprehensive review of the literature shows that the integration of huge open source and commercial data sources, user-generated content on a various online platform, Internet of Thing (IoT) data,

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

energy data, and open government data via the use of Elastic Stack for resolving different commercial and development projects have been conducted. Findings from this review reveal that the utilisation of these three online tools and technologies is lagging in the projects, studies, and research on CSA. None of the 13 CSA tools reviewed in this study utilised this software in mining, filtering or visualising social media data for conducting and implementing sustainable or green campus research.

3.3 Measuring Sustainability in Campuses: Indicators and Categories

Although there are several appraisal tools for measuring the level of sustainability in different parts of the world, it has been observed that a common approach of assessment exists among these tools. Assessment via the use of indicators remains the most widely adopted approach by many scholars in the field of sustainability in higher education (Alshuwaikhat et. al., (2017). CSA indicators can be regarded as the paramount component to be considered when conducting an appraisal of HEIs sustainability performance. This is due to their provision of reliable, useful and relevant information on specific attributes of HEI campuses. However, virtually all the CSA tools have a framework that is based on hierarchy in such a way that assessment indicators are categorised under criteria, dimensions, modules, aspects, principles, strategies, etc. A comprehensive review of 13 documents of the existing CSA tools reveals that there are diverse approaches to classifying the adopted indicators into a hierarchy. Findings show that three CSA tools adopted the criteria approach, five adopted the categories approach, two adopted the strategies approach and the remaining adopted the module, dimension, and principle approach each. In addition, a review of several works of literature on the subject of sustainability in higher education also shows that different scholars come up with a diverse classification of assessment tools into indicators as well. For instance, (Alghamdi et. al., (2017) adopted the hierarchy of assessment tools into criteria.

Also, there are multiple approaches that have been adopted by scholars in selecting suitable indicators for the development assessment tools for appraisal purposes. The two most widely adopted approaches are theory-driven and data-driven. Other approaches include but are not limited to policy-driven, reference values for indicators, ecological-based and spatial based indicators (Niemeijer 2002). The theory-driven approach to selecting indicators for sustainability assessment is based on the selection of sustainability indicators that are in line with a certain philosophical approach or theoretical framework. On the other hand, the data-driven approach is based on the availability and ease of accessing reliable and relevant sustainability data. It was discovered that the most widely adopted approach is data-driven.

A comprehensive review of 13 CSA tools shows that seven of these tools did not provide an explanation of the selection criteria for the adopted indicators. One of the tools adopted a subjective view of what the developers of the tools feel appropriate for sustainability in higher education with yearly modification. Another arrived at the adopted sustainability indicators for their tools by modifying the sustainability indicators contained in the Global Reporting Initiative (GRI) Sustainability Guidelines and thereafter validate the selected indicators at workshops on sustainability in higher education. The remaining two CSA tools conducted a comprehensive review of existing tools to extract sustainability indicators, thereafter adopted and developed a convenient filtering process for the selected indicators. After the filtering process, their final selection of indicators was concluded with the local expert analytic hierarchy process (AHP). It was observed that despite the involvement of local experts in the process of indicators selection by two of the existing CSA tools, none utilised the social media data, big data analytics tools and wide coverage of local stakeholders in HEI in arriving at the selection of sustainability indicators for their appraisal process. As such this study was designed to fill the existing gap in the literature. The next section presents the methodology adopted for this research.

4 METHODOLOGY

There are many well-known established assessment tools with the tendency of witnessing more in the coming years. After conducting a comprehensive review of extant literature, several CSA tools were studied and examined. However, the selected tools for this study were selected based on the following criteria: (1) they are all available in the English language and easily accessible on the internet. The tools that were identified but not written in English such as one developed by the German Commission for UNESCO was excluded from the list. (2) they are indicator-based appraisal frameworks. The selection of tools based on indicators was because they provide platforms for easy measurements and comparison. Appraisal tools based

on narrative assessment and an account of sustainability status were excluded. (3) they are developed specifically to be utilised in HEIs. These tools are mostly addressing specific requirements within HEIs campuses. (4) they are not designed for individual tertiary institutions but rather for institutions at either global, continental, regional and national level, and (5) their design approach, structure, background information, adopted criteria and indicators are all available in the form of either a technical manual, reports, documents or articles. Those tools that are online-based or well-known (such as The Green Plan and Benchmarking Indicators Questions – Alternative University Appraisal) but without their reference sources were excluded.

The comprehensive list of sustainability indicators that are peculiar to HEIs across the world was carried out by identifying and extracting all the various categories, indicators, and sub-indicators in the 13 CSA tools. A total of 55 categories, 220 indicators, and 266 sub-indicators were successfully identified (see Table 1). Thereafter, the indicators were subjected to exclusion criteria to ensure that the indicators that are only relevant to the scope and focus of this study were identified. The focus/scope of this study is on campus-wide (spatial) planning and measurable environmental pillar of sustainability that affect HEIs campuses in Nigeria. This is because HEIs campuses in Nigeria have substantial geographical areas (Adeniran, 2015; Adeniran, 2014) with severe impact and certain campus spatial data could be extracted without reliance on official data. The study also focuses on environmental and spatial-based indicators due to an increase in spatial decision support systems research which has not been extensively covered in campus sustainability research. As such, all the indicators that focus on aspects such as sustainability curriculum in HEIs, socio-economic sustainability and accountability and many more were excluded from the list.

Table 1: Overview of the 13 CSA tools analysed in this study

The stage that follows merged all the repeated indicators and then structured the reduced lists into only two hierarchies. This was done to eliminate the challenges of users of the proposed appraisal model of not being able to understand or utilise it due to complexities. For instance, (Lozano 2006) observed that the GRI indicators are too large and made it difficult for benchmarking and longitudinal comparison. In the process of structuring the sustainability indicators to fit the scope of this study, the authors carried out minor changes although the categorisation adopted in the 13 CSA tools was taken into considerations. The uniqueness of each sustainability indicator was investigated based on their operational definitions. This was considered to eliminate the challenges of differences in defining and measuring the indicators across the selected tools. Finally, the remaining indicators that are in line with the scope of the study were used as keywords to filtered the Twitter social media data that were mined from twitter handles of 142 Nigerian universities (34 Federal, 44 states and 64 private).

In ensuring that scholars conducting studies on big data and machine learning related topics, Twitter, Inc. made available data that the users have decided to release with people from around the globe for researchers

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

after an application is granted. At the initial stage of this study, Logstash was utilised to extract tweets from Twitter via Twitter Application Programming Interface (API). After several attempts without substantial data, a Python 3 library (GetOldTweets3 0.0.11) in addition to specific command lines and a specific timeline was used to mine around a million tweets in CSV format from 142 universities in Nigeria. Thereafter, Python 3 library was utilised again with another set of command lines to ensure piping to another file in nlJSON format and run yet another command (Logstash: configuration file to cloud with key). This was because the CSV file format extracted data are not in the proper configuration for data analysis. Then, Logstash was used to feed the mined data into Elasticsearch for data cleaning while Kibana was used for data analysis. As for the identification of indicators for sustainability peculiar with Nigerian HEIs, the approach adopted at this stage of the study is the identification of tweets that contain the environmental-based sustainability indicators that are line with the scope of this study. The final filtering/selection process in ensuring that only tweets containing the targeted indicators were carried out on the Elasticsearch interface, Elastic Stack 7.5.0 version.

5 RESULTS AND DISCUSSION

Table 1 shows the displays of the breakdown of the selected 13 CSA tools. While the oldest version of the reviewed tool was designed in 2001, the latest version of the tools was modified in 2019. The categorisation of the indicators and sub-indicators into categories and hierarchies varies across the tools. The adopted indicators and sub-indicators amongst the tools also diverse from the indicators ranging from 8 to 39 while that of the sub-indicators is from 0 to 69. While some of the tools were designed solely for indicators, others are established with the classification of the indicators into categories. The remaining further sub-divided the indicators into sub-indicators. However, it was observed that one of the tools was designed as a questionnaire survey classified into seven categories. There are 55 categorisations of indicators across the 13 tools of which no single categorisation was used in all the tools and more than 10 categories were used in only one tool. This vividly shows a lack of uniformity in the categorisation of indicators across the CSA tools. Similar variations are observed in the adopted indicators and sub-indicators. This finding is interesting because most of these tools are developed and utilised mostly by the campuses of higher education in developed countries with closely related values. The authors are of the view that these variations are due to the tools differences in scope as well as accessibility and availability of data on selected indicators. The comprehensive review of the 13 tools reveals that the majority of the tools are establishment based on the availability of sustainability indicators for the appraisal process and not on the basis of public participation via social media. Although two of the tools invited local experts' contributions in the selection of indicators for these tools, only one reported that eight local experts were involved which is small and cannot be regarded as being representative enough.

The filtering process towards the identification of peculiar sustainability indicators for the establishment of the appraisal model and evaluated started with removing all indicators and sub-indicators with their categories that are not campus-wide, spatial and environmental in nature. This led to the reduction of the attributes to 13 categories, 50 indicators, and 66 sub-indicators. At the end of this stage, there are campus-wide, spatial-based and environmental indicators that could (i) not be measured (ii) repeated across the tools and (iii) too generic and complex for sustainability appraisal. This led to another round of filtering that reduces the categories to seven (i.e., operations, environment, setting and infrastructure, energy and climate, waste, water, and transportation) and 29 indicators. After the identification of indicators that are in line with the scope of this study, the indicators were then validated to the case of universities in Nigeria. Rather than relying on validation of the indicators by consulting members of Nigerian university management, administrators or local experts in the area of a sustainable campus, validation based on social media was utilised in this study. When the seven categories were used as keywords to determine their peculiarity with the situation in Nigeria, six unique categories were finally identified. They are (1) environment (2) infrastructure (3) energy (4) waste (5) water and (6) transportation. On the other hand, the 29 indicators were reduced to 11 unique indicators peculiar to HEIs within the context of Nigeria. The data from twitter social media shows that the HEIs stakeholders in Nigeria did not discuss and pay attention to the issue of campus operations, settings and climate. Table 2 shows some indicators which relate to the planning and management of campus functions and space, thus have a spatial dimension. It indicates how GIS and 3D modelling software can assist in measuring the spatially-related indicators that have been compiled from the 13 existing CSA tools and validated to the case of Nigerian HEIs.

	Category	Indicator	Role of Spatial-based Software in Indicator Measurement
1	Energy	Energy consumption	quantity of electricity per source, area and percent of buildings that generate greenhouse gases
		Greenhouse gas emissions	
2	Environment	Open space area	area and percent of land use, acreage of green area, acreage of landscape area
		Forest vegetation	
		Landscape	
3	Infrastructure	Buildings	area of buildings
4	Transportation	Campus fleet	length of walkways, bicycle lane, and communication route
		Pedestrian and cycling	
5	Waste	Waste management	quantity of waste per source
		Sewerage disposal	
6	Water	Water consumption	quantity of water per source

Table 2: Spatially related indicators for assessing campus environmental sustainability

6 SPATIAL-BASED INDICATORS IN THE CASE OF NIGERIA

The use of campus-wide, environmental and spatial-based indicator framework in the case of Nigeria will provide an accurate and spatially referenced data set that will act as a fact-based establishment for the decisions that are required to be carried out to achieve a sustainable campus for both present and future generations. As Nigeria moves forward with ensuring to create a more sustainable regional development across all regions where the current generation can meet their needs without compromising the ability of the future generations to do the same, the swiftly expanding HEI campuses across the country are becoming the centre of attention due to an increase in demand of staff and students, energy, waste generation, housing, etc.

Given the national increase in the number of universities and colleges in Nigeria between 1990 to 2015, many considered HEI campuses to be the epicentre of several challenges. Despite these challenges, campuses provide a better life and economic chances for many stakeholders. Herein lies the opportunity to look at campuses afresh and to shift the focus of their development and assessment to a spatial-based model.

In Nigeria and other developing countries, access to data is very difficult, thus undermining the conduct of sustainability assessment. After review of literature, it became apparent that there is no use of 3D and spatial-based technology by decision-makers to assess campus sustainability as well as the creation of a more sustainable campus policy based on those assessments. However, with regards to measuring the indicators for environmental sustainability and conducting the assessment, the GIS-based approach can play a vital role. A campus-wide and spatial-based integrated framework can be primarily used to assess campus operations and management as this dimension of sustainability consists of spatially related indicators. As such, a Cityengine and other conventional 3D modelling software database should be developed for the indicators after which sustainability assessment can be easily conducted. When remote sensing images are incorporated into the 3D modelling software database, it can facilitate the extraction of data from satellite sources. These spatial data can then be used to measure some spatially-related indicators. Because indicator selection is context-dependent. In this study, the selected indicators are prioritised due to local context via the use of Twitter social media.

7 CONCLUSION

This paper established and formalised a systematic approach to comprehensively review the level of sustainability indicators identified in 13 CSA tools. Thereafter, Twitter Social Media and an online big data analysis tool (Elastic stack) were utilised in selecting environmental-based sustainability indicators for universities in Nigeria. The findings from the comprehensive review of the selected 13 CSA tools reveal that there are variations in the sets of their sustainability attributes and selection process. None of the tools have compatible attributes for campus sustainability appraisal and no different tools can assess the level of sustainability across university campuses with the same appraisal framework, threshold, and rating. This strongly justifies the purpose of this study that calls for the adoption of setting up of environmentally-based sustainability attributes that are peculiar to the geographical locations with similar challenges and

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

requirements that will bring about an appraisal framework that gives room for campuses to compare their CSA performance and interchange of standard practices.

The outcomes of this study have some pragmatic implications for scholars in the field of CSA. It also reveals how projects dealing with the identification, setting-up and developing CSA in developing and developed worlds can be enhanced. Firstly, this study shows that CSA attributes should focus more on the needs, preferences and the level of importance that the stakeholders within which the appraisal will be conducted rather than a comprehensive or long list of indicators based on developers' opinion. The comprehensive review of the 13 CSA tools reveals that there is no strong justification between the set of attributes adopted by each of the tools and their corresponding scope (the local area where it will be implemented). Findings from the literature also classify CSA tools with a long list of sustainability attributes as being complicated and difficult to use for users. Hence, this study established well-balanced sustainability attributes that are peculiar to the end-users and their campuses.

Secondly, the hierarchy of the CSA framework should not be extensively long and detail. Two-level (i.e., categories and indicators) makes it convenient and efficient to conduct a level of importance of the attributes using approaches such as the AHP and social media-based campus sustainability indicators preference model. Multiple levels will make the assessment process become complicated and difficult for adoption by other scholars. Thirdly, scholars conducting the setting-up of CSA attributes should ensure that a wide range of all environmental and spatial-based sustainability attributes was first considered before finalising the final set of indicators that meet the need of their study's scope, aim, and objectives. Selecting the adopted indicators without an initial full range coverage might introduce some scepticism in the final output of the appraisal.

Another finding of our research that has implications for CSA studies is the fact that setting-up or establishing a set of CSA indicators to be adopted for the specific geographical unit does not necessitate the development of a completely new set of indicators. Rather, they should be established by studying a comprehensive list of existing attributes and modify them to suit the new scope based on the requirements of that geographical region. How GIS, City Engine, and 3D modelling software based sustainability assessment for academic campuses and demonstrating its uniqueness as compared to other campus sustainability assessment frameworks and approaches was also discussed. For the said purpose, Geographic Information Systems will be used to develop a campus sustainability model within its sphere of operations. The use of GIS and CityEngine is primarily due to its application and ability to incorporate huge datasets within its program. Secondly, it has made more infiltration, than any other spatial application due to the increased awareness among policy and decision-makers to rely on these systems for public policy formulation. GIS, a computer-based system, can process the data from a variety of sources and integrating it with the geographical location while providing the user or the decision-maker with the information necessary for making informed decisions (Han and Kim 1989).

Lastly, the outcomes of this study show the importance of utilising social media data and Elastic Stack as a reliable, more efficient and intelligent way for selecting and setting-up CSA indicators for university campuses in both developed and developing countries. The approach as well as the findings of this research display paramount contributions that bridge the identified knowledge gap in the literature.

1 ABSTRACT

Making international headline news, the uncontrollable forest fires that have devastated much of Australia in the summer of 2019/2020 have added a dramatic sense of urgency to the focus of this paper on cultural controversies in Canberra – controversies that relate to key themes of the REALCORP 2020 conference: the links between climate change and immanent natural disasters; the problematic co-ordination of urban development among urban and regional authorities; the conflict-ridden connections between public planning and real estate interests; and the role of civil society in the urban transformation process.

The Australian Federal Capital has come a long way from its conception as a physical expression of parliamentary democracy designed in 1911 for a new, progressive nation, hailed at the time in Germany as 'The Social Continent.' Cultural controversies on ideals and issues such as urban vs. suburban ideal concepts, leasehold vs. freehold land, and welfare state politics vs. market-led development were reflected in the growth and change of the capital during the 20th century. By 1988, urban development under conditions of high planning control on leasehold land had led to the production of a city that could be summarized as 'a perfectionist garden city metropolis.'

This paper focuses on transformations that have eroded this ideal in recent years through a combination of dysfunctional inter-governmental relations, neoliberal policies, power plays among public and private actors, and superficial populism. In 1988, withdrawal of the Federal Government from most of its responsibilities for Canberra plunged the city into a fundamental crisis in term of its role and identity, its administration and its finance throwing up questions such as: Do we need a national capital at all? If so, which functions should the capital cater for? Should certain government departments be relocated to regional districts (preferably at the seat of the Federal politicians lobbying for such a strategy)? Does it make sense to maintain the ambitions the founders of Canberra had for creating a model city, 'The Pride of Time' or should Canberra pursue a path of 'normalization' by following the 'business as usual' pattern that characterizes urban development in most other Australian cities? Isn't public planning an expression of 'nanny state' ideologies anyway? And above all, how should the burden of national and local expenses for the capital be divided?

At the administrative level, Canberra was subjected to years of turbulent change, with negative consequences at many levels including poorly devolved responsibility for forest management. This contributed to the conditions for a devastating bush fire in 2003, a harbinger of the fires of 2019/2020, played out in a political climate of climate change denial. Establishment of new suburbs on the burnt-out western flank of the city, exposed to the same threat of wildfire as in 2003 are an ominous sign of a development ethos that has put real estate interests above sound planning principles. In another instance, independent review by the Auditor General of the Australian Capital Territory (ACT) exposed a serious "lack of transparency and accountability" in the way in which the ACT government mingled public and private real estate interests – an issue of continuing concern, particularly given the ACT's recent agreement to cross-border development on rural lands long-held by land owners in the state of New South Wales.

A core issue is that Federal Government divestment of all responsibilities beyond core national capital functions has meant that a substantial part of Canberra's local government revenue has been financed through the sale of greenfield land. Since this approach is unsustainable given the limited extent of developable land in the ACT, strategies have been adopted which have culminated in densification through high-rise luxury apartment blocks. The upshot has been an intense cultural controversy driven by a remarkably crude and aggressive campaign by local politicians in unison with one of the biggest local developers ridiculing the planning approaches of the past and literally smashing the long-established image of Canberra as 'The Bush Capital, ' a city oriented on the Australian landscape. Even the way in which the introduction of light rail is linked into this process does not come as the desired triumph of sustainability. One of the many issues there is that it is partly financed through the relocation of public housing to bushfire prone areas at the edge of the city. In the context of these cultural controversies, Canberra's civil society is beginning to raise its voice, but is still struggling to do so in a way that ensures more than sporadic victories.

2 CANBERRA – CULTURAL CONTROVERSIES AND URBAN CHANGE IN A CAPITAL REGION

2.1 Introduction – the significance of Australia, Canberra, the fires and the climate change debate

This paper begins with a perspective on the recent dramatic fires in Australia and its capital city. It does so not in order to wallow in sensationalism over the tragedy but to explore the significance of the cultural controversies confronting us in this context. These are controversies that relate to key themes of the REALCORP conference: the links between climate change and immanent natural disasters, the problematic co-ordination of urban development among urban and regional authorities; the conflict-ridden connections between public planning and real estate interests; and the role of civil society in the urban transformation process. These are themes that are confronting us on a global scale – in Australia no less than in Germany.

Uncontrollable forest fires burning in a continent at the other end of the world that made international headline news in the Australian summer of 2019/2020. Far away from the location of our Aachen conference, the bush fires were threatening not just any Australian city but Canberra, Australia's capital – a city that took pride in its name 'THE BUSH CAPITAL.' Even as the constant sea level rise diminishing the habitat of civilizations in the Pacific and elsewhere are continuing as silently as the expansion of the African desert, it was the roaring inferno of the Australian fires that added a dramatic sense of urgency to the threat of climate change – at least among those who believe that climate change is a reality.

The significance of Australia in the current international debate is that it has been the first country in which, in a short period of time, regions one third the size of Germany have gone up in flames killing dozens of people, destroying homes, leading to the possible extinction of entire species of animals and threatening the livelihood of the nation's big cities.[1] A dramatic wake-up call. Closer to the themes of our conference on planning and urbanism, the significance of Canberra lies in the fact that it directs our attention to the cultural controversies shaping the processes of urban and regional development.

Seventeen years before the current disaster, in 2003, Canberra had experienced a fire storm of similar ferocity, with 4 lives lost, more than 500 houses burnt and the historic Mt. Stromlo observatory destroyed. Built in 1924, the observatory had been part of the Research School of Astronomy of the Australian National University. Since its founding in 1946, the ANU has been a beacon of international research. In fact, research is one of the fields in which the small country with today 25 Million inhabitants has gained and maintained international recognition 'punching above its weight,' to quote a somewhat corny metaphor much used in Australia.

Research on climate change has been carried out at the ANU and in Australia's excellent national research organization, the Commonwealth Scientific Research Organisation CSIRO. But in the debate about climate change or global warming, its former professor of political studies and Chairman of the National Capital Authority, the body responsible for planning Canberra's areas of national concern, took a definite stand not long after the fires. Declaring himself an agnostic towards the findings of the Club of Rome, he urged everyone to 'keep a cool head' in the debate about the alleged connections between climate and 'the burning of coal and oil. ' Significantly, he did so in his address to the Planning Institute of Australia.[2] The following years saw budget cuts to the CSIRO which 'cut to the bone' of the organization's capacities for climate research.[3]

At the level of National politics, the Federal Minister Tony Abbott, later Prime Minister, has been quoted as saying that 'the science of climate change" was 'absolute crap'[4] and 'coal is good for humanity'[5] And at the level of symbolic Government actions, the enthusiastic advocacy of coal found its most curious expression in a spectacle staged by the then treasurer Scott Morrison. In order to demonstrate the innocent nature of the

[1] The fires in the Amazon rainforest are another tragedy of global dimensions.

fossil fuel he took a lump of coal to Federal Parliament. The admiration of his party members would later propel him into his current office as Prime Minister.

As late as July 2019, Abbott proclaimed that there were no problems with coal, that indeed windmills were the 'dark satanic mills of the modern era. '[6]

Beyond the ludicrous spectacle at Parliament, where the unresolved climate change issue had led to chronic instability with six Prime Ministers succeeding each other since 2010, the processes in which new and expanded coalmines are allowed to operate are experienced as frightening. This is so not only because of the environmental damage but also because of the perceived reduction of civil liberties, in particular with regard to protest.[7] In a recent major development, a one-billion-dollar subsidy has been granted to Indian coal mining giant Adani for the construction of a railway line connecting the mine in Queensland to newly created port facilities near the Australian Barrier Reef. The links between national politics, the 'uncertainties for the longer-term outlook for coal exports'[8] and the alleged 'end of Australia's resources boom'[9] are all objects of controversial discussions in Australia.

We should not dismiss these developments as fringe phenomena with little relevance for Germany.[10] Siemens is right now selling its train signalling equipment to Adani in the face of international protest, obviously displaying a similar instinct for disastrous involvement with noxious industries as Bayer did with its purchase of Monsanto. Bayer is now facing enormous claims for compensation in connection with the use of Roundup (Glyphosat). And of course, we must not forget the piles of Australian coal on the wharves of Hansa Port, Hamburg, delivered to Germany, the 5th largest market of Australia, by the world's largest coal exporter.

The controversies around climate change and other global challenges are taking a significant share of the Australian public discussion in politics, academia, think tanks, and the media. The latest contribution is an open letter of 3 February 2020, signed by 274 climate scientists, which outlines the scientific basis for the links between climate change and bushfires in Australia.[11] The Murdoch Press, which publishes most Australian newspapers, has been propagating the view that 'it has never been shown that human emissions of

carbon dioxide drive global warming. '[12] The most important of its daily papers, *The Australian*, has engaged eminent figures such as geologist (and director of multiple mineral exploration and mining companies) Ian Plimer, who proclaimed 'There are no carbon emissions. If there were, we could not see, because carbon is black! '[13]

Cultural controversies such as these have always found their expression in the processes by which cities have grown, be it as a consequence of central planning or through incremental planning by individuals and groups. They can be traced from antiquity via the periods of the emerging industrial city through the transformations between the politics of the Welfare State to neo-liberalism, the age of modernism to whatever we want to call the phases coming thereafter.

3 CANBERRA

Similar to a majority of cities globally, planning discourse and politics in Canberra circle around themes such as: sustainability[14]; heritage and strategic planning[15] relating to fields such as urban renewal and densification; public and private transport[16]; and urban economics. As elsewhere, they are shaped by broadly-based cultural controversies such as those addressed in this paper.

Specific features of Canberra, a city of 460.000 in 2020, lie in its character as one of the great planned capitals of the 20th century and in its identity as a Garden City and 'Bush Capital.'[17] The term addresses Canberra's character as an inland city situated in the typical savannah landscape of south east Australia – the Australian Bush. Originally deployed in the early 20th century as an ideological expression of nation building and later as a shorthand formula for a low-rise 'City in the Landscape, '[18] the label of 'The Bush Capital' has become an object of serious cultural controversy in the last decade.

Remarkably aggressive strategies for re-branding the city and of transforming the image of Canberra from what is depicted as a boring garden city and 'bush capital' into an exciting metropolis of luxury high-rise apartments were set in motion in 2010 by a twitter campaign by the then Planning Minister Andrew Barr[19]. In this perspective, Canberra is depicted as the product of a quirky, out-of-date plan, an escapee from a Simpsons' Family cartoon, unfit for adaptation to today's challenges and defended only by senile locals above the age of 40 (incidentally Barr's age at the time).

Although internationally recognized as one of the great metropolitan plans of the 20th century[20], the 1911 design by Chicago architects Walter Burley Griffin and his wife Marion Mahony Griffin has locally been an object of cultural controversies and has been subjected to a remarkable mixture of iconic reverence, ridicule and crude exploitation as a real estate branding device.[21] While the competition drawings have been inscribed in the UNESCO memory of the world heritage, the endeavours to recognize the ACT as National Heritage as a necessary step for UNESCO world heritage, have been thwarted. Similarly, at the level of civil society, the success of community-based campaigns has remained limited. A case in point is the campaign to recognize the biophysical resources of the ACT as a UNESCO biosphere reserve. This was defeated by local commercial interests – a strategic defeat of the informed scientific basis of Canberra's society.[22]

The attacks on the Bush Capital image reached a climax in a 2019 video clip by one of the biggest real estate developers, GeoCon.[23] In the commercial, a young female athlete wielding a pick runs towards a sign inscribed "Bush Capital," her face contorted with disgust and anger. She smashes the sign. Immediately, the

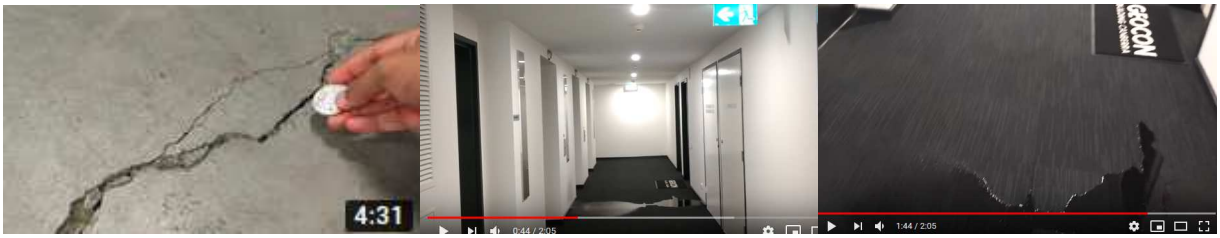
15 years on, people in Canberra wake up to realize that they need no longer listen to the fake news of the 24 hours news cycle as the gloomy voice of the narrator points out. GeoCon, so the film explains, have made their own market analyses and calculations. Thus the light rail introduced by the government in 2019, they were saying in another video, would connect GeoCon's Brave New World of luxury apartments in the nearby New Town with the City Centre in under ten minutes travelling time – in contrast to the transportation planners' assessment of a travel time of 25 to 30 minutes.[25] And the calculations appear simple and sure-fire: "When you buy off-the-plan at Metropol, you're buying today's prices; so in two years' time when it's finished, you've actually made money because the value of the property has increased."[26] The fact that it may not be wise to rely on such prognoses is evidenced by you-tube videos demonstrating that the newly erected luxury "Wayfarer" building was suffering from severe damage such as cracks in walls and floors and rain water leaks.[27]



These observations came at a point in time when the evacuation of the 35-storey Opal Building in Sydney was making headlines.[28] Shortly thereafter, structural damage in Sydney's Mascot Tower blocks sparked widespread concerns about new apartment buildings across the city. In Canberra, too, analyses indicated that "the overwhelming majority of high-rise apartment buildings… are likely to have major defects." With Canberra experiencing "its biggest housing boom since records began," it appeared that the territory's construction industry "had reached a crisis point."[29]

There is a close connection between high-rise development, real estate marketing, the transformation of the bush capital image, the (belated) introduction of light rail and the mode of financing the associated infrastructure. The inauguration of the first light rail line in 2019 was a success of sorts and was due in part to the new dynamic introduced in 2009 through a Labor-Greens political alliance. The results are nevertheless not broadly seen as the desired triumph of the persistent struggle for sustainability they might have been. The reasons lie in a combination of issues in the narrow field of transportation planning and the wider, more complex economic and urban development context.

At the heart of this problematic lies the strategy of financing light rail infrastructure largely through the sale of government owned land occupied by public housing and through value capture from the new high-rise development, which will spring up on up-zoned properties along the light rail route. The focus on public housing land is not only a consequence of the fact that this is the major source of land over which the municipal government can dispose. Another important factor lies in a central (Commonwealth) government policy of rewarding the 'recycling of public assets' by awarding national subsidies. This is a major basis for financing light rail, which, as pointed out, is in turn a motor for urban renewal through high-rise tower blocks.

When the public housing tenants are relocated in the city, they are sent to locations not served by the light rail and in most cases badly served by buses, often far away from the inner city support structure in the form of job centres, help centres, cheap clothes shops etc. Among the locations where we find them are the edges of town, such as the city's western fire prone edge, exposed to the hot westerly winds, which carried the embers of the 2003 bush fires.

One of the sites we might look at was originally identified as definitely bush fire prone in the maps issued by the ACT Emergency Services. However, following the decision to relocate the public housing tenants to this

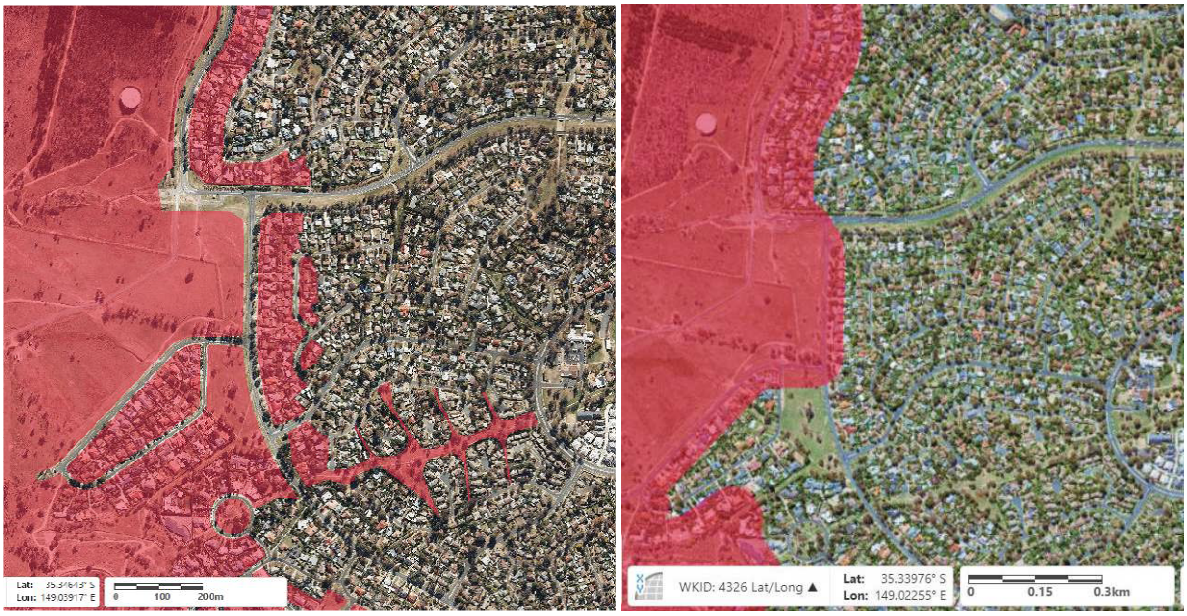
area, the bush fire rating was changed. The public housing is now going to be behind a line deemed to be safe. It goes without saying that this did not convince the people concerned. One of the ironic comments was 'of course the fire knows it must not cross these lines. '[30]



These maps show the bushfire-prone rural area (pink) leading into the bushfire-prone suburban edge. The top image is from February 2017. The second image is the revised BPA[31] from June 2017. (Source: actmapi.act.gov.au)

In fact, the Canberra bush fires are magnifying the underlying conflicts and indeed highlight the way in which these are interrelated. While public protest about these issues is continuing, it is apparent that the public debate is far from uniform and reflects cultural controversies that have shaped the very specific situation of Australia's National Capital.

The following pages briefly sketch a selection of major cultural controversies in the history of Canberra to arrive at the current controversies and their expression in urban politics from the angle of the interrelated REALCORP themes addressed above. These controversies have had immediate and lasting consequences for Canberra's achievements as well as for the interrelated issues culminating in the fire disasters of the 21st century.

3.1 Cultural Controversies: The 'Bush Capital' between Pride and Parochialism

The need to establish the Federal Capital as a new city arose in part out of the Australian constitutional debates of the 1890s, but principally the need out of the competition between Sydney and Melbourne.[32] Rivalries among all parties concerned have fostered a negative image of the circumstances of Canberra's foundation. As historian Keith Hancock put it, 'Canberra was conceived not in generous national enthusiasm, but in the haggling of provincialism.'[33] Those cultural controversies concerning the nature and even the very necessity of the capital have played an existential role throughout much of Canberra's history. They shaped planning processes around 1900 as much as they do today; and in fact, the underlying dialectic of pride and parochialism has persisted until this very day.[34]

[30] Costin 2003. https://the-riotact.com/2003-revisited-the-canberra-firestorm-is-still-a-health-hazard/230099

[31] The BPA is a risk-based map that shows the area of the ACT that has been assessed as being at high risk to bushfires. Canberra's urban areas that are adjacent to forest and grassland are defined as BPA, as is the ACT's entire rural area. Currently, close to a quarter of all dwellings in the ACT are located in the area identified as BPA. ACT Emergency Services Agency 2019: https://esa.act.gov.au/cbr-be-emergency-ready/bushfires

[33] Hancock 1930:278

[34] During the twenty-first century, affirmations of the national commitment to the capital, culminating in the centennial celebrations in 2013, have contrasted with crippling budget cuts, political statements of disdain and eventually with plans for the transfer of national agency staff to smaller provincial cities in the electorates of responsible ministers. In 2017, Deputy Prime Minister Barnaby Joyce declared 'moving public servants out of Canberra [was] core business for

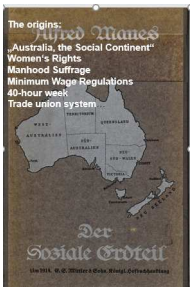
ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The 'haggling of provincialism' found an early expression in the site selection process, which became known as 'the battle of the sites.' Eventually, however, this led to the creation of Canberra as an inland city situated in the typical semi-arid savannah type landscape of south east Australia composed of grasslands with occasional trees and wooded hills – the Australian bush.[35] This is the origin of 'Canberra the Bush Capital.'

This notion of the Bush Capital was an object of conflicting sentiments, of different cultures to an extent. On the one hand, they reflected the 'Bush ethos' of the settler society as an ideological expression of nation building as well as romantic feelings associated with the typical Australian landscape.[36] On the other hand, the term was used in a derogatory way by public servants reluctant to leave the cultivated ambiance of the provisional capital of Melbourne and to move to what was derided as 'the Siberia of the Southern Tablelands.'

But there is an important other side, which lies in the realm of cultural aspirations and indeed achievements. From the beginning, Canberra's mission was to be more than an administrative capital. It was to become the prestigious symbol of a young federation, 'the finest Capital City in the World – the Pride of Time' in the words of Minister for Home Affairs King O'Malley.[37] As an expression of the will for nation building, these words were more than empty politicians' overblown political rhetoric. They rested on the economic optimism following the discovery of rich gold fields in Australia – arguably the beginning of a series of (intermittent) mining booms, which created the legendary wealth of 19th century Australia.[38]

Apart from this material background, early 20th century Australia was characterised by a social and cultural climate in which a strong will for democracy and egalitarianism led to the creation of legislation for women's rights, universal suffrage, the secret ballot, minimum wage regulations and the beginnings of a trade union system. It was a period in which Australian legislation was ahead of that of many older nations and in which the country found admiration in Germany as 'The Social Continent.'[39]



In one important respect, this political situation permitted Australia to learn from its bitter experience with the rampant land speculation in the early settlement years. This led to the adoption of a progressive policy of public ownership of for the capital. Canberra became an exemplar of an urban development process based on leasehold tenure.[40]

In a similarly commendable way, the task of assessing the qualities of the site involved leading scientific and professional figures of the day. These experts, together with the professional staff of the Commonwealth

the Turnbull government' (Canberra Times 2016. [35] From the first practical moves toward Canberra's establishment, principles of what we today consider as sustainability were central to the formation of the city. Beyond the principles of social and economic sustainability behind the land policy, principles of ecological sustainability, in particular in terms of a secure water supply, were paramount. This was particularly important because under Section 125 of the Constitution, the Seat of Government was to be located in New South Wales, no closer than 100 miles to Sydney and outside the range of naval bombardment. This suggested an inland location of the capital.

[36] Ward 1958

[37] O'Malley in 1911, quoted in Harrison 1995, p.6

[39] Manes 1914; Fischer 2004

[40] Brennan 1971. The leasehold provisions still exist today as the land tenure system of the capital, although the land rent component was lost when the system was mutilated in the 1970s.

Department of Home Affairs, assembled impressive documentation on the geology, geomorphology, hydrology, soils, vegetation and climate of the Canberra site, together with comprehensive topographic plans. They formed the basis for the exceptionally comprehensive documentation for the international competition.

It was on this information that the Chicago architects Walter Burley Griffin and his wife Marion Mahony Griffin prepared their entry in the competition for the Australian Federal Capital, launched by the Australian Government in 1911. The Griffins' winning scheme was a synthesis of amazingly advanced ideas on town planning combining the approaches of the City Beautiful and Garden City movements, underpinned by the model of the American parks movement of the nineteenth century, the architectural philosophy of Louis Sullivan, the political economy of Henry George and the democratic ideals characteristic of the Progressive Era in the United States.[41] The central area was thus conceived as a physical expression of parliamentary democracy. Features of the metropolitan plan included: neighbourhood units (explicitly named as such in 1911) and diversified urban sub-centres connected by a tramway system 'borne at public expense' ('Nulltarif'); ideas on functional and social mix and – of great importance in the light of sustainability and bushfire issues – principles of water recycling, decentralised sewerage treatment, urban gardening and hydroelectric energy from nearby dams. This was of particular importance for the vision of the "Bush Capital' in its semi-arid setting.[42]

So far so good. The further course of events in the early 20th century, however, can be read as a clash of local cultures – that of the experts and that of the politicians who subsequently co-opted the competition. The politicians' decision to act as the adjudicators in the process led to the Royal Institute of British Architects recommending its members that they not participate. Locally, the problems culminated in a muddle in which several of the winners' plans were combined into a 'Departmental Board Plan' derided by Patrick Abercrombie in the editorial of the Town Planning Review as 'a hodge-podge conglomerate scheme… [for] a third rate luna park.'[43] Eventually the ignominious treatment of the competition winner by Canberra's administrators drove Griffin out of his job as Federal Director of Design in Canberra. Present-day historians cringe with embarrassment similar to that experienced in the case of Utzon and the Sydney Opera house in the 1960s.

These processes are an expression of the parallel co-existence of far-sighted perspectives with blatant incompetence and pragmatic compromise – something which persists to the present day (although this phenomenon is of course not restricted to Canberra nor in fact to town planning).

3.2 Cultural controversies between urban and suburban ideal concepts[44]

At a different level, the cultural controversies that have shaped Canberra reflect a range of attitudes found world-wide towards such as urban vs. suburban and traditional vs. modernist conceptions. Thus, the low-rise, medium-density scheme and the clearly urban character of the Griffin plan morphed into the suburban conception of a city of bungalows in the 1920s – not so much a Garden City as a city or gardens. This was partly due to the economic realities of the inter-war years. But it was also an expression of a cultural preference for suburbia as a way of life. As early as 1909, the British-Australian architect John Sulman had predicted in his advice for the competitors: 'The European boulevard with its street cafés would be unappreciated in Australia.'[45]

[41] Weirick 1988

[42] When the site for the Bush Capital' had been selected, a secure water supply for a large inland population was the determining factor. Therefore, the city was set in a large territory determined by the natural boundaries of river catchments. The Australian Capital Territory catchment gave the ACT a hinterland of high-value wilderness areas, which have been protected as national parks and nature reserves since the 1980s. The overall area of the ACT – 2,400 sq. km – is more than twelve times the size of Washington D.C., mostly comprising these mountainous forested areas, an impressive backdrop and hinterland – but bush fire prone, posing considerable problems for ecological management and sustainability of the city.

[43] Abercrombie 1913:, p.222

[44] Fischer 1984, 1989 The notion of 'ideal concepts in planning' and the ways in which the glance through specific 'windows' have influenced city making have been essential to the publications between 'Myths & Models' (1984) and 'Windows Upon Planning History' (2018).

[45] Sulman, 1911, p.606

Following Griffin's dismissal in 1920, the skeleton of wide City Beautiful avenues was indeed merely fleshed out with 'mostly single storey, single family houses on generous allotments.' The City Beautiful avenues became automobile thoroughfares rather than settings for urban compositions. The rich semantic content of the plan was altered and impoverished.[46] The city entered an adolescent stage – seven pleasant but oddly proportioned suburbs in search of a city. Unified by the creation of Lake Burley Griffin in the centre in 1963, the garden suburbs developed in this period with their now mature trees have become much sought-after heritage real estate.

From the 1950s on, Canberra's development followed the growth patterns of British New Towns and the methods of US land use transportation planning. In 1957, after a long period of stagnation, Prime Minister Menzies – in many ways a close counterpart to Germany's Konrad Adenauer, created an exceptionally powerful new organization for planning and developing the capital. He ensured that the new National Capital Development Commission (NCDC) would have a large budget and that federal legislation and Parliamentary support would continue to give it a high degree of planning control on the basis of public ownership of land. Imbued by a sense of public responsibility, the NCDC's professional planners acted in the mode of benevolent dictator until their New Town model was firmly on the ground.

3.3 The tipping point: 1988

As a planned capital, Canberra was thus built and managed much in the manner of a government company town during the first 75 years of its existence. In 1988 then, completion of the new and permanent Parliament House was interpreted by Federal politicians as evidence that the Federal Capital was itself complete.[47]

So, the Commonwealth said, the time has come to talk of many things. If the city had come of age, it should henceforth fend for itself like other state capitals too. The Commonwealth would divest itself as far as possible of financial responsibility for the city beyond core capital city functions.

One authority would look after the associated Areas of Special National Concern and another municipal-style planning department at the territory level would be responsible for the rest of the city and the ACT.

However, what may have looked plausible at first sight, was associated with a range of problems at the interrelated levels of finance, governance, and urban structure.

First, finance: A 'city-state' like the ACT could not operate in the same way as the other state capitals by raising substantial revenue from mining, manufacturing and industry. It was therefore more dependent on Commonwealth government grants than these; and in a system set up with the intention of minimizing Federal funding, Commonwealth grants would always be a bone of contention.

Second: Finance and governance: One consequence of this arrangement was chronic underfunding of the agencies responsible for the planning and development of the capital. Creation of these authorities in 1988 was followed by almost never-ending turbulent administrative reform and a proliferation of governance arrangements and overlapping and conflicting plans.

Third: finance and urban structure: It soon turned out that the territory government could not afford paying for the city it had inherited from the Commonwealth on the basis of the revenue from rates and local taxes.

That city, the Canberra of 1988, was a perfect manifestation of Australian ideals of urban/ suburban living and could be seen as 'the perfectionist Garden City Metropolis. '[48] It was a city with high development standards across the entire urban area. At the same time, it was a problematic low-density, car-dependent urban conglomeration extending over a north-south length of 40 km with a population of 400.000 in 2016. This corresponds to the east-west extension of the urbanized core of Germany's Ruhr district with a population of several Million.

In order to continue paying for this city in the face of parsimonious Commonwealth contributions, the Territory Government resorted to a strategy of financing a significant part of its revenue through the sale of its principal asset, greenfield land.[49] This approach is of course unsustainable. It has resulted in a vicious

[46] Fischer 1989, p.168;
[47] Weirick 1989; Fischer & Weirick 2013
[48] Fischer 2013, p.ix
[49] Corbell, 2005; ACT Government 2005; Sansom 2009; Stanhope & Ahmed 2019

circle of further extending an already extended city and exacerbating the very costs of urban management it is seeking to defray. Among the consequences has been the constant encroachment on the City's greenbelt system. Even more critical in the light of the bushfire events, a new satellite district with a population of 50,000 was established on the area devastated in the major bushfires of 2003. This is further extending and exposing the western flank of the city in the era of climate change to fires driven from the wilderness areas by hot westerly winds from the deserts of Central Australia. Other suburbs on the edges followed suit.

3.4 The fires 2003 and 2019/2020

With all the complexity regarding what caused the ACT fires in 2003 and also 2019/2020, the connection between the dysfunctional division of responsibilities decided upon at self-government cannot be overlooked. At the time it seemed to make sense, at first sight, for the Commonwealth to focus its interest and responsibility on the Parliamentary Zone, the visually significant Inner Hills and the lakeside parklands. But in that process, the responsibility for the huge National Park that forms the backdrop of the ACT was shifted to the municipal-style agency which was not able to pay its way even in the city area. This arrangement was problematic to say the least.

As James Weirick put it in 2003, 'in this way, the National government became responsible for a city park, and a city government became responsible for a National Park. Here lay the seeds of tragedy.'[50] The new arrangements following self-government constituted a rupture and a tipping-point also for the practice of the National Park management. Due to the lack of resources, the complex hazard reduction programs preceding the new arrangements, which had involved back-burning in experimental programs by the CSIRO, were discontinued. Understaffed and under-resourced, the authorities were overburdened and inefficient in their reactions in 2003.

The dislocation and chaos which spread across the south-western suburbs of the city seemed to take on a surreal and terrifying intensity in inverse proportion to the planned perfection of Canberra's suburban landscape. Indeed, the elemental force of the firestorm mocked the very order and perfection which has distinguished the city since its inception.

While since then, improvements have been made to the park management system in the ACT, many questions remain. What difference the continuation of the back-burning practice would have made for the fires in 2003 and in 2019/2020 remain a complex issue hotly debated on technical as well as ideological grounds by science, politics and the public including individuals and bots in social media. The national debate over bushfire management is polarized between many groups including forester/farmer demands for large-scale prescribed burning and land clearing and conservationist concerns for the maintenance of biodiversity.

Since the firestorms of 2019/2020, a completely new dimension of the climate change and fire calamity has emerged. A phenomenon that was once considered a 'rare and unique' weather event seems to have become more common. The bushfires in Australia are creating violent weather systems that can spark new fires, conjure fire tornadoes and make fighting existing fires much more challenging. They can project embers up to 30 km ahead of the fire front. The rising heat from the intense bushfires creates massive, powerful clouds called pyrocumulonimbus, or pyroCb. These 'fire clouds' are created 'when fires lift enough heat and moisture into the atmosphere to produce a smoke-infused thunderstorm.'[51] The fires are creating their own weather, and at present, these firestorms cannot be modelled and their behaviour predicted.[52]

In other words, climate change in Australia is producing more extreme bushfires.

This uncontrollable situation has arisen during the decade of climate change denial in the Australian political sphere that is still destabilising national governance as Parliament House at the centre of the 'Bush Capital' disappears from view in choking clouds of bushfire smoke.

4 CONCLUSION

This paper has looked at Australia's capital city though the window of the cultural controversies that have shaped its development – from conflicts between narrow-minded competitive thinking and the visionary perspectives that created one of the great planned capitals of the 20th century; the unique controversies around the Bush Capital image as well as the common controversies around urban vs. suburban ideal concepts; the crisis which emerged with the unfortunate dysfunctional arrangements at self-government in 1988 and which created the issues of governance and finance and urban management; on to the ensuing interrelated problematic strategies of urban and regional development in recent years.

It has identified the close connection between the necessity of subsidising the municipal household through unsustainable strategies such as the sale of greenfield land from its limited territory, the consequent loss of greenbelt land; the mechanisms of financing the light rail infrastructure through the relocation of public housing to make way for urban renewal through high-rise tower blocks – all embedded in aggressive strategies directed at a selective re-writing of history aimed at demolishing the traditional Bush Capital brand; and finally how the interlocked issues have contributed to the weakened response to the fires of 2003. Canberra has been lucky in the 2019/2020 fires, but on the basis of our current knowledge about the fact that the embers can travel up to 30 km ahead of the fire, we have to realise that it would only have taken a change of winds for large parts of Canberra to be worse affected than in 2003.

At the structural level, we can draw a connection between Canberra and the locus of our conference, the University of Aachen. The Canberra story in this paper provides a spotlight on a cultural dimension behind the discourse on 'the production of the city' as developed at the department of Planning Theory some 50 years ago.[53] What Harald Bodenschatz identified then as the 'block of interests' between local politicians, architects and the building industry in Berlin,[54] finds an echo in the Australian capital. At this point in time it is evident that following the withdrawal of central government from its responsibility for the Australian capital, local development interests have trumped the national and international concern for the meaning of Canberra to the world

Climate Urgency and Cities: Action and Reaction, Evidence and Reluctance

Judith Ryser, Teresa Franchini

(Judith Ryser, DiplArchEPFL/SIA, MSc (UCL), MCIOJ, ISOCARP, UDG; CityScope Europe, Senior Adviser Fundacion Metropoli, judith@urbanthinker.com, jryser@dircon.co.uk, www.urbanthinker.com)
(Teresa Franchini, Temanova, Mexico City, Mexico; terefran@temanova.com)

1 ABSTRACT

The first section of the paper gives a brief critical overview of the situation of climate change strategies at the global level, from Kyoto to Paris, Madrid and Glasgow. It also discusses the measures taken by the European Union, and their level of implementation at selected member state and city levels. The impact of pressures groups such as extinction rebellion and the green movement are also examined, together with awareness raising actions such as films and documentaries demonstrating the tangible effects of man-made climate change.

The second section focuses on activists and environmentalists, their proposed solutions and selected proposed interventions in places which have been adversely affected by man-made climate change impacts, such as flooding or drought. It also briefly discusses the state of scientific knowledge and how it is dealt with by politicians, activists and climate change deniers.

The third section looks at the political evolution of climate change intervention at city level. It focuses on Madrid and London in the context of EU actions and respective national targets and examines the direction of travel of the two cities. It briefly synthesises the policies of lowering carbon emissions and proposed actions taken in 2008 in Madrid and London what actions have been taken between these dates and now and what effects they had on reducing carbon emissions, fuel consumption and air pollution. The paper finally compares these approaches with the current strategies for mitigating and adjusting to climate change in the latest city plans and offers critical comments.

Keywords: carbon emissions, green movement, policy, climate change, mitigation

2 BRIEF OVERVIEW OF CLIMATE CHANGE STRATEGIES AT GLOBAL AND EU LEVELS

Scientific evidence on climate change draws a complicated picture for the planet and the adoption of policy responses for this most important global phenomenon can only be global. It is difficult to be optimistic though about aligning national interests with a common global objective as they do not always coincide and are even opposed.

2.1 From Kyoto to Paris

The concern of scientists for human activity on the planet was visible at the Rio de Janeiro Summit in 1992. In parallel to the need to create sustainable environments, the urgency to reduce greenhouse gases (GHG) was one of the issues that led 194 countries, two observer states - Palestine and the Vatican City - and the European Union as a supranational body, to sign and ratify the United Nations Framework Convention on Climate Change (UNFCCC).

This convention assumed that global warming is a result of the increase of GHG in the atmosphere as a consequence of the formidable consumption of energy from fossil fuels. The convention promoted the implementation of an energy transition process towards the decarbonisation of national economies by using renewable energies to reduce these emissions produced by human activities.

The first annual follow-up meeting of the agreement, the Conferences of the Parties (COP) was held in Berlin in 1995, initiating a long process that, despite the difficulties, made it possible to reach various agreements, most notably in Kyoto in 1997 and Paris in 2019. The Kyoto Convention (COP 3) set the basis for the commitment on GHG emissions in industrialised countries and for the conditions of the carbon market.

The Paris Agreement (COP 15), which will replace the Kyoto Protocol from 2020, obliged countries to make cuts to their GHGs emissions so that the temperature of the planet does not to exceed 2ºC with respect to pre-industrial levels and, as far as possible, not exceed 1.5ºC. The Agreement also provided for periodic reviews of the results of the cut plans, the first in 2020, when targets would be set for 2030 and 2050, the final date for neutralising emissions.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The regulation implementing these commitments was incorporated in Article 6, which refers to the trading of GHG emissions rights between countries and even between private companies belonging to the sectors obliged to make cuts, such as aviation companies. The treatment of accounting to avoid that the same right can exist in the balance sheet of two countries, as well as the terms of the inclusion of private companies in the market, was postponed for COP25.

2.2 From Madrid towards Glasgow

COP 25 was held in Madrid in December 2019 instead of the planned host Chile due to social unrest there in response to price increases of transport or fuels, similar to France, Iran and Ecuador.

The challenge facing COP25 was twofold: political and technical. It represented an opportunity to demonstrate the will of countries to avoid global warming and to complete the Paris Agreement by setting the criteria for implementing emissions markets postponed there due to disagreement between countries.

The summit took place among a dramatic lack of international leadership and weakening multilateralism to fight climate change. Trump had begun the process of getting the US out of the Paris Agreement, China showed no sign of cutting its greenhouse gases, Russia did not present a programme for reducing them, and the EU had failed to agree on a zero emissions target for 2050.

The conflicting position between national interests for the development of article 6 made the mission of COP 25 impossible. The reluctance of the major emitting countries to tighten up their plans for cuts - USA, China, Russia and India, together with Brazil, Australia and others where environmental concerns were not among their aspirations, prevented the adoption of the market rules proposed by the Paris Agreement.

The enormous investments that the transformations entail, the resistance of the economic and social sectors that would be affected in the short term and the lack of a supranational authority to guide the process and propose sanctions, highlighted the fragility of the international agreements. Even in the EU a difficult process was underway, due to the heavy dependence on coal of some countries, including Germany, and especially Poland, Hungary and the Czech Republic but ended in a compromise later.

Faced with the slowness of governments to address their adaptation and improvement plans and the lack of leadership among large emitting countries, other actors took the initiative. At COP25, the commitment of local and regional administrations to respect the agreement was achieved through effective and timely action plans. Likewise large companies showed their commitment by producing new products and services, generally related to the transport sector and urban services. The Spanish Group for Green Growth, which comprises almost 50 large companies, is firmly committed to the decarbonisation of the economy by incorporating available technology, thereby demonstrating the change in attitude of today's business world.

Agreement on changing the dominant production model by initiating an economically and socially viable transition was not achieved and the development of the content of the Paris Agreement postponed to COP26 scheduled in Glasgow in 2020.

3 FACTS, PLANS AND PEOPLE CONCERNING CLIMATE CHANGE AND ACTIONS UNDERTAKEN

3.1 What does science say?

Studies led by the IPCC - the Intergovernmental Panel on Climate Change, a group of experts that advises the United Nations- and other bodies linked to the UN warn that countries are not on track to meet the goals of the Paris Agreement. They must multiply by 5 their cut plans to achieve the 1.5º C target and by three for the 2ºC target. The concentration of GHGs in the atmosphere has not been reduced, they have only fallen during the crisis period (2008-2014) and in December 2019 they have increased by 1ºC and the forecast is that they will continue to increase until at least 2030. In this current situation it would be necessary to cut emissions by far more than 3 degrees foreseen in the current plans.

According to the World Meteorological Organisation, 2019 ended with maximum temperatures and carbon dioxide (CO2) emissions with 75% from fossil fuels. About half of the GHG go into the atmosphere, the rest into forests and the sea, which act as sinks. The acidification of the sea has increased by 26% since the beginning of the industrial era and extreme weather events, especially heat waves and storms, have increased.

The figures collected by the Global Carbon Project show that emissions are stagnating, but this is not enough to tackle the climatic crisis. In 2018 they grew by 2.1%, in 2017 by 1.5%. In 2019 by 0.6%, due to two factors: the fall in coal consumption in the USA and the European Union, linked to the increase in prices of this fuel, the fall in natural gas prices and overall economic slowdown. CO2 emissions in China are expected to increase by 2.6% and in India by 1.8%, while in the USA and the EU they are expected to fall by 1.7%.

According to the International Union of Public Transport (UITP), which unites more than 1,700 companies in the sector, only 35% of the countries that signed the Paris Agreement have included public transport strategies, even though experience shows that appropriate public transport systems demonstrate their effectiveness, displacing the use of private vehicles.

Globally, various pressure groups are studying global warming tipping points, points of no return and the change to positive feedback loops. The Climageddon Extinction Scenario is one of them.[1] Conversely the climate change deniers dismiss the imminent threat of climate change. Ten key ones are mentioned on the Before the Flood website[2] many of them connected with the fossil fuel industry and right wing media and political parties. The controversy between these camps was played out at the Davos 2020 meeting between President Trump and Greta Thunberg, the climate change activist where the mood of global leaders seem to have changed toward more attention to climate change.

3.2 What kind of plans?

It's impossible to think of decarbonised economies without tackling emissions cuts. At the moment, country-designed cutting plans are not sufficient to cope with the climate transition. Most political leaders do not act out of fear of social unrest since every transition has its victims. Climate agendas must help the most vulnerable sectors by adopting fair measures that accompany the losers. Politically, the energy transition cannot be at odds with economic growth, especially in developing countries.

A transformation of the economic and social model generates tensions and difficulties for vulnerable groups. Fossil fuel producing countries, whose fiscal revenues and GDP depend on this sector, run the risk of being trapped in the transition as they do not have the revenues to finance public policies. Conversely, for industrialised countries dependent on fossil fuels it is necessary to ensure transformation processes that accompany the economic and industrial reality of the affected areas.

Even the EU had not achieved consensus on a commitment to go carbon neutral by 2050 due to the reluctance of some countries until reaching a compromise position after COP25, exempting Poland from the 2050 zero carbon target. The European Green Deal's Investment Plan - the Sustainable Europe Investment Plan, SEIP - was presented on 14 January 2020 to start the transition to a green, competitive and inclusive climate-neutral economy. 1 trillion over the next decade will help unlock private funds through EU financial instruments, mainly the European Investment Bank. This bank, considered a "climate bank", will finance projects for the development of green energy and carbon capture and storage. A Just Transition Mechanism will provide financial and practical support to regions according to the degree of economic affection and transformation. Through the Just Transition Platform, the Commission will provide technical assistance to Member States and investors and ensure that affected communities, local authorities, social partners and non-governmental organisations are involved.

3.3 Public pressure

Citizen pressure is important for governments to take action and has played an important role at COP25: 800 organisations joined the parallel event, the Social Summit on Climate in Madrid. Thousands of people demonstrated to denounce the inaction of governments on climate change. Perhaps the most visible demonstrations globally have been organised by Extinction Rebellion with the cooperation of schools and young persons. Global environmental lobby Avaaz and many other NGOs are also achieving results.

Respected scientists are raising awareness with their TV documentaries. In the UK David Attenborough's Planet Earth TV programmes are widely viewed and his participation in public events such as the newly created Climate Change Citizens Assembly commissioned by 6 House of Commons select committees [3] to discuss how to meet the net zero carbon target by 2050 is influential.

Even if it is assumed that emissions are produced directly by everyone's activity, and indirectly by the energy consumed in the manufactured products used by everyone, the profile of environmental awareness and individual commitment has contradictory facets depending on the issue under consideration.

According to the European Commission, 93% of the population perceives warming as a serious problem. The survey carried out by the newspaper El País between 29 November and 4 December, in the middle of the COP25, refines the content of this global figure. The results indicate that 93.6% of the Spanish population recognise the existence of climate change; 59.5% consider that it is very urgent to take action, 31% that it is quite urgent; 65.1% are in favour of banning the use of gasoline and diesel cars and 53.4% would accept to pay special taxes (between 1 and 20 euros per month) to finance the fight against climate change. Reducing the consumption of animal proteins had less acceptance, despite Greenpeace pointing out that 14% of emissions come from intensive livestock farming.

4 POLITICAL EVOLUTION OF CLIMATE CHANGE INTERVENTION AT NATIONAL LEVEL: SPAIN & UK

This section looks at the political evolution of climate change intervention at national and city level. It focuses on Spain and the UK, and Madrid and London in the context of EU actions and examines the direction of travel of the two cities in respect to national targets. It briefly synthesises the policies of lowering carbon emissions and proposed actions taken in 2009 in Madrid and London, what actions have been taken between these dates and now and what effects they had on reducing carbon emissions, fuel consumption and air pollution.

It aims to critically evaluate progress or otherwise with climate change mitigation in Spain and the UK and in particular Madrid and London over the last ten years, in the context of other geo-political developments, such as trade wars and political upheavals in many parts of the world. Rising populism, often supporting climate doubters and protectionist trends also contributed to climate change challenges.

The climate change debate attracted prime political attention at global as well as national, city and even neighbourhood and individual level. The argument that actions undertaken by individual countries or cities were too negligible to make a difference and might hamper their competitiveness were countered by increasingly active pressure groups, often supported by very young persons who see their future at stake. Over the last ten years more countries and cities have not only set stringent targets for adverse impacts on climate change but taken action [4] to implement them at national and city level.

4.1 Climate change strategies and targets at national level in Spain and the UK

4.1.1 Population issue

Since 2009 many threats to climate change have not waned. Rapid urbanisation especially in the global South and relentless population growth are acerbating the climate change challenge. Although slowing down, population increases in both Spain and the UK (as well as in Madrid and London) are forecast to continue over the longer term and will add to their climate change pressures.

4.1.2 Decarbonisation strategies

In 2009,[5] Spain and the UK were among the leading countries to take positive actions towards their climate change problems and chose to play a global role, arguably because they were aware of their high pollution levels owing to their prolific energy consumption.

	Spain	Spain	UK	UK
overall energy consumption in mt/ktp oil equivalent/pa	147 *(2007)*	3, 261 ktp (2017)	240 *(2001)*	*143 (2018)*
overall CO2 emission in mt/kt CO2 equivalent/pa	330,497 (2004) 349m230 (2017)	10.769 kt CO2 (2017)	587,261 (2004)	364 (2017) 373.2 (2017)*

Comparative Table. Is-state: national - city energy consumption and CO2 emissions (2009 – 2019). Sources: Spain: National Greenhouse Gas Inventory Report 2019. Ministry for Ecological Transition; Madrid Energy Balance of the Municipality of Madrid, Report 2017, Madrid City Hall. UK: Climate Change Committee 2019, Carbon Brief (190204), 2017 UK Greenhouse gas emissions, final figures, statistical release, national statistics, DBEIS 2019

Spain and the UK set stringent targets for CO2 emission reductions, allocated funds for mitigation and adaptation, and acted on what was in their direct control, e.g. improving energy efficiency of their own buildings and decarbonising their transport vehicle fleet, besides awareness raising campaigns to change consumer behaviour. Ten years on, the effects of these measures are real and both countries as well as their capitals remain committed to a carbon neutral future by 2050. Although the target to reach zero carbon emissions by 2050 was agreed by COP25 in Madrid in 2019, it has been adopted by the EU in 2019 (albeit without Poland), as well as by both Spain and the UK, and London in 2017 [6] (labour) and Madrid in 2019 [7] (socialist).

Since 2009 the policies for CO2 reductions per sector have evolved and changed, influenced in part by the results of measures achieved as well as by the various sectoral lobbies. At state level, the commitment to overall CO2 emissions reductions remains firm, as well as the commitment to act on own estates and transport fleets. However, the pressures on other sectors by lobbies have impacted on targets and measures.

4.2 Spain: current situation

The challenge of climate change for Spain is particularly challenging, due to its geographical position and socio-economic conditions. While the planet increased its global temperature by 1.1ºC since the pre-industrial period, in Spain the temperature has risen by 1.7ºC.[8] 70% of Spain's surface area is at risk of desertification, and the coasts of the Mediterranean, the Balearic archipelago and the Canary Islands are especially vulnerable to rising sea levels.

The report "Climate Emergency in Spain", prepared by the Spanish Sustainability Observatory for COP25, details the effects of climate change in the country at present, which in brief are:

- the country's average temperature increased by 1.57 ºC in just 57 years, rising from an average of 14.0 ºC between 1970-1979 to 15.7 ºC between 2010-2019
- the average temperature in the provincial capitals has increased by one degree in the last 30 years. In some cities such as Madrid, Barcelona and Alicante the increase is more than 2 ºC
- the current summer is 5 weeks longer than at the beginning of the 1980s
- the surface temperature of the Mediterranean has increased by 0.34ºC per decade since the beginning of the 1980s
- the increase in the level of the Mediterranean is estimated at 3.4 mm per year from 1993 to 2017
- the increase of CO2 concentration in the atmosphere is 1.9 ppm per year since 1984
- 33 of the 52 glaciers that existed in 1850 have disappeared, most of them after 1980
- the effects on biodiversity are reflected, among other phenomena, in the distribution of species and migrations, in changes of habitats, behaviour and food
- GHG emissions fell by 2.3%, but increased by more than 15% in 2018 since 1990. Spain is the EU country that has increased its GHG emissions the most since 1990: in 27 years they have increased by 17.9% while in Europe as a whole they have decreased by 23.5%
- the ten dirtiest companies release 62% of the fixed emissions and 25% of those of the whole country
- in certain areas there have been unprecedented levels of rainfall in the last 100 years and floods have caused losses in the millions
- the last decade has seen more, larger, more intense and longer heat waves than in previous decades
- the longest, most extensive and lowest temperature cold waves were recorded in the 1980s and only one in the early the 2000s
- in 2019, 80,000 hectares of forest were burnt[9]

The solution before the damage becomes irreversible is to achieve climate neutrality by 2050, as scientists have been advocating since the 1970s.

4.2.1 National Strategies: from Kyoto to the “climate emergency" declaration

As a result of the Kyoto Protocol Agreement, Spain committed itself to limiting the increase in its emissions to 15%. The path that began in 1997 developed irregularly, associated with the political will of successive governments and the economic fluctuations of the national and international scene.

In 2004 the European Commission sent the first air quality warning to Spain - along with Austria, France, Germany, Ireland, Italy, Luxembourg, Portugal and the United Kingdom - urging it to intensify its efforts to reduce air pollution, particularly in their urban areas.

[8] according to the Spanish Meteorological Agency in December 2019
[9] "Climate Emergency in Spain", prepared by the Sustainability Observatory for COP25.

The actions adopted during the socialist government's term of office (2004-2011) were numerous, including the promotion of renewable energies and the approval of a wide range of legal instruments: National Plan for Adaptation to Climate Change 2006, Technical Building Code 2006, Spanish Air Quality Strategy 2007, Spanish Strategy for Climate Change and Clean Energy, Horizon 2007-2012-2020, derived from the Spanish Strategy for Sustainable Development 2007, Plan for Urgent Measures, Action Plan E4 2008-2012, Renewable Energy Plan 2005-2010, National Emission Rights Plan 2008-2012.

The inactivity of the subsequent conservative government (2012-2018) in environmental matters was limited, since the measures of the National Air Quality and Atmosphere Protection Plan 2013-2016 did not give the expected results and the concentrations of the main pollutants continued to increase, while the next Plan for the period 2017-2019 was not executed. During these years, affected by the severe economic crisis that devastated the country's productive base, the lack of support for renewable energies, the maintenance of coal-fired power stations and the scant attention paid to reducing polluting vehicles exemplify the absence of political interest in global warming. Faced with inaction by the central government, actions were taken by some city and regional governments. One of the main environmental organisations, Ecologistas en Acción (Ecologists in Action), highlights the dismantling of a good part of the existing environmental legislation between 2011 and 2015 - Coastal Law, Forestry Law - and the blocking of initiatives by other groups, which have prevented significant advances in environmental protection.

The results of these actions were insufficient and during these almost 20 years, the Kyoto Protocol ended up being fulfilled due to the purchase of emission rights from surplus countries and the sharp fall in emissions due to the economic crisis. Even so, Spain was warned by Brussels on numerous occasions about air quality, especially in Madrid and Barcelona, where nitrogen dioxide (NO2) limits had been exceeded for almost a decade.

According to the European Environment Agency, Spain was the European Union country where greenhouse gas emissions grew the most in absolute terms between 1990 and 2017. During this period, they increased by 51.7 million tonnes, which is 17.9%. This figure contrasts with the EU as a whole, which reduced its emissions by 23.5% in those 27 years while GDP grew by 58%.

For the socialist government elected in 2018, the climate change problem became a state issue. The creation of the Ministry for Ecological Transition (MITECO) in the same year was intended to meet the objectives set by the EU for the 2050 horizon.

The 2017 data provided by the National Greenhouse Gas Inventory Report, 2019 edition, prepared by MITECO, confirmed the seriousness of the situation: total GEI emissions amounted to 340,230.88 kilotons of CO2, which represented +4.24% compared to 2016, +17.9% compared to the base year 1990 and -23% compared to 2005. The sectors with the highest level of emissions were transport (26%), electricity generation (20%), industrial activities (19%) and agriculture (12%). The main reductions were in the commercial and residential sector (-3.3 %) and in the use of fluorinated gases (-17.2 %). Emissions covered by the Emissions Trading Scheme (40.1 % of total) increased by +10.3 % compared to the previous year.

This situation was slightly reversed in 2018. According to data provided by the National Statistics Institute (INE), GHG emissions fell by 2.3% over the previous year, making it the fourth lowest level in the last ten years.

4.2.2 National Strategies: from Kyoto to the “climate emergency" declaration

Spain officially declared a climate emergency in the country on 21 January 2020, in line with the approach taken by other countries - Ireland, Canada, France, Austria, Argentina, Malta, Bangladesh and Andorra - and many cities and regions. The fight against climate change as one of the main objectives of political action of the socialist government established in 2018.

This initiative will implement 30 lines of action, some of which are priorities:

-drafting of the climate change and energy transition act to guarantee the country's decarbonisation by 2050, using a 100% renewable electrical system, emission-neutral vehicles and a non-polluting agricultural system

-drafting of the second national adaptation plan, including the national climate observation system and the development of impact indicators

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

-creation of the citizens' assembly on climate change, a participation mechanism that strengthens cross-cutting and equal representation of the civilian population

-promotion of productive transformation, to encourage the transformation of the industrial model and the service sector through just transition agreements, to favour the sustainability of economic activities and the creation of quality jobs

This initiative affects many aspects: circular economy, sustainable tourism, demographic challenge, fight against desertification, waste treatment, sustainable mobility, financing of public transport, establishment of low emission areas in municipalities with more than 50,000 inhabitants, improvement of forestry activity, increase of protected marine areas, rural development, protection of biodiversity, opportunities for energy transition and generation of green jobs.

The Climate Change Act includes investment of more than 200 billion euros for the decade 2020-2030. The first step will be to draw up a National Sustainable Finance Action Plan and a programme for the issue of green bonds by the Public Treasury. The fiscal policy will integrate the climate change variable by generating a "green taxation" that will set dissuasive taxes and fiscal incentives to drive the transformation of the productive sector. Subsidies and tax benefits for energy products of fossil origin will be eliminated, except in cases justified by social or technological reasons, and no applications for exploration, research permits or concessions for the exploitation of hydrocarbons or fracking activities will be authorised. This is the beginning of a new path at state level, the results will be seen during the march.

4.3 United Kingdom: current situation

In the UK, more extreme weather conditions since 2009, fiercer storms, recurrent flooding, hotter and drier summers and coast erosions have risen public awareness of climate change and its impact on people's wellbeing. Consumer movements have started to demand more action from commerce and industry to curb adverse effects. Among public requests are to reduce the use of plastic in packaging, inbuilt redundancy in products, lower meat and dairy product consumption and curbing travel by air and by car, while turning more to cycling and walking.

Besides aiming at carbon neutrality by 2050, the UK has upgraded several sectoral targets as regards climate change since 2009. In 2019, UK renewable energy targets were updated to 20% by 2020, up from 15% from base line 2008 and the Climate Change Committee advised for 30%-45% renewables by 2030. However, this includes a large % of nuclear energy which needs new generation plant, while nuclear waste issues are not addressed. The transport GHG and CO2 emission targets were also updated.

sector	1990	2000	2010	2015	2020	2025	2030	2035
agriculture	58.9	54.8	48.6	49.1	46.6	44.8	44.4	44.3

UK Greenhouse gas emissions by selected source, MtCO2e (2019). Total net GHG emissions. Source UK NECP, 2019 (p 99), Updated Energy and Emissions Projections 2017. https://www.gov.uk/government/publications/updated-energy-and-emissions-projections-2017

However, despite UK targets for transportation air pollution reductions road traffic increased in Great Britain from 255 billion miles travelled in 1990 to 328 billion miles in 2018, an increase of 29%. While total fuel used for road transport in the UK remained relatively stable from 1990 to 2017 diesel use overtook petrol use in 2005. Greenhouse gases increased and made up 21% of UK total GHG emissions in 2017 while those from other sources had decreased. Nevertheless, due to more stringent exhaust emission limits, the most damaging pollutants to health decreased (CO, particulate matter, NOx), but in 2018 only 0.5% of all licensed vehicles were ultra-low emission vehicles. [10]

[10] In-Depth Q&A, the UK climate change projections 2018, CarbonBrief 190917, https://www.carbonbrief.org/in-depth-qa-the-uk-climate-projections-2018

It should be noted that changes of consumer behaviour had some impact on the government, together with the latest Climate Change Scenarios for the UK (UKCP18) which show that the trend to drier summers and hotter wetter winters in increasing, together with sea level rises. The government has introduced some measures toward some of these requests and updated its climate change related legislation generally.

4.3.1 Legal position

The main updates of UK legislation and strategies since 2009 are:

- the UK's Integrated National Energy and Climate Plan, 2019 (NECP)
- the National Planning Policy Framework, updated in 2019 (NPPF)
- the Energy Act, 2011
- UK Building Regulations Part L, 2013
- Clean Air Strategy 2019
- Lean Growth Strategy
- Climate Change Scenarios, UKCIP 02, 09 and 18
- UK 5 Carbon Budgets (latest 2028-2032, -57% by 2030, 1,950 MtCO2e).

Some competences related to climate change are devolved to the UK nations, Scotland, Northern Ireland and Wales. Despite new national legislation and recent government interventions, pressures on industry and commerce as well as on farming remain moderate. This points to a growing discrepancy between political objectives and changing wishes of the population as awareness of the climate change stress has entered the social media and public debate. An illustration of this are the disruptive demonstrations of Extinction Rebellion which were tolerated by the inconvenienced public but are under threat to be outlawed in London, despite the civil right enshrined in UK legislation to demonstrate peacefully. The frailty of climate change measures remains a crucial issue as they are subjected to sudden reversals when opposing executive political powers obtain majorities at state and city level.

5 POLITICAL EVOLUTION OF CLIMATE CHANGE INTERVENTION AT CITY LEVEL: MADRID AND LONDON

A defining issue is that implementation of state legislation and measures is bound to take place at lower levels: in regions and cities, by civic pressure groups and even individuals. Moreover, climate change issues range across traditional functional sectors and their respective competences. This points to the need of horizontal and vertical cooperation rather than confrontation driven by political self-interest which hampers progress also at global level. Furthermore, Implementation tends to stand a better chance with genuine devolution of operational competences and related budgets.

5.1 Madrid

Madrid is aware that the prevention of climate change is one of its main challenges, since the conditions of its geographical location aggravate the effects of emissions produced by urban activities and give rise to periods of dangerous levels of contaminants.

5.1.1 Air pollution

The city of Madrid adopted the first Ordinance on air pollution control in 1968. In 1978 the Automatic Pollution Monitoring and Control Network was created and in 1982 the Atmospheric Sanitation Plan was drawn up, leading to the first emissions inventory. The incorporation of Spain into the EU in 1986 meant the transposition of Directive 80/779/EC and the setting up of the reference framework for air quality assessment. The city council's actions in this respect in the 1990s focused basically on the replacement of coal-fired boilers.

The high level of air pollution recorded in the first decade of 2000 led to the approval of the Local Air Quality Strategy 2006-2010. Its action programme addressed several aspects - transport, fixed sources of pollutant emissions, urban waste - and even the need to act against climate change in response to the Kyoto Protocol. While the plan succeeded in reducing pollution levels, the Air Quality Plan 2011-2015 recognised the difficulties of meeting the targets set by the EU, in particular those produced by urban traffic which

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

accounted for 65% of NOx emissions in 2009. The main objectives of this plan were to discourage and restrict the use of private motorised vehicles and to promote public transport and alternative modes of mobility. The most relevant urban development action was the delimitation of a Low Emission Zone in the city centre, a proposal that was never implemented. The actions were limited to the pedestrianisation and tempering of some streets and the delimitation of four Residential Priority Areas in which access to non-resident vehicles was restricted.

In parallel to these measures, critical air conditions at certain times of the year due to a combination of meteorological factors and pollution levels, led to the adoption in 2016 of the Protocol of measures to be taken during episodes of high nitrogen dioxide pollution, activated since then every December, with the exception of 2019.

Nevertheless, these measures were not sufficient to meet the objectives of national and European legislation despite successive EU warnings. The left-wing municipal government which took office in 2015 drew up Plan A, proposing a set of measures organised into four lines of action: sustainable mobility, urban regeneration, adaptation to climate change and citizen awareness-raising.

5.1.2 Territorial and design measures

The most outstanding action of Plan A was the delimitation of the Central Zero Emissions Area, 472 hectares free of vehicles and with new spaces for pedestrians, bicycles and public transport. This measure included the reform of the main access roads to the city centre, especially the Gran Via. Despite the fierce reaction of the political opposition party, previously in municipal power, and certain social factions which were reluctant to eliminate vehicle traffic, the proposal was carried out between 2017 and 2018. The implementation of Madrid Central and the reform of the Gran Vía not only meant the reduction of pollution levels in the city centre but also the most important urban transformation developed by the city council during the last decades.

The first action of the conservative government that won the municipal elections of May 2019 was to eliminate Madrid Central due to its alleged lack of effectiveness, allowing vehicles to enter the area again. The intervention of Ecologistas en Accion, Greenpeace and the Plataforma en Defensa de Madrid Central (Platform in Defence of Madrid Central) led to the Madrid courts alleging health and environmental reasons for not eliminating the entry of vehicles into the capital's low-emission area.

5.1.3 Revision of GHG emission targets

The proposal of 2019 includes the design of a specific plan and initiatives, political as well as economic, to guarantee the progressive reduction of greenhouse gases in order to reach zero net balance no later than 2040 and, if possible, before 2035.

The response to this legal setback was the presentation in January 2020 of a new plan that will replace the current one: Madrid 360. The new plan aims to be the tool with which Madrid city council will definitively comply with the air quality limits established in Directive 2008/50/EC of the European Parliament and of the European Council of 21 May 2008. It intends to reduce nitrogen oxide emissions by 15% more than what was proposed in Plan A, as it provides for a 20% reduction in NOx by 2023.

5.1.4 New measures

One of the most unique measures included in Madrid 360 will be the pedestrianisation of the Puerta del Sol square and its surroundings with the aim of turning it into a true zero emissions zone. Another flagship measure is the Zero Line, zero emissions and zero cost for users, formed by two bus lines to move across the Centre district. In addition, another low emission perimeter line is proposed around the Central district, for a fee. All the buses of the Municipal Transport Company will also be renewed, incorporating electric vehicles.

With regard to traffic restrictions, they will depend on the environmental marking of each vehicle and no non-resident may park on the surface. Unlike the previous plan, vehicles belonging to shopkeepers in the area and those occupied by more than two people will be allowed to circulate freely, a measure that has already been contested by environmental groups that are committed to the total elimination of traffic. To facilitate the decarbonisation of the city, economic aid is planned to replace polluting vehicles with technologically advanced ones.

It is hoped that the actions taken by the new administration will fulfil their mission, since at the end of 2019 the Madrid City Council, in line with the EU, declared a climate emergency.

5.2 London

Over recent years, the Greater London Assembly and the Mayor of London have acquired a number of new competences, but only few related to climate change issues, and their tax and fund raising powers remain very limited and tend to be ultimately under the control of central government.

5.2.1 London climate change strategies and targets under changing governance

Regarding London's environmental policy, the political position of climate change has altered in London since the inception of its own government, Greater London Assembly and directly elected Mayor in 2000. The fist mayor of Greater London Ken Livingstone (labour, 2000-2008) had a very progressive approach to the environment. He had commissioned scientific studies and projection methods to establish London's is state and what targets and measures were needed to curb environmental pollution.

This was not least due to his lobbying that under the Greater London Authority Act 2007 the mayor has a new statutory duty to contribute towards the mitigation of, or adaptation to, climate change in the UK and to produce statutory strategies for climate change mitigation and energy and for adaptation to climate change in London. In 2008 this included retrofitting existing buildings which contributed 73% of CO2 emissions and make fuller use of Combined Cooling Heat and Power (CCHP) technologies. [11]

The subsequent mayor Boris Johnson (conservative, 2008-2016) had other priorities but did not alter the environmental policies of the previous London Plan significantly. He did not rock the ecology boat because it was in his political interest, not for reasons of continuity. Reaping the fruits of the Olympics to London brought to London by the previous mayor gave him greater political gains.

The current mayor Sadiq Khan (labour, 2016-2020) continues to support climate change mitigation actions but with a less firm approach as his priority is with social housing provision (which is not happening though, due to the structure of the neo-liberal housing market system in the UK, the vested interests of land owners and property investors, including unchallenged global ones and lack of mayoral competence in this field).

5.2.2 The new Draft London Plan 2017 and updates

Mayor Sadiq Khan considers his "Replacement Plan" as different from its predecessors with its declared focus on sustainable development. Climate change holds a modest role in the mayor's concept of "Good Growth" - socially and economically inclusive and environmentally sustainable - which is underpinning his new statutory draft London Plan 2019. Policy GG6, "Increasing efficiency and resilience", seeks to improve energy efficiency, support move towards a low carbon circular economy, contribute to London becoming a zero carbon city by 2050 and ensure that buildings and infrastructure are designed to adapt to a changing climate.

His broad environmental goals, climate change targets and actions are laid down separately in non-statutory documents: The London Environment Strategy, 2017[12] (for public consultation), The Climate Action Plan, 2018[13] where the overall CO2 reduction target is set at 40% to be reached between 2018-2022, 50% between 2023-2027 and 199% by 2050 and the Zero Carbon London, A 1.5C Compatible Plan, with its amendments in December 2018.

In 2014, London's GHG emissions were estimated at around 38 MtCO2e, 7% of UK's total emissions. They have fallen by 26% since 1990, largely due to reduced gas consumption and decarbonisation of the national electricity grid. In 2014 35% of emissions were estimated generated from homes, 42% from workplaces, and 23% from transport. Measures will include retrofitting existing buildings and higher insulation standards for new build. The London Environmental Strategy shows how reaching the 2050 is expected to be achieved through combined electricity and gas grid decarbonisation and local action, the latter subject to funding.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

London electricity demand accounts for almost half of total CO2 emissions which are decreasing with increasing use of renewable electricity generation (25% of total UK generation, to reach 59% by 2030 included nuclear energy). Unfortunately, no similar actions are taken to decarbonise gas which amounts to about half of total energy consumption in London, contributing 30% of London's total GHG emissions.

Energy consumption is to be reduced by reaching 15% of renewable district energy supply by 2030. Measures are local zero emission zones and increasing numbers of ULEZ (Ultra-Low Emission Zones), zero emissions of own car fleet by 2025, of heavy vehicles by 2030 and of buses by 2037. As regards buildings all new building should be zero carbon by 2019, and minimum energy performance standards introduced in all rented properties. Smart meters should be installed in every home by 2020 and lofts and cavity walls insulated by 2020, as well as gas boilers replaced by high efficiency models. By 2030 there should be wide deployment of low carbon heating like heat pumps. London carbon budgets show the required energy efficiency levels for housing, non-domestic and transport to meet these targets.

London produced 18 mt of waste in 2015 (3.1 mt household is 17%, 5.0 mt commercial industrial is 28%; 9.7 construction demolition excavation is 54%). Direct GHG emissions from waste represent 2% of London's total. Only 52% is recycled and the target is to increase recycling to 65%, reduce food waste by 20% by 2025 as well as single use packaging waste and to generate low carbon energy from residual waste, leaving very little to landfill. This is estimated to save 101,000 t of CO2 in 2021, 169,000 t by 2025, and 535,000 tCO2e by 2031.

A number of policies consolidated in Chapter 9 "Sustainable Infrastructure" contribute to the mayor's commitment to London becoming a zero-carbon city by 2050. They are: [14]

Policy SI1 improving air quality, Policy SI2: minimising greenhouse gas emissions, Policy SI3 energy infrastructure, Policy SI4 Managing heat risk, Policy SI7 Reducing waste and supporting the circular economy.

[14] Policy SI1 improving air quality
Reference to Air Quality Focus Areas. Large developments should use Air Quality Positive approach, and others should be Air Quality Neutral, and comply with the Non Road Mobile Machinery Low Emission Zone (reduce emissions from demolition and construction). Air Quality Assessments -AQAs should be submitted with new developments. Onsite reduction is preferable but offsite equivalent provision is possible. Measures to reach Air Quality Positive could include with low or zero emission heating and energy, improvement of public transport, walking and cycling infrastructure, avoid street canyons which prevent effective dispersion of pollutants, use sensors. See GLA's LAEI: the London Atmospheric Emissions Inventory. See also Air Quality Focus Aras (AQFA) map, 2017. Key performance indicators and measures: air quality. Positive trend in approved referable development applications demonstrating that they meet at least air quality neutral standard for emissions (based on a rolling average).
Policy SI2: minimising greenhouse gas emissions
A major development should be net zero carbon (reducing CO2 emissions from construction and operation, minimise annual and peak energy demand. Major developments should include besides an Environmental Impact Assessment a detailed energy strategy to demonstrate how the zero carbon target will be met within the framework of the energy hierarchy (see diagram: reduce energy use, clean through energy efficiency, green through renewable energy, offset) and be monitored, re energy performance. A minimum of 35% of on-site reduction beyond building regulations 2013 part L is expected (10% for residential, 15% non-residential through energy efficiency measures). London Boroughs to use BREEAM measures and targets in local plans.
BUT in lieu: cash to borough carbon offsite fund and/or offsite alternative proposals are possible but should be minimal by using carbon offset price mechanism. Maximise onsite electricity and heat production (using solar, photovoltaic, thermal, innovative building materials, smart technology. More in London Environment Strategy.
Policy SI3 energy infrastructure
Produce energy masterplans for large scale developments (establishing most effective energy supply options)
Development plans should identify suitable sites for necessary energy infrastructure requirements and upgrades of existing ones.
Large scale developments within heat network priority areas should have a communal heating system following the heating hierarchy (e.g. decentralised heat pumps, heat from zero emission sources, fuel cells, low temperature networks, low emission CHP, low NOx gas boilers, secondary heat sources, connected to existing heat networks where feasible, facilitate new connections.
See map heat network priority areas. Increase use of renewable energy sources and CHP.
Policy SI4 Managing heat risk
Developments should minimise internal heat gain and impact on urban heat islands, reduce potential overheating and reliance on air conditioning.
Policy SI7 Reducing waste and supporting the circular economy
Increase recycling and reuse, produce low carbo energy from waste (65% by 2030 from municipal waste, 95% by 2020 from construction and excavation waste). But waste bags are littering London streets inordinately which are a health hazard, an environmental pollution risk and an image problem.

5.2.3 Sustainable transportation policies and GHG emission reductions

GHG emissions from transport were around 8.6 MtCO23 per her in 2914. They aim is to reduce it to 1.5 MtCO2e a year by 2050. The Mayor's Transport Strategy aims to reduce CO2 emissions from road, rail and shipping by 72% by 2041. Aviation which contributes 2,5% of GHG in London (around 950,000 tVO2e per year) and curbing them appears difficult. Heathrow expansion is likely to increase them by 1/3.

The mayor's key London transport strategy is that 80% of all trips in London will be made on foot, by cycle or using public transport by 2041. Towards this aim he has developed a walking action plan, a cycling action plan.

London's congestion charge was conceived by the first London mayor and implemented. The next conservative mayor revoked the planned extension of the congestion zone in central London (in the richest borough), while the current labour mayor introduced ULEZ, Ultra low Emissions Zones in central London in 2018 and plans to extend them to the outer ring road (North and South circular) In 2011, the congestion charge cut CO2 emissions by 16% (100,00 t) = -1% of London's total road traffic in 2011. Half was due to 75,000 fewer vehicle daily, and half to remaining traffic experiencing less congestion. [15] Since then, car traffic has increased again in the congestion charge area but no monitoring data is available. ULEZ has reduced emissions of nitrogen oxides (NOx) by some 29% in January 2020 since its inception in April 2019.

The London Plans put more emphasis on cycling, A hire cycle infrastructure was provided with sponsorship from banks. Cycle superhighways were constructed across London and are planned to extend to outer London. Where lanes were established it is estimated that cycling has increased by up to 53%. Total daily distances cycled have reached 4 km in 2018-2019. [16] Car pool companies obtained licenses to operate in London. Charging infrastructure was gradually provided for electric cars but the uptake is slow and the charging facilities considered insufficient and too slow. Walking is advocated but facilities are hampered by prioritising traffic flows, although they average only 11 miles in central London during rush hours and idling engines are a pollution problem. The cycle highways have attracted or catered for increasing numbers of cyclists (commuters) in London, but the reason for this increase may also be extensive commuter train strikes and steep fair rises of rail and regional and local transport. The aim of the current mayor is to shift transport modes toward cycling, walking and public transport.

In the London Mayor's Transport Policy 2018 the target of mode share is in 2041: 20% car, taxi, private hire vehicle - 80% walking, cycling, public transport for 33 million day trips, from 2015: 37% car, taxi, private hire vehicle - 63% walking, cycling, public transport for 26.7 million day trips

5.2.4 Energy strategy, consumption reduction targets and energy efficiency measures

The London Energy and Greenhouse Gas Inventory (LEGGI) presents the factual situation of energy consumption and level of carbonisation of London for all sectors (homes, workplaces and transportation from 2008 to 2017.[17]

London's energy consumption was 134,653 GW in 2017 in total (54,829 GW domestic, 47.727 GW industrial and commercial, 32,098 GW transport). This compares with 149.388 GW in total in 2009 (63,462 domestic, 54,413 industrial and commercial, 32,479 GW transport). [18] London's CO2 emissions from energy use were 30.3 mt, a 30% reduction on 1990 levels, and a 40% reduction since peak emissions in 2000. This is despite an increase of population by nearly 30% since 1990. London's per capita emissions are estimated at 3.4 t of CO2e in 2017, down from 3.5 of CO2e in 2019.

London's energy strategy includes measures to reduce electricity consumption,[19] decentralise energy generation, decrease fossil fuel use and increase renewable energy use. Energy consumption has indeed declined in London since 2009, but for various reasons and efficiency measures are among them. The Draft London Plan is poor in is-state data on energy consumption, CO2 emissions, energy status of building stock, etc. not least because sources of information are fragmented and often privatised. This may pose a problem

for proper monitoring of the effectiveness of the targets. Natural gas consumption has decreased in London by 25% since 2000, according to the London Energy and Greenhouse Gas Inventory (LEGGI).

A key problem with all these targets is that the Greater London administration does not have the competence of implementing most of them and has to rely on the London Boroughs to act upon their own housing stock and transport fleet, and mainly on the private sector which owns and supplies the bulk of London's built environment. Nevertheless, the Mayor of London has competences over a number of specialised agencies: Transport for London, the London Development Agency (Olympic site), the London Fire and Emergency Planning Authority, the Metropolitan Police. He can influence their operational actions directly and make them lower adverse effects on climate change in the Framework of the London Plan. The London Plan has also certain powers to influence the London Boroughs, through guidance toward lowering adverse climate change impacts and reducing GHG emissions. The key actions focus on transportation, retrofitting existing building stock and standards for new build.

It has to be stressed that targets are not reality, and measures to implement them are of the essence at all levels. Monitoring results show that most of these targets are not met within the prescribed timeframe. Nevertheless setting targets it useful to mobilise public opinion and change behaviour.

Overall, the current mayor has adopted the 2050 zero carbon target for London in 2016 and laid down implementation objectives in his Draft London Plan. Quite a few actions can be undertaken by the Greater London Authority itself and the agencies under the Mayor, in particular Transport for London, but the majority of its targets will need to be pursued by lower tier authorities, the London Boroughs and the private sector which owns the energy utilities and some transportation networks in London.

However, while targets have been made more ambitious, their realisation lags behind when measured at interim periods which would require increasingly stringent actions to achieve a carbon neutral state in 2050. It means also more efforts to reach consensus and cooperation from all stakeholders who will weigh up how achieving these targets will affect their habits, living standards and aspirations against saving them and the planet from climate crisis.

6 CONCLUSIONS

Environmental concerns are not new and have evolved over time. A major wave of environmental awareness occurred in California in the 1960s, followed and sustained elsewhere. The language was different then. Activists talked about environmental protection, ecological footprint reduction and balancing the eco-system. In the 1970s the Gaia hypothesis (Earth System Science in the USA) of perpetual conditions for life became popular. [20]

The discussion shifted to global warming in the 1980s and to climate change in the 1990s. Greenhouse gas emissions from energy production and use were already mentioned as harmful in the 1950s and NASA studied their evolution from the 1970s to today. Global warming became a political issue with governments which were setting targets and promising action. In the 21st century the discussion moved to the green economy combined more recently with the circular economy. In 2020, climate change gained political and market attention at the World Economic Forum in Davos. Safe on the benefits of trees, little consensus transpired on a way forward though. The UN was and remains actively involved in curbing adverse climate change effects, but as a voluntary intergovernmental agency it has little power over global action.

At national level, politicians have more control over their commitments and actions than international agencies. Both Spain and the UK have signed up to the Paris Agreement, and introduced a target of zero carbon emissions by 2050. Moreover, they have introduced strategies for practical measures to achieve these goals.

Implementation however is mainly in the hands of lower tier administrations and in market economies in those of the private sector, besides individual behaviour change. Clearly, operational interventions are mainly carried out by regional and city governments and private industry. Community groups and individuals also play a role by both realising local schemes and exercising pressure as consumers which can influence industry and commerce. Indeed, large corporations have started to rethink their attitudes and even take measures toward climate change concerns, while some investors have moved their assets out of fossil

[20] James Lovelock. Gaia, a new look at life on earth, 1979, Oxford Landmark Science.

fuels. Company accounting standards for climate related risks and a price on carbon may accelerate that, although many firms still resort just to 'greenwash'.

Looking back at two decades of climate change and its responses in Spain and Madrid and the UK and London, what are the lessons to be learnt? A number of overarching issues seem to emerge from the empirical data and the changing debate on the future of the planet.

6.1 Climate change targets

Ambitious climate change targets have been set at both the state and city levels, but their materialisation seems very unlikely. So the question is, should their decision makers abandon targets or reduce them to more doable levels or should they tag their visions high as an incentive for others to follow?

Despite tangible effects of climate change any consensus on what goals to adopt and what actions to undertake seems to be difficult to achieve both at city and national level, and even more so by the international community at global level.

A major impediment to climate change mitigation and adaptation which by nature are long term is the political system with its short term cycles and its often abrupt swings between opposite parties. In this complex game key players make their moves at their convenience, but subject to specific rules: the international level dependent on national interests, the European Union as guarantor of collective compliance, the nation states dependent on the economy and the political constellations, the municipalities dependent on votes, and civil society according to their beliefs and prejudices. Moreover, at all levels the players are divided between those who believe that the planet has reached its limits and those who let others make the sacrifices.

6.2 Political power swings

The paper corroborates that every democratically elected swing of political power tends to reverse previous directions of travel and seriously undermine long term progress of combating adverse effects of climate change, despite some efforts at both national and local levels of future proofing such actions. Only a multiparty adoption of remedial objectives stands a chance of realisation. Similar differences of opinion permeate the private market and sometimes civil society, in particular opposing protagonists of the circular green economy to those who believe in purely technological fixes which would enable them to continue with business as usual.

6.3 Actions by civil society

Increasing consumer pressure for sustainable products and services may influence the corporate world, but dependence on energy and fear of declining living standards may overrule such change also among consumers. International 'green' pressure groups requesting sustainable alternatives to current practices and their detrimental impact on global warming, as well as local communities which undertake measures to curb global warming may draw attention of the media but do not command the necessary critical mass to enforce radical change. Not surprisingly in a world where global corporations are often more powerful and wealthy than sovereign countries even in representative democracies the electorate does not necessarily obtain actions to mitigate greenhouse gas emissions promised in political manifestos.

6.4 Who is leading climate change action of the future?

The question remains of where the combat against global warming is going from here, and who will be responsible to lead it in the future? The last word ought to remain with the very young who will have to live with the consequences of the rapid march to global warming. The deserve all the support of those who try to understand the phenomenon and are searching for practical solutions.

Co-Creation and Sustainable Urban Planning: Who Co-Creates Sustainable Mobility Solutions at the Neighbourhood Level? Experiences from the Horizon 2020 Project "Sunrise"

Nadine Haufe, Lukas Franta

(Nadine Haufe M.A., TU Wien, Institut of Spatial Planning, Research Unit Sociology, Karlsplatz 13, 1040 Vienna, nadine.haufe@tuwien.ac.at)
(Lukas Franta Msc., TU Wien, Institut of Spatial Planning, Research Unit Sociology, Karlsplatz 13, 1040 Vienna, lukas.franta@tuwien.ac.at)

1 ABSTRACT

Co-creation is applied as a key concept to develop, implement, assess, and facilitate learning about new ways to address urban mobility challenges at the neighbourhood level in the HORIZON 2020 project SUNRISE[1] ("Sustainable Urban Neighbourhoods - Research and Implementation Support in Europe"). SUNRISE's objective is to contribute to sustainable urban development by stimulating co-creative processes and problem solutions in neighbourhoods in the field of new mobility concepts and new forms of mobility. Towards this aim, six cities (Bremen, Budapest Jerusalem, Malmö Southend on Sea, Thessaloniki) are fostering comprehensive collaborative processes with various actors in specific neighbourhoods with the explicit mandate to implement sustainable mobility solutions.

The involvement of different actors is an important aspect and a challenge for co-creation processes. On the one hand, the involvement of residents and other stakeholders in sustainable urban planning is seen as promising. in terms of achieving better results to improve the adaptability of socio-ecological systems. On the other hand, there are often questions such as: "who is participating?", "how can different actors be reached?" and "what results can be achieved with co-creation?". This paper provides answers to these questions based on experiences from co-creation processes in the SUNRISE project. After defining and embedding the term co-creation in planning theory, this paper gives an overview of the involved actors in the co-creation processes in SUNRISE, the co-creation activities carried out, and the mobility solutions developed on the neighbourhood level. Finally, the challenges of involving various actors in co-creative processes and the opportunities for co-creation when planning sustainable mobility solutions on the neighbourhood level will be discussed.

Keywords: Sustainable Mobility, Mobility Planning, Participation, Co-Creation, Neighbourhood

2 INTRODUCTION

New calls for transformational development processes and fresh urban planning agendas are being fuelled by the effects of climate change, discussions about necessary shifts in energy and transport, as well as the demand for liveable cities. In urban planning, participation is considered an important element in promoting sustainable spatial development (Zimmerman & Höflehner 2016: 1). In participatory planning, residents and other stakeholders are invited to participate in planning or decision-making processes with the idea that participation can influence the content of planning (see Healey, 1997; Innes, 1998; Innes and Booher, 1999). The involvement of residents and other stakeholders in urban planning is seen as promising, for example to achieve better results and improve the adaptability of socio-ecological systems (Healey, 1997; Innes and Booher, 1999; Olsson et al., 2004).

Participatory planning allows for integrating the needs and requirements of local stakeholders into urban planning and is often seen as a good lever to solve urban challenges (Zimmermann & Höflehner 2016: 1). Nevertheless, existing participation practices in urban development are partially insufficient to address new demands and needs arising from these urban problems creating dissatisfaction among stakeholders. Furthermore, participatory planning processes are often criticized for inefficiency. Residents and other actors are disappointed with the lack of opportunities to have an influence on the planning process while planners remain uninformed about residents' concerns, experiences, and the local conditions (Reed, 2008; Grönholm, 2009). Therefore, urban planners, policy makers, and citizens are experimenting with new collaborative approaches like co-creation to tackle persistent urban issues, such as climate change adaptation, quality of life, and urban inequalities (Puerari et al. 2018: 1).

[1] This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 635998

In the HORIZON 2020 project SUNRISE, co-creation is the key concept applied to the development, implementation, assessment, and facilitation of learning about new ways to address urban mobility challenges at the neighbourhood level. SUNRISE's objective is to contribute to sustainable urban development by stimulating innovative, participatory, and problem-solving processes in neighbourhoods in the field of new mobility concepts and new forms of mobility. Towards this aim, six cities including Bremen, Budapest, Jerusalem, Malmö, Southend on Sea, and Thessaloniki apply comprehensive collaborative processes in specific neighbourhoods. Their explicit mandate is to foster and implement innovative solutions for and with their residents and other actor groups.

The involvement of different actors is an important aspect of and challenge for co-creative urban planning processes. On the one hand, the involvement of residents and other stakeholders in sustainable urban planning is seen as promising, like to achieve better results and improve the adaptability of social-ecological systems. On the other hand, there are often questions such as: "who is participating?", "how can different actors be reached?" and "what results can be achieved with co-creation?". This paper provides answers to these questions based on experiences from SUNRISE co-creation processes for planning sustainable mobility solutions on the neighbourhood level. After defining and embedding the term co-creation in planning theory, this paper gives an overview of the involved actors in the co-creation processes in SUNRISE, the co-creation activities carried out, and the mobility solutions developed on the neighbourhood level. Finally, the challenges of involving various actors in co-creative processes and the opportunities to co-creatively plan sustainable mobility solutions on the neighbourhood level will be discussed.

3 CO-CREATION AS NEW FORM OF PARTICIPATORY PLANNING IN SUSTAINABLE URBAN DEVELOPMENT

3.1 Co-Creation: A new term in urban planning

In urban planning, participation is an important element in promoting sustainable spatial development. New participatory concepts like co-creation are developing and spreading worldwide, with the aim of supporting sustainable urban transition and transformation. Originally conceived in the 1990s as a new business strategy for customer engagement (Leading Cities 2014: 1), co-creation is an increasingly common concept in the context of urban planning today integrating various actors in planning processes to create something together (Schönfeld et al. 2019: 1). However, the concept of co-creation in urban development is by no means clear and well-defined (Leading Cities 2014: 3; Lund 2017: 29; Puerari et al. 2018: 4).

In the program "ERA-NET Cofund Smart Urban Futures", the European Commission defines co-creation as "an approach where heterogenous actors collaborate to produce knowledge, instruments, technology, artefacts, policy, know-how, etc." (JPI Urban Europe 2016: 52). Schneidemesser et al (2019: 3) add a processual aspect and define the concept of co-creation based on the following three dimensions:

- In a social dimension, co-creation describes a reciprocal exchange-based collaboration between heterogeneous actors.
- In a material dimension, co-creation describes how the interaction of different perspectives generates something unexpected, which the involved actors can use.
- In a temporal-spatial dimension, co-creation describes those processes that enable relatively autonomous actors to exchange ideas or to create values together.

From this perspective, co-creation is a form of collaboration in which knowledge, instruments, technology, artefacts, policy, know-how, plans etc. are created through an ongoing process among heterogeneous actors (Schönfeld et al. 2019: 3). The research group Leading Cities (2014: 3) identify the heterogenous actors and define co-creation as "the active flow of information and ideas among five sectors of society: government, academia, business, non-profits, and citizens - the Quintuple Helix - which allows for participation, engagement, and empowerment in developing policy, creating programs, improving services, and tackling systemic change with each dimension of society represented from the beginning".

In summary, co-creation is characterized by the fact that heterogeneous actors from different sectors are mobilized in a collaborative process to create something together. Based on the definitions above, Haufe & Franta (2019: 55) understand co-creative urban planning as the set of interconnected processes in which heterogeneous actors mutually interact and work together to develop answers to urban challenges in the form

of knowledge, instruments, technology, artefacts, policy, know-how, and plans, etc. (Haufe & Franta 2019: 55).

In contrast to traditional participatory practices in urban planning, which still often only aim at engaging citizens, the inclusive nature of co-creation provides the public, private, non-profit and academic sectors as well as citizens themselves the opportunity to serve as equal stakeholders. In co-creative processes, new forms of cooperation and mutual learning processes emerge between actors among different sectors of society (Zimmermann & Höflehner 2016: 1-2). In order for this to happen, it is necessary to socio-culturally (open of diverse group of participants), strategically (thematic openness, open-ended results, open structures) as well as operationally (open flow of information, knowledge and ideas) open up the processes (Raffl et al. 2014: 47). Doing so provides the opportunity for everyday and expert knowledge to work together to solve problems and to develop ideas (Petrin 2016: 163). Co-creative urban planning thereby focuses on integrating different forms of knowledge into urban processes in order to create innovative solutions for complex urban problems (Haufe & Franta 2019: 58).

What further distinguishes co-creation from other participation initiatives is the involvement of the various stakeholders from the beginning to the end of the planning process. Rather than ask people to “plug into” existing pre-determined programs, initiatives, or campaigns, co-creative approaches should help people form and promote their own decisions, create new stakeholder maps, and develop open-ended processes (Leading Cities 2014: 5). Co-creation is ideally an endless process and can be understood as an overarching development philosophy (Davis & Andrew 2016: 653). Therefore, co-creation focuses primarily on long-term culture change, rather than on short term outcomes, issues, or achievements, and includes a cross-section of entire communities rather than parts of them (Leading Cities 2014: 5). In this sense, co-creation is not only an approach for creating product or service innovation, but also a way of creating social innovations such as the intentional reconfiguration of social practices like collectively shared values, knowledge etc. (Puerari et al., 2018: 5).

In recent years co-creation has become a buzzword in urban planning and is often also seen as a new concept in planning. However, as a form of collaboration among multiple actors, the concept of co-creation in planning is based on participatory literature of previous decades. The following section shows that co-creation is not a new concept but rather a concept based on the communicative and collaborative planning theory developed within the last four decades.

3.2 Urban planning as collaborative practice

In response to the growing crisis of technocratic planning in the 1970s, various planning approaches in the 1980s and 1990s focused on the stronger involvement of different actors in planning processes. With the realisation that expert knowledge alone did not achieve the ‘optimal’ solutions for spatial development, a new paradigm of planning developed, which defined planning as a communicative practice (e.g. Forester 1989, Healey 1992, Innes 1995, Selle 1996). This new planning paradigm is based on an understanding which recognises the diverse ways of living that exist in pluralist societies. In comparison, traditional planning focuses on scientific rationalism in a culturally homogeneous community with a public interest (Healey, 2006). In planning literature, this change is also called "communicative turn" or "argumentative turn" (Forester 1989, Healey 1992, Healey 1996). Several scholars (Innes and Booher 1999; Margerum 2002; Healey 2003; Maginn 2007; Lofgren and Agger 2008) have also defined this new planning paradigm as collaborative planning.

Patsy Healey, one of the main proponents of collaborative planning, outlines that a city its residents identify with requires the inclusion of the diverse urban actors and the actors’ various interpretations of the city in the planning process (Healey 2002: 1778). The collaborative understanding of planning assumes that common solutions to planning problems can be found only through participation of all relevant actors, the consideration of their life worlds and the creation of political communication and cooperation structures (Healey 1997). The focus is on negotiating a consensus that represents the best possible solution for all involved (Streich 2005). Collaborative processes thus include the articulation of different interests, the critical questioning of expert opinions, the agreement on relevant topics and content, the formation of opinions and a final decision, which everyone can agree upon (Innes 1996). The aim is to overcome one-sided communication between government or experts and the population by initiating active exchanges

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

between all state, economic, and civil society actors (Innes and Booher 2004) to establish a common understanding for future planning (Healey 1992).

Collaborative planning theory approaches operate at the intersection between planning bureaucracy and actors in society (Ipsen 2010: 238). These collaborative planning approaches question both, the hierarchical relationship between bureaucracy and societal actors, and the role of state-sovereign planning as the only planning authority. Instead, a consensus-oriented planning process is designed in which the legitimacy of planning practices only can be produced by negotiating with various public and private actors (Gribat et al. 2017: 10). According to communicative planning perspectives, participation is at the root of planning (e.g. Friedman 1987 & 1989, Healey 1992, Innes 1995). To plan according to this view is to communicate, argue, debate, and engage in a discourse for the purpose of aligning attention and defining the possibilities for action (Puerari et al. 2018: 4).

Habermas' theory of communicative action (1981) and his discourse ethics (legitimacy, truth, accessibility, argumentation logic) provided the basis for communicative and collaborative planning (Ipsen 2010: 238). Healey described collaborative planning as "a new form of planning, a respectful argumentative form of planning through debate, appropriate to our recognition of the failure of modernity's conception of 'pure reason', yet searching, as Habermas does, for a continuation of the Enlightenment project of democratic progress through reasoned inter-subjective argument among free citizens" (Healey 1992: 160).

The distinguishing feature of collaborative planning to technocratic planning is that it delegates the responsibility for planning directly to involved actors (Gunton & Day 2003: 6). It encourages people to engage in a dialogue in a situation of equal empowerment and shared information, to learn through mutual exchange, to create innovative outcomes, and to build institutional capacity. The dialogue promotes sharing information, understanding the perspectives of other partners, and creating innovative results. Institutional capacity, which is considered a combination of social, intellectual, and political capital, proliferates through networks of mutual trust and makes civil society more competent (Innes and Booher, 2004; Healey, 2006). The collaborative process is a cycle that includes dialogue, trust building and commitment, shared understanding, and (intermediate) outcomes (Purbani 2017: 138).

Co-creation is a form of collaboration in which knowledge, instruments, technology, artefacts, policy, know-how, plans etc. are created through ongoing process among heterogeneous actors (Schönfeld et al. 2019: 3) This section showed that co-creation is not a new concept but is rather based on the communicative and collaborative planning theory developed in the last four decades. Nevertheless, co-creation has become a buzzword in urban planning because urban planning today is based on the assumption that urban spaces have a social significance that cannot be met by technocratic planning alone. The increasing demands on the city require an approach that takes the needs and perspectives of different actors into account in an inclusive and democratic manner. For this reason, it is important to keep an eye on the diversity of urban society in order to ensure constructive development of topics and processes that are difficult to predict (Grünzel 2014: 75).

When arenas for mutual exchange and collaborative planning are created, the focus is on questions such as "Who is participating?", "How can different actors be reached?", "What is being negotiated?". With the Horizon 2020 project SUNRISE as an example, the following section will analyse the implementation of co-creative processes with local actors for finding sustainable mobility solutions at the neighbourhood level.

4 CO-CREATION IN PRACTICE - THE HORIZON 2020 PROJECT "SUNRISE"

4.1 Development of sustainable mobility solutions at the neighbourhood level: The Horizon 2020 project SUNRISE

Since the Paris Climate Accord of December 2015, it is clear global carbon dioxide emissions will have to be dramatically reduced if global warming is to be limited to 1.5 degrees compared to the pre-industrial era. For the mobility sector, this means the need for (infra-)structural and behavioural changes in addition to the phasing out of fossil fuels also at city level. In 1989, Newman and Kenworthy were able to determine in an international comparative study of urban regions that the use of cars, the volume of traffic, and the energy requirements of transport negatively correlated with the density of settlements. These results are an argument for compact, mixed-use neighbourhoods, which not only helps to reduce greenhouse gas emissions, but also offer great potential for the attractive design of cities and neighbourhoods (Neumann 2010: 207). Therefore,

neighbourhoods are increasingly becoming the focus of sustainable urban development (Roselt, 2016: 1). For co-creation, neighbourhoods may be ideal "real-life laboratories" to experiment, learn, and advance transformation which ideally has a positive impact on the entire city (Brocchi 2019: 250).

In the HORIZON 2020 project SUNRISE ("Sustainable Urban Neighbourhoods - Research and Implementation Support in Europe"), co-creation is the key concept to develop, implement, assess and facilitate learning about new ways to address common mobility challenges at the neighbourhood level. Towards this aim, six SUNRISE cities (Bremen, Budapest, Jerusalem, Malmö, Southend on Sea, Thessaloniki) are fostering collaborative processes in specific neighbourhoods as "Neighbourhood Mobility Labs" with the explicit mandate to implement innovative solutions for and with their residents and other actors.

All SUNRISE activities are structured along the phases of the innovation chain and based on co-creation. In a multi-stage process, actors from different sectors of society jointly identify mobility-specific problems in the neighbourhood and cooperatively develop mobility solutions. These mobility solutions will be jointly implemented as part of the SUNRISE project. Continuous monitoring and evaluation accompany the co-creation process in SUNRISE as well as dissemination and learning activities.

The co-creation processes in each SUNRISE neighbourhood are initiated by local city partners from administration, community management or by integrated planning offices. A steering committee called "Core Group", composed of different local actors representing their neighbourhood, steers the co-creation process. For the collaborative planning processes, each SUNRISE action neighbourhood combines various methods and tools to bring together citizens and other stakeholders to learn from each other in order to address urban challenges in transforming neighbourhoods and cities.

By halfway through the project duration (05/2017 to 04/2021), all SUNRISE neighbourhoods have completed the phase of problem identification and measure development. Reaching such a milestone calls for reflection upon several aspects of the SUNRISE project such as involved actors, the methods and tools of collaboration applied and the outcomes of the co-creative processes so far..

4.2 Actors in the process of problem identification and mobility solution development

In general, co-creation is characterized by the fact that heterogeneous actors from different sectors are mobilized in a collaborative process to create something together. The research group Leading Cities (2014: 3) delineate the different actors and define co-creation as "the active flow of information and ideas among five sectors of society: government, academia, business, non-profits, and citizens - the Quintuple Helix - which allows for participation, engagement, and empowerment in, developing policy, creating programs, improving services, and tackling systemic change with each dimension of society represented from the beginning."

The SUNRISE mission is to develop, implement, assess and facilitate co-learning about new, collaborative ways to address common urban mobility challenges at the urban neighbourhood level. The conceptual key-term of this project is the idea to "co-create" a more sustainable mobility future. Therefore, local actors and other stakeholders should be involved in all phases to live up to SUNRISE's "co-creation" spirit. By means of regularly-updated stakeholder mapping exercises, relevant actors for co-creating sustainable mobility futures were identified collaboratively in each partner city, showing a diverse actor composition unique for each neighbourhood. Table 1 shows the actors that took part in defining mobility problems and developing and selecting measures across all SUNRISE neighbourhoods.

Despite the broad range of actors in the SUNRISE processes, government, academia, business, NGOs, citizens and media rarely collaborate directly in physical space. Rather, these local initiators of the co-creation processes collect the information, ideas, and solutions proposed by the individual groups of actors and pass them on to other groups of actors.

Central aspects of the concept of co-creation is the openness for diverse groups of participants, the thematic openness as well as open flow of information, knowledge and ideas (Raffl et al. 2014:47). Co-creation focuses on an ongoing and iterative collaboration (Davis & Andrew 2017: 653), but as every open planning process, co-creation also needs shared information in order to achieve innovative outcomes (Haufe & Franta 2019: 57). Therefore, SUNRISE shows that beyond the Quintuple Helix (government, academia, business, non-profits, and citizens), the media sector is an important actor for promoting the flow of information

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

including knowledge of and ideas from the co-creation processes. In the SUNRISE neighbourhoods, the local newspapers were particularly important to inform the actors of the different sectors of society about the current status of the co-creation processes and the opportunities for participation. Local newspapers also spread mobility-related knowledge about the developed ideas to the wider public.

Sectors of Society	Actor Groups
Government	district administration, district development agency, members of the district parliament, district mayor, departments of the city administration (environment, transport, urban planning, education, work, social affairs, tourism, business development, communication)
Academia	universities
Business	local businesses, real estate / housing companies, business associations, tourism associations, representatives from planning, architecture, participation, industrial design
Non-Profits	cultural associations, traffic associations, representatives of the police, the fire brigade, healthcare, mobility providers, educational institutions, schools, youth centres, cultural centres
Citizens	residents, citizens' initiatives, citizens from other neighbourhoods, seniors, youth, students, parents
Media	local newspapers

Table 1: Actors of the co-creation process in SUNRISE (adopted from Haufe & Franta 2019: 66)

In collaborative planning processes like co-creation, residents and other actors are invited to participate in planning or decision-making processes with methods such as questionnaires, web forums, public meetings, and field trips, with the idea that participation can influence the content of planning (Faehnle & Tyrväinen 2013: 332). In diverse actor settings (see Table 1), specific attention has to be paid to methods and tools in order to be able to target each actor according to their needs. Methods which were used for the co-creative problem identification and mobility solution development in SUNRISE and actors which were reached with these methods will be covered in the next chapter.

4.3 Methods for the co-creative problem identification and mobility solution development in SUNRISE

A co-creation process has specific requirements which define the successful, purposeful, and inclusive involvement of heterogeneous actors. Therefore, selecting suitable methods and tools out of the plethora of participation formats available is an important aspect. The local actor setting needs to be taken into account for defining and selecting suitable methods and tools for co-creation. In principle, a method or tool may be aimed at the general public and thus to all interested actors in order to reach as many potential actors as possible. A method may, however, also target a selection of representatives from different interest groups or to all those directly affected by a particular topic or the subject-matter of the participatory procedure. In order to address various target groups in co-creation processes, it is useful to apply a mix of methods. A good mix consists of different, complementary methods (Senatsverwaltung Berlin 2011: 160) that promotes dialogue in a situation of equal empowerment and shared information in order to enable the exchange of mutual learning, to create innovative outcomes, and to build institutional capacity.

Every co-creation process and every single method of participation needs to take local culture, customs, and socio-spatial context into account. Spaces and places in the neighbourhood are needed not only because they provide the relevant conditions to facilitate interaction among and access to actors, but also because they bring innovative ideas and resources which catalyse interactive learning and innovation (Puerari et al. 2018: 6). Therefore, in order to reach the different target groups in the SUNRISE neighbourhoods, people were addressed in their everyday life spaces (markets, subway stations, squares, etc…), in "learnt" spaces (schools, museums, community centres, etc…), and local networks (sports club, folklore groups, etc...). Given the trend of digitization, the importance of digital tools in developing urban solutions is growing, especially if urban planning is understood as a collaborative societal effort. Digital tools also create options for integrating local actors into decision-making and implementation processes relevant to urban development (Dübner et al. 2018: 141). Therefore, the SUNRISE action neighbourhoods combine a blend of offline and online methods to bring together heterogeneous actors around shared information, to learn from each other and create new mobility solutions.

An important aspect at the beginning of the co-creation processes in SUNRISE were public events in the neighbourhoods. The objective of these public events was to inform as many people as possible about the process and encourage them to participate. Citizens and other stakeholders were invited to SUNRISE-specific events like the public meeting, but also market-type stands at public street festivals or other events in the neighbourhood where informational material and plans were shared to involve the visitors in the SUNRISE process. At the beginning, the public events were used to advertise the co-creation process and spark interest in participating. During the process, these formats were also used to inform about the current status of the SUNRISE process. Depending on the type of event, different groups of actors can be reached. These public events in SUNRISE were aimed mainly at "citizens", but actors from government (district mayor, district and city administration, members of the district parliament), business (local businesses, business association, tourism association) and the "non-profit "sector (representatives from cultural associations, healthcare, youth / cultural centres from the neighbourhood) also participated at these events. From the sector of media, representatives joined the public meetings to report on SUNRISE. In addition, an often-used method to involve the wider public was an on-tour series of smaller activating events where problems, needs, and ideas are collected via mobile stands in various highly-frequented locations in the public space (streets, market places, shopping centres, cultural centres, train stations, schools, universities etc.). The mobile stands at different locations can reach a large number of people on the one hand and specific user groups on the other by visiting places where these groups can be found. Through the direct exchange, this method can not only be used to share information, but also to learn from each other and to create innovative outcomes. This can happen through a more extensive exchange by discussing ideas together, negotiating advantages and disadvantages and discussing further cooperation especially when smaller groups meet at the mobile stands and engage in a conversation. Different groups of actors can be reached with the mobile stands. In SUNRISE, this method enables reaching a wide range of interested citizens from the neighbourhood and from other neighbourhoods who work, shop or have any other business in the neighbourhood as well. Especially if set up near schools, playgrounds or parks, specific sub-groups of the sector citizens like pupils, youth, parents, and seniors could be reached via these mobile stands. Also, in some SUNRISE neighbourhoods, information points have been created as a point of contact for residents and local actors. In order to operate information points in a way that conserves resources and at the same time intensifies the network of the project within the neighbourhood, cooperation's with local associations, community centres or other NGOs were established. Embedding the information centres in this way through cooperation's allows multiplier effects to be used in the neighbourhood and to build institutional capacity. The visibility and perception of SUNRISE was also increased by various public relations activities (flyers, posters, press releases, etc.) in the neighbourhood. Mainly local actors (citizens, non-profits, businesses) in the SUNRISE neighbourhoods could be reached with these methods.

Furthermore, the SUNRISE cities used methods for co-creation that are based on a selection of representatives from different interest groups or to those directly affected by a particular topic. An important part of the co-creation process in SUNRISE was an entity called "Core Group", which was formed with the aim of serving as a steering committee to accompany the whole process. The Core Group consists in most neighbourhoods of a stable group of 5 to 10 committed people, some of whom operate on an honorary basis while others are members of the city administration or from local politics. The main purpose of the Core Group is to guarantee transparency for the process and its contents internally and externally. Through regular updates, the core group ensures the flow of information in the processes, advises and reflects on the process, and communicates transparently to the wider public, media etc. In most neighbourhoods, the Core Group was also consulted when decisions had to be made, whether of a substantive or procedural nature. In this way, the Core Group served as a co-creation method, not only to promote dialogue in the process, but also to learn from the process through reflection and to advise and co-validate decisions.

A central aspect of the co-creation processes in the SUNRISE neighbourhoods were workshops in which a selection of representatives from different interest groups could participate in defining the problems and developing the measures. Playful approaches with building blocks or other materials in combination with maps or orthophotos have greatly promoted the exchange and creativity among the participants. In the phase of measure development, the workshops proved to be fundamental: design workshops, mini-future workshops or similar activities were used in the SUNRISE neighbourhoods to elaborate the content of the mobility solutions and to locate them in the neighbourhood. In addition to the development of measures, the

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

workshop formats also offered the opportunity to discuss, adapt, and select specific measures. Therefore, workshops in SUNRISE offered the generation of information, dialogue but above all collaboration between selected interest groups to create innovative outcomes. The workshop formats in the SUNRISE neighbourhoods allowed the involvement of different groups of actors, for example, citizens (residents, pupils, youth, seniors), government (district and city administration), businesses (housing companies, local businesses, business association, tourism association, representatives from architecture, planning, industrial design), and non-profits (cultural associations, traffic associations, fire brigade, police, educational institutions, youth centre, mobility provider). In general, actors from academia rarely took part in the SUNRISE processes. Only in workshops did academic partners from within the SUNRISE project (representatives from international universities) involve themselves as consultants.

The aim of the SUNRISE process was not only to involve the usual suspects who regularly share their points of view, but also the perspectives of hard-to-reach groups (e.g. older people, children, young people, people with a migration background or people with disabilities). Therefore, various methods were used to address specific groups. These were, for example, walks through the neighbourhood with people with disabilities or targeted interviews in retirement homes, schools, and community centres. The methods had a mainly informative, but in some cases also a conversational nature which increased the inclusivity of the engagement methods. In addition, excursions were also used to take a look beyond the borders of the neighbourhood to get ideas or learn from best practice examples. In SUNRISE, excursions as a method were used for selected actors who participate with long-term commitments (in SUNRISE, the members of the "Core Group") to visit other cities that are facing similar challenges but have already developed or implemented solutions.

In addition to face-to-face methods, digital tools also create options for integrating different groups of actors and provide opportunities for information, dialogue, learning and creating innovative outcomes. In SUNRISE, mainly neighbourhood-specific project websites were used as an online tool for actor information and involvement. The websites were used as virtual information centres, where all information material is made available. Some SUNRISE-neighbourhoods, a web-based mapping forum was implemented through the website. The objective of this forum was the collection of geo-referenced problems, needs and ideas, which are subsequently rated or commented by other users. Websites and online tools in SUNRISE were largely aimed at sharing information with the wider public. Through an exchange among each other (e.g. in SUNRISE the mapping tool), moments of dialogues and co-creation can also be generated, especially if the online tool allows open discussion and has the option for joint steps in the direction of common ideas or vision development. Digital tools create options for integrating the wider public into co-creation processes, but many online tools like the mapping tools in SUNRISE have the disadvantage that it remains often unknown who participated.

4.4 Developed mobility solutions and side effects of the co-creation process

Co-creation is characterized by the fact that heterogeneous actors from different sectors are mobilized in a collaborative process to create something together (Haufe & Franta 2019: 55). Co-creation can have two distinct goals: One purpose of the co-creation can be "making" together a situation where people work together towards an output such as a product, service, or process innovation. A second purpose of co-creation can be "learning" together through situations where actors collaborate towards building knowledge, learning from one another, and creating networks between actors (Puerari et al. 2018: 4). Frequently, both goals are sought, though often the "making together" or the output is in the focus of co-creation in every day practice.

In the co-creative processes of the six neighbourhoods in SUNRISE, a total of 33 solutions for the identified mobility problems of the respective neighbourhoods were developed. Between three and nine mobility solutions were developed for each neighbourhood. The mobility solutions result from the individual neighbourhood-specific, co-creative processes and reflect the respective problems of the neighbourhoods, but can be divided into six categories:

- Public space (10 measures): As part of the co-creative processes, a number of improvements for the quality of stay in public spaces were developed. These include the construction of street furniture (in particular benches), the greening of squares and streets, additional opportunities for children to play, and activities (e.g. festivals, events, initiatives with specific focuses in cooperation with local associations) in public spaces to increase the feeling of security.

- Bicycle traffic (8 measures): Improvements for bicycle traffic were a result of the co-creative processes in five of six SUNRISE neighbourhoods. The measures developed include the installation of bike racks at central locations in the neighbourhoods and in housing complexes, the establishment of rental stations for cargo bikes, the redesign of bicycle underpasses and intersections, as well as information campaigns for the use of bikes in the neighbourhood and the intermodal use of the bike.
- Pedestrian traffic (7 measures): Mobility solutions for pedestrian traffic were developed in all SUNRISE neighbourhoods. In many neighbourhoods, the focus was on improvements of school routes, including information and education campaigns for safe and sustainable school routes as well as a walking bus ("school bus on foot") for kindergarten children and pupils. In addition, pedestrian routes in the neighbourhood will be redesigned and pathfinding improved.
- Motorized private transport (6 measures): In three SUNRISE neighbourhoods, measures were developed that aim to reduce motorized private transport. The measures developed include the establishment of Tempo 30 zones, targeted parking management and micro-hubs for delivery services and car-sharing stations. Measures for sustainable and safe school routes have also been developed, including measures to reduce delivery and pick-up traffic by means of motorized individual transport and kiss & ride zones in front of schools and kindergartens.
- Local public transport (2 measures): In only one SUNRISE neighbourhood, measures for local public transport were developed. The focus here is on public transport stops, including measures to improve the quality of stay at stops as well as improved information through timetables, neighbourhood maps, and real-time information.

In addition to the mobility measures developed, SUNRISE showed that the co-creation process produces side-effects due to the opportunity to "learn" together, to build up knowledge and to create networks between people. New collaborations and learning processes developed between departments of the city administration that had never worked with each other before in some SUNRISE cities. The co-creative development of mobility solutions with and for the neighbourhood also created new collaborations and learning processes between local actors. For example, in a SUNRISE neighbourhood, residents organised in an initiative that wants to implement a temporary SUNRISE measure on a permanent basis. These side-effects are an indicator that co-creation is not only an approach for creating product or service innovations, but also a way to create social innovations, responsibility, identification, and acceptance of mobility solutions in context.

5 CONCLUSION

In the context of urban planning today, co-creation is an increasingly common concept to integrate various actors in planning processes to create something together. In general, co-creation is characterized by the fact that heterogeneous actors from different sectors are mobilized in a collaborative process to create something together. Co-creative urban planning can be defined as the set of interacting processes in which heterogeneous actors mutually interact and work together to develop answers (e.g. knowledge, instruments, technology, artefacts, policy, know-how, plans etc.) to urban challenges.

Nowadays, co-creation has become a buzzword in urban planning and is often also seen as a new concept in planning. This paper shows that co-creation is not a new concept but based on the communicative and collaborative planning theory developed in the last four decades. Co-creation is a form of collaborative planning practice in which knowledge, instruments, technology, artefacts, policy, know-how, plans etc. are created through an ongoing process among heterogeneous actors. The distinguishing feature of collaborative planning from technocratic planning is that it delegates the responsibility for planning directly to involved actors. It encourages people to engage in a situational dialogue of equal empowerment and shared information, to learn through mutual exchange, to create innovative outcomes, and to build institutional capacity.

With the Horizon 2020 project SUNRISE as an example, this paper gives an overview of the involved actors, the applied methods, the formats of collaboration, and the outcomes of a co-creative process for finding sustainable mobility solutions at the neighbourhood level. The six co-creative processes in SUNRISE show that in practice co-creation offers the opportunity to involve a wide variety of different actor groups from different sectors in the planning process. In addition to the Quintuple Helix (government, science, business, non-profit organizations and citizens), the co-creation processes in SUNRISE show that the media sector in co-creation processes is also an important actor to promote the flow of information to the wider public.

In order to address various actors and target groups, it is useful to apply a mix of methods. The SUNRISE neighbourhoods have used a variety of different face-to-face and online methods to reach both a large public and specific target groups. Despite the broad range of actors in the SUNRISE processes, government, academia, business, NGOs, citizens, and media rarely collaborate directly in physical space. Rather, the local initiators of the co-creation processes collect the ideas and solutions proposed by the individual groups of actors and pass them on to other groups of actors.

The co-creation approach in SUNRISE offers an opportunity to develop local mobility solutions or neighbourhood mobility concepts. A total of 33 solutions for the identified mobility problems of the respective neighbourhoods were developed in the course of the co-creative processes in the six SUNRISE neighbourhoods. Between three and nine mobility solutions were developed for each neighbourhood. The mobility solutions result from the individual neighbourhood-specific, co-creative processes and reflect the respective problems of the neighbourhoods. The developed mobility solutions include improvements for the quality of public spaces (e.g. greening of squares, construction of street furniture), for bicycle traffic (e.g. installation of bike racks), mobility solutions for pedestrian traffic (e.g. safe and sustainable school routes), and for reducing motorized private transport (e.g. tempo 30 zones) as well as individual measures for local public transport (e.g. quality stay at stops).

The mobility solutions developed in SUNRISE are small-scale measures tailored to local conditions to attract and improve sustainable mobility in the neighbourhood. Mobility solutions are less about the objective (technological) novelty than about the question of whether an idea or solution is new or innovative for the neighbourhood. For this reason, the solutions developed in co-creative processes need to be viewed less from a global or supra-local, but rather from the perspective of the local socio-spatial constellation. Only through the local context can the degree of innovation of the solutions developed with co-creation be understood and classified in a meaningful way.

In addition to the developed mobility measures, SUNRISE shows that co-creation processes also built institutional capacity and created new collaborations and learning processes between local actors. In some SUNRISE cities, new collaborations and learning processes developed between departments of the city administration that had never worked with each other before. In one SUNRISE neighbourhood, residents organised an initiative to implement a temporary SUNRISE measure on a permanent basis. These side effects are an indicator that co-creation is not only an approach to creating product or service innovations, but also a way to create social innovations, responsibility, identification and acceptance for the mobility solutions and its context.

Regarding the potential of the co-creation approach in sustainable urban planning, we conclude that co-creation offers opportunities to create broad awareness and sense of responsibility for sustainable urban development in a local context. Whether co-creation is able to lead to long-term changes in local culture, collaborations, learning processes and institutional capacities, however, requires further research. In terms of mobility, the impact of mobility solutions on sustainability at the neighbourhood level (e.g. shifting traffic to other neighbourhoods) needs to be closely examined.

1 ABSTRACT

The worldwide expansion of electric vehicle usage comes with the challenge of adapting the respective traffic and charging station infrastructure in cities, resulting in profound changes not only to traffic itself but also to the way energy is being distributed. An ongoing all-embracing real-time IoT-network will provide a vast amount of new possible data for planners, for example in order to get useful insights into the relationship between traffic flow patterns and loading patterns of e-vehicles. For this, the use of e-mobility data is essential. This paper will present potential ways of gathering data for infrastructure planning and user-oriented recommendations, such as movement patterns and charging status of vehicles, since this information is already available but not being shared by car companies. The given perspective will take into consideration individual vehicles and vehicle fleets as well as the traffic network as a whole. Efficient access to current and predicted load for charging stations in the electric vehicle transition would be a beneficial factor for the promotion of electricity-powered vehicles. In this paper, we lay out different approaches. Besides manufacturer related data-acquissition, this includes as well to provide this information via user-generated content (UGC), and to derive charging recommendations from a user-oriented, intelligent recommendation system. Furthermore, the challenges regarding the effects towards the electricity network and the necessity of physical charging infrastructure will be discussed. In a future situation of more heterogenous and dispersed energy supply, being able to predict the energy consumption of e-vehicles individually and instantaneously based on collected data will be a necessity for energy supplying companies. This will intentionally lead to more grid stability, by distributing electricity inside the network based on predicted loads, as well as work as an incentive for drivers to make the transition to e-mobility, because finding e-charging stations will eventually not be an issue. This paper will take the respective questions and potential control mechanisms for traffic patterns into consideration.

Keywords: Smart Grid, e-Mobility, User-generated-content, Traffic planning, Smart mobility

2 INTRODUCTION

A major factor holding back the expansion of renewable energy are the shortcomings of today's power grids that are unable to effectively handle decentralized and periodically fluctuating power production. One of the most far-reaching political topics in Germany is fostering the development of a smart energy grid, an integral part of the transition to green, renewable energy, the so-called "Energiewende". Offering great ecological, economic, and social opportunities- the growing share of renewable energies in energy production also poses enormous challenges for energy supply in general. But these problems do not only concern the production, but also the consumption side of the electricity infrastructure, especially considering the advent of e-mobility. A secure and sustainable energy grid of the future must take e-mobility into consideration and meet its fundamental prerequisites. The ongoing proliferation of charging stations for electronic vehicles puts an ever-growing strain on the electricity grid, not only because of the additional load but also because of the fluctuation in load during peak times. An adapted build-up of the electric vehicle (EV) charging infrastructure, including the need for embracing loading patterns in all parts of the mobility network, is needed to further facilitate sustainable e-mobility.

The approach to solving the problem laid out in this paper involves gathering relevant data, such as movement patterns of vehicles and information provided by charging stations like location, time and load to predict and thus manage electricity distribution in the grid. By intelligently distributing electricity to places with high demand at peak hours, the risk of energy oversaturation as well as shortage are minimized, and the groundwork is laid for further expansion of the charging infrastructure, thus creating incentives and lowering the cost of opportunity to charge electric vehicles. First, this paper will establish a theoretical framework incorporating viewpoints from different perspectives, such as urban planning, energy infrastructure and

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

smart mobility, in order to emphasize the need for a systemic perspective on the issue. After that, a methodological approach to gathering relevant data will be introduced. This data can also be used in other contexts, for example by adding an intelligent pricing system at EV charging stations based on expected load, that could be used as an implicit way of traffic control akin to conventional city toll systems. Therefore, the last step is to consider potential further use cases for the collected data.

3 THEORETICAL FRAMEWORK

Other than conventionally fueled vehicles, which can rely on established infrastructures such as petrol stations, the expansion of e-mobility is highly dependent on infrastructures that are not sufficiently available yet. The buildup of those infrastructures needs to take into consideration the comparatively small energy storage of e-vehicles and long charging times as well as constraints of today's power grid and employ a systemic perspective. The low energy efficiency of e-vehicles necessitates the availability of charging stations practically everywhere, which means that a sufficient supply of electricity has to be available even in rural areas. Therefore, the proliferation of e-mobility must be one of the driving forces behind the overhaul and expansion of the existing power grid, and vice versa.

From a systemic perspective, this opens other areas, where the relationship between e-mobility and infrastructure must be considered. In urban planning for example, the expansion of e-charging stations needs to be extensive, but at the same time additional traffic congestion caused by short loading cycles and long loading times must be prevented. Transmission system operators and electricity distribution operators, on the other hand, need to build a secure and sustainable power grid equipped to incorporate highly fluctuating energy production and consumption. Developers and system engineers must craft an ICT environment around those systems in order to enable them in the first place, by gathering, transmitting and processing data that power intelligent machine learning processes, able to predict changes in energy consumption or traffic routing instantaneously and operating the elements autonomously. Additionally, and often overlooked, politics have to shape adequate laws and regulations as well as offer incentives in order to facilitate this overall transition process. The development of e-mobility and energy infrastructures will be strongly connected in the future and enable new methods for data gathering.

4 ASSESSMENT OF METHODOLOGICAL APPROACHES

The methodological approaches differ between their nature of data gathering regarding the location information and in addition the respective charging patterns.

4.1 Manufacturer-related data acquisition

Today's cars are utilizing sensor technology to gather a wide variety of user and vehicle data. McKinsey estimates that modern cars collect up to 25 gigabytes of data per hour, much of which is then transferred to the manufacturer by Wi-Fi or mobile data connection to be analysed for performance control and maintenance. The most notable data collected by a car is illustrated in a study conducted by German automobile club ADAC (2020). According to them, a new Mercedes B-Class for instance collects data such as GPS position, mileage, consumption, tank filling, tire pressure and various liquid levels like coolant, brake fluid and screen wash, which is sent to the Mercedes backend every two minutes. Sensors also record the style of driving by measuring how often the seatbelt is tightened up by breaking too hard or how often the engine running speed and engine temperature are too high. Additionally, the car collects data allowing the manufacturer to create a detailed user profile by tracking the last one hundred charging cycles with GPS coordinates, date, time and mileage. While this approach by Mercedes is basically a standard procedure for modern cars, other manufacturers like Renault employ much more curious practices. Not only can they read the data provided by the different sensors, they can also send commands to the car via mobile connection, for example to prohibit drivers from charging their car, if they failed to pay a bill for example, activate remote diagnosis, which is deactivated by default, or remotely extend the kind of data being transmitted. Practices like these open up a lot of questions regarding data privacy, one of which is: What happens with all the collected data? A good example of how to profit from this data is GM. They offer a service called GM Marketplace that brings personalised advertisements into your car, thus for example guiding you to a specific gas station or local restaurant by offering discounts. But vehicle data isn't just valuable because of suchlike business models. Car manufacturers want to improve their product and increase lifetime value, insurance

companies want to provide more accurate, individual estimates for usage-based insurance, urban planners want to know more about people's movements and developers want to build new products and services utilizing this data. Therefore, McKinsey predicts as much as $750 billion of value in vehicle data by 2030 (Peters 2019).

This paper aims to present potential ways of gathering some of the same data, also independent from the car manufacturers, in order to better inform infrastructural planners as well as potentially drivers. The underlying technical approach to this will be presented in the following paragraphs. Furthermore, corresponding use cases for the approach shown are presented. E-fleet-Management is such a use case, because E-fleets are an essential component of future e-mobility, and they will generate large, local energy fluctuations in the power grid if they are not charged in a coordinated manner. This problem is prevented with the following, data-driven methodology.Sensor and telematics-based data gathering. One approach could be to collect data by a telemetry module, which reads the energy status of the car. One use case is to minimize the energy costs of a fleet with the help of a recommendation assistant for intelligent charging management. The first component of the solution is a recommendation wizard for the load operation strategy. This recommendation wizard creates a charge plan for all vehicles in the fleet under a fixed timetable, depending on network charge estimates, for example, or flexible electricity tariffs and solar yield forecasts using optimization methods and artificial intelligence methods. This plan contains which vehicle is charged when and with which power source and thus attempts to minimize the maintenance costs of the eFleet and indirectly brings stability to the energy grid. This can be further improved by adjusting the schedules. This adjustment depends strongly on the energy consumption of the vehicles during a journey. Based on this, the second component for this use case is the forecast of the energy consumption of a vehicle for one journey. This can be predicted using artificial intelligence methods on the basis of destination, starting time and the route to be taken - for the destination as well as for each part of the route. Among other things, neural networks, especially recurrent networks, can be used for this forecast.

The next component is the adaptation of the timetables to further improve the results from the first component. For instance, ferry schedules include which vehicle is assigned for which trip at which time. For this purpose, the forecasts from the second component and other data such as vehicle specifications, in particular the loading capacity and performance of the vehicle and the requirements of the trip (number of people/goods transport) are used. This can be solved with methods of combinatorial optimization such as Evolutionary Algorithms.

Another use case of this data is the optimal positioning of charging infrastructure. This depends above all on the level of demand for charging at a particular position. Such data is very difficult to obtain at the moment. But with this approach it can be also calculated by user generated content, because the demand of charging depends mainly on the traffic flow of electric vehicles and the charging status of these vehicles. Whereas some of these mentioned solutions were used in the fleet-management context for a dedicated set of vehicles, the principles could be transferred also the mobility network as a whole.

4.2 Data gathering by UGC

A potential way to collect location and charging data is with user-generated-content (UGC). In this way, a platform based on UGC could be the foundation for an improvement in the efficiency of future charging infrastructures, targeting electric vehicle owners, with the intent of making the charging process effective for both the users and the mobility network in general. The focus on UGC from other approaches, is the scheme to collect user-generated content, that has been created with a collaborative effort of individuals, contrary to using data from third parties, because it is not certain if this data will be provided by car companies. We consider a platform where users exchange information with each other, including several important parameters such as how long they plan to charge, flexibilities that state whether they can, for example, make a 30-minute charging break for a user who needs an urgent charge. This data is transmitted to all users of this network, and they can plan their route in advance or real-time accordingly. This platform would be ideal for an EV owner, as they would be able to have an expectation time for how long they would need to charge their vehicle at a station, with respect to the demand at charging stations nearby, by using an intelligent system that learns user preferences and peak load times on local or regional charging stations. The motivation is to save their time and make the EV charging experience more efficient and comfortable. Besides this approach, there are also potential other ways of gathering, like for instance with a camera based

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

solution or if that's not possible, by a camera, which takes pictures of the charge display. This data can be collected until the drive ends and uploaded to the cloud. An artificial intelligence service such as a convolutional neural network can classify these pictures into an energy status.

Once UGC is available from other users, the model capable of predicting peak loads on a charging station and estimating the typical waiting time for a user at a specific station, will be used to build a user-oriented recommendation system. The system is capable to handle each user individually and create their own route recommendation based on estimated charging times and preferences. The vision for this application is, however, broader than just information exchanging in a narrow network connecting the EV owners.

We plan to use this user-generated content to train an Artificial Intelligence model to make predictions of the electricity and traffic load on the charging station during various times of the day or week or year as well as getting insights to the mobility traffic patterns at the charging stations. This would aid in monitoring and limiting traffic congestions in cities. Crowdsourcing in real time can provide great input data to current applications for computing optimized routes to current and forthcoming users. One of the reasons for such an approach is to be independent of collecting data from the third-party EV companies or EV charging stations, which can become quite a difficult task due to information sensitivity, competition, and data ownership. This data retrieval method is known as user generated content mining which is formatted into a knowledge representation entity, used for downstream tasks. One of the main advantages of user generated content mining for data in a recommender system is the initial setup time period. The duration is relatively short, some data is ready instantly, and the system can start using its algorithms to make recommendations for the users. Another feature is the ability to adapt to changes quickly. This can be an advantage in comparison to other methods, when the environment (in our case the amount of charging stations, chargers, and electrical vehicles) changes rapidly. Since the Artificial Intelligence model needs data to learn a function to make a load forecast, using newly collected data would increase the accuracy of the model and prevent data from going out of date. When using data collected over time, the AI responsible for decision making would only learn the trends of EV usage at certain charging stations for the given time period. However, as soon as the number of electrical vehicles would change, new data would be needed for the training of the AI, whereas with the user generated content approach, no changes would be needed. One disadvantage of this mining method is that data can contain false information, as it is no requirement of proving the validity. Another challenge that we would face is to motivate the users to submit data. However, if the product is rewarding, as it would make it easier for users to get used to the EV charging and avoid conflicts at charging stations, there would be a positive dynamic of people using the platform and submitting their data. Crucial aspects in this approach is the user acceptance and willingness to contribute UGC for the named purpose, since this data would allow very detailed personal movement patterns to be analyzed, so there should be necessary mechanisms to protect the privacy of users.

Data mining with sensors and by user generated content do have their own strengths and weaknesses. Sensors for example can be quite intrusive by not being transparent on what kind of data is collected precisely. This raises issues of data privacy and leads to negative public reception. They are also intrusive in the way that they are either part of the road network or your car, as a driver you don't have a lot of control over them. On the positive side, they're quite cheap and easily employed and they can reliably collect vast amounts of very different kinds of data. While this sounds good, it also comes with the challenge of transferring and analyzing huge amounts of data effectively. User-generated content on the other hand will most likely not raise any questions regarding data privacy as the user has full control over what kind of data he wants to send to whom. The data generated here is also processed already by the user who puts it into some kind of website or application, thus the chance of collecting irrelevant data is much lower and it is presumably easier to process the data. But the kinds of data that can be gathered is limited to something that can easily be perceived by the users and it likely suffers from subjectivity, either in the way it is perceived or whether it is recognized as relevant in the first place.

5 POTENTIAL APPLICATIONSFOR URBAN AND TRAFFIC PLANNING

Theoretically, urban and traffic planners can apply the data in two different ways, on the one hand there is the location data enabling the informed improvement of traffic routing and on the other hand the information on charging patterns are helpful for upgrading and expanding the energy infrastructure. Generally, digitization will have a drastic and lasting impact not only on mobility, individual transport as well as public

transport, but also on infrastructure planning overall, especially the relationship between traffic control and energy distribution. Thus, the future development of urban areas and districts will require a new and innovative approach to energy supply, particularly involving solutions for renewable energy, storage possibilities and adequate e-mobility infrastructure.

The following chapter will introduce a potential additional use case for the data generated by the proposed methods, aiming to further demonstrate the intricate relationship between e-mobility and energy infrastructure, at the same time taking political control mechanisms into consideration.

5.1 Potential further data use traffic planning

The data collected by the presented approach can be used for infrastructural planning purposes in primarily two ways, firstly for monitoring purposes in general and secondly for traffic management, for example by providing incentives and restrictions.

5.1.1 Real time traffic Monitoring

A smart e-mobility charging infrastructure, as outlined in this article, would be an integral part of a holistic mobility concept for future smart cities and the potential synergies between such a system and other key elements of smart urban mobility promise to offer an interesting outlook into the future. As a conclusion to this article, the following chapter investigates the potential interaction between a smart charging infrastructure and a real time traffic management system. Smart traffic management is often perceived as synonymous with smart mobility in an urban context even though it is only one component of it. An integrated real time traffic management system could possibly circumvent issues such as traffic congestion, insufficient parking space capacities, high emissions and low quality of life for residents, e.g. because of noise pollution. While the goals and presumed benefits of such a system are clear, the implementation is still severely lacking. This is because it is heavily reliant on several preconditions, some of which are technological ones, that have not yet been realized. In order to illustrate this, it is helpful to envision the implementation of a smart traffic system as a multi-stage process (Citron 2019):

- Developing (Vehicle Detection & Data Collection): Camera, sensor, GPS data Focus on traffic planning
- Managed (Traffic Analytics & Evaluation): Traffic routing is possible Travel time analysis Optimization of traffic lights
- Mature (Advanced Traffic Management): Real time control of systems Integrated in vehicles AI & cloud-based platforms Data exchange with other places

In order to realize a fully manageable real time traffic control system, several enabler technologies need to be widely available and controlled via a shared platform, e.g. IoT, Cloud Computing, Machine Learning / AI. A smart way of energy distribution, that can supply energy needs when und where they occur, will be an integral part of such a system. One example for an integrated system like that could be a connected grid of charging stations for e-vehicles that is supplied depending on traffic flow. Thinking even further, a smart charging infrastructure that is integrated into a smart traffic control system could be used as a way of controlling traffic flow itself, by providing a system of incentive-based pricing. One of the reasons why data is often referred to as the ‘oil’ of the digital age, is because of its ‘raw’ nature and its ability to be refined into a plethora of useful states. This means the same data can be used for different means, depending on how it’s processed. The data produced by the means presented in this paper for example can also provide the basis for smart traffic management.

5.1.2 Incentive based pricing for e-mobility as a way of traffic management

Theoretical incentives could be distinguished into “positive” and “negative” approaches. Be it positive ones, such as tax exemptions, money grants or other benefits like free parking, being able to drive on bus lanes or being exempt from paying city tolls, or negative ones, like city tolls, auto free zones or combustion engine bans, incentives already are a main driver behind the proliferation of e-mobility (Wang et al. 2015). Other approaches for toll systems based on location data (Nagothu 2016) as well as potential applications in highway networks (Lee, Tseng, and Wang 2008; Tan et al. 2017) are discussed in relevant literature (Sanal et al. 2019). While suchlike measures are mostly explicit and therefore obvious, possibly leading to negative repercussions, additional implicit measures promise a way of more subtle control. A possible way of

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

'nudging' residents to use specific routes could be to employ smart pricing at e-charging stations. For example, an app in your car or on your phone, like electrific (electrific 2020), that aims to optimize your routing through everyday traffic based on anticipated congestion and other factors, may be able to guide you to charging stations that have lower prices, therefore disincentivizing you from using 'more expensive' routes. The prices at such stations would of course be variable and based on the current traffic flow or on city policies, e.g. to make districts car free, etc. A system like that could even work better than city tolls, that are generally not very appreciated by most residents. An implicit system, that guides you based on prices on charging stations, could eventually replace city tolls altogether.

City tolls have been established in many cities around the world (e.g. Civitas 2013), while implementation practices differ widely. Whether there is a ring of toll stations around cities or there are electronic means of tolling residents (Sanal et al. 2019), while effective, these measures tend to be unpopular with local inhabitants. The challenge with a system like that is that it needs a highly integrated, interoperable ICT and energy infrastructure. While IoT-sensors or cameras need to measure traffic flow and/or other environmental data, this information needs to be bundled, analysed and interpreted by AI in a cloud computing environment, and the derived optimizations need to be communicated, e.g. by changing traffic light circuits, adjusting energy prizes at charging stations or directly messaging drivers (Popoola et al. 2018; Abari et al. 2015; Soylemezgiller, Kuscu, and Kilinc 2013). This in turn requires drivers to be able to receive such information, either by phone or directly in the car and acting on it. All in all, a system like that is only imaginable in a holistic integrated smart city environment.

Research in this field is scarce. Most projects are limited in scope to specific use cases, for example lokSmart (LokSMART 2020), which is focussed on local flexibilities for e-mobility, 3connect (Smartlab 2020), mainly concerned with commercial e-mobility in smart grids or electrific (electrific 2020), a consumer side platform for smart routing. Only very few research projects, such as iMove (Hubject GmbH 2019), are trying to bring data from different sources together and craft an integrated ICT infrastructure. But even those are mostly limited to a technological perspective and don't account for political viewpoints. Incentive based routing options could also be used ultimately for virtual city tolls. They can be designed theoretically with "soft barriers". Tolling by making charging costs related to geographical location (expensive charging prices in the city center) as well as with a stricter concept, like a geofencing for vehicles. This means that toll barriers could theoretically be installed everywhere in the urban area, flexible in location and also time. This enables new possibilities for real-time-traffic management for planners, such as influencing the rush-hour traffic as well as reactions to natural disasters like flooding for instance. In addition, this potentially enables new business models. Though, this far reaching possibilities have to be critically considered reagarding legal, privacy and ethical aspects. There are first concepts regarding privacy-preserving toll systems (Jardí-Cedó, Castellà-Roca, and Viejo 2016), but the embracing view regarding the mentioned aspects have to be taken into consideration.

5.2 Requirements for energy infrastructures

It will be important to demonstrate how intelligent grids with a majority of renewable energy ensure a secure and efficient energy supply and which concepts and technologies can be used for this purpose to achieve efficient and safe energy networks, especially in the traffic context. The core functionality of Smart Grids itself is connectivity. With this, it is possible to connect plants, systems and devices via the Internet, regardless of location. If the systems and components involved can communicate quickly and securely, they can, for example, be combined into virtual power plants and controlled as required for instance. These aspects will be especially crucial regarding the development towards a more e-vehicle based transport model. The resulting effects of a higher rate of e-vehicles for the grid will be enormous. Besides, for instance the potential location finding process and approval of combined heat and power plants, district-based energy storage, geothermal powerplants the impacts of the mobility sector will seriously induce some effects. General question concerning the general model of transport (more public transport, more individualized, more car-sharing) have their own demands for the design of the urban space and the corresponding connection to the electricity network. In this way, the design of a mobility concept is inseparably connected to the design of a Smart Grid in the light of a Smart City (Exner et al. 2019). Especially with question of using approaches such as vehicle to grid, the planning and use of grids has to be linked to real time – as well as strategic - traffic management.

6 CONCLUSION

From a systemic point of view, fundamentally new requirements for vehicle-related charging will develop, as well as an increasing demand on the power grid. It will be crucial, how the amount of investments in the low, medium and high voltage grid by 2050, in case of a strong electrification of transport (more than 50% of all vehicles), will be held at a level comparable to the historical investment level by the use intelligent management of charging all vehicles. This new digitized world of electrified transport provides multiple new options for planning purposes based on location data and charging status. Society will face a post-fossil fuels – future, but in this world, data will be the new oil. The transport and mobility network and stable electricity network won't work together efficiently, if there aren't any real time information available regarding location and charging of vehicles within the traffic network. We presented different methods to collect a coherent dataset, with all respective advantages and disadvantages. From one perspective, this database enables totally new possibilities for monitoring the traffic network as a whole, but also for an embracing traffic management, even towards the use of virtual city tolls, which are flexible in time and location. Though, this raises issues of security and data privacy, especially when new technologies have to be applied (blockchain for instance) in order to address these problems. Also, ethical questions will arise in this context, if restrictions could be applied, regarding who can drive where and if these issues will also be incentive-based. All of these aspects have to be considered from a multidimensional and interdisciplinary perspective which will strengthen the need for cooperation of urban planners, traffic planners, data scientists and respective other partners.

1 EINFÜHRUNG

Seit circa zehn Jahren wird das Konzept der Regiopole in der deutschen Raumordnung diskutiert. Das Konzept zeigt als Entwicklungsmöglichkeit für (kleinere) Großstädte und Regionen, die sich im ständig verändernden Wettbewerb um Bevölkerung und Unternehmen positionieren möchten, eine Alternative zu etablierten stadtregionalen Instrumenten (z.B. Metropolregionen) auf. Angelehnt an das metropolitane Konzept sieht sich eine Regiopole als kooperative Organisationsform zur Vernetzung unterschiedlicher Akteure einer Stadtregion und deren Verflechtungsbereich. Historische, kommunale Verwaltungsgrenzen können dabei durch moderne Governance-Strukturen überwunden werden und an tatsächliche, funktionale Stadt- und Regionsstrukturen angepasst werden. Durch Einbindung von Akteuren der Raumentwicklung (z.B. Regionalverbände, Kommunen, wirtschaftliche Akteure, Bürger- und Zivilgesellschaft) soll die Gesamtregion durch eine gestärkte regionale Identität nach innen sowie ein gestärktes regionales Image nach außen profitieren.

Seit 2006 haben sich sieben Städte und Regionen in Deutschland als Regiopolen positioniert und im deutschen Regiopole-Netzwerk zusammengeschlossen. Diese informellen Stadt-Umland-Kooperationen stützen sich auf Strategien wie das Leitbild „Wettbewerbsfähigkeit stärken“ der Ministerkonferenz für Raumordnung aus dem Jahr 2016, sind jedoch (noch) nicht als Raumkategorie in der deutschen Bundesraumordnung verankert.

In diesem Beitrag wird am Beispiel von drei ausgewählten bestehenden Regiopolen diskutiert, welcher konzeptionelle Ansatz hinter einer Regiopole steht und welcher Mehrwert für die jeweiligen Stadtregionen erwartet werden kann. Dabei wird anhand der in diesen Regiopolen in den Mittelpunkt gerückten Zielen und Aktivitäten auch verdeutlicht, welche Kooperationen – trotz auch weiterhin bestehendem innerregionalen Wettbewerb in anderen Bereichen – eingegangen werden, um im nationalen Kontext Wettbewerbsvorteile zu generieren.

Abschließend werden am Beispiel der potentiellen Regiopolregion Koblenz-Mittelrhein-Westerwald Eckpunkte der Ausgestaltung einer Regiopolregion diskutiert. Das Oberzentrum liegt im nördlichen Rheinland-Pfalz und umfasst mit seiner Verflechtungsregion Mittelrhein-Westerwald einen Einzugsbereich von über einer Million Einwohnern. Seit einigen Jahren findet sich, initiiert durch einen regionalen Verein, die Regiopolenidee in der Region wieder. Aktuell sind Akteure wie die Stadt Koblenz, die Planungsgemeinschaft Mittelrhein-Westerwald, die IHK oder ein regionales Unternehmensbündnis im Prozess eingebunden. Die Diskussion um die konzeptionelle Ausgestaltung einer Regiopolregion in Koblenz und der Region Mittelrhein-Westerwald wird anhand folgender Fragestellungen geführt: Welche potentiellen Ziele und Aktivitäten könnte das Konzept in der Region aufgreifen? Welche lokalen und regionalen Akteure sind in den Etablierungsprozess und die Organisationsstruktur einzubinden? Wie könnte eine räumliche oder funktionale Abgrenzung der Regiopolregion ausgestaltet werden? Welchen Mehrwert würden Koblenz und die Region durch eine Stadt-Umland-Kooperation erfahren?

Anhand dieser Fragestellungen zeigt der Beitrag einerseits auf, ob und in welcher Form Koblenz und die Region Mittelrhein-Westerwald durch die Initiierung einer Regiopolregion langfristig profitieren können. Andererseits wird ausgehend von diesem Fallbeispiel der Frage nachgegangen, inwieweit Verflechtungen in einer Stadtregion durch neue oder zusätzliche Governancestrukturen (wie z.B. einer Regiopole) besser abgebildet und dadurch auch Stadtregionen insgesamt erfolgreicher entwickelt werden können.

Keywords: Regiopole, Regiopolregion, Stadt-Umland-Kooperation, Stadtregion, Governance

2 REGIOPOLEN IN DEUTSCHLAND

Die Stadtplaner Jürgen Aring und Iris Reuther (beide Universität Kassel) haben im Jahr 2008 ein Vorgehen zur Identifikation potentieller Regiopolen in Deutschland entwickelt. Hierzu wurden die drei grundlegenden Kriterien „Großstadtschwelle“, „vorhandenes Potential an Wissen und Innovation“ sowie „Lage außerhalb von Metropolregionen“ herangezogen. Anhand dieser Kriterien wurden 33 deutsche Großstädte als potentielle Regiopolen identifiziert und daraufhin anhand einer aufgestellten Gravitationsthese klassifiziert. Diese besagt, dass das Potential einer Stadt als Regiopole umso höher ist, je größer die räumliche Entfernung zu einer Metropole (Distanz) und je größer ihr demografisches und ökonomisches Gewicht (Masse) ist.[1]

Von den 33 durch Aring und Reuther identifizierten Regiopolen haben sich aktuell sieben als solche positioniert bzw. etabliert. Auf den nationalen „Vorreiter” Rostock folgten Bielefeld, Erfurt, Paderborn, Siegen, Trier und Würzburg. Diese haben sich bereits im Jahr 2009 das Ziel gesetzt, analog zur Metropolenstruktur, ein deutsches Netzwerk aller Regiopolen als Interessensvertretung zu schaffen. Ähnlich dem Initiativkreis Europäische Metropolregionen in Deutschland (IKM) versprechen sich auch die Mitglieder des RegioPole Netzwerks eine Verbesserung der Wettbewerbs- und Handlungsfähigkeit, um Motoren der nationalen Entwicklung darzustellen. Durch eine Zusammenarbeit der Mitglieder, anderer regionaler Akteure und politischer Vertreter, soll zum einen eine Stärkung der regionalen Identität erfolgen, zum anderen der Ausbau und die Verstetigung der Zusammenarbeit zwischen den Regiopolen.[2]

2.1 Ziele, Funktionen und Mehrwert des Regiopolenkonzepts

Durch die Positionierung als Regiopole zielen Stadt und Region auf eine positive Entwicklung und eine Generierung von Wettbewerbsvorteilen im nationalen Kontext. Ziel des Konzepts der Regiopole ist zunächst, eine neue Raumkategorie der zentralörtlichen Gliederung für kleine Großstädte unter der Ebene der Metropolregionen einzuführen. Gleichzeitig soll diese neue Raumkategorie auch in den raumordnerischen Leitbildern der MKRO Berücksichtigung finden. Durch die Weiterentwicklung der „Leitbilder und Handlungsstrategien für die Raumentwicklung in Deutschland” im Jahr 2016 konnte in Bezug auf die Erreichung dieser Ziele bereits ein erster Schritt gemacht werden. Durch das Konzept der Regiopolen soll weiterhin die Beachtung dieser im Bund-Länder- sowie den kommunalen Finanzausgleichen angestrebt werden. Die Anerkennung als Regiopole sollte eine besondere Berücksichtigung in diesen Systemen finden, um finanzielle Mittel für die regionale Entwicklung zwischen Metropolregionen und ländlichem Raum zur Verfügung zu stellen.[3] Ziele einer einzelnen Regiopole sind

die Bündelung regionaler Kräfte als Impulsgebeber und strategischer Partner des Umlands für eine Stadt-Umland-Parterschaft[4],

die Stärkung von endogenen Innovations- und Wettbewerbspotentialen,

Standortentwicklung und Standortmarketing für die Stadtregion sowie

Netzwerkbildung und Kooperation zwischen lokalen Akteuren.[5]

Zur Erreichung dieser und weiterer Ziele ist es unabdingbar, dass eine Regiopole ein breites Spektrum an Funktionen wahrzunehmen hat. Regiopolen fungieren v.a. vor dem Hintergrund des demografischen Wandels als „räumliche Konzentrationspunkte”[6] abseits der Metropolregionen, um „Räume zu stabilisieren und Funktionen zu bündeln”.[7] Die Leipzig Charta spricht in diesem Zusammenhang von einer Übernahme der “Verantwortung für den territorialen Zusammenhalt [durch] Kristallisationspunkt[e] der stadtregionalen Entwicklung.”[8] Funktionen einzelner Regiopoen sind

die Übernahme der Rolle als regionaler Entwicklungsmotor[9],

[9] vgl. Aring, Jürgen/ Reuther, Iris (2008): Die Regiopole. In: Aring, Jürgen/ Reuther, Iris (Hrsg.): Regiopolen, S. 8

die Erfüllung oberzentraler Funktionen über die Grundlagen des Zentrale-Orte-Systems hinaus (v.a. Versorgungsfunktionen),

die Übernahme von Gatewayfunktionen im nationalen Raum in multiplikativer Ergänzung der Metropolregionen[10] sowie

die Übernahme metropolitaner Teilfunktionen aus den Bereichen Politik, Wirtschaft, Wissenschaft, Verkehr und Kultur (= „regiopolitane Funktionen").

Mehrwerte erfahren regionale Akteure einer Regiopole bzw. Regiopolregion hauptsächlich durch die zielführende Nutzung lokaler Potentiale und Synergieeffekte, die durch Vernetzung und Clusterbildung entstehen. Ob für Städte und Gemeinden, Landkreise, Planunsgverbände, lokale Unternehmen oder Bürger – alle Gruppen erfahren durch Integration und verbesserte Zusammenarbeit spezifische Vorteile:

die gemeinschaftliche Wahrnehmung kommunaler Aufgaben durch Initiierung von „Ein-Themen- und Mehrzweckverbänden" [11] (z.B. gemeinsame Wirtschaftsförderung mit dem Ziel regional optimierter Unternehmensansiedlungen),

Prozessvereinfachungen durch Abbau doppelter (Verwaltungs-) Strukturen,

Erhöhung des fachlichen Austauschs und Generierung von Vorteilen durch direkter Kontakt zwischen Unternehmen, Kammern und politischen Entscheidungsträgern,

eine hohe Quantität und Qualität infrastruktureller Einrichtungen der Daseinsvorsorge

eine positive Einwohnerentwicklung sowie

eine gestärkte regionale Identifikation als weicher Standortfaktor.

2.2 Akteure und Organisationsformen der deutschen Regiopolen

Aufbau und Organisation sowie die involvierten Akteure und Partner der bestehenden Regiopolen in Deutschland sind sehr different. Da es keine Vorgaben oder Richtlinien zur Etablierung einer Regiopole gibt, sind die Organisationsformen unterschiedlich und an regionale Gegebenheiten angepasst. Stadtregionale Arbeits- und Organisationsformen von Regiopolen bündeln eine Vielzahl an Ressourcen und stellen Synergien zwischen den einzelnen Akteuren her, um insbesondere der Entwicklungsfunktion der Region gerecht zu werden. Daher wird das Modell der Regional Governance auf die Organisationsform einer Regiopole übertragen. Hierbei wird die regionale Selbstorganisation mit einer hervorgehobenen Rolle der regionalen und privaten Akteure in den Mittelpunkt gerückt.[12] Eine Regional Governance lässt sich von einer „gewöhnlichen" Steuerung auf regionaler Ebene, die sich auf politisch-administrative Akteure begrenzt, differenzieren. Regional Governance kann als „weiche" Form der Selbststeuerung bezeichnet werden und ist ein auf Netzwerken basierender territorialer Ansatz, der politisch-administrative, wirtschaftliche und sonstige nichtöffentliche Aktuere einbindet.

Die Regiopolregion Rostock verfügt über eine eigene Geschäftsstelle, die zwischen den verschiedenen Akteuren und Organen vermittelt. Die Geschäftsstelle ist im Planungsverband Region Rostock angesiedelt, der als Projektträger fungiert und die Grundfinanzierung der Geschäftsstelle sichert. Die Leitlinien zu Zielen und Projekten der Regiopolregion legt ein Lenkungsausschuss, bestehend aus je einem Vertreter der Partner der Regiopolregion (u.a. Städte und Gemeinen, Landkreis, IHK, Ministerien, Marketinginitiative), fest. Im Lenkungsausschuss, der bei Bedarf um fachkundige Experten ergänzt werden kann, werden konkrete Vorhaben, zu beteiligende Partner, Träger und Netzwerke sowie der Einsatz, die Zusammenstellung, Auflösung oder Veränderung der Arbeitskreise beschlossen.[13]

Die Regiopolregion Paderborn ist im Gegensatz dazu als eingetragener Verein organisiert, welcher sich aus ordentlichen (Städte und Gemeinden) und fördernden Mitgliedern (Institutionen, Kammern, Einrichtungen und Verbände aus den Bereichen Wirtschaftsförderung, Bildung, Sport, Kultur, Tourismus etc.) zusammensetzt. Die Mitgliederversammlung des RegiopolREGION PADERBORN e.V. hat direkten Einfluss auf die zentrale Geschäftsstelle der Regiopolregion, die an das Stadtplanungsamt der Stadt

Paderborn angedockt ist. Analog zur Regiopolregion Rostock erfolgt von dort die Vermittlung zwischen Mitgliedern, Partnern und anderen Akteuren sowie die Steuerung der Arbeitskreise, die sich themenbezogen mit Strategien und der Umsetzung von Projekten beschäftigen.[14]

Wiederum über eine andere Art der Organisationsstruktur verfügt die Regiopolregion Bielefeld. Eine Arbeitsgruppe Regiopolregion, der kommunale Vertreter aller zehn Partnerkommunen angehören, kann als Hauptausschuss angesehen werden. Inhaltliche Konzepte sowie die Koordinierung der themenspezifischen Fachgruppen werden von hier gesteuert. Parallel dazu sorgt eine Geschäftsstelle, die im Büro des Oberbürgermeisters Bielefelds angesiedelt ist, für die Sicherstellung der Kommunikationsflüsse. Strategische Ziele und Eckpunkte für das operative Handeln der Regiopolregion werden im Steuerungskreis beschlossen. Dieser ist das zentrale Gremium und setzt sich aus den Bürgermeistern der Partnerkommunen sowie dem Bielefelder Oberbürgermeister zusammen.[15]

2.3 Aktivitäten deutscher Regiopolen

Ähnlich different wie die Organisationsformen stellen sich die inhaltlichen Aktivitäten der deutschen Regiopolen dar. Abhängig von regionalen Gegebenheiten und Einflussfaktoren wie Einwohnergröße, Lage, kommunale Finanzkraft usw. unterscheiden sich Ziele, Themenfelder und Projekte der Regiopolen. Anhand der Regiopolen Rostock, Bielefeld und Paderborn wird beispielhaft die inhaltliche Ausgestaltung des Konzepts verdeutlicht.

Die Stadt Rostock mit der zugehörigen Verflechtungsregion bildete als Abschluss eines langwierigen Findungs- und Kommunikationsprozesses der verschiedenen involvierten Akteure schließlich die erste Regiopolregion Deutschlands. In Anschluss an die Gründung der Geschäftsstelle, stellte diese 2013 einen Aktionsplan auf, in dem sieben Kernziele für die Entwicklung der Region festgelegt wurden, auf die alle Handlungsfelder und Aktivitäten ausgerichtet sind. Hierbei gibt es sowohl Ziele, die auf die Innenentwicklung abzielen („Potentiale voll ausschöpfen"), die auf die Innen- und Außenwahrnehmung ausgerichtet sind („Standortstärkung nach innen und außen"; „Regionale Identifikation und Imagegewinn") und die auf die Wettbewerbsfähigkeit nach außen abzielen („Positionierung als starker Wachstumskern zwischen den Metropolregionen"; „Etablierung einer Dachmarke"; „Kategorie der zentralörtlichen Gliederung"; „Beachtung im Finanzausgleich des Bundes und der Länder").[16] Zur Erreichung dieser Ziele wurden sechs thematische Handlunsgsfelder bestimmt, die nach Bedarf angepasst und weiterentwickelt werden können. Die Handlungsfelder, die den inhaltlichen Rahmen für die Projektentwicklung geben, sind: „Verkehr und Mobilität", „Wirtschaftliche Entwicklung", „Daseinsvorsorge", „Bildung und Wissenschaft", „Umwelt-Energie Konzepte" und „Tourismus und Kultur".[17] Insgesamt ist die Regiopolregion damit prozesshaft und inhaltlich sehr breit aufgestellt und versucht die Region in vielen Bereichen weiterzuentwickeln.

Die Regiopolregion Paderborn hat in ihrem Zukunftskonzept „Entfaltung + Ausstrahlung, Anziehungskraft + Energie" fünf Themencluster definiert, in deren Bereichen sie Herausforderungen und Handlungsbedarfe der Region sieht. Innerhalb der unterschiedlichen Themenfelder wurden zentrale Zukunftsfragen und Ziele formuliert, die durch Umsetzung von Projekten erreicht bzw. realisiert werden sollen. Das Themencluster „Siedlungsentwicklung und Wohnungsmarkt" untersucht den regionalen Wohnungsmarkt und die Wohnorientierung der Menschen, die sich nicht an administrativen Grenzen, sondern an funktionalen Verflechtungen, Mobilitätsangeboten und Arbeitsplätzen orientieren. Im Bereich „Mobilität und Verkehr" werden das sich wandelnde Mobilitätsverhalten sowie veränderte Ansprüche an Mobilität untersucht. Ausgewälte Ziele sind die Nutzung digitaler Möglichkeiten zur Vernetzung sowie die Förderung von E- und Sharing-Mobility. Die Bindung von Schulabgängern und Hochschulabsolventen an die Region oder die Sicherung regionaler Raumbedarfe sind beispielhafte Zielsetzungen der Bestrebungen im Themencluster „Wirtschaft, Arbeitsmarkt und Bildung". Ein weiteres Themencluster umfasst die Herausforderungen des Bereichs „Daseinsvorsorge, Gesundheit, Sport und Kultur", wobei insbesondere die Parallelität von Wachstum und Schrumpfung in engen räumlichen Zusammenhängen einen zu lösenden Konflikt darstellt. Ziel ist die Gewährleistung von Daseinsvorsorgeangeboten wie medizinische Versorgung, zum Beispiel

[14] vgl. RegiopolREGION PADERBORN e.V. (2018): Vereinssatzung
[15] vgl. Stadt Bielefeld: Arbeitsstruktur der Regiopolregion, unter: https://www.bielefeld.de/de/dob/rr/as/
[16] vgl. Regiopolregion Rostock (2013): Der Aktionsplan der Regiopolregion Rostock 2013-2015, S. 4
[17] vgl. ebd, S. 7

durch Modellprojeke zur Nutzung lokaler Kompetenzen im Bereich E-Health. Das fünfte Themencluster der Regiopolregion Paderborn „Zusammenarbeit und Verwaltungskooperation" verfolgt den Grundsatz, Identitäten und Kompetenzen der Kommunen zu wahren und gleichzeitig offen und wirkungsvoll zu kooperieren. Auf Basis von Netzwerken, Plattformen und Wissenstransfer sollen administrative Hürden gemildert werden, um eine gemeinschaftliche regionale Entwicklung vorantreiben zu können.[18]

Die Regiopolregion Bielefeld, bestehend aus elf Partnerkommunen, zielt unter dem Slogan „Intensivierung gemeindeübergreifender Kooperation" auf eine regionale Entwicklung durch gemeinsame Aufgabenwahrnehmung. Hierzu verfügt die Regiopolregion über fünf themenspezifische Fachgruppen: „Mobilität", die sich insbesondere mit dem Aufbau eines Radwegesystems beschäftigt, „Kultur" mit Ziel ein regionsweites Kulturportal zu schaffen, „Hochwasserschutz", die einen regionsweiten Leitfaden zu diesem Thema entwickelt, „Geoinfirmation", die Kartenmaterial zur Analyse und zu Marketingzwecken erstellt und „Ökoprofit", die sich mit Ansätzen des betrieblichen Umeltmanagements beschäftigt. Neben den dauerhaft bestehenden Fachgruppen hält die Regiopole Informationsaustausche zu unterschiedlichen Themen vor. Beispielsweise erfolgen fachliche Erfahrungsaustausche zwischen den Partnerkommunen in den Bereichen „Schulentwicklung" und „Kostenoptimierung von Bauhöfen".[19]

2.4 Vergleich der Akteurs- und Organisationsformen sowie Aktivitäten der untersuchten Regiopole

Alle drei Regiopolen haben die Ziele des Gesamtkonzepts (vgl. Kap. 2.1) in ihre Agenden übernommen und richten ihre inhaltlichen Strategien daran aus. Zur Erreichung der Ziele übernehmen sie die Funktionen als regionaler Entwicklungsmotor und erfüllen mindestens oberzentrale Funktionen. Alle drei Regiopolen übernehmen metropolitane Teilfunktionen und sind dadurch Standorte regiopolitaner Funktionen. In Bezug auf die Übernahme nationaler Gatewayfunktionen kann lediglich Bielefeld die Funktion durch einen regelmäßigen ICE-Systemhalt erfüllen.

Die beteiligten Akteure und Organisationsformen der Regiopolen unterscheiden sich in wesentlichen Punkten. Die Regiopolregion Rostock wird von einer Geschäftsstelle im Planungsverband Region Rostock koordniert und bindet kommunale Vertreter wie auch Marketinginstitutionen und Kammern bzw. Verbände mit ein. Die Regiopolregion Paderborn entstand durch einen Bottom-up-Ansatz aus der Region heraus, was sich in einer sehr akteursorientierten Ausgestaltung niedergeschlagen hat. Durch die Organisation als eingetragener Verein können zahlreiche Akteure aus kommunalen, wirtschaftlichen und zivilgesellschaftlichen Bereichen beteiligt werden. Im Gegensatz dazu orientiert sich der regiopolitane Ansatz der Regiopolregion Bielefeld sehr nah an vorhandenen politischen Strukturen. Die Organisationsform sieht (bisher) keine direkte Einbindung von Akteuren außerhalb der Politik bzw. Verwaltung vor.

Im Hinblick auf inhaltliche Aktivitäten verfügen die drei Regiopolen über breite Themenspektren. Besonders hervorzuheben sind dabei die Themen Mobilität, Wirtschaftliche Entwicklung, Bildung, Daseinsvorsorge und Kultur, die in allen drei Regiopolregionen Beachtung finden.

3 DIE REGIOPOLREGION „KOBLENZ-MITTELRHEIN-WESTERWALD"

Neben der Darstellung des Konzepts der Regiopolen, ist es Ziel dieses Beitrags mögliche Eckpunkte der Ausgestaltung einer Regiopole zu diskutieren. Hierfür wird beispielhaft die potentielle Regiopolregion Koblenz-Mittelrhein-Westerwald herangezogen. Der Untersuchungsraum der als Grundlage durchgeführten sozioökonomischen Strukturanalyse umfasst die kreisfreie Stadt Koblenz sowie das Gebiet der umliegenden Planungsregion Mittelrhein-Westerwald. Anhand dieses Fallbeispiels werden thematisch-inhaltliche, strukturell-organisatorische sowie räumlich-funktionale Aspekte der Ausgestaltung diskutiert.

Die Idee, eine regionale Identität herzustellen bzw. zu stärken und somit die Entwicklung der Region voranzutreiben existiert bereits seit der Auflösung des ehemaligen Regierungsbezirks Koblez im Jahr 2000. Seitdem versuchen regionale Akteure, wie die Initiative Region Koblenz-Mittelrhein e.V., Impulse zur Initiierung einer Regiopolregion zu setzen. Konkretisiert wurde die Regiopolenidee in der Zukunftskonferenz „Regiopolregion Koblenz-Mittelrhein" im März 2017 sowie schließlich durch die Vergabe einer wissenschaftlichen Vorstudie zur Etablierung einer Regiopolregion im Auftrag der Planungsgemeinschaft Mittelrhein-Westerwald.

3.1 Koblenz und die Region Mittelrhein-Westerwald

Die Stadt Koblenz mit 112.586 Einwohnern liegt im Norden des Bundeslandes Rheinland-Pfalz, in der Planungsregion Mittelrhein-Westerwald an der Mündung der Mosel in den Rhein. Die Region gliedert sich in eine kreisfreie Stadt und acht Landkreise, sechs verbandsfreie Gemeinden, vier große kreisangehörige Städte und 52 Verbandsgemeinden sowie 898 Ortsgemeinden.[20] In einem Umkreis von ca. 100 Kilometern findet sich keine Metropolregion, wodurch das Oberzentrum Koblenz einen großen Einzugsbereich vorweisen kann. Aufgrund der großen Distanz besteht keine unmittelbare Beziehung zwischen Stadt und Region zu Metropolregionen. Koblenz, als Universitätsstandort, erfüllt demnach alle drei grundlegenen Identifikationskriterien einer Regiopole nach Aring und Reuther.

Als Ergebnis einer sozioökonomischen Strukturanalyse der regionalen Voraussetzungen und ergänzenden Expertengesprächen[21] lassen sich einerseits Aussagen zu Standorten regiopolitaner Funktionen (Politik, Wirtschaft, Wissenschaft, Verkehr und Kultur, vgl. Abb.1) innerhalb der Region machen und andererseits eine räumlich funktionale Abgrenzung ableiten.

Der Funktionsbereich „Politik", der sich vor allem durch Sitze nationaler Regierungen und Nicht-Regierungsorganisationen abbildet, ist in abgestufter Form in der potentiellen Regiopolregion vorzufinden.

[20] vgl. Planungsgrmeinschaft Mittelrhein-Westerwald (2018): Regionaler Raumordnungsbericht 2018, S. 3
[21] Expertengespräche vgl. Weber, Tobias (2019)

Die Stadt Koblenz bildete bis 1999 den Sitz des gleichnamigen Regierungsbezirks. Die darauffolgende Struktur- und Genehmigungsdirektion Nord hat bis heute ihren Sitz in der Stadt. Weiterhin ist Koblenz Standort von Verbänden wie der IHK und HWK und stellt einen der größten Bundeswehrstandorte Deutschlands mit Einrichtungen wie dem Bundeswehrzentralkrankenhaus dar. Ausgelagerte Teile der rheinland-pfälzischen Landesregierung sind in Koblenz und Bad Ems angesiedelt, die demnach Standorte von regiopolitanen politischen Funktionen sind.

Weiterhin wird die Funktion des regionalen Entwicklungsmotors durch den Funktionsbereich „Wirtschaft" abgebildet. Standorte finden sich v.a. in Koblenz und in direkt angrenzenden Städten wie Neuwied oder Mülheim-Kärlich. Sie bilden das Arbeitsplatzzentrum der Region. In und um Koblenz finden sich zum einen Standorte großer Unternehmen, zum anderen auch Sitze kleinerer „Hidden Champions", wie EWM AG in Mündersbach oder Griesson – de Beukelaer GmbH & Co. KG in Polch. Ein weiterer bedeutsamer Wirtschaftsstandort findet sich mit dem europaweit einmaligen Keramik-Cluster in Höhr-Grenzhausen.

Der regiopolitane Funktionsbereich „Wissen und Innovation" ist in der Region Mittelrhein-Westerwald stark ausgeprägt und stellt eine Stärke dar. Zahlreiche Universitäten und Hochschulen mit unterschiedlicher Schwerpunktsetzung und eine hohe Anzahl an Studierenden in der Stadt Koblenz verdeutlichen das Bild der bildungs- und wissenschaftlich geprägten Region. Bedeutend für die (Aus-) Bildung innerhalb des Bundeslandes Rheinland-Pfalz sind auch die Hochschule der Polizei (HdP) am Flughafen Frankfurt-Hahn und die Hochschule für öffentliche Verwaltung (HöV) in Mayen. Über bundesweite Bedeutung verfügt die staatliche Hochschule der Deutschen Bundesbank in Hachenburg. Zudem finden sich in Höhr-Grenzhausen, Remagen und Wissen innovative Forschungseinrichtungen. All diese Faktoren zeugen von einem hohen Innovationspotential sowie der Rolle der Stadt Koblenz und der engeren Verflechtungsregion als Motor regionalen Wachstums.

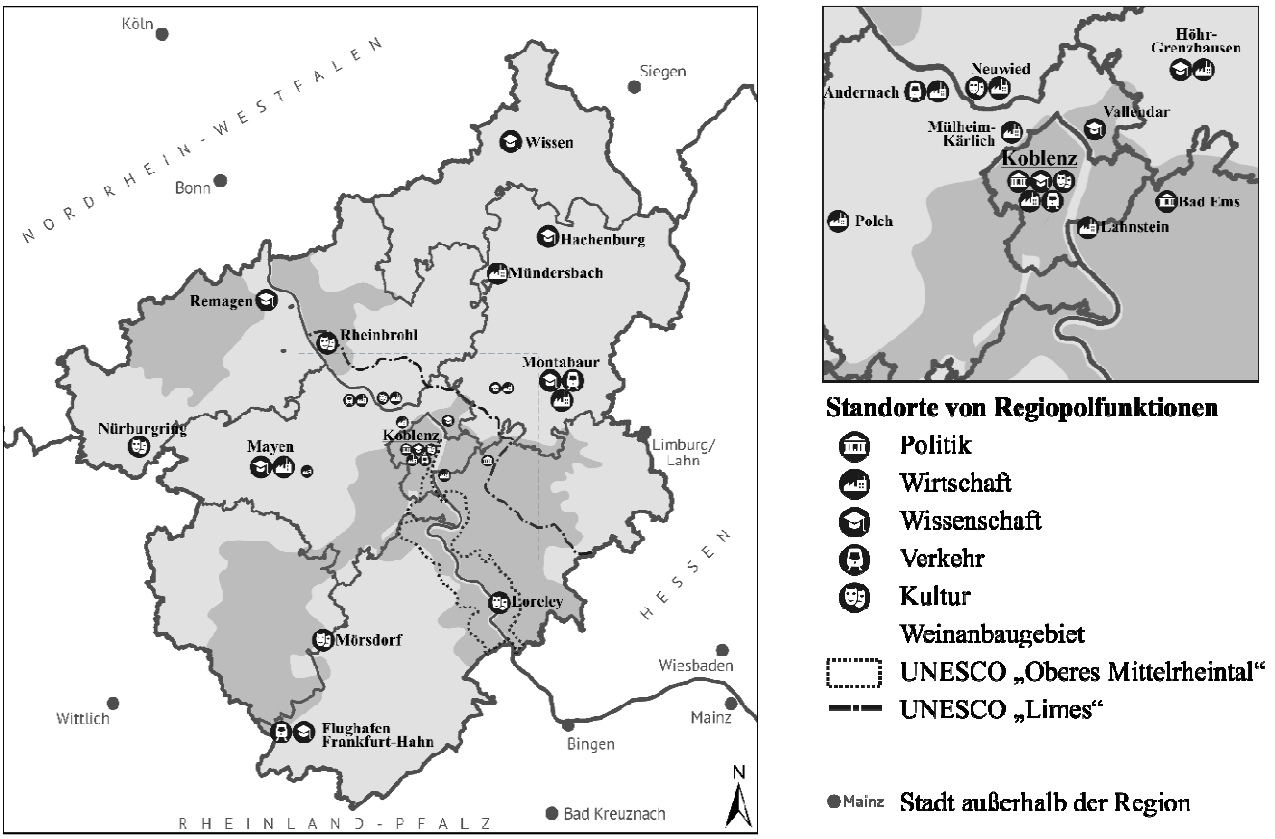

Abb. 1: Standorte regiopolitaner Funktionen in der Region Mittelrhein-Westerwald
(Quelle: Weber 2019, S. 62)

Die Gatewayfunktionen werden durch den Funktionsbereich „Verkehr" abgebildet und durch die überregionalen Bundesautobahn- und Bahnfernverkehrsverbindungen in das Rhein-Main-Gebiet und die Metropolregion Rhein-Ruhr erfüllt. Zusätzlich trägt die Stadt Montabaur mit der Anbindung an die ICE-Schnellfahrstrecke Frankfurt-Köln zur Wahrnehmung dieser Funktion bei. Als Standort der internationalen Verknüpfung gilt der Flughafen Frankfurt-Hahn im Süden der Region.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Der regiopolitane Funktionsbereich „Kultur" als weicher Standortfaktor und Identifikationsmerkmal ist mit zwei UNESCO-Welterbestätten und einer großen kulturellen Ausstattung (z.B. Theater in Koblenz und Neuwied, Freiluftbühne auf der Loreley) gut ausgeprägt Die naturräumliche Vielfalt sowie die Weinanbaugebiete an Rhein, Mosel und Ahr tragen zu einer hohen Lebensqualität in und Identifikationsmöglichkeiten mit der Region bei. Die Profilierung im Bereich Sport, durch identitätsstiftende Vereine oder große Sportereignisse, findet sich in der Region vor allem am Nürburgring im Westen der Region, einer der bedeutendsten Rennstrecken weltweit.

Wie in Abbildung 1 erkenntlich, bündeln sich zwar insgesamt die Standorte aller Funktionsbereiche im Oberzentrum Koblenz und dem umgebenden Verdichtungsraum des Neuwieder Beckens (von Andernach bis Lahnstein), verteilen sich aber funktionsbezogen nahezu in der gesamten Region.

3.2 Ziele der potentiellen Regiopolregion

Oberstes Ziel der potentiellen Regiopolregion stellt eine verbesserte Positionierung im Standortwettbewerb der Städte und Regionen dar. Auf Grundlage der strukturellen Analyse, Aussagen von regionalen, in den Prozess involvierten, Experten sowie Aussagen des Landesentwicklungsprogramms IV Rheinland-Pfalz und des Regionalen Raumordnungsplans Mittelrhein-Westerwald, lassen sich folgende Entwicklungsziele für die zukünftige Regiopolregion ableiten:

Etablierung eines „Dachs über der Region" zur Milderung von Problemlagen und Nutzung von Potentialen und Chancen durch interkommunale Kooperation[22];

Nutzung der Brückenfunktion ziwschen den Metropolregionen Frankfurt/Rhein-Main und Rhein/Ruhr[23];

Nutzung zukunftsfähiger Entwicklungspotentiale der Region auf demografischer, wirtschaftlicher und infrastruktureller Ebene[24];

Steigerung der regionalen Identifikation und Imagegewinn durch Herstellung einer regionalen Identität bzw. eines regionalen Images[25];

Kanalisierung des vorhandenen Siedlungsdrucks im Neuwieder Becken[26];

Verbesserung der regionalen und überregionalen öffentlichen Mobilitätsinfrastrukturen[27];

Etablierung eines Exzellentszentrums durch Clusterbildung mit unternehmensnahen Dienstleistungen im gewerblich-industriellen und wissenschaftlichen Bereich[28].

Diese Entwicklungsziele stellen eine Sammlung bisher nebeneinanderstehender Leitideen zur Entwicklung der zukünftigen Regiopolregion Koblenz-Mittelrhein-Westerwald dar. Es kann aber festgehalten werden, dass die regionalen Akteure mit diesem „Kanon" an Entwicklungszielen die Ziele und Funktionen des Konzepts der Regiopolen voll abdecken und damit eine gute Basis für die Gründung einer Regiopole gegeben ist. Gleichwohl sind die Entwicklungsziele im weiteren Prozess zu konkretisieren.

3.3 Aktivitäten der potentiellen Regiopolregion

Die untersuchten Regiopolen in Deutschland weisen breit aufgestellte Themenspektren auf und entwickeln Projekte in nahezu allen strukturellen Bereichen. Anhand einer Clusterung von Themen zu potentiellen Handlungsfeldern sollen mögliche inhaltliche Ausrichtungen der Regiopolregion Koblenz-Mittelrhein-Westerwald aufgezeigt werden. Die Auswahl bezieht sich vor allem auf, in Experteninterviews mit involvierten Akteuren genannte Themen und stützt sich zudem auf die sozioökonomische Strukturanalyse.

Die Erarbeitung und Einigung auf eine regionale Strategie im Sinne eines Handlungsrahmens (vgl. Aktionsplan in der Regionlregion Rostock bzw. Zukunftskonzept der Regiopolregion Paderborn) mit einer Analyse, einer Leitvorstellung, Zielen, Handlungsfeldern und Maßnahmen, die von allen Akteuren getragen wird, kann als wesentlicher Erfolgsfaktor für eine effiziente Arbeit einer Regiopolregion betrachtet werden.

[22] vgl. Vorsitzender Initiative Region Koblenz-Mittelrhein e.V.
[23] vgl. Planungsgemeinschaft Mittelrhein-Westerwald (2017): Regionaler Raumordnungsplan: G3, S. 1
[24] vgl. Vorsitzender Initiative Region Koblenz-Mittelrhein e.V.
[25] vgl. Referent Planung der IHK zu Koblenz
[26] vgl. Leitender Planer der PG Mittelrhein-Westerwald
[27] vgl. Vorsitzender Initiative Region Koblenz-Mittelrhein e.V.
[28] vgl. Ministerium des Innern und für Sport Rheinland-Pfalz (2008): Landesentwicklungsprogramm IV, S. 68

Denn wird diese in einem gemeinsamen Prozess erarbeitet, spiegelt sie einerseits die Motivationen und Erwartungen der Akteure und dient anderseits der Identifikation mit dem anvisierten Mehrwert, der aus der Regiopole entstehen soll.

Zentrales Themencluster, das zur Erreichung der formulierten Entwicklungsziele Beachtung finden sollte, ist „(Aus-) Bildung, Wissenschaft, Forschung, Innovation und Wirtschaft". Auf Grundlage der guten strukturellen Bildungs- und Innovationslandschaft kann durch die Nutzung der vorhandenen Potentiale die Dachmarke „Innovations- und Wissenschaftsregion" zu einem Standbein der Regiopolregion werden und die Standortentwicklung fördern. Dafür gilt es, den wissenschaftlichen mit dem gewerblich-industriellen Bereich stärker zu vernetzen, um durch Synergieeffekte positive Entwicklungen auf dem Arbeitsmarkt zu generieren.

Besonderes Augenmerk sollte auch auf die Themen Innen- und Außenwahrnehmung, Marketing, regionale Identität, regionales Image, Kultur, Natur, Weinbau und Tourismus gelegt werden. Zur Erreichung der formulierten Entwicklungsziele ist die Entwicklung einer regionalen Identitäts- und Imagestrategie als „Dach"[29] über der Regiopolregion sinnvoll. Gleichzeitig kann durch die Umsetzung von Projekten innerhalb dieses Bereichs zum einen die Akzeptanz der lokalen Bevölkerung, zum anderen die Wahrnehmung von außen erhöht werden.

Nach Vorbild der bestehenden Regiopolregionen und Aussagen von Experten und des LEP IV, sind Themen wie Mobilität, Verkehr und Erreichbarkeiten essentieller Bestandteil einer regionalen Standort-Entwicklungsstrategie.[30] Der Ausbau von Mobilitätsinfrastrukturen sollte jedoch stets unter Beachtung der Umweltverträglichkeit und Nachhaltigkeit stehen. Daher ist eine Verknüpfung dieser beiden Themenfelder zu einem Handlungsfeld (z.B. „Grüne Infrastruktur") empfehlenswert. Schwerpunkte sollten dabei Projekte im Bereich der E- und Sharing-Mobility bilden.

Zur Steuerung der Siedlungsentwicklung, die an ungleiche demografische Entwicklungen der Region anzupassen ist[31], finden die Themen Wohnen, Leben, Daseinsvorsorge und Versorgung Berücksichtigung in der regionalen Entwicklungsstrategie. Hierbei gilt es gleichermaßen die Herausforderungen des demografischen Wandels, wie auch die des wachsenden Siedlungsdrucks in Kernbereichen zu beachten. Die Priorität des Handlungsfelds, das diese Themen clustert, stellt die Entwicklung des regiopolitanen Zentrums als zusammenwachsende Stadtregion dar[32].

Die Clusterung dieser Themen zu Handlungsfelden stellen einen ersten inhaltlichen Rahmen für die potentielle Regiopolregion Koblenz-Mittelrhein-Westerwald dar. Dabei ist die Liste keineswegs abschließend und bedarf einer ständigen Evaluierung und Anpassung an externe Trends und veränderte Rahmenbedingungen. Letztendlich sind Themen, die in einem Strategiekonzept verankert werden, wie oben beschrieben, durch partizipative Prozesse der involvierten Akteure festzulegen.

3.4 Akteure und Organisationsform der potentiellen Regiopolregtion

Maßgebliches Element der Etablierung einer Regiopolregion ist ein entsprechender Akteurskreis, der die zielführende Entwicklung der Region als übergreifendes Ziel ansieht. Hierbei sind insbesondere die bisher in den Prozess involvierten Akteure gefragt, die die Idee einer Regiopolregion als Bottom-up-Ansatz aus der Region heraus entwickeln. Im Sinne einer Regional Governance gilt es einen Akteurskreis aus kommunalen Vertretern, Akteuren der Wirtschaft sowie Vertretern der Bürgerschaft und Zivilgesellschaft zu schaffen.

Der Impuls zur Initiierung einer Regiopolregion mit Koblenz als Zentrum ging von der Initiative Region Koblenz-Mittelrhein e.V. aus. Die Initiative verfügt durch ihr breites Spektrum an Mitgliedern aus wirtschaftlichen und zivilgesellschaftlichen Bereichen bereits über ein vorhandenes Netzwerk, das zur Akquirierung von Akteuren genutzt wird. Weiterhin hat die Planungsgemeinschaft Mittelrhein-Westerwald mit der Vergabe einer wissenschaftlichen Vorstudie zur Etablierung einer Regiopolregion innerhalb ihres Einzugsbereichs das Thema im vergangenen Jahr aufgegriffen. Die Planungsgemeinschaft stellt dadurch ebenfalls einen bedeutenden Akteur im Entwicklungsprozess dar, da sie über regionales Know-How verfügt,

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

in der Kooperation mit den Kommunen der Region geübt ist und als Träger der Regionalplanung dezidiert auch einen Entwicklungsauftrag für die Region hat

Diesen beiden Hauptakteuren obliegt es nun, in dem Ziel eine Regiopole zu gründen sowie weitere Partner der Regiopolregion zu gewinnen, um ein leistungsfähiges Kooperationsnetzwerk aufzubauen. Allen voran gilt es kommunale Vertreter aller Gebietskörperschaften einzubinden: Gemeinden, Verbandsgemeinden, Städte und Landkreise, sowie Vertreter von Kammern und Verbänden und führender regionaler Unternehmen einzubinden. In der Region findet sich aktuell ein Zusammenschluss aus neun Unternehmen, die durch Kooperation versuchen, die Attraktivität der Region für Investoren, Fachkräfte und Politik sichtbar zu machen: die R56+ Regionalmarketing GmbH & Co. KGaA mit Sitz in Koblenz. Diese kann ein bedeutender Teil der Vertretergruppe der wirtschaftlichen Akteure bilden. Weitere potentielle Institutionen zur Einbindung könnten sein: Universitäten und Hochschulen der Region, Wirtschafts- und Wissenschaftszusammenschlüsse, Forschungseinrichtungen, Verkehrsverbünde und Mobilitätsbetriebe, Tourismus-Institutionen oder Gewerkschaften. Zudem sollten Vertreter der Umwelt, Landwirtschaft sowie verschiedener Generationen und Geschlechter in den Akteurskreis integriert werden. Ohne ein solch breit aufgestelltes Netzwerk an involvierten Akteuren und Kooperationspartnern wäre eine wirkungsvolle Arbeit der Regiopolregion eingeschränkt.

Als Basis der strukturellen Organisation bietet sich die Gründung eines Vereins an, der alle zu einer Zusammenarbeit motivierten Akteure durch Mitgliedschaft an die Regioopolregion bindet. Hierbei dient die Regiopolregion Paderborn mit dem „RegiopolREGION PADERBORN e.V." als Vorbild. Positive Aspekte der Gründung eines Vereins sind zum einen eine erste Grundfinanzierung durch die Beitragszahlungen der Mitglieder. Zum anderen ist die Regiopolregion durch regelmäßig stattfindende Mitgliederversammlungen stets präsent und auf der Agenda der Akteure. Den bedeutendsten Vorteil eines Vereins bietet jedoch die Möglichkeit, die aktuell involvierten Akteure, wie die Mitglieder der Initiative Koblenz-Mittelrhein e.V., in leitenden Positionen abzubilden.

Organisation, Kommunikation und Marketing sowie Projektleitung sind durch eine zu schaffende Geschäftsstelle abzudecken und zu steuern. Dabei bietet sich aus mehreren Gründen ein Andocken an die bestehende Geschäftsstelle der Planungsgemeinschaft Mittelrhein-Westerwald an. Zum einen hat diese einen regionalen Entwicklungsauftrag, zum anderen verfügt sie über das benötigte Wissen über die Region, das für eine nachhaltige Strategie von Nöten ist. Weiterhin findet sich die Planungsgemeinschaft bereits in einem bestehenden interkommunalen Konsens mit den Städten und Gemeinden der Region, worauf eine weiterführende Kooperation im Sinne der Regiopolregion aufbaut. Neben organisatorischen und kommunikativen Aufgaben umfasst die Funktion der Geschäftsstelle die Koordiniierung bzw. Leitung der Projekte der Regiopolregion. Zur Initiierung von Projekten sollten entsprechend den inhaltlichen Handlungsfeldern (siehe 3.3) Arbeitskreise gebildet werden, die bei Bedarf auf die Unterstützung externer Experten zugreifen können.

Die tatsächlichen Organisationsstrukturen sind abhängig von der Zusammensetzung und dem Engagement der regionalen Akteue vor Ort. Das strukturelle Grundgerüst als Regional Governance sollte jedoch in einer Anlehnung an vorhandene administrative Verwaltungsstrukturen vorgezogen werden.

Die räumliche Abgrenzung der Regiopolregion wird sich letztendlich durch das Kommittment der Gebietskörperschaften und weiteren Akteuren ergeben. Die Analyse der regiopolitanen Funktionen hat gezeigt, dass diese in der gesamten Planungsregion verortet sind, mit einem Schwerpunkt auf Koblenz. Entsprechend auch dem regionalen Verflechtungsbereich, sollte sich eine Erstansprache zur Partnerschaft in der Regiopole auf die Gebietskörperschaften, Wirtschafts- und Sozialpartner der Planungsregion Mittelrhein-Westerwald beziehen. Diese werden vor dem Hintergrund einer potentiellen Vereinsmitgliedschaft sicher realitätsnah entscheiden, ob sich die Verflechtungen und die Orientierung der Bevölkerung in der Planungsregion abbilden und dementsprechend eine Mitgliedschaft und Zugehörigkeit zur Regiopole von Vorteil ist.

4 MEHRWERT UND AUSBLICK

Bislang forcierten Leitbilder, Handlungsstrategien oder Konzepte der Raumordnung vor allem zwei Ebenen: Wirtschaftliche Wachstumsräume um Metropolen und den ländlichen Raum. Eine Verankerung der Regiopole als Raumkategorie im System der deutschen Bundesraumordnung würde die

Entwicklungschancen dieser Großstädte erhöhen und eine Verflechtung zwischen Wachstums- und Schrumpfungsräumen generieren. Die sieben Regiopolen in Deutschland haben in den letzten zehn Jahren vereinzelt auf sich aufmerksam gemacht. Durch die Etablierung des RegioPole-Netzwerks existiert ein bundesweites Gremium, welches die Bekanntheit des Konzepts weiter steigern wird. Durch innovative thematische und inhaltliche Konzeptionen und auf das Konzept angepasste Organisationsformen, werden Regiopolen in den kommenden Jahren eine Wahrnehmungssteigerung erfahren.

Die etablierten Regiopolregionen, als akteursorientiere stadtregionale Ansätze, unterscheiden sich gerade hinsichtlich ihrer Organisationsformen in vielen Punkten. Eines eint jedoch alle Organisationsstrukturen: der Drang nach einer regionalen Entscheidungsebene. Entwicklung, Bestehen und Wachstum einer Stadtregion richten sich nicht (mehr) nach historischen administrativen Grenzen, sondern sind von funktionalen, organischen Faktoren abhängig. Eine Loslösung von diesen administrativen Grenzen durch eine neue, stadtregionale Entscheidungsebene, die Verflechtungen einer Stadtregion durch Governancestrukturen abbildet, scheint die Lösung der Organisation einer Stadt-Umland-Kooperation zu sein.

Governancestrukturen, die zusätzlich zu bestehenden Verwaltungsstrukturen geschaffen werden, um Stadt-Umland-Herausforderungen zu lösen, bedürfen der Akzeptanz durch die Bevölkerung und sollten in der Gesellschaft Verankerung finden. Hierfür können folgende Elemente hilfreich sein: Etablierung von Kommunikationsprozessen als konstituierendes Element des regionalen Entwicklungsprozesses, die Bestimmung gemeinsamer regionaler Entwicklungsleitbilder und eine Bandbreite regionaler Zielsetzungen. Gleichzeitig sollte ein Paradigmenwechsel von einer alleinstehenden hoheitlichen Planung hin zu einem dynamischen Initiieren, Formen und Begleiten – stets in kooperativen Partizipationsprozessen – regionaler Entwicklung erfolgen.

Können Koblenz und die Region Mittelrhein-Westerwald durch die Initiierung einer Regiopolregion langfristig profitieren? Die Großstadt Koblenz und ihr Verflechtungsbereich bieten alle strukturellen Voraussetzungen und verfügen über einen ausreichend motivierten Akteurskreis, um eine Regiopolregion zu initiieren. Durch die Umsetzung einer regionalen Strategie können Stadt, Region sowie die involvierten Akteursgruppen eine positive Entwicklung und einen spürbaren Mehrwert erfahren. Funktionale Vernetzung und Clusterbildung ermöglichen Wettbewerbsvorteile für einwohnerorientiere, wirtschaftliche oder wissenschaftliche Standortwettbewerbe. Eine weiterentwickelte regionale Identität kann die Regiopolregion sowohl nach innen als auch nach außen sichtbar mit einem innovations- und zukunftsorientierten Profil abbilden. Eine Regiopolregion Koblenz-Mittelrhein-Westerwald könnte, mit dem beschriebenen Akteursverbund, so als starker Wissen- und Wirtschaftsraum mit der Stadt Koblenz als Zugpferd positive Entwicklungen in demografischer, wirtschaftlicher, infrastruktureller und kuklturelle Hinsicht generieren.

Insgesamt stellt das Konzept der Regiopole als neue Raumkategorie eine gute Alternative für kleinere Großstädte zur Positionierung zwischen Metropolregionen dar. Die nationalen „Vorreiter-Regiopolen“ Rostock oder Paderborn zeigen, dass der Ansatz vor allem auf (stadt-) regionaler Ebene eine große Entwicklungschance bietet. Stadt-Umland-Herausforderungen gilt es auf einer funktionalen Ebene zu entwickeln – administrative Verwaltungsgrenzen sind oft nicht zuielführend.

Deciphering and Modelling Spatiotemporal Patterns and Processes across Scales – Migratory Flows and their Implications under a Healthy City Scenario in the Ruhr Area, Germany

Janka Lengyel, Jan Friedrich

(Janka Lengyel, Institute of Mobility and Urban Planning, Universitätsstr. 5, 45141 Essen, Germany, janka.lengyel@uni-due.de)
(Dr. Jan Friedrich, Univ. Lyon, ENS de Lyon, Univ. Claude Bernard, CNRS, Laboratoire de Physique, 69342 Lyon, France)

1 ABSTRACT

As it has been stated over and over again, today's large-scale urban structures are becoming increasingly hard to be grasped and understood through the lens of conventional spatial and temporal scales. Due to their dynamic interactions and complex interdependencies, cities are expanding way beyond traditional - such as municipal, regional or even national – barriers and boundaries. Nevertheless, comprehensive methods and innovative tools for effectively deciphering and designing complex urban systems are still relatively few. Here, we introduce a five-step integrated methodology to understand, reveal and model dynamic spatiotemporal patterns and processes across scales. The main focus of this paper will thereby lie on factor and cluster analysis of prevailing socioeconomic contexts and on their embedding into multiscale urban modelling. We contend that a meaningful connection between empirics and modelling is a quintessential and often missing link of endeavours simulating long-term development of urban environments. Therefore, we demonstrate how - with a machine-learning mechanism called self-organising maps - empirical findings may effectively infiltrate into modelling attempts of complex urban systems. Subsequently, we will use the example of the residential and employment migration subsystem of the multiscale urban model (Lengyel and Friedrich, 2019), to study the effects of demographic change, local and regional migration flows, as well as their interdependencies with the ongoing economic structural change between 2011 and 2050 in the Ruhr region. Furthermore, we show how we can use micro-scale outcomes to identify the small-scale anchoring of latter regional processes. In our example, we determine neighbourhoods with substantial changes in their local economic and land value profiles: which might be indicators for future hot and cold spots of gentrification processes. The main aim is to inform and instigate meaningful cooperation and synchronised action between urban stakeholders and decision-makers on different scales. The latter task is perhaps even more pressing and challenging for large-scale polycentric regions such as the Ruhr Area in Germany, which will serve as the case study for this paper.

Keywords: multiscale, exploratory spatial data analysis, self-organizing maps, modelling complex urban systems, residential and employment migration

2 FIVE-STEP METHODOLOGY FOR DECIPHERING AND MODELLING SPATIO-TEMPORAL PROCCESSES ACROSS SCALES

First of all, we provide a general overview of the five-step comprehensive methodology for deciphering and modelling spatiotemporal patterns and processes across scales. Each step is being illustrated with some relevant examples from the Ruhr Area in Germany. Additionally, they seek to give practical advice for increasing the real-world applicability and efficacy of corresponding efforts. In this paper, step one, three and five are only discussed shortly (for more information please see Lengyel and Friedrich, 2020), whilst the crucial step of effectively bringing empirics and modelling together (step two) will be reviewed in detail in Section 3, followed by an extensive description of the residential migration sub-model in Section 4 (which is a crucial part of step four).

2.1 Step 1: Analysing trends and deciphering their spatial projections

To start with, we must try to identify the most influential historic as well as current trends of the area in question and thereby comprehend their important shaping factors and mechanisms. Henceforth, the operational scale of this step is a macro spatial boundary e.g. city, regional or even national layers, combined with an investigation time period of the minimum past 25 years (depending on data availability). Such macro-scale trends may include demographic (age or ethnic structure), economic (sectoral shifts) or societal (household, gender) processes. In order for this step to be applicable for both planning and policy, as well as for modelling purposes, one may carry out the following three main consecutive tasks: firstly, with the help of historical data analysis carefully quantifying spatiotemporal development tendencies, and secondly, studying their connections and interdependencies. Closely connected to this is the third and very important

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

task (since we are dealing with urban environments), with the main goal to deduce the spatial impact of identified trends. As an example, we studied how the ongoing economic structural change in the Ruhr Area has left its massive traces on land use development of the last couple of decades and how the amplitude of impact is roughly distributed throughout the region (see Fig. 1). Over the course of this first step, we suggest an alternating method of literature review and spatiotemporal data analysis.

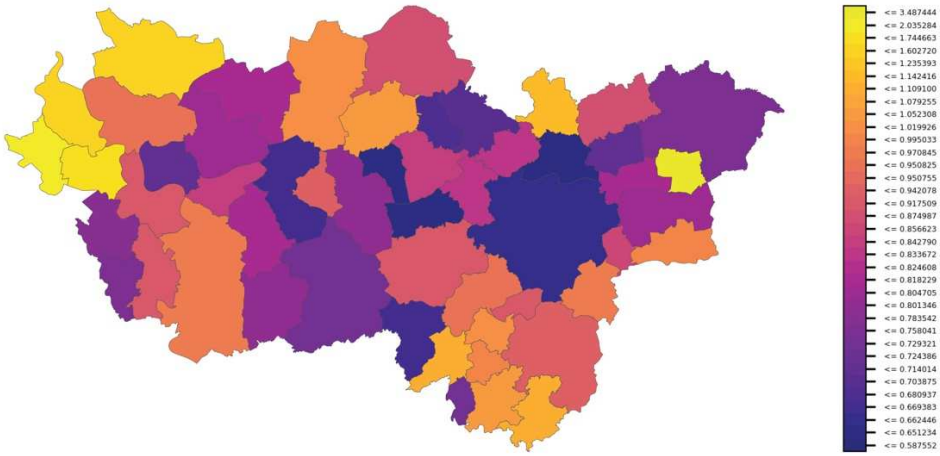

Fig 1: Commercial and industrial land use change between 1994 and 2015 (factor of change compared to 1994 values). Own graphic. For data source: see Section 4.3

2.2 Step 2: Unravelling spatiotemporal patterns and building clusters

Now that we are aware of the major influencing trends of our area, we shift focus from macro towards subjacent scales, and observe their local impact and anchoring. Firstly, with the help of exploratory spatial data analysis we study the spatial, demographic, socio-economic and economic patterns and try to capture their corresponding characteristic scales. Throughout our investigations into the Ruhr Area we observed that the spatial distribution of large number of socioeconomic indicators are still displaying a pattern which follows very closely the layered structure of the historical development zones of the region. Thus, today's city boundaries are almost invisible (see Fig. 3). Both industrialisation and deindustrialisation processes took place in several consecutive phases from the south northwards (Wehling, 2014), leaving behind some very important characteristic scales for age, economic, ethnic and socioeconomic structures. Secondly, we demonstrate how - with a machine-learning mechanism called self-organising maps – latter empirical findings can by synthesised for more clarity and for their effective infiltration into modelling attempts of complex urban systems (the latter method will be reviewed at length in Section 3). This second step may be considered as the first effort towards delineating new spatial and temporal dimensions for action, which may prove to be more efficient for some measures than operating on the scale of traditional urban boundaries.

2.3 Step 3: Delineating Future Development Tendencies

The goal of step three is envisioning possible long-term urban development scenarios for the study area and testing solutions for prevailing issues or impulses for potentials. When it comes to examining future urban development paths, one might take two important points into consideration. First, we may integrate already existing design concepts of the region in our scenarios: let these be large-scale projects such as international expos or locally relevant urban design projects at selected study areas. For this paper, we assume that the "generational project" (URL-1) implementing the re-naturalisation measures of the river Emscher and its tributaries, which have for decades served as an open sewage system, is a unique opportunity to provide sustainable intermodal mobility for the Emscher zone as well as for the whole Ruhr region. Additionally, the new transport infrastructure will most probably have a major influence on all other urban subsystems (demographics, employment, land use, etc.) and vice versa. Secondly, one might try to integrate issues of great societal relevance and interest at the time of conception – in our case this will be the transition towards more sustainable mobility patterns ("Verkehrswende" in German). The latter two efforts combined may substantially increase both the interest and acceptance by the local and regional stakeholders. In pursuance of studying these alternative development paths we use a scenario approach (Schmidt and Klemm, 2019). In more detail, this paper will review results under a "Healthy and Sustainable City" scenario. The starting point is an increased overall acceptance and awareness of the scientifically proven health risks (UN

Environment, 2019) of man-made pollution and environmental damage, such as that of fine-particulate air pollution in cities (Pope III et. al, 2009). Urbanites are now widely aware of their right to a healthy city, leading incrementally to the emergence of new sustainable models for political and administrative decision-making processes. In terms of mobility patterns, car-free and thus sustainable neighbourhoods are becoming more and more widespread in the region, where both owners and tenants progressively commit themselves to corresponding lifestyles. Sharing and on-demand transport options are becoming popular, whilst car lanes are gradually being reconstructed for autonomous buses and cycle-routes.

2.4 Step 4: Multiscale urban modelling and its calibration for a selected scenario

The multiscale urban model (MURMO) has been specifically designed for high-density polycentric urban regions (Lengyel and Friedrich, 2019). Throughout simulations, the six subsystems of population, residential migration, employment location, land price, land use and accessibility evolve simultaneously in an interactive manner. Residential and employment dynamics are captured by the well-known master equation approach from statistical physics (Haag and Weidlich, 1984), whilst land price relies on a novel method whose emphasis rests on the analogy between spatial land price fluctuations and velocity fluctuations in turbulent flows. We provide a detailed overview of the master equation method in section 5, the description of remaining MURMO methodology is however beyond the scope of this paper (please see Lengyel and Friedrich, 2019 for more information). Accessibilities values used for simulations in this paper are provided externally by the MatSIM transport model (Kaddoura et. al, 2019). Calibrated on a 100 x 100-meter spatial grid, the model is able to delineate small-scale trends of variables. At the same time it can intrinsically recognise meaningful trajectories in regional economic, land-use and population dynamics. For the example used in this paper, simulations are running from 2011 to 2050. In pursuance of translating the healthy city scenario (see Section 2.3) into MURMO we make the following assumptions:

- Immense reduction of man-made pollution and environmental damage: former large-scale industrial production and excavation sites available for new development
- Urban settings are becoming increasingly compact whilst at the same time further expansion of urban sprawl is restricted with the help of a variety of push and pull measures: areas with above average share of medium and high-density urban land use (URL-2) will become 20% more attractive by 2050. For the description of attractivities see Section 4
- Mobility in 2050 is foreseen to be intermodal, shared, walkable and active. Investment in new transport infrastructure accordingly: neighbourhoods in the vicinity of the Emscher river win attractiveness by 5% until 2050, largely due to the re-naturalidation process, improved accessibilities, etc. Accessibility values according to MatSIM measures come into existence (Kaddoura et. al, 2019)
- New urban areas may only emerge according to the official land use plan (URL-3) however they shall be strictly mixed use.

2.5 Step 5: Formulating recommendations for stakeholders on different spatial and temporal scales

We strongly believe that the combination of analysis and modelling results helps us to reveal competition as well as potentials for collaboration and shared interests within the 53 cities of the Ruhr area. A large potential of long-term and spatially highly resolved simulations lies in the effective application of outcomes to find suitable urban design and planning measures on and in between the newly defined characteristic scales. The overall aim is to inform and instigate meaningful cooperation and synchronised action between urban stakeholders and decision-makers.

3 SOCIOECONOMIC FACTOR AND CLUSTER ANALYSIS

Here, empirical results are brought together with the purpose of unravelling meaningful relationships between the different socioeconomic and demographic parameters as well as for dimensionality-reduction and modelling purposes. To this end, we use Self-Organising Maps (SOM) a machine learning mechanism, which “is able to convert complex non-linear statistical relationships between high-dimensional data items into simple geometric relationships on a low-dimensional display” (Kohonen, 1990). SOM is an artificial neuron network (ANN), made up of interconnected nodes - or artificial neurons - that are able to

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

communicate with each other via signal-transmission, similar to the synapses in animal or human brain. These signals are numerical values that are being received by each neuron and then further processed according to the learning mechanism in question, in order to come to the output. Furthermore, there are weights assigned to both the nodes (or neurons) and their connections (or edges) which are being incrementally adjusted through the learning process. In case of the SOM, data projection happens in a way that similar values in the input space are mapped into the same neuron or to its close vicinity in the output space. Therefore, as Kourtet et. al put it, ”the output of a SOM can be thought of as a spatial representation of the statistical relations between the observations; in this map, the axes are not north-south or east-west but measures of statistical similarity, which is expressed in the distance between observations” (Kourtit et. al, 2012). In order to carry out the computational part of this analysis we used the Python package ”Sompy” (with some minor adjustments) developed by Vahid Moosavi, Sebastian Packmann and Iván Vallés (URL-4).

In our case, ten factors (see Fig. 2) are brought together and subsequently clustered into twenty-five distinct groups (see Fig 4). Figure 2 shows the component maps of the neural network, which may be interpreted in the following way. Firstly, brighter yellow colours correspond to higher values and darker colours to lower ones. Secondly, if we move on the surface showing the clusters on Fig. 4 from the right to the left (from less towards more transparency on the bivariate graph) we observe increasing median age and decreasing household size. If we move from the bottom towards the top, we encounter rising socio-economic advantages and a decrease in foreign population (from red towards blue). Henceforward, districts located in the upper left corner of the output space, can be characterised by the following parameters (each being in a strong statistical relationship with each other, in accordance with SOM rules): very high purchasing power and rent prices, below average share of foreign population and high percentages of above-65-year-olds. These would then belong to the clusters 24, 19 and 11 according to Fig. 4.

If we now observe the distribution of clusters on the regional map (Fig. 3), there is an evident pattern of more red and yellow districts in the central area (Emscher and Hellweg zones) and gray and blue colours dominating the outer regions. Firstly, these results correspond and underline the already described relationships on zonal scale (see Section 2.2). Secondly, on the two-dimensional maps on Fig. 2, the three types societal segregation patterns (Wehling, 2014) in the Ruhr area become clearly evident: namely those of nationality, age and economic power. Thirdly and perhaps most importantly, the clusters were found to be highly invaluable tools for the embedding of empirical findings into modelling as well as for an adequate implementation of scenarios into our simulations. We refer the reader to Section 4.2 for follow-up.

4 MODELLING RESIDENTIAL MIGRATION WITH THE CAREFUL INTEGRATION OF SOCIOECONOMIC CLUSTERS IN THE RUHR AREA

In this section we give a brief review of the recently developed multiscale urban model (Lengyel and Friedrich, 2019). One of the main questions that we hope our model will answer is how the Emscher (and Ruhr) region and its inhabitants may react to different influences, e.g., changes of infrastructure (the re-naturalisation of the Emscher river, transport, housing, recreational areas), economic changes (labour market, increased spending power of certain neighbourhoods), and attractiveness changes (urban amenities, land price, congestion phenomena) that arise from in- or outside the urban system. In this context, we contend that due to many uncertainties in such systems, especially if we take long-term urban development into consideration, we cannot expect to capture each and every decision that is being made individually. Therefore, the residential and employment model relies on a *statistical description of urban structures* via probability density functions (PDFs) of certain key quantities, using the statistical model by Haag and

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Weidlich (1984). We also refer to the monographs (Haag, 2017 and Weidlich and Haag, 1999) for further details and applications. Here, the PDF $f_N(\mathbf{n},t)$ of a certain socio-configuration $\mathbf{n} = \{n_1,n_2,...,n_L\}$, where n_i denotes the number of members of the population in area i, is governed by the so-called *master equation*

$$\frac{\partial}{\partial t} f_N(\mathbf{n},t) = \sum_{\mathbf{k}} \left[p(\mathbf{n}|\mathbf{n}+\mathbf{k}) f_N(\mathbf{n}+\mathbf{k},t) - p(\mathbf{n}+\mathbf{k}|\mathbf{n}) f_N(\mathbf{n},t) \right] \quad (1)$$

where $p(\mathbf{n} + \mathbf{k}|\mathbf{n})$ stands for the *transition probability* from socio-configuration $\mathbf{n}$ to socio-configuration $\mathbf{n} + \mathbf{k}$. Transitions from area i to area j are favoured if the so-called *utility function* $g_i(n_i)$ in area i exceeds the utility function $g_j(n_j)$ in area j. Therefore, utility functions can be roughly considered as a measure of "**attractiveness**" of a given area in comparison to another area. The latter feature makes this modelling approach particularly suitable for urban design and planning purposes, since it makes scenario-calibration rather straightforward. The utility functions (2) are further evaluated in terms of a Taylor series of the population number n_i

$$g_i(n_i) = \delta_i + \kappa_i n_i + \rho_i n_i^2 \quad (2)$$

of each area i. Utility functions are being constructed with the help of three trend parameters, which are divided into the *preference parameter* δ_i (availability of schools, cultural offerings, climate, landscape, desire to remain in someone's birthplace), the *cooperation parameter* κ_i (offers of employment, increasing rent, accessibilities), and the *saturation parameter* ρ_i (constricted housing situation). As the intricate interplay of the three trend parameters fully determines where residents (and firms) may move to, their precise and adequate definition is of outmost importance – the task of Section 4.1 and Section 4.2.

4.1 Household types

In case of residential migration, we were interested in the drivers of a household's decision to move or to stay at their prevailing places of residence. Henceforth, we were curious about what crucial variables might affect the attractiveness of a region for the different household types or, in other words, which are the location choices that residents are most likely to make (once they decided to move). In the followings we refer to such influencing variables, according to the Weidlich-Haag model, as spatial preferences parameters. Due to data limitations, where we could not get hold of precise number of individuals per household-type per grid cell, we substitute households with age groups in our simulations. They can be hypothesised to have the following associations with household structure, living-space demand, urban amenities, land price and tendency to migrate (Haag and Weidlich, 1984, Haag, 2017, Lengyel and Friedrich, 2019):

- Under 18; Households with children. Vicinity to kindergarten, schools and playgrounds may be significant. Potentially high living-space demand per household. Low mobility (0.00005).
- Between 18-29; Association with single households or flat shares. Young adults possibly moving out from home for the first time. Probable importance of closeness to higher education, daily urban amenities and public transport. Might prefer lower rent prices. Normally low per capita living-space demand. Age group with the highest mobility (0.0002).
- Between 30-49; Young professionals that may or may not be starting a family. Associated with both single households and couples with children. Might be able to afford higher housing and land prices. Potential importance of proximity to jobs, cultural, and recreational facilities as well as to kinder-garden and schools. Might be moving towards ever higher living-space demands per household. High mobility (0.00023).
- Between 50-64; Double households living with or without child or children. Possible role of vicinity to jobs, schools or leisure facilities. Low to medium mobility (0.00008).
- Over 65; Associated with households with seniors-only as well as with single households. Potential importance of proximity to health facilities, daily urban amenities and public transport. Lowest mobility (0.00002).

4.2 Spatial preferences of socioeconomic clusters

Over the course of our simulations, each household type (see Section 4.1) is described by its own master equation (1) and has its own set of preference parameters. We compiled values for more than hundred parameters on our grid and sought to find the most influential locational factors for each of the age groups with the help of multiple regression models. Moreover, we carried out the regression analysis for the twenty-five SOM clusters separately. The latter step is extremely significant for two reasons. Firstly, we gain a very detailed knowledge of the spatial preferences for each socioeconomic cluster and therefore a better numerical description of the real-world situation. Secondly, since it is the tangled combination of preference, cooperation and saturation parameters which drives the master equation (see Section 4) and therefore our migratory flows, we may have achieved a highly effective way of interlinking the findings of empirical analysis with the internal dynamics of our model. We now demonstrate the regression analysis on two selected clusters.

Results are summarised in Table 1 (for cluster 24) and Table 2 (for cluster 5). The first column of the tables displays the explanatory variables which were identified to be significantly associated with one or more of the household types in the neighbourhoods belonging to the two selected clusters. What stands out in these tables is that there is not only a difference between the coefficients and statistical weights belonging to one parameter, but also that differing preference parameters were found to be significant both for the response variables and for the clusters themselves. As an example, for Cluster 24 (C24) the average building size, the level of commercial building stock and mean purchasing power seemed to be the best predictors of the percentage of under 18-year-olds per grid cell. What is interesting is the relatively high positive parameter estimate for purchasing power (which is somewhat uncommon in the Ruhr area for this age group), suggesting that households with children are rather affluent in C24 neighbourhoods. Let us now compare these results with those of Cluster 5 (C5). Firstly, the intercept shows that children are much more likely to live in C5 than in C24 clusters and that the share of under-18-year-olds is in a very strong positive correlation with vacancy rates. Furthermore, their corresponding parent-clusters seem to be living in the vicinity of commercial and industrial areas, which is in general a rather undesirable locational factor. Finally,

no significant (positive) correlation was found for any of the age groups with more desirable determinants, such as that of new building-stock, ownership or rising rent prices. These three findings are pointing towards more disadvantageous life settings for people living in C5 cells. As a last example, we observe a very high occurrence of seniors in C24 clusters, as daily urban amenities, good access to public transport and proximity to green seem to be the most important locational factors for them. Finally, cooperation parameters κi of the residential sub-model (see section 4) were obtained by similar methods as described above, and were found to be associated with land price, employment rates and the different accessibility values (public transport, car, walk, bike) for a given area.

4.3 Data Sources

For the purposes of this study we only used secondary observational data. All city level information stems from the official database of North Rhine-Westphalia (URL-5). For more detailed analysis, we subdivided the 53 cities into their 736 municipal districts. Values on this level were either provided by local municipal authorities or aggregated using higher-resolution data from the following sources. Socioeconomic and employment data was acquired from the German 2011 census database (URL-6), the micro-dialog data of the German post, and from the Hoppenstedt firm database (URL-7). We collected land use material from the Urban atlas of the Copernicus Land Monitoring services (URL-2), and from the database of Regionalverband Ruhr (URL-3). Points of interest were provided by the Regionalverband Ruhr. Finally, in accordance with the 100 x 100-meter grid of the German Population Census in 2011 (URL-6) we further sub-divided city districts and obtained almost half a million grid cells for the whole Ruhr area. Data sources of this level are either directly from the German Census Database (URL-6) or accumulated using the same data sources as described above.

5 RESULTS OF MIGRATORY PROCCESSES UNDER A HEALTHY-CITY SCENARIO

This section is dedicated to the discussion of modelling results using the example of the residential migration sub-model. The goal is to unravel some important effects of demographic change, local and regional migration flows as well as their interdependencies with small- and medium-scale changes in rent price profiles between 2011 and 2050. First of all, and as expected - due to assumptions made under the healthy city scenario - there is the ubiquitous tendency of falling population numbers: by 5.64% on a regional scale compared to values of 2011. What is interesting though is that zones of the outskirts (Kreis Moers, Kreis Recklinghausen and Lippe zones) have lost 4.61% more residents than their central counterparts (Emscher, Ruhr, Hellweg), implying rather strong densification tendencies and periphery-core migration flows. It is the

Northern and Southern Emscher zone combined, which is showing the least population decrease with solely minus 2.67%. Spatial projection of latter trends is the incremental occupation of vacant and newly accessible land (former industrial sites) in between already high-density urban areas to cater for the increased interest in central zone living (which is clearly observable on Fig. 6). As for the Emscher zone, changes were most likely further amplified by the accumulative effect of improved accessibilities, enhanced environmental qualities, new land availabilities and a massive investment in public infrastructure (see Section 2.4).

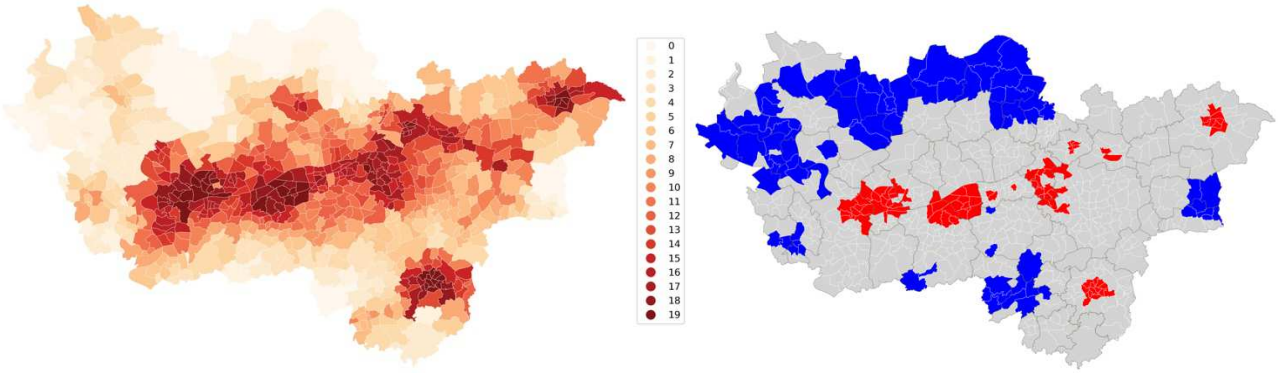

Fig. 5: Spatial lag twentiles of relative change of mean rent price on the district level between 2011 and 2050 (left). Hotspots (red) and cold spots (blue) of change in mean rent price values on district level between 2011 and 2050 (right). Own Graphic.

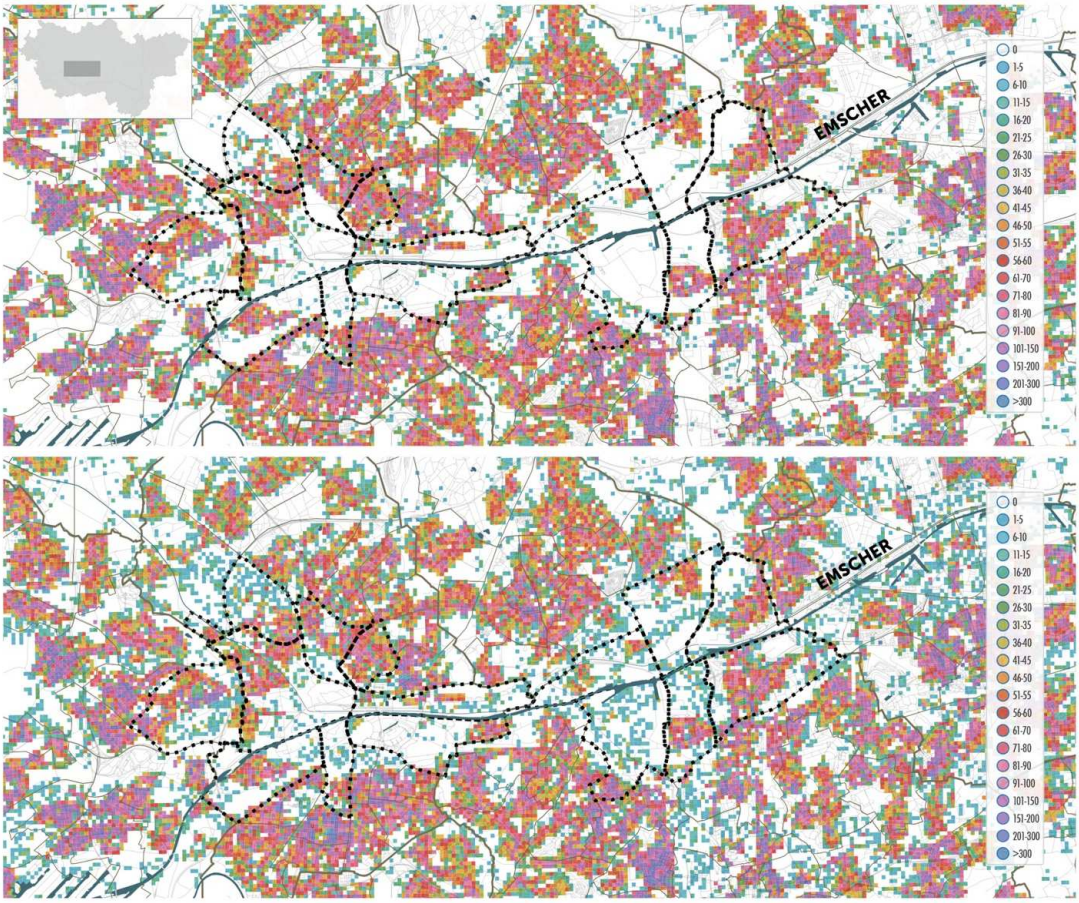

Fig. 6: Number of Residents per Grid cell in 2011 (Above), Number of Residents per Grid Cell in 2050 (Below). Own Graphic

Against the above background, it may come as no surprise that the observed spatial and demographic development trajectories around the Emscher river are associated with a substantial increase in average net rent prices: by 60.20% between 2011 and 2050 compared to an only 26.17% growth in the whole Ruhr region. Hence, it would now be extremely important to find clues for the amplitude and location of potential gentrification processes, in order to apply timely alleviation measures. Due to the high spatial resolution and the innovative computational methods of the MURMO model, we can easily identify districts which are hotspots and cold spots for rent price changes under the Healthy City scenario. Figure 5 reveals that hotspots concentrate in central Oberhausen, north of Essen, south of Bottrop, Castrop-Rauxel, the western

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

neighbourhoods of Dortmund and in the urban cores of Hamm and Hagen. In contrast, cold spots accumulate in the outskirts of the Ruhr area. We must stress here, that latter changes in mean rent price are largely outcomes of residential and employment location choices as well as demographic, transport and land use change processes, as the six subsystems are in close interaction throughout the modelling process.

6 CONCLUSIONS AND OUTLOOK

The present study firstly set out to give an overview of the five-step integrated methodology for deciphering and modelling urban processes across scales and illustrated it with practical examples from the Ruhr area in Germany. Secondly, it made a case for effectively connecting analysis findings with the internal dynamic of the multiscale urban model. Thirdly, we have seen that over time the closely entangled reciprocal dynamic of the six MURMO subsystems led to a variety of substantial changes in the urban structure. These may be indicators for the following processes: attracting new landscape and urban design projects, anchoring a range of additional businesses (or superseding existing ones) or altering real estate prices along with their local socioeconomic profiles. Finally, we showed how modelling results can be applied to identify small scale anchoring of major urban development processes under a chosen scenario. The primary intention of this paper was that the generated knowledge may provide a cohesive framework for both spatial and non-spatial measures. Several questions however still remain to be more carefully investigated. For instance, there is an urgent need to improve the scenario approach specifically for computational modelling attempts of urban environments. We should seek ways to enhance their quantifiability and modelling-applicability in order to yield even more transparent simulation results.

7 ACKNOWLEDGEMENTS

The New Emscher Mobility project (NEMO) funded by the Mercator Stiftung provided partial support for this research. In the frameworks of the NEMO project, we would like to acknowledge and thank the MatSIM-team (Kaddoura, 2019) for making their accessibility data available for MURMO-modelling purposes under the Healthy and Sustainable City Scenario. J.L. would like to thank the strategic partners (Regionalverband Ruhr and Emschergenossenschaft) of the NEMO project as well as the city authorities of the Ruhr Area for providing invaluable data. J.F. acknowledges funding from the Alexander von Humboldt foundation within a Feodor-Lynen scholarship.

1 ABSTRACT

Contemporary urban development in Russia differs from that of the Soviet period by the presence of many new actors, the existence of private property and capital influencing development decisions. A new season of public investment in city planning is emerging in Russia. There is an ongoing discussion of creating new master plans. However, how can be designed and proposed these tools useful and efficient? How to characterize them in their strategic and regulatory aspects? Above all, how to make sure that the master plans are truly tailor-made on the problems of the cities and not standardized tools that do not respond to the needs of the local communities? All these open questions call responsible authorities considering different interests in planning and policymaking. The previous system of administrative planning had to be changed to correspond adequately to new conditions. Officially, the current version of the Russian Urban Planning Code requires 'public discussion' of any urban development project that should be organised by local authorities. However, the formal evolution of the planning law has found little consequences in practice. Regularly organised public discussions remain more rituals than a real planning tool; they have 'recommendatory nature' according to the law that allows public administrations to ignore public opinion in their final decisions.

The paper represents the results of the one-year experience of the CRISALIDE (EU/Russian Federation financed project through Eranet Rus Plus) project consortium in enhancing public participation in the urban development process. The R&D project, aiming at bringing together technological, social and organizational innovations, uses the area-based approach and experiments within the territory of a brownfield (old airport) in the selected city Rostov-on-Don. The chosen work area attracts notable attention of different local and regional actors due to its size, location, marketing potential and regional significance. Design of a decision support system for this area redevelopment becomes a kind of provocation that helped to involve in the design process local experts, activists and policy-makers. Through a series of the organised by the CRISALIDE consortium events, the new collaborations between the local and external actors established and the public discussions of the possible future redevelopment scenarios boosted. Public participation influences the DSS design process and is resulted in the system's goals and methods used that was its main target. At the same time, public discussions at the pre-planning stage is not a common practice in Russia, CRISALIDE proposed and tested a methodology for effectively and efficiently running a participatory planning process capable of grasping the local territorial demand coming from citizens and stakeholders. Moreover, the development of a smart platform, driven by IGis technology, aims at shaping the local decisional environment towards smart design and land use planning.

Keywords: smart cities, smart design & planning, urban planning, participation, DSS, Russia, Eranet Rus Plus.

2 INTRODUCTION

The sharp increase of innovations introduced in the field of urban planning going in parallel with the development of GIS technologies, Big Data technologies and smart city concept popularisation characterise the recent years. Many tools and modelling approaches are being developed to support decision making in

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

urban planning (Leeuwen & Timmermans, 2006) based on land-use or movement simulation, virtual environment, or augmented reality. However, to be innovative, the process of urban planning should go beyond technological innovations and imply organizational and social innovations that often lag behind technology. Moving towards democracy and civic engagement in urban planning requires the involvement of many stakeholders. It makes decision-making in urban development quite a challenging task, especially in the societies that do not have accumulated experiences and legitimized practices of public participation.

The project CRISALIDE (City Replicable and Integrated Smart Actions Leading Innovation to Develop Urban Economies) is a winner of the second call of the EU/Russian Federation Programme called ERA.Net RUS Plus. Its goal is to bring innovations into the field of urban planning in the Russian city Rostov-on-Don. The project is experimenting a joint EU-Russian research and collaborative approach for the creation of an Innovative Decision-Making Tool (IDMT), designed to facilitate the renewal and regeneration of abandoned areas and brownfields.

The CRISALIDE R&D project is being developed on the background of the post-socialist transition of the Russian cities and its urban planning system. This system is still top-down, centralised, comprehensive and does not consider public participation as an essential element of decision-making. At the same time, following the global trends in the development of the information technologies, the Russian state introduces projects and programs targeting information technologies development, such as the national project 'Smart City'. The ‚Smart City' national project being a part of the National program ‚Digital Economy of the Russian Federation 2024' claims innovative principles to base on: people-centred; manufacturability of urban infrastructure; improving the quality of urban resource management; a comfortable and safe environment; emphasis on economic efficiency, including the service component of the urban environment. However, in practice, the declared principles are far from being integrated into the urban development process, and innovations in urban planning in Russia are mainly seen in the usage of the new technological tools, such as GIS or e-platforms.

Together with the immaturity of the Russian civic society and little experience in public participation in urban development that has still been implementing through top-down approach create critical conditions for introducing social and organizational innovations. CRISALIDE's approach is to build innovative solutions through a dialogue between stakeholders placed before the transformation of a given urban context, the practice that is not common in Russian urban development projects. The paper represents the results of the first year of the project implementation in which several events organized within the project framework enhanced public participation in urban development and created conditions for the new collaborations between local and external stakeholders. The construction of collaboration between the CRISALIDE partnership and the local authority was a significant project's achievement that implies the introduction of innovations through the bottom-up process.

3 URBAN DEVELOPMENT AND PUBLIC PARTICIPATION IN RUSSIA

The Russian cities are following the in-depth transformation process since the USSR dissolution, and this process is far from being complete (Zupan, 2015). The transformations that change the Russian cities include institutional (political and economic), social (peoples' behaviours and cultural norms) and urban transformations (Sykora and Bouzarovski, 2012) which also means the transition of the urban planning system and planning methods and tools used. However, the mentioned changes do not follow each other in a linear way (Zupan, 2015) and institutional and social transformations can be slow. The urban planning system and practices in Russia, relying on an entirely different compared to the socialist period legislative base created from zero (Golubchikov, 2004; Jounda, 2004) still have many attributes borrowed from the soviet past such as the tendency to centralization, bureaucratization and technocracy (Iyer, 2003). Introduction of private property, new actors interested in shaping decisions in urban development and redistribution of power between territorial levels of governance call for developing new tools enhancing public participation in decision-making. The administrative planning had to be changed to realise the advantages of democratization and decentralization (Jounda, 2004). The new Urban Planning Code enacted in 2004 formally introduced such tools as public hearings that is an obligatory event before approval of any urban development project. According to the Urban Planning Code, urban residents have the right and the opportunity to participate in the discussion of urban planning projects and to express their needs through public hearings' (Ivanova, 2017). However, the practical impact of public hearings on urban development is

minimal since their results have the recommendatory nature and municipal or regional governments have rights not to consider any proposals or critique expressed during the public hearing process even if such proposals can be in thousands (Ivanova, 2017). The local authorities have the right to approve or decline any project taking this decision on their own without public influence.

Another critical point is that, according to the Russian Urban Planning Code, public hearings consider an already complete project developed by the local or regional government together with an urban planning or architectural company hired after tenders. In this case, the discussion is usually limited by one version of the project prepared without any pre-design investigations of public opinion and the projects often do not receive support from the society (Jounda, 2004). Using such an approach provokes inertia and inactivity of citizens (Ivanova, 2017), who understand that their opinion cannot influence the final decision and is not essential in urban development projects.

The situation has been slightly changing, and some local authorities try to introduce new tools for people's engagement, actively using information technologies and promoting e-participation. These participation strategies are usually formed under the dominance of a 'vertical' approach and may not change the relationship between citizens and government but may lead even to conflicts between them (Chugunov, Kabanov & Misnikov, 2017). The non-organised by the government forms of public participation are represented by the traditional NGOs, expert NGOs and spontaneous initiatives which rise as a reaction to the threats to the population (Belokurova & Vorob'ev, 2011). There is always a lack of horizontal communication and their intersection with the developed ‚vertical' mechanisms of participation. It worth noting that civil society in Russia is still immature, and there is no tradition of ist participation in decision-making (Ivanova, 2017).

4 PARTICIPATION PRACTICES IN ROSTOV-ON-DON

The same disadvantages in the process of the local citizens' involvement in urban planning characterise the city of Rostov-on-Don, where the CRISALIDE project is being implemented. The city is the capital of the Rostov region in Southern Russia and the administrative centre of the Southern Federal District with a population of 1,130,305 people. The city's population has a high intellectual potential and entrepreneurial activity due to a relatively diversified economy and the presence of many higher education institutions. However, citizens' participation in urban development is quite modest. At the stage of decision making the local experts are usually involved personally – they advise government departments in person or through advisory groups, but usually, they have little influence on the final decisions. The most active public participation in Rostov-on-Don is evident in so-called ‚problematization' (Belokurova & Vorob'ev, 2011) in the form of protests when people manifest their disagreement with the decisions taken by the local authorities. In Rostov protests, for example, were against the construction of a landfill and a plant near the residential area Leventsovsky in 2019. The other protests were against the transport reform in 2017 when several routes and transport units the local authority planned to reduce.

Public hearings required by the Urban Planning Code have not become an important tool in decision-making in Rostov-on-Don. First, very few public hearings are organized in the city. Second, there are few initiative groups and social movements able to influence final decisions in urban development. Thus, in 2017, 29 projects of urban design in Rostov-on-Done were developed and presented for public hearings, and 20 of them were approved without any comments and suggestions. Only one project was sent for revision based on the results of comments and suggestions. (Merkulova & Kozlov, 2018). Considering the results of public hearings in Rostov-on-Don, it is possible to conclude that this tool is too far from being effective in communication between the local authorities and the public.

Like many other Russian municipalities, the city of Rostov-on-Don implemented instruments of e-participations – city portals. The official City Duma and the Administration of the city of Rostov-on-Don portal (https://rostov-gorod.ru/) is an information system containing a broad array of data about the city (history, official documents (decisions, draft decisions and regulatory legal acts), city events – both past and upcoming, the structure and powers of the city government, and public chamber. Open data located in this information system allows obtaining information for subsequent decisions on urban development divided into several categories: social sphere, roads and transport, education, culture, safety, housing and communal services, construction and architecture, trade or service industry. The portal claims that the above data has to

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

ensure the transparency of the authorities and the reliability of information about them allows citizens to obtain data for solving everyday tasks and needs. The portal provides top-down communication between local authorities and Rostov's citizens.

Fig. 1: The start page of the official portal of the City Duma and the Administration of the city of Rostov-on-Don with the citation of the Head of Administration' words: 'City development should be carried out taking into account the opinion of the architectural community and the wishes of Rostovites' [Accessed 29 January 2020]

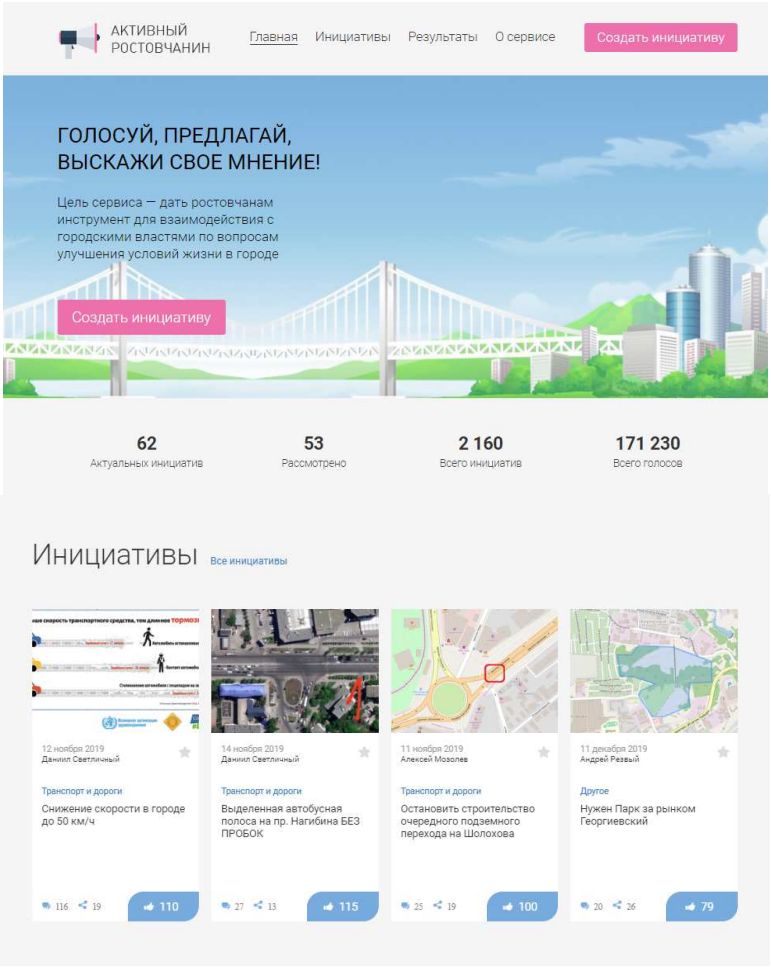

Fig. 2: Start page of the service 'Active Rostovite' or 'Aktivny Rostovchanin' (https://ar.rostov-gorod.ru/

In addition, the official web-portal includes several services among which there is a service 'Active Rostovite' or 'Aktivny Rostovchanin' in Russian language (https://ar.rostov-gorod.ru/). This service provides

a possibility for bottom-up communication. Its start page says that 'The service is designed to identify the most popular initiatives by citizens on improving living conditions in the city of Rostov-on-Don, as well as to obtain the citizens' opinion on the initiatives of the local authorities'. The citizens can propose initiatives and vote for the initiatives made by others. The municipality considers the initiative when it collects over 500 votes. However, the statistic published on the web-portal 'Active Rostovite' is not that promising: the municipality considered only 53 initiatives among 2,160 proposed by the citizens.

The analysis of the vertical and horizontal communication concerning urban development in Rostov-on-Don demonstrates lack of dialogue between local authority and citizens, lack of bottom-up activities and initiatives and little interest of municipality to involve citizens in decision-making in urban development.

5 CRISALIDE IMPLEMENTATION

The CRISALIDE project leverages on the principle of participatory planning and its methodology being guided by establishing a multi-stakeholder group to sustain the collaboration in the field of R&D and innovation through a set of participatory events. The key idea of the CRISALIDE project was in the involvement of the local stakeholders at different stages of the R&D, including the pre-design phase.

5.1 Experimentation area

The experimental site selected for the CRISALIDE project implementation is the area of the former airport 'Rostov-on-Don' located in the eastern part of the city in nine kilometres from the city centre, in the Pervomaysky administrative district. The airport stopped its operation in December 2017, when the new international airport opened - Platov International Airport. The local planning documents consider the old airport's territory as an internal spatial resource for development years before the actual realization. Thus, the city's General plan approved in 2015 proposed the construction of 1,596 thousand square meters of housing within the plot of 267 ha until 2035. After the new airport construction, the local authority started to promote the area for redevelopment and several projects have been done, one of which was presented at the Russian Investment Forum in Sochi in 2018.

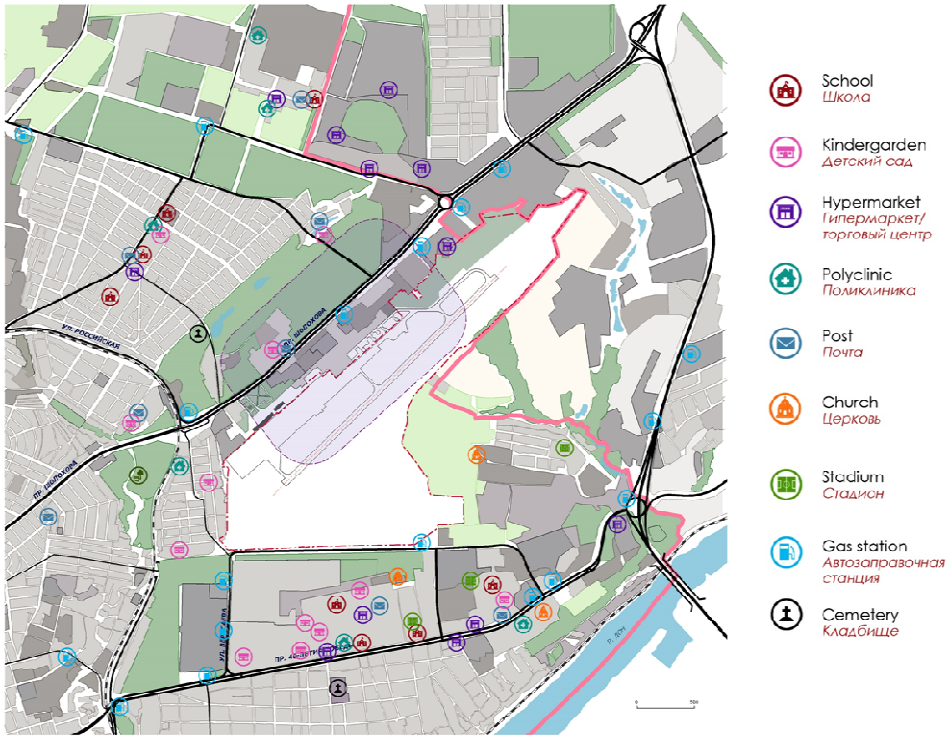

Fig. 3: The former airport 'Rostov-on-Don' area with the existing services in its surroundings.

The local authority does not have many alternatives for the former airport's area development. In essence, the most desirable scenario assumes the arrival of a prominent investor able to implement a large-scale project in the construction of housing and commercial real estate. However, the value of such a significant territorial resource for the development of the city, the potential for creating a high-quality urban

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

environment and opportunities for innovative economic development, forming a positive image of the city and attracting investments provide advantageous conditions and excellent prospects for the application of innovative methods and technologies in planning and development of this territory.

5.2 CRISALIDE participation process

The CRISALIDE project aimed at enhancing bottom-up participation in the urban development process. Through the selection of an experimental area that is an essential site for different types of local stakeholders – authorities, business or public representatives – CRISALIDE creates conditions for the collaborations and public discussions of the area's future. This practice is very distant from the standard practices used in Russia in general and in the city of Rostov-on-Don in particular. The CRISALIDE methodology builds the solutions from the bottom and works with the stakeholders in identifying the problems to be faced. It defines the figure of the planner as that of a mediator and facilitator of complex processes. A methodology does not offer a priori solution, which does not have the innovation package ready to be sold and applied top-down. The process aims at bringing to the project the local values and discover opportunities for long-term collaborations' construction. The process was designed divided into several steps.

The first initial step had the purpose of announcing the project, attract local experts interested in the areas' development and introducing new tools in decision-making and expand experts' networks that would promote future collaborations. The first event resulted in constructed cooperation between the CRISALIDE partners and local stakeholders representing science, business and public sectors. The first stage of the project presentation was followed by the work of partnership members with the local and external experts to develop a hypothesis about the structure of the future decision support tool.

The second step included active involvement of the local stakeholders (experts, public activists and representatives of the local authorities) into the participatory process aimed at joint elaboration of the visions that could become the basis for the decision-making. The participatory process was organized through a one-week workshop that had a double purpose: 1) to lay the foundation for the design of a decision support system by mapping existing knowledge and collecting evidence, and 2) to develop technical and local requirements for innovative decision-making tool.

However, the results of this participatory practice implementation went beyond the objectives of IDMT design and provoked a broad public discussion on the area's future development. Most experts participated in the workshop agreed that with the development of the territory of the old airport, one could not use outdated approaches to planning and construction. The general opinion was the need to consider this area as an experimental platform for the introduction of new planning methods and practices, advanced construction technologies, organization and management of the urban environment, taking into account such modern challenges as climate change, environmental pollution, demographic problems, socio-economic stratification of society and the rapid development of new technologies. Avoiding the construction of commercial housing, the formation of high-comfort public spaces, the introduction of new forms of mobility and environmentally friendly technologies, the creation of conditions for maintaining the health of the population, the realization of its creative and intellectual potential, the activation of innovative forms of economic activity - these key positions were voiced by most experts. Several unexpected development scenarios were proposed, including 'standby mode' in which the areas' development should be postponed until the local society will be able to use and enhance its advantages effectively.

The next step of a participatory process was built on the defined set of values discussed and agreed with a multi-stakeholder group. The values' discussion resulted in a set of key performance indicators (KPIs). The current stage of the IDMT development includes collaborative work between the CRISALIDE partners and the Rostov-on-Don municipality which has as the main objective integration of a formalised set of values, scenarios, knowledge, methods and tools evolved during the participatory workshops into the existing decision-making process. At this point, the main CRISALIDE goal is to create an intersection between the government (vertical) and public (horizontal) perspectives.

Simultaneously, a series of public events such as conferences and workshops organized to promote CRISALIDE ideology and involve new participants.

The final stage of the project development will include testing the IDMT use by different users in a variety of scenarios which will impact both decision-making process in municipality and level of public involvement in

this process that will be another step to the democratization of the decision-making in urban development in Russia. Since the project has been implemented in the city included as a pilot city into the Russian national project 'Smart City', there is an opportunity of the CRISALIDE methodology dissemination and upscaling.

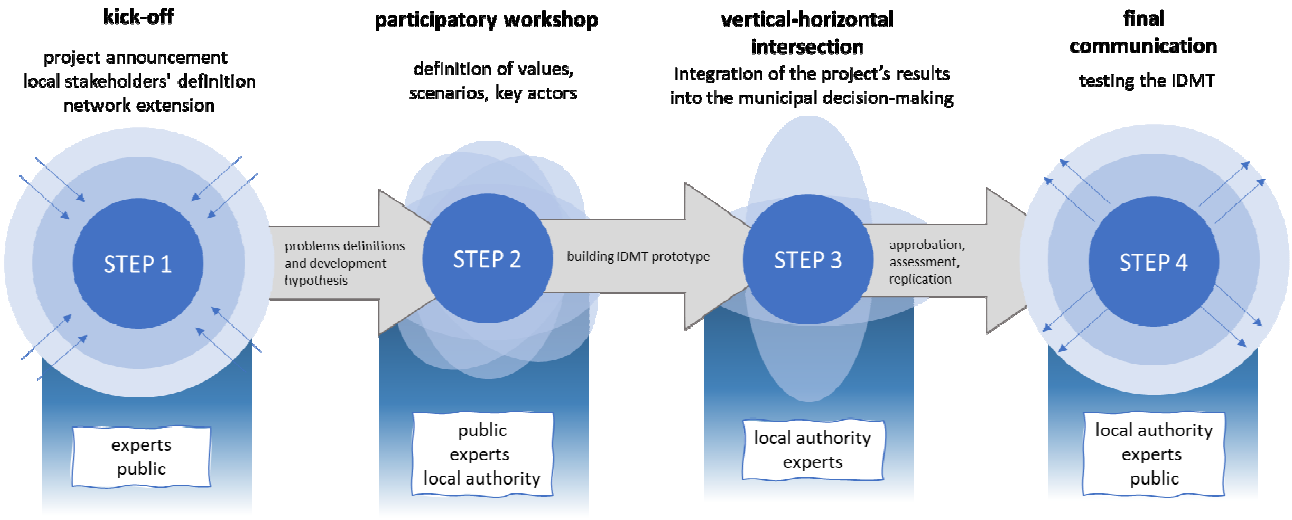

Fig. 4: CRISALIDE participation process.

6 CONCLUSION

The CRISALIDE project aimed at establishing a decision support system in urban development creates an opportunity to enhance dialogue between public and local authorities and integrate bottom-up initiatives into the local decision-making system. The practice of public involvement at the pre-design stage is uncommon in Russian cities. It, therefore, is an innovation that allows consolidating public opinion, taking into account the various interests of the present and future periods, including most effective local development resources in the use and launch processes at the local level that activates socio-economic development. The CRISALIDE participation process demonstrated that local community in Rostov-on-Don is ready for a constructive dialogue and that public discussions should accompany the development of the territory at all stages of project design and implementation. The appearance and support of the bottom-up initiatives in urban development might positively contribute to the development of the new approaches in urban development decision-making. Introduction of public participation at the different stages of urban projects development (especially at the pre-planning stage) might significantly increase the public impact on urban development.

7 ACKNOWLEDGEMENTS

This paper is based on the project "CRISALIDE: City Replicable and Integrated Smart Actions Leading Innovation to Develop Urban Economies", the winner of a joint Russian-European competition of innovative projects under the ERA.NET-RUS PLUS program (project no.42016, application ERA-RUS-4188).

The implementation of the CRISALIDE innovative project is funded by the Foundation for Assistance to Small Innovative Enterprises in Science and Technology (FASIE), Russia, Executive Agency for Higher Education, Research, Development and Innovation Funding (UEFISCDI), Romania; and Austrian Research Promotion Agency (FFG).

1 ABSTRACT

A fledgling and still scattered knowledge stream on multi-disciplinary Smart city phenomena is developing. For the development of smart cities intellectual minds and a synthesis of quite diverse competences are required to shape cities to becoming smart with the overall objective to ever more improve the quality of life of its citizens in the most efficient and sustainable way. Both, the master minds and operators behind this development need to embark on an intensive change process, unlearn ingrained behavioral patterns and internalize an innovative competence set. This research is aiming to address the shortage of both, digital and transferrable skills that are needed for the various smart cities' sectors differentiated by more strategic roles of Smart City Planner and Chief Digital Officer as well as the more operational IT Officer. This study addresses the gap of competences by providing preliminary quantitative and qualitative research findings of the still ongoing DevOps project.

Keywords: Chief Digital Officer, Smart City Planner, Technical Competences, Transversal Competences, Smart Cities

2 INTRODUCTION

The ever increasing popularity and speed of the Smart City movement is reflected by the results of a Bosch initiated study revealing that the Smart City (SC) market grows at a yearly rate of 19% amounting to an investment volume of 800 bio US$ (Boehne, 2018). A further recent study by Berger (2019) with SC decision makers and experts in 50 mid-sized cities asked, for example, about the key success factors of SC projects. A well- defined strategy and guidance achieved with 58% the highest frequency level. Contradictory to the primacy of strategy and guidance, only 20% of the asked city representatives had a strategy pointing to a still existing research gap.

The aim of this research is to differentiate perspectives and competencies between SC planners, chief digital officer and IT officers. In order to successfully cope with this intensive change and digital transformation process and prepare for an effective and efficient future Smart City development, the administrators must thoroughly understand the complexity of smart city areas, new digital technologies facilitating the SC development and map newly required technical and transversal capabilities with newly emerging job profiles. Aiming to support strategic and operational SC administrators, the DevOps project, supported by ERASMUS + Sector Skills Alliances, (Project No.: 601015-EPP-1-2018-1-EL-EPPKA2-SSA Erasmus+ Program) KA2: Cooperation for innovation and the exchange of good practices-Sector Skills Alliances) addresses the gap between today's and future's skills demands of municipal workforce by emphasizing on the exploitation of emerging employment paradigms such as DevOps (http://devops.teilar.gr/). The final aim of the project is the development of VET MOOCs curricula to impart newly required technical and transversal competences and skills provided on a Moodle platform. The project, furthermore, aims to create an international community of best practice. It strives to cover the following identified research gaps:

a. lack of explanation of the nexus between Smart City Applications, DevOps (Agile Software Development) differentiated by a Citizen driven or Technology driven perspective.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

b. Lack of a, so far, not existing integrated Competence/Skill Portfolio (IoT & DevOps Related Skills & Transferable Skills) from a Citizen Perspective differentiated by Planners and Chief Digital and IT Officers.

c. Lack of academic models for individualized or standardized Smart City Planning differentiated by European countries.

The research is designed to achieve the following objectives:

(1) To investigate how the SC philosophy (citizen/identity driven, or technology driven or both) influences the competences of SC team members.

(2) To investigate how the SC philosophy (citizen/identity driven, or technology driven or both) influences SC service priorities and DevOps related decisions.

(3) To research to what extent different SC administrative profiles (Smart City Planner, Chief Digital Officer and IT Officer) require different IT/IoT specific and general/transversal competences.

(4) To identify to what extent different SC Service priorities, require different competences (specifically as to DevOps) and training.

(5) To explore the situations when Smart Cities prefer either to work independently or to co-operate with external partners.

(6) To develop a conceptual model explaining the nature of relationships between the three foci of the project.

3 DEFINITION OF A SMART CITY

The interest in SCs was sparked exponentially only in 2010. Harrison et al. (2010) specifically described a SC as an instrumented, interconnected and intelligent city (van den Bosch, 2017; Unhelkar, 2008; Celino and Kotoulas, 2013). The operations follow the main mission of SCs which is to improve the quality of live for its citizens pursuing the purpose of sustainability (Ahvenniemi et al., 2017). The 17 Sustainable Development Goals of the UN Agenda 2030 serve as a normative sustainability framework (United Nations, n.y.). Expanding on the technological focus of the aforementioned definition, the preconditions for a SC to flourish refer to the existence of a knowledge society (Barth et al., 2017), an open innovation System (Paskaleva, 2011), a user friendly connected infrastructure (Albino et al., 2015), the use and smart integration of resource endowments/equipment and activities (http://www.smart-cities.eu/model.html, in: Griffinger und Haindlmaier, 2010) and, last but not least, self- decisive, independent and conscious citizens (Griffinger and Haindlmaier, 2010; http://www.smart-cities.eu/model.html, in: Griffinger und Haindlmaier, 2010). Hence, Smart Cities must ensure congruency between needs and knowledge of citizens and community at large, investments, social and ecological sustainability, digitalization, urban responsibility and technology (Angelidou, 2015; Bas Borsma, 2017).

4 CITIZEN AND/OR TECHNOLOGY DRIVEN SMART CITIES

Following Angelidou (2015), two main sub- categories for smart cities may be found in the literature: the technology-oriented class and the people-oriented one. Within the technology-oriented direction, the term “smart cities” was examined primarily in relation to potential improvements on city services in relation to ICT developments, infrastructure and the greater ecosystem. Within this approach, smart SC technologies are providing the foundation for initiatives of strategic importance to be developed (Angelidou, 2014). The people-oriented approach places priority on the role of human resources, at individual or community level (Albino, Berardi and Dangelico 2015). Here, mostly social, economic and environmental sustainability issues are addressed implying the heightened importance of socio-technicality and of the richness of diversity of perspectives among involved stakeholders (i.e. citizens, businesses, NGOs or governmental agencies).In line with Angelidou (2015), Zait (2017) sees a predominance of soft smart SC dimensions such as human and social capital over the hard SC dimensions as they affect all other SC dimensions.

Taking the people orientated version into account, sociological factors such as urban attachment, belongingness or social and environmental relationships have a high impact on urban services (Belanche et al., 2016; Angelidou, 2014). According to Zait (2017), SC are currently assessing and developing their idiosyncratic identity. The emphasis on citizen engagement or civic culture in this context is supported by Gartner (2018): “Smart city initiatives are no longer about optimized traffic patterns, parking management,

efficient lighting and improvements to public works. The way forward today is a community-driven, bottom-up approach where citizens are an integral part of designing and developing smart cities, and not a top-down policy with city leaders focusing on technology platforms alone," said Bettina Tratz-Ryan research vice president at Gartner" (Gartner, 2018). However, literature suggests that the importance of citizens in the development of smart cities is often overlooked (Hollands, 2008; Hollands, 2015; Vanolo, 2014).

The importance of urban attachment, belongingness or the quality of social and environmental relationships point to consider sociological theory when developing S.C. Relating exemplarily to identity, Arnett's, German's, and Hunt's (2003) pioneering work calls for providing additional social benefits to customers or - in the case of smart cities- citizens, beyond a merely economic exchange relationship, as a logical consequence of the integration of the sociological identity theory. Identity focuses on the human factor in a conceptual and methodological context, and can be regarded as both, a desirable finality (i.e. social identity or livelihoods of smart cities) and a mechanism to achieve it, as the central internal and external communication platform (Balmer, 2008; Kaufmann, Czinkota and Zakrzewski, 2015).

Relating technological developments to smart city service domains, Tratz- Ryan and Finnerty (2018), in an interesting longitudinal study, portray an life cycle of technological progress. According to these authors this life cycle consists of five phases: innovation trigger, peak of inflated expectations, trough of disillusionment, slope of enlightenment and plateau of productivity. In their 2018 study, the authors hold that none of the SC technologies, so far, has reached the plateau of productivity stage. Only Smart Lighting has reached the slope of enlightenment stage predicted to reach the plateau in less than 2 years. The most innovative technological off springs, on the other hand, are Artificial General Intelligence and Autonomous driving level (both still requiring more than 10 years to end up in the plateau stage), smart building, data for good, data market place and 5 G, all occupying the Innovation Trigger stage (Tratz- Ryan ad Finnerty, 2018).

Summarizing, whilst a focus on technologies may increase efficiency in designing IS systems, it may ignore or neglect more complex social, organizational and technical factors (Eichhorn and Tukel, 2015). A fair balance of the two directions is endeavored by the DevOps project.

5 DEVOPS

Specially, the analytics, application and participation (citizen centric) perspectives imply the enhanced importance of software development. SC which need to become more flexible to react to rapid environmental changes, competitive and citizen centric, require innovative, albeit under researched, agile software development approaches, such as DevOps. The literature review revealed a still existing gap of explanatory research in this knowledge stream. For example, Feijter et al. (2018) point to the lack of a clear overview of practices aiding the DevOps adoption. A definition of DevOps knowledge is provided by the DevOps Institute (2019, p.15): "Working towards a common goal that enables the fast flow of planned work into production while achieving world-class stability, reliability, availability, and security".

To shorten the time to market for the software product, DevOps is assembled from the words „Development" and „Operations ". In software development, this method is used as an acronym combining the software development (Dev) and software implementation/production (Ops) phase (Lwakatare, Kuvaja and Oivo (2015) requiring integrated work flows of IT operative and DevOps focused IT teams within one business unit to facilitate and speed-up the continuous deployment of new software features (Sebastian et al. 2017). From a business perspective, DevOps is better predisposed to address customer needs in short cycle times (Lwakatare, Kuvaja and Oivo, 2015) than other software development approaches. A framework describing elements and outcomes of DevOps as well as problems addressed by DevOps by Lwakatare, Kuvaja and Oivo (2015) provides a basic insight into the functioning of the DevOps approach.

Furthermore, Senapathi, Buchan and Osman (2018, p. 5) provide a framework suggesting that DevOps leads to improved user experience. A high level of agility in product and services and a rapid deployment of fixes through frequent continuous deployment of new features result in being more responsive to customer needs. In addition, by avoiding infrastructure delays and late problems by the eliminations of the dev and ops team silos, a higher level of team productivity is created supported by more team control over deployment and more automation. In tandem, improved user experience and higher team productivity result in higher levels of competitive advantage.

6 DEVOPS COMPETENCES FOR SC ADMINISTRATORS

This research synthesizes a wide range of literature and frameworks for a DevOps competence typology. As to be expected in this innovative research stream much literature is from grey sources and many models are of conceptual or exploratory nature. One framework guiding this research was that of Wiedemann and Wiesche (2018) with seven seven skill categories (full-stack development, analysis, functional, decision-making, social, testing, and advisory skills) and additional 36 skill- sub-categories. One key finding of this research strongly points to the integration of technical and general/transversal management skills/competences. A further skill categorization is provided by Fitsilis, Tsoutsa, & Gerogiannis (2018) differentiating by technical, behavioral and contextual sills. Another framework which seemed suitable to be validated resulted from the conceptual work of Hecklau et al. (2016). They clustered the competences into a holistic competence model consisting of 4 categories and 26 sub-categories. The researchers suggest an applicability of the model in terms of an 'industry 4.0 readiness check' by displaying multivariate data into a two-dimensional radar chart. The key characteristics of the Industry 4.0 phenomenon in terms of increased interconnectivity, real time data exchange, machine learning based on artificial intelligence implying self-controlling production systems suggested the relevance of the model to be validated. Expanding on the model of Hecklau and al. (2016), especially in terms of contextual skills Fitsilis, Tsoutsa, & Gerogiannis (2018, p.132) suggest that training of technical, transversal and contextual skills should be differentiated by the respective industry sector, software development and operations lifecycles, proficiency, up to date digital technological developments and job profiles.

The importance of innovation stimulation and start-up acceleration was underlined by Bas Boorsma (2017). In addition, civilizational competences to operationalize the soft SC dimensions which are forwarded by Zait (2017) are suggested to be added to the competence pool. Civilization competences comprise entrepreneurial culture, discoursive culture, civic culture and daily culture. Furthermore, Minnesota (2016) points to still existing training gaps relating to specific aspects in the technological competence category: skills related to product design in relation to product discovery; skills on user experience design and on software architecture; covering IoT topics. Moreover, Betz (2016) relates to gaps of digital competences currently not covered by curricula: product management related ones; software lifecycle related ones; infrastructure and operation related ones; resource management related ones and cultural ones. DevOps practitioners (DevOps Institute, 2019) highlight key categories of skills to be agreed upon by three levels of employees: C-level executives leading the business or IT strategy; management and IT team and project leaders; and individual skill contributors. They differentiate between must have, nice to have and optional skills, a method also applied for this research. A descriptive research of the Institute shows that process skills and knowledge as well automation skills are must-have (>50%) skills whilst soft skills are a must have for C-Level employees and team and project leaders. It is interesting that team interaction patterns for software delivery at scale are regarded a very important success/fail factor by the DevOps practitioners. Besides focusing on internal stakeholders, Feijter et al. (2018) suggest including external stakeholders, such as customers and software/components providers, when adopting DevOps. The researchers suggest a DevOps competence model based on three primary perspectives: Culture and Collaboration are paramount important and regarded as the 'roof of the house"; Product, Process and Quality mainly relating to a DTAP street (development, testing, acceptance and production environments); Foundation focusing on configuration management, architecture and infrastructure. A research by Bang et al. (2013) support the findings of Feijter et al. (2018) holding that knowledge and abilities on agile software development methodologies (in particular, Scrum) support the following four perspectives of DevOps: Collaboration Culture; Automation; Knowledge (architecture, cloud computing, threat modelling); Sharing of knowledge (product and sprint backlogs). A study in the Italian setting was conducted by Minchelucci, Marco and Tanda (2016). Based on a low response rate, the researchers chose an exploratory qualitative study and an exploratory factor analysis to analyze the quantitative data. Five factors appeared: technical skills including management of innovation and territorial planning; knowledge of private and public laws about procurement, innovation management, public private partnerships, and open data; soft skills relating to general management, relationship and mediation as well as leadership and personality; financial tools and economic principles and general management basic skills such as familiarity with ICT, knowledge of foreign languages and professional experiences.

Derived from the literature, exemplarily from the perspective of the Smart City Planner, a total number of 102 competences in 8 categories (specific technical, general technical/transversal, methodological, social/transversal, personal/transversal, legal, city planning, civilizational) were included in the initial survey. A conceptual framework to be empirically tested (Figure 1) was developed from the literature.

7 METHODOLOGY

From an ontological and epistemological stance, the research is based on the philosophy of Critical Realism triangulating an initial quantitative research with qualitative findings using four European countries (Germany, Italy, Greece, Cyprus) as study settings. Due to the still emerging and scattered body of knowledge in this research stream, a narrative literature review was regarded preferable. The research was designed in three stages: initially, surveys with fully structured questions were developed and via the Unipark system distributed to SC administrators in the four countries. The data were analyzed via SPSS. Informed by the survey data, interviews and focus groups were conducted in the four countries sampling SC administrators and related other strategic members of the SC ecosystem. The qualitative data will be analysed via content analysis supported by NVivo software. The analysis of the quantitative data, at this very stage, is still in progress. Notwithstanding very intensive personal efforts of the researchers in pretesting and personally contacting SC decision makers and experts either on conferences or via Smart City associations, a low response rate to the online questionnaire (i.e. 63 for the SC Planner: Cyprus 5, Germany 9, Greece 20, Italy 28, Romania 1) could only be achieved. Regarding the whole sample across all countries frequency analysis, correlation, regression analysis and factor analysis was applied. Additional, due to the existing knowledge gap, a more exploratory and qualitative stage followed. Initially, based on three very general questions 9 interviews with senior decision makers of successful smart cities (i.e. awards) were conducted.

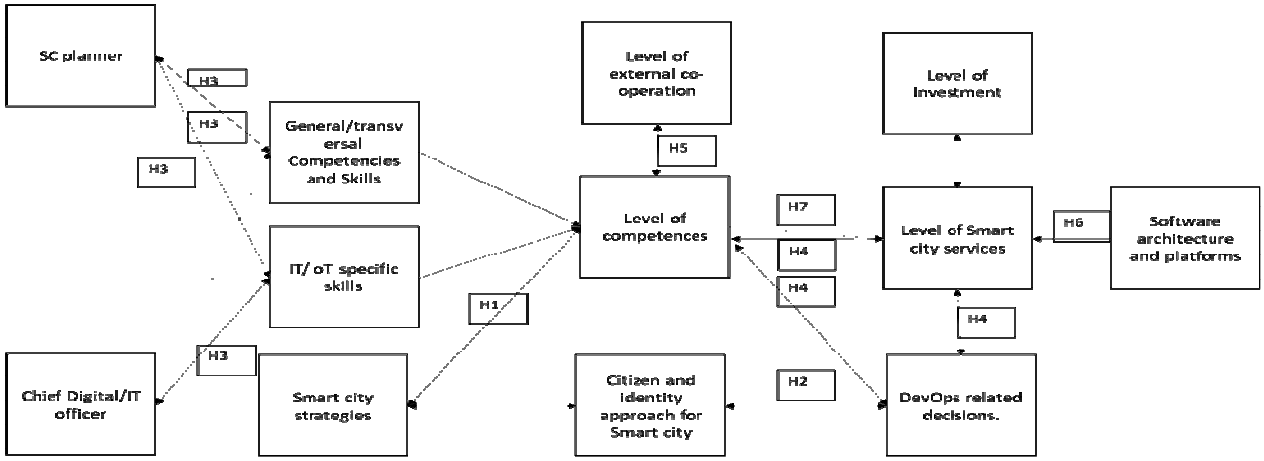

Figure 1 Initial conceptual framework

8 EXEMPLARY RESULTS OF THE FREQUENCY ANALYSIS

Key results of frequency analysis across all countries are

- Regarding the overall SC strategic approach, the majority tends to be more technology orientated (33%) compared to citizen orientated (28,6%) whilst only 9.5% focus on a people (HR) orientated approach. The majority (47,6%) prefers a combined technology, citizen, process and people driven approach.
- More specifically as to the citizen driven approach, 93,7% prefer a co-decision process.
- Regarding the most preferred citizen related goals, respectively 47,6% refer to the creation of a regional innovation resource pool followed by urban attachment of citizens (42.9%).
- Regarding the most important issues to help citizens, the majority (71%) mentioned to provide access to services followed by protecting citizens' physical and cyber security (56,5%).
- The majority (63,5%) does not already use collaboration or networking tools to enhance the SC ecosystem relations.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

- The main challenges encountered in the SC development process relate to coordinating the SC ecosystem (55,6%), followed by developing strategies (52,4%) and skill gaps (50,8%).
- 85,7% of the respondents, so far, have not adopted any method and set of indicators to monitor the SC performances from an ICT perspective.
- In the future, the SC anticipate adding value mainly to the SC service domain of transport and mobility (58,3%), followed by economy and society (48,7%), natural resources and energy (47,5) and smart building and smart homes (47,3%). The biggest leap between current and future focus is, again, in the field of transport and mobility (38,9) followed by smart building and smart homes (38,7%) and smart governance (36,2%).
- Looking at the future focus on SC service domains in more detail, the respondents mentioned telecommunication networks, pollution control, health care (74,6% respectively), public security and cultural heritage (respectively 73%), waste management (69,8%) and human capital management (68,3%).
- Asked for the perceived lowest competence levels as to the SC service domains, the respondents referred to smart grids (71,4%), power grids (65,1), smart logistics/infrastructure (63,4%), smart mobility information (62,3%), energy management systems (61,9).
- To fully address SC citizens' requirements, the majority (55,6%) calls for SC guidance material followed by regulations/legislation (50,8%) and codes of practice (46%).
- Regarding exchanging best practice, only 47,6% know SC that have a smart city strategy.
- Regarding investing into citizens' perspectives, a high majority of 74,6% state that they do not have the research know how, whilst 73% already have SC units dealing with social problems.
- 63% do not implement specific measures (i.e. training) to raise awareness of personnel on the need of smart citizens to be technologically and digitally savvy.
- Most respondents still apply classical programming (50.8%) followed by web- programming (33.3%), agile development life cycle (19%) and DevOps (17.5%) when deciding to purchase or adapt software. As to external co-operation with DevOps team representatives, the main contact persons are developers (38.1%), followed by product owners (25.4%) and testers (11.1%). The most often applied KPI to measure the efficiency of a DevOps team are quality performance (55.6%), followed by innovation and hard skills (38.1% respectively, soft skills (34.9%), delivery time (25.4%), scope (23.8%) and budget (17.5%).
- Only 25.4% are expecting to co-operate with an external DevOps team in the future, whilst 44.9% are not expecting it, and 28.1% are indeterminate. In the same vein, only 22.2% are expecting to integrating DevOps competence into their team, whilst 38.1% are not expecting it, and 33.3% are still indeterminate.
- Consultants (44.4%) and online/distance learning are the most preferred training course providers.
- Asked on the respective requested competences for the profiles of Smart City Planner and Chief Digital/Information officer and co-operation and training demand in this context, the following table highlights exemplarily the respective 3 ones most often mentioned:

Competences	Smart City Planner	Chief Digital/IT officer	Co-operation with external partners	Training demand
Specific Technical Competences	-Teamwork (57,1%) -Urban Innovation (50,8%) - User Experience Design (44,4%)	- Big Data Management (57.1%) - Software Architecture (50.8%) - Coding (50.8%)	- Mobile Development (55.6%) - IT &Cyber Security (50.8%) -Artificial Intelligence (50.7%)	-IoT specific knowledge (49.2%) -DevOps (44.4%) -Machine Learning & Deep Learning (42.9%)

Table 1 DevOps Specific Technical Competences

Transversal or generic Competences	Smart City Planner	Chief Digital Officer	Required from External IT experts, consulting service provider, University
General technical/ Transversal	-Technical skills to switch from operational to strategic tasks (54%) - Broad & Deep Process - Understanding (complexity) (49.2%) - Geospatial competences (38.1%)	- Geospatial competences (54%) - IT security (49.2%) - IT media/IoT specific skills (42.9%)	- ICT Hybrid Media literacy (41.3%) - IoT Supportive skills (41.3%) - Combining IoT supportive skills with existing skills (39.7%)
Methodological	-Creativity (44.4%) -Design Thinking (44.4&) -Efficiency Orientation (41.3%)	-Efficiency Orientation (41.3%) - Analytical Skills (34.9%) - Problem solving (34.9%)	-Research Skills & Continuous Learning (41.3%) - Entrepreneurial Thinking (34.9%) - Creativity (33.3%)
Social	-Ability to merge different skills (47.6%) - Resilience (46%) -Co-operative (46%)	-Networking (44.4%) -Ability to work in a Team (44.4%) -Create Relationships (44.4%)	-Language Skills (42.9%) -Intercultural Skills (31.7%) -Resilience (30.2%) -Networking (27%) -Ability to work in a team (27%)
Personal	-Sustainable Mindset (47.6%) -Strategic Vision (44.4%) -Open-Minded (42.9%)	- Flexibility (39.7%) - Compliance (39.7) -Leadership (every employee is a leader (38.1%)	- Motivation to learn (31.7%) - Sustainable Mindset (28.6%) - Ambiguity Tolerance (25.4%)
Legal	-Public Procurement (36,5%) -Contractual Public Private Partnerships (33.3%) - Legal notions regarding Big Data Management (31.7%) -Data Security (30.2%)	- Data Security (36.5%) - Legal notions regarding Big Data Management (34.9%) - Public Procurement (31.7%) - Contractual Public Private Partnerships (28.6%)	- Data Security (33,3%) - Contractual Public Private Partnerships (31.7%) - Public Procurement (27%) - Legal notions regarding Big Data Management (23.8%)
Smart City Planning	-Territorial Planning (49.2%) -Urban Innovation (41.3%) - Management of Urban Facilities (31.7%)	-Territorial Planning (28.6%) -Management of Urban Facilities (27%) -Urban Innovation 25.4%)	- Management of Urban Facilities (38.1%) - Urban Innovation (33.3%) - Territorial Planning (28.6%)
Civilizational Competences	Engaging Citizens (38.1%	Engaging Citizens (27%)	Engaging Citizens (27%)

Table 2 DevOps Transversal Competences

9 QUALITATIVE RESEARCH

Three countries have been targeted for these initial interviews. The respondents were from Greece (R1,R2, R7, R8), from Italy (R3,R4) and Germany (R5, R6, R9).The in-depth interviews consisted on main three main questions: 1.which key success factors are making your city a ‘smart city of the future’.2. what are the most important management skills and IT skills identified in your ‘City of the Future’?.3.how would you describe the unique identity of your city?. After the analysis has been conducted, for question 1, three main

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

categories have been identified: the smart city infrastructure, the strategy and its citizens. For question 2, the category of skills and education were identified; for the last question 3. the category city identity revealed the main aspects.

9.1 Smart City Infrastructure

For this category (R1,R2, R3 and R4) agreed on the importance of having in place the right infrastructure to support and promote the implementation of a smart city. (R1) explained that in their SC committee 'all city bodies, chambers, universities and institutes of technology are involved to guarantee the commitment of action. Special emphasis has been placed on the development of collaborative platforms. (R2) refers, for example, to educational and technological institution platforms. (R3, R4) related more to internal and external stakeholder platforms for joint planning activities. (R3) explain how the Roman capital administration 'uses the stakeholders for the construction of ecosystems for the creation of smart systems by investing in projects such as Pago PA, City Data Platform, CRM, SPID (Digital Identity Public System) and CIE Electronic Identity Card) which represents enabling technologies for services in a Smart city perspective'. Another example also coming from Italy refers to Florence: (R4) stating that 'it was immediately understood that there could not exist a smart city without the involvement of the participating companies, which are the driving force behind most public services in the city. Thanks to the presence of an association that includes them all in Tuscany (Cispel Toscana), it was possible to lead all public utilities in the city's innovation processes.

These processes have been described and implemented with Triennial Action Plans in which many systemic actions have been realized, possible only with a strong city cohesion of all the innovation stakeholders. Similarly, (R6) explained that 'the decision-making process will change and be based much more on valid and relevant information. Connectivity and Networks between Administration, Stakeholder and Citizens of the Smart City have to be established and will be emerging.

Finally, it was highlighted the resource's potential by having synergies between the different stakeholders. An example of this synergy is utilized in the case of Florence as explained by (R4): synergy between the Municipality, Chamber of Commerce and the Region. Florence utilities the reclamation and alignment of data with the master data of the Municipality (e.g.: reclamation of more than 200,000 addresses in Alia, periodic alignment of the data of the water and sewage infrastructure of Publiacqua and the gas infrastructure of Toscana Energia with the municipal SIT). Apart from this synergy consortium (R4) explains the work they are currently involved in supported by the government 'the governance path leads us to the launch of the Smart City Control Room. The data are the gold dust of the new millennium, it is used by the largest multinationals to increase their business. They are now known to all, but not so obvious it is to find in the Public Administration who, concretely, invests and develops on data'.

9.2 SC Strategy

For (R6) a comprehensive framework needs to be taken into account 'to be understood, planned and managed through balanced and innovative management and IT skills: this framework consists of the political, social, technological, urban planning and economic dimensions of a Smart City. Opportunities and risks of the two central smart-city competence fields of digitization and urbanization must be managed in a balanced manner.

(R1) coming from the municipality of Heraklion in Crete (Greece) indicated their pioneer spirit, already 10 years ago, they were the first municipality in Greece developing a comprehensive strategy to digitize the municipality.(R4) focuses on the important of the SC vision and explains that 'Florence has always approached digital innovation with a strategic vision of the city system, exploiting synergies and promoting cooperation and participation among all the stakeholders of Florence. In the Manifesto for Firenze Digitale in 2014, the main values of innovation in the city were affirmed with an act of Council: sharing the main digital assets (data, infrastructures for digital identity and electronic payments, public WiFi, sensors) and cooperation in jointly promoting the various innovation initiatives of the various institutions and public utilities on a city scale. In the Smart City Plan

(http://www.spesconsulting.com/sites/default/files/Firenze%20Smart%20City%20Plan.pdf)

we have included the vision on the city to 2015, 2030 and 2050, with indicators and guidelines for the development of the Florence Smart City on different areas (Integrated Planning, Public Administration

Improvement, Energy Efficiency, Mobility, ICT means and tools for innovation, Prosperity for the sustainability of the Plan, Communication)'.

9.3 SC Citizens

For (R9) it starts with a strong top down involvement from the town's lord major with his broad team to integrate the citizens. They need to convince them to participate in this great change and to win their commitment. (R4) explains that the main focus on engagement with citizens is always looking for new "fun" forms of involvement of the population at all levels, so that the relationship with the public administration becomes more and more a pleasant. Moreover, he explains that 'only in Florence it has been possible to start the firenzesemplice.it System that allows to put the citizen back at the center and to get out of the logic of "it is not my responsibility", giving way to anyone in live chat to ask for information about any utilities service, Chamber or the Region of Tuscany. For (R7) the adoption of technology by citizens would be the key success factor.

9.4 SC Skills

For (R5, R6, R8) IT systems and digital skills are emerging and therefore, management becomes more complex and traditional management skills are changing too. (R3) support this statement and add the need from the public administration to develop these digital skills together with relational soft skills and knowledge of communication and finance leading to a more multidisciplinary learning. (R4) explained the Florence digital transformation, 'since 2018 Florence is the second smart city in Italy and the first for Digital Transformation according to ForumPA's iCityRank (https://www.forumpa.it/citta-territori/icity-rank-2019-milano-firenze-e-bologna-sono-le-citta-piu-smart-ditalia/). A synthesis of more than 100 indicators (based on more than 250 variables) that, aggregated in the final ICity Rank index, allow to draw up the final ranking of the 107 capital cities. Florence is the city most capable of fully exploiting the potential offered by digital technology, followed by Bologna and Milan. The Tuscan capital obtains the highest score in four indicators (municipal apps, digital openness, public wi-fi and digital transparency) and excellent performance in four others (broadband access, IoT and network technologies, availability of online services, social PA), demonstrating an overall approach that involves not only the municipal administration but all the stakeholders operating in the urban context. (R8) highlights the strength of the Larissa municipality in the field of IT service and project management competences. For (R7) the important skill rely on 'openness' . To be able to turn SILO systems which didn't communicate between them e.g. municipalities, public administration, ministries etc. into an open Big Data management. In addition, for him a smart city is a 'city that thinks' therefore skills to understand and work with artificial intelligence are very relevant. (R9) sheds light on 'patience' as the process involve the integration of masses and therefore time is required. In addition, he regards good communication skills, also communicating at a political level as very important. Finally, knowledge about how the town works an its needs is relevant.

9.5 SC Education

In relation to education and training (R4) explained how the citizens where involved. 'The citizens participated in every process, both in the co-design phase the firenzesemplice.it system was shared in a senior center with the "digital grandparents" of Florence) and in the learning and training phase on the new digital services possible in Florence. They created by the integration of data and processes at the city level. In 2018 (R1) explains that Heraklion was selected by the EU as one of the 27 most powerful digital cities in Europe. This gave them the opportunity to get seminars on how to build a smart city. The training was financially supported by the EU.

9.6 SC City identity

This category focuses on the identification of city aspect which characterized a town. For example (R1 and R5) indicate elements like a SC culture development, having great business development opportunities, technology and IT in other words having a strong and innovative region companies contribute to the implementation. (R3 and R5) highlighted elements more related to the uniqueness of the town e.g. the historical tradition of the town, being a touristic or cultural center or having extensive sport opportunities contributes to the town identity. (R6) provides the concrete example of Berlin being regarded as 'the world-famous capital of modern Germany stands for world-class architecture, culture, night-life and a challenging

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

history in the middle of Europe and the world'. (R9) underlines the Mannheim entrepreneurial spirit by having one of the biggest innovation centers in Germany together with a vibrant music (pop academy), culture and international environment. Finally (R8) offers a more holistic perspective stressing that 'the combination of policies and technology in finding solutions that serve the coexistence of the human and natural capital of our city. It is the harmoniously coexistence between the two factors.

10 CONCLUSION

The multitude of technical and transversal/general competences required for this unprecedented SC system transformation found by this study reflects the immense challenge for SC administrators requiring high levels of open-mindedness, motivation to learn, ability to change, creativity, efficiency and speed, as well as interdisciplinarity and cross- functionality on all levels. To accomplish this competence build-up is the mission of the DevOps for SC project by typologizing SC competences according to different newly emerging administrator profiles and by imparting them via MOOCs courses. The holistic character of the competence pool has been confirmed by the research to be crucial to cover the still existing strategy and skill gaps. Competence gaps and significant training demand both, in technical and transversal competences have been signaled, and, specifically, the attitude towards DevOps seems to be rather indeterminate and reluctant with the SC still focusing on more traditional software development approaches. Also, the continuous existence of a strategy gap has repeatedly become apparent. Whilst a combined technology, citizen, people and process orientated approach is preferred by most of the respondents, an even stronger citizen orientated philosophy when embarking on the SC strategy development is recommended. The still ongoing multivariate analysis stage of this research will certainly contribute to better explaining the interrelationships of concepts involved. The findings, so far, imply a lacking body of knowledge. Therefore, specifically, from the perspective of the SC administrators, the knowledge field still seems to require in-depth qualitative research. A promising route to follow for SC administrators is to join communities of international best practice to complement cognitive learning with affective and experiential learning approaches.

1 ABSTRACT

Geodesign wird in den räumlichen Disziplinen oft als der wichtigste analytische Schritt und manchmal auch als der erste wichtige Entwurfsschritt beschrieben, ohne den ein Raumkonzept nicht mehr planbar ist. Obwohl diese Analyseschritte aufseiten der Stadtplaner wichtig sind, da sie alle für die Beurteilung relevanten Fragestellungen berücksichtigen und in räumliche Modelle übersetzen, interpretieren sie den eigentlichen Entwurfsprozess sehr technokratisch. Diese Entwurfslücke versuchen wir mit unserem neuen ganzheitlichen Entwurfsansatz zu schließen. Dazu verwenden wir einen digitalen Workflow, der Geodesign als Bestandsaufnahme und räumliche Analysemethode methodisch unterstützt, aber eher als Basis/Umfrage für den eigentlichen Entwurf dient.

Der Artikel versucht, die folgenden Fragen zu beantworten: Wie können wir einen Workflow in der Lehre vermitteln, der es Architekten und Stadtplanern ermöglicht, in Zukunft sowohl mit frei verfügbaren Datensätzen als auch mit einem bewussten Einsatz von Software effizient zu arbeiten? Welche Vorteile bieten uns geodätische Ansätze in dieser Hinsicht? Und wie können wir mit einfachen Werkzeugen aus den Analyseergebnissen unsere Entwürfe in Echtzeit planen und überprüfen?

Nach einem kurzen Forschungsstand zu Geodesign-Ansätzen in der Stadtplanung und einigen Anwendungsbeispielen dieser Ansätze vergleichen wir diese Ansätze mit bestehenden Wettbewerbsbeiträgen (competitionline, 2019) und stellen unseren neu entwickelten Workflow mit OpenSource GIS und Realtime Editing and Virtual Reality Rendering Tools zur aktiven, partizipativen Verbesserung von Entwurfsprozessen vor. Neben den bekannten Modellierungswerkzeugen wie Rhino, Sketchup, Revit und ArchiCAD stellen wir Enscape3D und Twin Motion als gut handhabbare Echtzeit-Rendering-Tools für den Städtebau vor.

Keywords: Virtuelle Realität, Geodesign, Digitalisierung, Städtebauliches Entwerfen, Echtzeitplanung

2 EINLEITUNG

Räumliche Analysen und algorithmische Denkweisen sind bei städtebaulichen Entwurfsprozessen und -fragestellungen von großer Bedeutung. Denn je größer die betreffende Maßstabsebene, desto komplexer erweist sich meist auch die mit der Entwurfsaufgabe verbundene Aufgabenstellung, sodass sich vor allem die Auswahl und die Anwendung geeigneter räumlicher Analysemethoden als essenziell für einen erfolgreichen Lösungsvorschlag – also für einen gelungenen Entwurf – erweist (Steinitz, 2012).

Tatsächlich lässt sich methodisch in der relativ breit gefächerten und auf unterschiedlichen Maßstäben intervenierenden Disziplin der Architektur- und Stadtplanung jedoch feststellen, dass einige Methoden und Entwurfsprinzipien zwar auf einer gewissen Maßstabsebene funktionieren mögen, sich aber unter Umständen nicht auf einen anderen Maßstab übertragen lassen. Die Wahl einer adäquaten methodischen Herangehensweise und die Auseinandersetzung mit der Reichweite eines Projekts entscheidet also zwar maßgeblich über den Erfolg eines Entwurfs, ist in der Praxis allerdings bei Weitem kein leichtes Unterfangen.

Eine starke Diskrepanz herrscht auch zwischen den in der Lehre vermittelten, logisch aufeinander aufbauenden Entwurfsschritten und den subjektiv von gestalterischen Aspekten motivierten Argumentationsketten vor. Gerade die berufliche Praxis stützt sich immer noch auf diese „Methodik“, die einen Entwurf jedoch anfechtbar macht. Doch je größer die Maßstabsebene eines Projekts ist, desto schwieriger gestaltet es sich auch, der räumlichen Komplexität der Fragestellung im Entwurf gerecht zu werden.

Der hier vorgestellte Workflow ist ein Beispiel dafür, wie mithilfe von digitalen Werkzeugen eine effiziente Herangehensweise an komplexe Entwurfsaufgaben möglich ist und dabei schnittstellen- und plattformübergreifend die Idee des Arbeitens mit einem „Digitalen Stadtzwilling“ über die Maßstabsebenen begleitet.

3 STAND DER FORSCHUNG

Im nachfolgenden Kapitel werden die für die Entwurfsmethodik relevanten Quellen und Technologien näher erläutert.

3.1 Geodesign

Im Kontext des Designs mit GIS und der Verknüpfung von „Design Professions“ und „Geographic Science“ ist Carl Steinitz „A Framework for Geodesign“ (2012) der meist diskutierte Ansatz. Dabei ist sich Steinitz der zwei Probleme des “Warum müssen „Design Professions“ und die „Geographic Sciences“ zusammenarbeiten”? und deren Unterschiede – schon vonseiten der Ausbildung, der Denk- und Herangehensweisen oder der Maßstäbe – bewusst. Eine enge Zusammenarbeit von beiden Seiten ist zwar erwünscht, die Trennung nach Designer und Wissenschaftler soll allerdings auch nicht verschwimmen.

Interessant ist jedoch, dass im Geodesign-Prozess alle für eine raumplanerische Bestandsanalyse wichtigen Fragen formuliert und als “Modell” beschrieben werden und auch hier dem Muster „Aus Daten wird Information und aus Information Wissen über den Ort“ folgen. Im Einzelnen sind dies die folgenden Modelle, Verfahrensschritte im Geodesign nach Steinitz:

- „Representation Model“: Wie soll der Raum inhaltlich, räumlich und zeitlich beschrieben werden – datenbasiert
- „Process Model“: Wie funktioniert momentan der Untersuchungsraum?
- „Evaluation Model“: Wie gut oder schlecht funktioniert der Untersuchungsraum?
- „Change Model“: Wie könnte der Raum verändert werden?
- „Impact Model“: Welche Unterschiede könnten die Veränderungen bewirken?
- „Decision Models“Soll der Untersuchungsraum so verändert werden?

Steiner und Shearer (2016) geben hierzu einen umfassenden Überblick, wo „Geodesign“ eingesetzt wird, angefangen von allgemeinen Planungsprojekten und Szenarien (Lee, 2016), über die Rolle des Computers im Design (Tulloch, 2016), bis hin zu der Fragestellung, ob Geodesign eine Möglichkeit bietet, soziales Lernen und kollektives Handeln zu ermöglichen (Wissen Hayek et al., 2016).

Jedoch wird gerade von Städtebauern, den Praktikern, die GIS als Entwurfshilfe nutzen, immer wieder kritisiert, dass die Methodik bei aller notwendigen Abstraktion oft als technokratisch empfunden wird. Es entsteht der Eindruck, dass Komplexität und gute Planung „wie ein automatisierbarer Ablauf gestaltet seien, bei dem ein Ergebnis auf Knopfdruck erzielt werden könne (Berchtold, 2016: 45). Aber genau hier steckt das Dilemma vieler Entwerfenden: Wie komme ich nach einer dezidierten Bestandsaufnahme auf meine neue Form?

3.2 Digital Twins

Der Begriff des „Digitalen Zwillings“ steht synonym für eine Schlüsseltechnologie der Digitalisierung vor allem im Bereich der industriellen Prototypenerstellung im Kontext von Industrie 4.0. Eine Definition angelegt an Kuhn (2017) beschreibt dabei den Zwilling als ein virtuelles Modell, das im Idealfall seine Daten in Echtzeit integriert und gemeinsam, herstellerübergreifend und plattformunabhängig bereitstellt. Dadurch ist die Kombination von Simulationsmodellen möglich und „Was-wäre-wenn-Analysen“ können virtuell durchgeführt werden, um neue Prozesse und Produkte zu testen. Der Vorteil liegt in der Tatsache, dass reale Prozesse davon unbeeinträchtigt bleiben und die reale Produktion erst dann startet, wenn eine optimale Lösung gefunden ist. Dabei ist der digitale Zwilling keineswegs eine exakte Kopie der realen und neu entstehenden Wirklichkeit, da wie bei allen Modellierungsprozessen das klassische Dilemma der Abstraktion vorliegt (Dembski et al., 2019). Michael Batty (2018) kritisiert hierzu im Kontext der Stadtplanung richtig, dass digitale Zwillinge nur eine begrenzte Menge an Variablen und Prozessen abstrahieren können und somit die wirklich stadtrelevanten Funktionen wie soziale und wirtschaftliche Vorgänge nicht korrekt abbilden (Batty, 2018). Trotz dieser Einschränkungen und Kritik ist die Idee, mithilfe des digitalen Zwillings stadtplanerische Prozesse besser abzubilden und zu kommunizieren, eine der Herausforderungen im Kontext Digitalisierung und Stadtplanung des 21.Jahrhunderts.

3.3 Städtebauliches Entwerfen

Sämtliche Literatur und Lehrbücher zum Themenfeld des “Städtebaulichen Entwerfens” im Rahmen dieses Beitrages aufzuzählen würde den Umfang sprengen. Vielfach liegt der Fokus jedoch auf dem Entwurfsprozess an sich, wie z.B. welche qualitativen Merkmale wie Sehgesetze, Gestaltungssätze und Proportionen bzw. Ordnungsprinzipien wichtig sind (Schenk, 2018), oder mit welcher Grammatik und Bausteinen die Stadt entworfen werden kann (Reicher, 2017) so wird das “Geheimnis des Entwerfens”, der Schritt von einer fundierten und wissenschaftlichen Bestandsaufnahme (wie im Geodesign) zum eigentlichen Entwurf nur selten beschrieben. Dies liegt wohl auch an der eingangs erläuterte Komplexität städtebaulicher Entwurfsprojekte. Es erscheint evident, dass eine rein subjektive und überwiegend von gestalterischen Aspekten geleitete Argumentationskette spätestens ab einer gewissen Größe des Planungsgebiets an ihre Grenzen stößt. Für Planer wird es demnach zukünftig unabdingbar sein, eine strukturierte und konsistente Herangehensweise an städtebauliche Aufgabenstellungen zu entwickeln.

Viele Entwurfsprozesse in der Disziplin des Städtebaus sind tatsächlich vergleichbar mit einer wissenschaftlichen Arbeit, geleitet von einer relevanten und exakt formulierten Fragestellung, einem reichhaltigen Methodenrepertoire, sowie der Umsetzung als Testentwurf, die wiederum, evaluiert, adaptiert und kritisch hinterfragt werden. Die entwickelten Prototypen sind somit nicht nur als ein gestalterischer Vorschlag anzusehen, sondern dass sie auch durch einen Zugang zu ihrer zugrunde liegenden Argumentationskette, eine Überprüfbarkeit auf wissenschaftlich fundierten Fakten gewähren. Oder wie es Walter Schönwandt und Kollegen so treffend formulierten: “Problems first” (Schönwandt et al., 2013)! Genau diese Problemdefinition – was fehlt dem Raum und wie wird dieser mit räumlichen Abfragen und Analysen räumlich abgegrenzt – hilft dabei, einen ersten Entwurf zu skizzieren, was in Kapitel 4 kurz angerissen werden wird.

3.4 Virtual Reality im Städtebaulichen Entwerfen

3.4.1 Modelling

Die Arbeit mit dreidimensionalen Modellen ist bei komplexen städtebaulichen Aufgabenstellungen seit jeher unverzichtbar, sondern dienen vor allem auch dem Vorstellungsvermögen im eigenen Entwurfs- und Arbeitsprozess. Eine Vielzahl an Programmen bieten Planern hier die Möglichkeit, anstelle der zeitaufwendigen Erstellung eines physischen Modells, den eigenen Entwurf in einem digitalen Modell abzubilden und ein Gefühl für die reale Situation zu entwickeln. Virtual Reality schafft darüber hinaus die Gelegenheit, das Modell nicht nur über den Bildschirm zu betrachten, sondern sich mithilfe einer VR-Brille scheinbar tatsächlich in der geplanten Situation zu befinden. Volumen, Raumeindrücke, Materialien und Lichtverhältnisse können auf diese Weise nicht nur für den Planer erfahrbar gemacht werden, sondern auch in Echtzeit evaluiert und verändert werden.

3D-Stadtmodellen waren hier seit jeher, beeinflusst durch die Gaming-Industrie, in Kombination mit hochwertigen Modelling-Software-Tools eine eher den technischen Experten vorbehaltene Anwendungsdomäne. Game-Engines und klassische 3D-Design-Software wie die Kombination aus Maya 3D / 3D Studio Max und C++ Game-Engine (Zeile et al., 2005), Quest3D (Kretzler, 2005), Torque Engine mit verknüpften Geodaten oder Unreal-Editor (Jones and Lowe, 2005) waren die ersten „einfacheren Ansätze“ zur Echtzeitmodellierung. Ein Paradigmenwechsel geschah mit der Einführung von "Lumion" im Jahr 2010. Hier konnten ganze Modelle schnell importiert und unkomplizierten zu qualitativ hochwertigen Visualisierung ohne spezielles Expertenwissen bearbeitet werden (Mach, 2018). Mit der Vorstellung von „Enscape“ und dem aus dem Gaming-Bereich kommenden Twinmotion können gängige 3D-Programmen nun direkt aus dem Arbeitsprozess gekoppelt in den VR-Entwurfsprozess eingebunden werden.

3.4.2 Enscape3D

Als Purgin ist Enscape mit den CAD-Programmen Revit, ArchiCAD und SketchUp kompatibel. Vectorworks Unterstützung ist für März 2020 angekündigt. Das Programm bietet dabei schwerpunktmäßig Echtzeitplanung und Visualisierung an. Änderungen im bestehenden 3D-Modell werden direkt in Enscape dargestellt und in einem separat erscheinenden Fenster sowohl in der gleichen Perspektive angezeigt, als auch in Echtzeit synchronisiert.

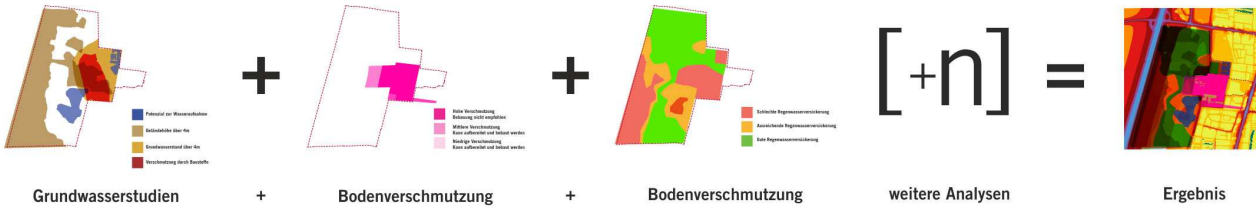
ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Durch die detaillierte Ausgestaltung des Modells mit Materialien und Objekten wird es mit dem Plugin ermöglicht, entweder am Bildschirm, oder über eine VR-Brille einen möglichst realen Eindruck der Situation zu gewinnen. Wird das Modell über den Entwurfsprozess hinweg konsequent gepflegt, so kann Enscape dazu beitragen, nicht nur den Entwurfsprozess dynamisch zu gestalten, sondern erleichtert das Generieren von Präsentationsmedien wie Perspektiven, Videos auch erheblich und minimiert die grafische Nachbearbeitungszeit auf ein Minimum.

3.4.3 Twinmotion

Im Gegensatz zu Enscape legt Twinmotion seinen Schwerpunkt auf die Präsentation des Entwurfs in belebten Szenen und Videos und eignet sich weniger gut für die Planung und Anpassung des Entwurfs in Echtzeit. Die Problematik ist hierbei, dass das bestehende 3D-Modell nicht wie bei Enscape über ein Plugin bearbeitet wird, sondern alle Anpassungen direkt in Twinmotion vorgenommen werden. Ein bestehendes 3D-Modell kann also zwar mühelos in Twinmotion importiert, angepasst und mit zahlreichen Objekten realistisch gestaltet werden, jedoch werden diese Änderungen nicht in das Ausgangsprogramm überführt. In der VR-Ansicht ist lediglich eine Änderung der Materialtextur möglich, dies aber direkt im virtuellen Raum.

Im Unterschied zu Enscape ist es in Twinmotion aber möglich dynamische Objekte über einen Pfad im 3D-Modell zu verorten. Auf diese Weise kann das Modell über nur wenige Klicks mit beispielsweise sich bewegenden Fußgängern, Autos und Vegetation angereichert werden. Es entsteht ein höchst realistisches Raumgefühl, weshalb sich das Programm bestens für die Erzeugung von Videos eignet.



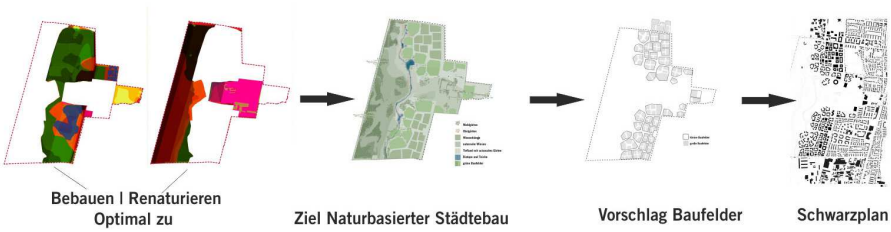


Abb 1: Ablaufschema des Entwurfs „Growing a City – Haunstetten Süd“ von Cobe Architects – durch konsequente Analyse und räumlich umgesetzten Zielvorgaben entsteht im digitalen Workflow der Entwurf bis hin zum 3D-Modell, Film über QR-Code [Eigene Darstellung unter Verwendung von Cobe auf Stadt Augsburg 2019]

4 WETTBEWERB AUGSBURG HAUNSTETTEN

Der im Jahr 2018 gestartete Beteiligungsprozess zur Zukunft des Augsburger Stadtteils Haunstetten kann in vielerlei Hinsicht als ein Beispiel für die heutigen Anforderungen städtebaulicher Planungsverfahren dienen. Aus vorangegangenen Informationsveranstaltungen, Expertenworkshops und Arbeitstreffen ging ein städtebaulicher und freiraumplanerischer Wettbewerb hervor, der sich, unter Einbeziehung neuer Formate und Medien, mit der sensiblen Erweiterung des bestehenden Stadtteils Haunstetten um einen neuen, südwestlichen Teil „Haunstetten Südwest“ widmet. Nicht nur das Verfahren selbst, sondern auch der erarbeitete Maßnahmenkatalog definierte für die geplante Erweiterung des bestehenden Stadtteils die Anforderung, die beiden Quartiere eng zu verzahnen und dadurch gleichermaßen für beide Teile den größtmöglichen Nutzen zu erzielen. Mit dem Maßnahmenkatalog soll darüber hinaus auch die Stärkung von lokaler Zentralität, Nahversorgung, öffentlichen Freiräumen, sozialen Einrichtungen sowie einer nachhaltigen Mobilität gefördert werden. Unter den 25 Planungsteams, die im Frühjahr 2019 aus ganz Europa dazu eingeladen wurden, Vorschläge für die Entwicklung des zukünftigen Stadtquartiers zu erarbeiten, wurden im Juli 2019 neun Planungsteams für die Bearbeitung in der zweiten Stufe ausgewählt (Stadt Augsburg, 2019).

Der vorhergehende beispielhafte Wettbewerbsbeitrag „Growing a city“ des dänischen Büros COBE zeigt auf, in welcher Form Geodesign dazu beitragen kann, eine belastbare Grundlage für städtebauliche Entwurfskonzepte zu bilden.

Nach der Analysephase, in der alle für die Abwägung relevanten Belange eingepflegt wurden, sofern sie einen Geobezug besitzen, konnte eine erste Aussage über das optimal zu bebauende und das für Grün freizuhaltende Areal getroffen werden. Die Planungsziele wurden danach räumlich formuliert, sodass erste Baufelder entstanden. Der gesamte Prozess ist in einem gut verständlichen Video aufbereitet (https://youtu.be/6FvRkeSIlOA).

5 WORKFLOW ECHTZEITPLANUNG

Mit dem Master-Entwurfsstudio zum Thema “Die digitale Linde– Wie entwerfen wir Zentren für die zukünftige europäische Stadt?” im Sommer 2018 auf dem Gebiet des Patrick-Henry-Villages in Heidelberg wurde erstmals der erarbeitete Workflow zum digitalen Entwerfen in der Lehre methodisch vermittelt und von den Studierenden angewandt (s. Abb.1). Das Projekt bewegte sich in enger Kooperation mit der Internationalen Bauausstellung “Wissen schafft Stadt”, die bis 2022 in Heidelberg stattfindet.

5.1 Die STQP Toolbox

Angeleitet durch wöchentliche Betreuungen und Arbeitstreffen erlernten die Studierenden nicht nur neue Software und Methodiken, sondern waren dazu angehalten, ein digitales dreidimensionales Modell ihres Entwurfs über den gesamten Projektverlauf hinweg zu pflegen. Analog dazu wurde auch als Abgabeleistung von den Studierenden kein physisches, sondern ein digitales Modell des Entwurfsprojekts samt einem kleinen Image-Video zur Veröffentlichung gefordert.

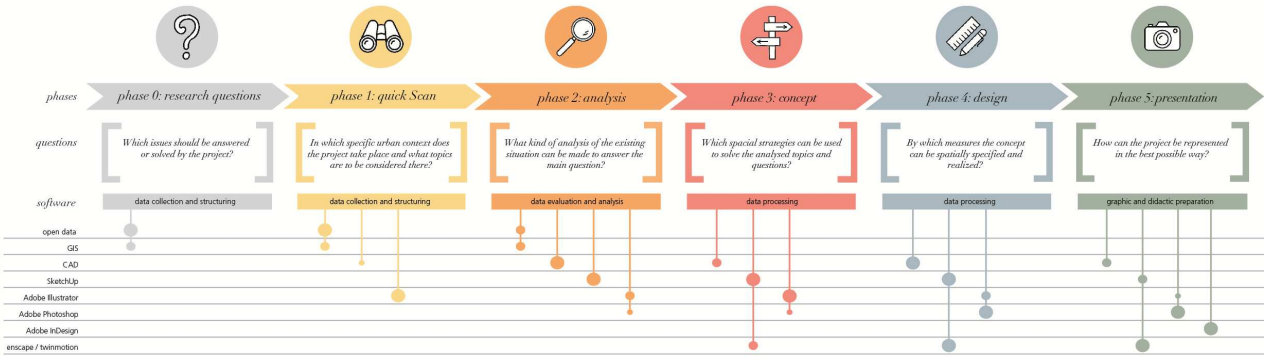

Abb. 1: Ablaufschema des „Digitalen Entwerfens“, unterteilt in 6 Phasen mit den zugehörigen eingesetzten Technologien.

5.1.1 Research Question und Geo-Design

Bereits von Beginn an wurde den Studierenden mit dem Workflow vermittelt, dass Digitales Entwerfen bereits in der Phase 0 mit wichtiger Grundlagenarbeit beginnt. Für diesen wichtigen, ersten Schritt im

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Entwurfsprozess bedeutet das einerseits, sich der Aufgabenstellung bewusst zu werden und andererseits aber auch, sich mit den Datensätzen über das Entwurfsgebiet vertraut zu machen, sie zu strukturieren und zu vervollständigen.

Wichtig ist die richtige Fragestellung, wie Russell Ackoff treffend formuliert hat (Ackoff, 1974):

„Successful problem solving requires finding the right solution to the right problem. We fail more often because we solve the wrong problem than because we get the wrong solution to the right problem“.

In der Arbeit mit den Studierenden bedeutet dies vor allem, ein hohes Maß an Eigenständigkeit und Bewusstsein über Datenquellen und Methodiken zu vermitteln. Wo erhalte ich frei verfügbare Geodaten über mein Entwurfsgebiet? Wie kann ich mit den Informationen arbeiten? Welche Möglichkeiten können Geografische Informationssysteme darüber hinaus für die Analyse und die Konzeption des Projekts bieten?

Mit dem neu erlernten Werkzeug GIS, im Speziellen die frei verfügbare Software QGIS, erhielten die Studierenden Zugang zu den gigantischen Mengen an frei verfügbaren Geodaten und erlernten Schritt für Schritt, die Daten zu strukturieren und GIS als ein Werkzeug im eigenen Entwurfsprozess zu nutzen. Mit den Geodaten strukturierten die Studierenden ihre Plangrundlage für die weitere Arbeit in ihrem individuellen CAD-Programm und erstellten erste räumliche Analysen.

Die Vorteile, die ein überlegter Einsatz von Geografischen Informationssystemen in dieser Anfangsphase dem Entwurfsprozess bieten kann, erschloss sich den Studierenden schnell - Die mit GIS angestellten Analysen waren deutlich weniger anfechtbar und erwiesen sich auch für die eigenständige Konzeptentwicklung als eine konsistente Argumentations- und Entscheidungsgrundlage.

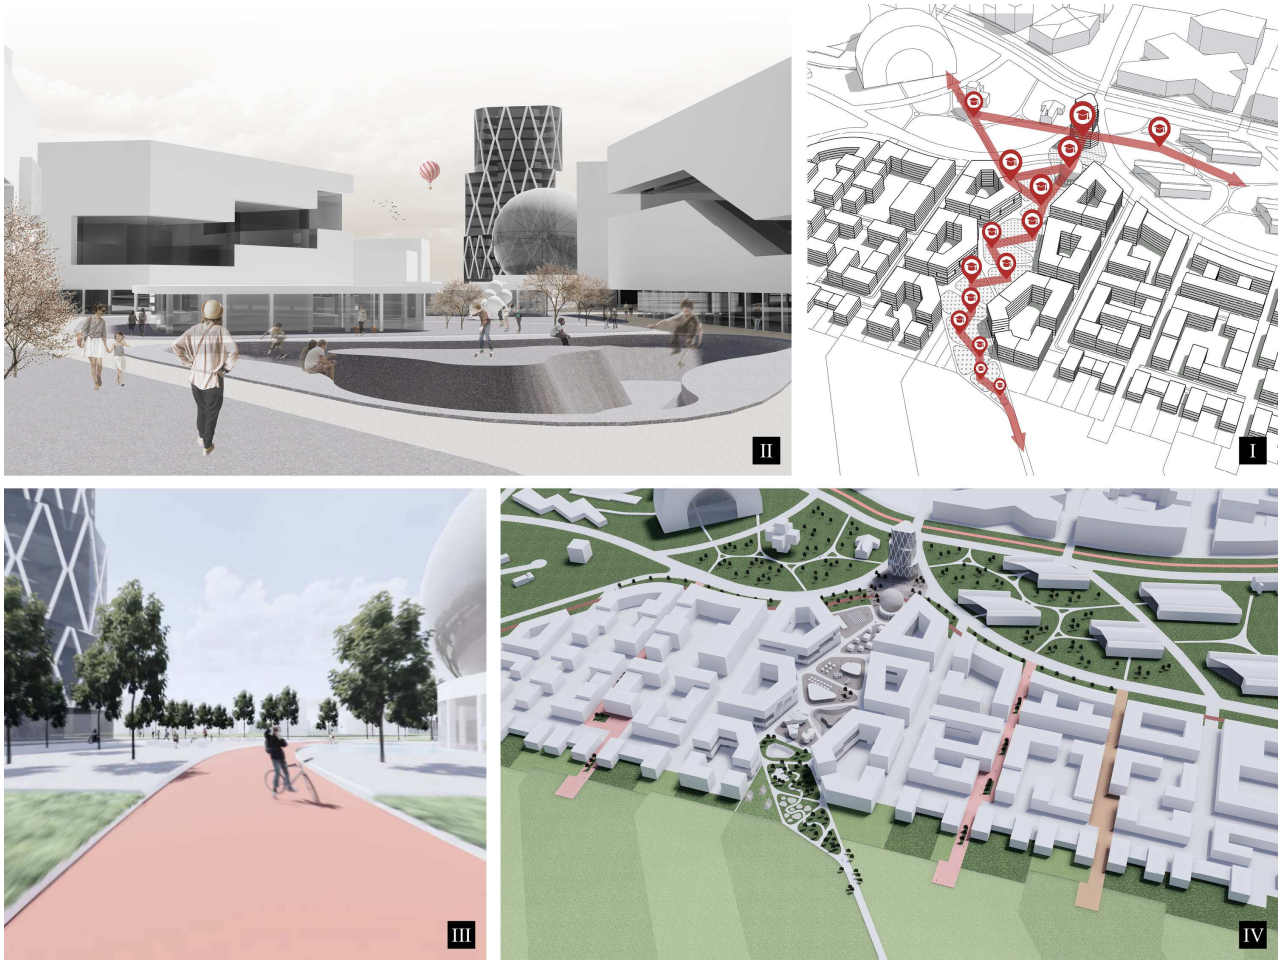

Abb. 2: Vom Funktionsmodell (I) über die Collage (II) zur virtuellen Entwurfsprüfung in VR (III) und dem fertigen 3D-Gesamtmodell (IV)

5.1.2 Schwarz- und Lagepläne

Die eigenständig mit QGIS erstellten Grundlagenpläne wurden im fortlaufenden Prozess als Basis für die weitere Bearbeitung im jeweiligen CAD-Programm der Studierenden dazu genutzt, um Lagepläne und

Schwarzpläne der Entwurfssituation zu erstellen. Ergänzend zu den thematischen digitalen Workshops, in denen sowohl der strukturierte Umgang mit den diversen Ebenenstrukturen der diversen CAD-Programme, als auch wertvolle Tipps zum zeitsparenden Arbeiten mit Bildbearbeitungsprogrammen vermittelt wurde, waren auch Inputs zur Darstellungstiefe mit Beispielen diverser Wettbewerbe ein fester Bestandteil des Lehrplans für das Entwurfsstudio.

5.1.3 Modelling

Um die konsequente Arbeit mit dem digitalen 3D-Modell bereits in den ersten Phasen des Entwurfs fest im Workflow zu verankern, wurde schon in den ersten Wochen damit begonnen, die Studierenden in wöchentlichen Arbeitstreffen und Übungen mit SketchUp vertraut zu machen. Im Rahmen dieses kollaborativen Settings entstand, im Vergleich zu den bislang von den Studierenden verwendeten Workflows, in kurzer Zeit ein differenziertes 3D-Modell der Bestandssituation, in welchem die Volumina der eigenen Entwurfsidee schon bald erprobt werden konnten (s. Abb. 2).

Ergänzend zu der analogen Betreuung des Entwurfs anhand maßstäblicher Pläne, wurden die Studierenden in diesem Semester erstmals auch dazu aufgefordert, ihren Entwurf gemeinsam mit den Dozenten direkt mit dem digitalen Modell zu diskutieren. Als besonders effizient stellte sich dabei die Vorbereitung verschiedener Varianten heraus, die den Diskurs auf anstehende Entwurfsentscheidungen lenkten und eine zielgerichtete Evaluation ermöglichten.

5.1.4 Virtual Reality (für interaktives Entwerfen)

Mit zunehmender Detaillierung und Sicherheit im Konzept, wurden auch die 3D-Modelle realistischer mit Materialien, Objekten und Personen gestaltet und in Verbindung mit den Programmen ArchiCAD und SketchUp das Plugin Enscape als Werkzeug für den Entwurfsprozess dazu genutzt, ein Gefühl über die geplanten Dimensionen, Materialien und Raumeindrücke zu schulen. Die wöchentlichen Betreuungen konnten nun von den Studierenden und Dozenten dazu genutzt werden, mit der VR-Brille über die reale Situation zu diskutieren und etwaige Änderungen in Echtzeit vorzunehmen (s.Abb.3).

Abbildung 3: Exploration des ersten Entwurfs bis hin zur Echtzeitkorrektur im HLS-Modell

5.1.5 Werbefilm

Der anschaulichen und präzisen Vermittlung architektonischer und städtebaulicher Konzepte wird zukünftig eine immer größere Bedeutung beigemessen werden. Längst ist in diesen Disziplinen der Trend zu beobachten, Wettbewerbe nicht länger anhand von analogen Präsentationen an Plakaten zu entscheiden, sondern den Sieger über kurze, pointierte Image-Videos auszumachen. Ein Entwurf, dessen zugrunde liegendes Konzept sich nicht innerhalb weniger Minuten erläutern lässt, hat innerhalb dieser Verfahren kaum eine Chance.

Die Studierenden wurden zur finalen Präsentation deshalb dazu aufgefordert, ihre Ideen für das Patrick-Henry-Village nicht nur anhand von Plakaten zu erläutern, sondern ein zweiminütiges Image-Video zu erstellen. Darin sollten neben den wichtigsten Konzeptskizzen, einem aussagekräftigen Titel und den verschiedenen Layern des Entwurfs auch einige Überflug-Videos und Perspektiven Platz finden.

Durch die konsequente Pflege und die zunehmende Detaillierung, die die Studierenden über den gesamten Entwurfsprozess an ihrem digitalen Modell vornahmen, bedeutete die Produktion des Videos - und das war

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

auch für die Studierenden selbst eine große Überraschung - nur einen geringen Aufwand, bzw. umfasste nur die Konzeption der Ausschnitte und die Bearbeitung des Videos in gängigen Filmschnittprogrammen, wie zum Beispiel iMovie.

5.1.6 Lern-Repositorium

Um eine möglichst große Reichweite der Lerninhalte zu erzielen, wurden die wöchentlichen Betreuungen und Inputs sowohl durch eine Online-Lernplattform, als auch durch einen analogen Reader in Broschürenform ergänzt.

Neu erlernte Methodiken und Software konnten die Studierenden mithilfe dieser beiden Medien zu Hause nachbereiten, oder auftretende Fragen gezielt nachschlagen. Die Online-Plattform bietet den Studierenden darüber hinaus auch die Möglichkeit, die Inhalte in kleinen Tutorials und Übungsdateien nachzuvollziehen. Sowohl die Lernplattform, als auch der Reader befinden sich selbstverständlich in stetiger Rückkopplung mit den Studierenden und werden in regelmäßigen Abständen aktualisiert und um neue Themenfelder ergänzt.

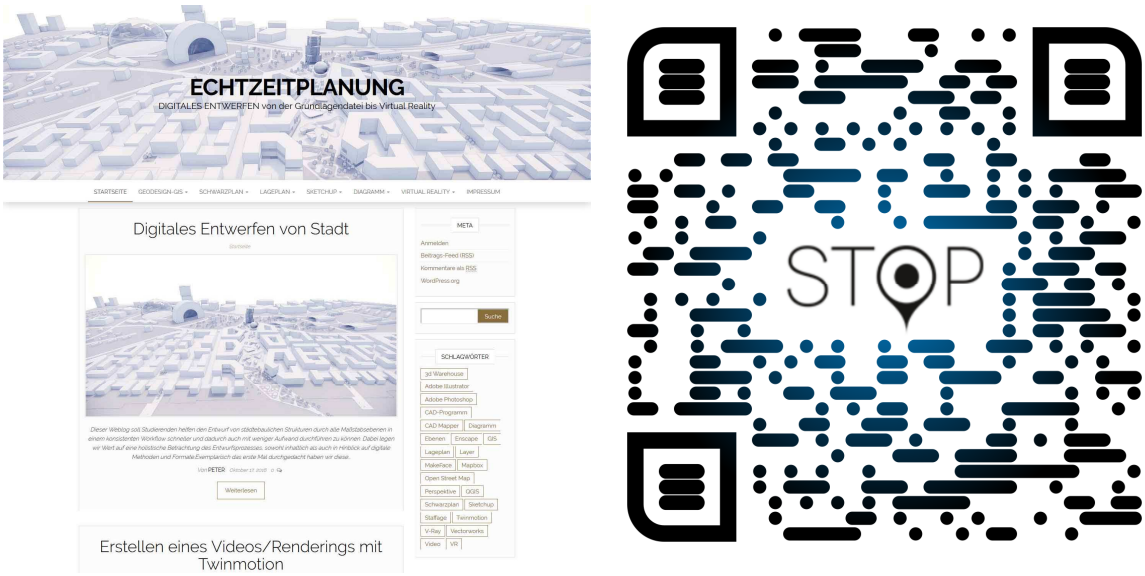

Abb.4: Übersicht über das Lernrepositorium und smartphone-freundlicher Zugang über responsive Design

6 DISKUSSION & AUSBLICK

Der hier vorgestellte Workflow ist die Grundlage für eine konsequente digitale Entwurfsmethode, vom Plangebiet bis zum fertigen (virtuellen) Modell. War in den ersten Entwurfsprojekten Geodesign als Entwurfswerkzeug noch wenig ausgeprägt und beschränkte sich das Arbeiten mit Geodaten noch auf das Erstellen von Kataster- und Schwarzplänen, so ist die methodische Integration des „Geo“-Aspektes zukünftig vermehrt integriert werden. Das systematische Analysieren räumlicher Gegebenheiten wird hinsichtlich der immer mehr an Bedeutung gewinnenden, belastbaren Argumentationsketten im Entwurfsprozess zunehmend an Wichtigkeit gewinnen, da mit Geodesign die Grundlagenermittlung auf eine breiter anerkannte, wissenschaftliche Basis gestellt wird. Gerade die entwerfenden Disziplinen diskutieren gerne über „Schönheit“, das Eingehen auf den „Genius Loci“ sowie das Einhalten von formalen Aspekten, die in einer objektiven Beurteilung schwer zu fassen sind. Der vorgestellte Workflow soll auch diese Eigenschaften nicht negieren, sondern ähnlich der Begründung bei einem Bebauungsplan zu einer stärkeren Argumentationstiefe verhelfen. Sind die richtigen Fragen zu der Entwurfsaufgabe gestellt und die Rahmenparameter für das Gebiet abgesteckt, so bietet das Arbeiten im virtuellen Modell und der Diskussion in Gruppen besser Möglichkeiten sogenannter „iterativer Loops“ zur Anpassung und Entwicklung an die ästhetischen als auch an die „harten“ Fakten.

Der hier vorgestellte Ansatz ist ein erster Versuch, das digitale Entwerfen konsequent über alle Maßstabsebenen und auch Planungshaltungen hin konsequent durchzuziehen. Er ist kein abschließendes Ergebnis, sondern ein Gerüst, an das immer wieder neue Technologien angedockt werden können. Jedes Design-Studio ergänzt in der Zusammenarbeit zwischen Lehrenden und Studierenden den Prozess, ähnlich im Entwurfsprozess selbst, wird auch der Workflow immer wieder kritisch hinterfragt.

Diskussionspunkte sind häufig der Umstand, warum soll den eine schon erlernte Software verlassen bzw. mit anderen Technologien ergänzt werden, wenn es denn auch anders schon digital gut klappt. Dabei werden Trends im digitalen Bauen und Planen wie BIM, XPlanung, CityGML, allgemein das (gewünschte) Zusammenwachsen von GIS und CAD oftmals außer Acht gelassen. Ein weiterer Umstand ist oftmals, dass viele VR und GIS Anwendungen keine „große Tradition“ auf iOS besitzen, und deshalb von den Studierenden übersehen werden. Eine weitere Frage wird sein, wie kann mit Parametrischen Entwerfen und Lösungen in dem Workflow umgegangen werden?

Die Frage nach dem „richtigen Workflow“ kann und wird wahrscheinlich nie abschließenden geklärt werden können, jedoch sollte bei jeder räumlichen Fragestellung als auch beim Einsatz der Technologie immer der „Problems First“ Ansatz beherzigt werden, um zielgerichtet zu einer guten Lösung auf die richtige Frage zu finden.

"Digital.Labor" – Co-Creation for the Digital City of Tomorrow

Sven Funk, Jennifer Krauß

(MSc. Sven Funk, Fraunhofer IAO, Nobelstraße 12, 70191 Stuttgart, sven.funk@iao.fraunhofer.de)
(MA. Jennifer Krauß, Fraunhofer IAO, Nobelstraße 12, 70191 Stuttgart, jennifer.krauss@iao.fraunhofer.de)

1 ABSTRACT

In ordert to design and develop urban solutions successfully, the need to include a wide and diverse range of stakeholders is becoming evermore apparent. These tasks must be recognized as a societal task and perceived jointly, and provide a platform for bringing together several actors to colaborate effectively. Digitization is providing new orrprtunities to integrate a large number of (local) actors into decision-making and implementation processes, relevant to urban development through both conventional and innovative participation methods (HANZL;2007). But, how might such new integrated approaches look? How is it ensured that the impulses of a heterogeneous stakeholder landscape are equally taken into account? Moreover, how is it guaranteed that cities integrate the results of open idea processes into traditional urban planning?

One such emergent approach is that of co-creation (ALVES;2013), which focuses on the collaboration of transdisciplinary actors who jointly address challenges in a "process of creation" to develop new and successful solutions to existing problems. Practical experience are combined with expertise knowledge and specialized skills and solutions are developed "on the ground", regardless of professional background. In such a co-creation process, all backgrounds and approaches are recognized as equally valuable and accompany all stages of the process, from the initial idea to (prototype) implementation. Thereby such approaches promise the creation of holistic and sustainable (systems´) solutions with a high innovation potential. They offer a new format for stakeholder participation in urban processes, given the wide variety of urban challenges we are currently facing.

The Fraunhofer Institute for Industrial Engineering IAO, in cooperation with the Institute of Human Factors and Technology Management IAT of the University of Stuttgart, has launched the Municipal Innovation Center (Kommunale InnovationsCenter (KIC@bw)). The focus is on creating experimental spaces and new innovation partnerships between administration, business, science and civil society. The goal is to develop and implement innovative solutions for cities, towns, counties and regions. The Municipal Innovation Center is funded by the Ministry of the Interior, Digitization and Migration Baden-Württemberg as part of the digitization strategy of the state government of Baden-Württemberg digital@bw.

To test the possibilities of digitization for cities, the Fraunhofer IAO has developed a process for prototyping. Central is the "Makeathon" (from "to make" and "Marathon") as a format in which local actors from the city administration, politics, civil society, business and the creative sector are brought together in a limited period of time. In the process, which is moderated by Fraunhofer IAO and Tinkertank, not only ideas are developed and conceptualized, but also implemented as prototypes. The format can be individually adapted and enables almost all questions relating to urban digitization to be tackled jointly. In total, eight of these digital laboratories, in cities and municipalities, will be completed by mid-2020.

Keywords: Future, City, Mobility, Scenario, Planning

2 CO-CREATION - CREATING SOMETHING TOGETHER

The origin of the Digital.Labor is the endeavor to establish a format to support all urban actors around the topic of digitization. It builds on the principles of co-creation and participation, which is why these principles are considered in more detail below.

The step model of the participation of Sherry Arnstein, the "Ladder of Citizen Participation", which defined eight intensity levels of participation, clearly shows that participation not always means participation. Arnstein defines the lowest form of participation as the provision of information, which is countered by the complete relinquishment of decision-making power (ARNSTEIN;1969). According to the authors' understanding, participation should be interpreted as a color palette: for each question, an individual mix of participation intensities is necessary to achieve a successful result.

The central aspects of co-creation are generating ideas and cooperation. In order to develop new solutions according to urban challenges, the co-creation approach focuses on the cooperation of transdisciplinary

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

actors who jointly address challenges in a "process of creation". Regardless of the professional background, something is created together at eye level, from the first idea to the concept, to the (prototype) implementation. The following three basic rules are considered essential for co-creation by the authors of this article:

- Creativity: Finding answers to complex questions and challenges requires a correspondingly complex set of skills, (everyday) knowledge and expertise. Co-creation formats promote creativity in the development of innovative and diverse solutions by integrating heterogeneous actors.
- Identity: When designing new digital services or physical urbane environment, the identification of users with the public space is relevant. By addressing needs and jointly developing solutions, the identification potential can be maximized, which in turn leads to a sense of responsibility for what has arisen and its context and is accordingly relevant for the acceptance of new solutions.
- Solidarity: For the integration of heterogeneous skills, expertise and knowledge, the cooperation of the various actors is necessary at eye level. The "learning from each other" in the creative process is in the foreground and relates to the everyday knowledge of residents and users, the knowledge of formal urban development processes (legal restrictions, process flows) and technology knowledge.

We can encounter co-creation in different contexts. In this article, the Makeathon will be discussed later as an event format, which takes up and applies the principle of co-creation.

3 DIGITAL.LABOR - PROTOTYPING PROCESS FOR DIGITAL URBAN SOLUTIONS

3.1 Makeathon-Format

To test the possibilities of digitization for cities, the Fraunhofer IAO has developed a process for prototyping. Central is the "Makeathon" (ZHANG;2012) (from "to make" and "Marathon") as a format in which local actors are brought together in a limited period of time. In the process, which is moderated by Fraunhofer IAO and Tinkertank, not only ideas are developed and conceptualized, but also implemented as prototypes. The format can be individually adapted and enables almost all questions relating to urban digitization to be tackled jointly.

3.2 Actors

One of the special features of the process is the heterogeneous mix of participants. The aim is to mix as many actors of the city society as possible and to win them over as participants. These range from city administration, politics, civil society, business to the creative sector. They all represent a differentiated set of skills and knowledge while sharing a local identity.

The selection and invitation will be made in coordination with the cooperating municipality. Targeted addressing by the city administration can lead to a limited representation of the group of civil society participants. Against this background, cooperation with the local adult education center is sought where possible. It includes the format in its program and offers the opportunity for interested people to apply.

3.3 Process

The Digital.Labor also lives from the active participation of all attendees and their exchange, not only during the implementation itself, but from the very beginning. The process from the first contact to the continuation of the project can be divided into four phases, each of which has a corresponding scope: On the one hand, the preparation of the Digital.Labor with the identification of the main topics, as well as the implementation and the processing of the Digital.Labor itself. On the other hand the continuation. For the Digital.Labor and the participants themselves is it essential, that not only ideas are developed and conceptualized within this process, but that they are also implemented as prototypes.

3.3.1 Preparation

The biggest challenge when preparing a laboratory is to understand the respective municipality and local conditions. In order to guarantee this as best as possible, a core team is defined in a first step, which accompanies the entire process. This includes representatives of the city administration and the Fraunhofer Institute. The city administration is responsible for the selection and addressing of the participants, the provision of suitable rooms and the catering during the event.

Fig. 1: Digital.Labor localities Illertal und Constance[1]

In joint coordination meetings on site, up to three questions are set which need to be dealt with in the laboratory. It is important to find the right framework between a specific challenge and creative freedom. The selection of questions is based on experience from previous laboratories and can be refined as the number of events progresses. Experience has shown that not every question is suitable for the process. If these are spatially too extensive or thematically too complex, targeted processing by the participants is unlikely. The same applies if the questions were chosen too specifically and there is no longer any space for creative approaches.

Each selected issue is accompanied by a responsible person from the city administration. This supports the participants in the process with comprehensive information and prevailing framework conditions.

3.3.2 Implementation

The 1.5 day or about 15-hour makeathons are divided into three phases: idea generation, experimentation and prototype development. Each participant is welcome to find a challenge that suits his/her interest. Continuous dialogue between the working groups and exchange with the assigned mentors ensure the integration of the results.

An exemplary process of a Makeathon can be divided into four phases, which can be flexibly adapted to the circumstances in the respective municipality, the participants and the premises.

(1) Thematic introduction and background information

(2) Idea development and conception

(3) Experimentation and prototype development

(4) Presentation

The focus of the overall process lies in the area of "Experimentation and prototype development", which takes up 70 to 80 percent of the time. Iterative testing of the designed approaches without intellectual restrictions is essential. Mentors support the participants in the implementation with technical and procedural know-how. Regular exchange between the individual thematic groups helps to refine solutions and to solve possible problems with a new approach.

The conclusion of a digital laboratory is the final presentation in front of top administrators, community council members and other interested parties. It is important to clarify that the developed products are prototypes and not finished products, so that there are clear expectations.

3.3.3 Processing and continuation

All of the results will be prepared appropriately after the event and made available to the participants as well as to those responsible for the municipality. Developed digital prototypes are handed over to the city and analog exhibits remain with the organizing municipality immediately afterwards.

All results are also presented to the city council. Not only are the prototypes presented, but parts of the laboratory are also exhibited and the process can be experienced. Every laboratory is committed to putting at least one prototype into practice. Appropriate funding programs at federal and state levels are identified and the municipality is supported in the application process. This forms the basis for the fact that the laboratory was not a one-time beacon, but a continuous process.

4 MOBILE LAB

4.1 The development and necessity

In order to create an experimental space and to initiate innovation processes in different cities, communities and districts, a mobile lab has been developed, which makes it possible to carry out the format on site. For this purpose, a scenario simulation was carried out in the first step of the development process. In the next step, the toolset was defined, whereby the requirements for the mobile laboratory were derived and thus the individual modules determined. Afterwards all modules were transferred into an overall concept.

4.2 Modules and field of activity

In total, the digital lab consists of four modules; a planning table, a sensor station with LoRaWAN transmission technology, a Virtual Reality station with multiple VR-Headsets and a coffee station. All modules were installed in flight cases with castors, whereby the individual walls of the flight cases as well as the flight cases themselves functionally serve as station or tables.

Fig.2: Digital.Labor modules setup[2]

4.2.1 Planning Table

The module "planning table" contains a notebook, a projector with digital pen, Lego Serious Play and various materials with which building, handicrafts and haptic work can be done. At the planning table the participants should be able to plan and replant different areas, sites and buildings together by drawing changes with the digital pen into projected maps or by tinkering and building with the different materials available to them.

4.2.2 Sensor system for recording real-time data

[2] Photo: © Ludmilla Parsyak, Fraunhofer IAO

On the basis of an open LoRa infrastructure and an intelligent sensor system, municipal and economic actors are enabled to codesign their future city. This infrastructure is provided by the Fraunhofer IAO within the mobile labs in order to develop new sensor applications with local actors and ultimately to be able to implement them in the field. The resulting prototypes can, for example, record environmental data (particulate matter, NOX, humidity, noise) but also more complex movement data of the city in order to generate new data-based value-added services.

4.2.3 Virtual Reality Station

The “VR Station” is another experience station within the Digital.Labor. Here the participants can experience their own city, streets, houses, regions, areas in 3D. They can walk through their streets, draw buildings, change paths or build bridges within virtual reality. It is also possible to create your own virtual reality environments using 360° photography. The corresponding camera technology and software are available for this, which are accompanied by the simplest possible process. The aim is to reduce fears of new digital tools and changes and increase their creativity.

4.2.4 Coffee Station

The module of the "Coffee Station" will serve as a meeting point for the participants within the Digital.Labor, inviting them to a further relaxed "group-spanning" exchange and thus offering the experimental space even more room for creativity and innovative ideas.

Fig. 3: Impressions Tools and Prototypes[3]

[3] Photos: © Ludmilla Parsyak, Fraunhofer IAO

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The Digital.Labor should not only create added value for the local players, but should also provide all interested parties with an insight into the participating community and access to the prototypes developed. For this purpose, the so-called "digital road show", a web-based story telling with map elements, is currently being developed. All the laboratories, the process, and the prototypes are shown there. Completion is scheduled for summer 2020.

5 PERFORMED LABS

In order to be able to spread and replicate innovative solutions, it is necessary to clarify their potential and added value and to make them tangible. In this way, possible barriers to entry can be reduced and a broad understanding of the added value and applicability of solutions can be gained. The digital roadshow of the mobile laboratory is thus intended to illustrate the opportunities and possibilities of municipal digitization using concrete exhibits and prototypes. For this reason, seven digital labs were carried out in different regions, cities and districts within one year. Explicit attention was paid to a healthy variety of different thematic focuses such as mobility, tourism, data infrastructure, the living space per se with air quality, traffic and noise as well as regional needs. The Digital.Labor travelled from the very rural areas to the more or less well connected rural areas and into cities. Design thinking workshops were held in the Black Forest, Illertal, Baden-Baden, Constance and Tuttlingen.

The Digital.Labor in the northern Black Forest for example was preceded by the Oberwolfach mobility project "Mitfahrbänkle", which impresses with its uncomplicated and simple application. Pure red-marked benches along certain streets of the community signalise a need for a ride along by a citizen. The content of the Digital.Labor workshop was to develop solutions that would make the offer more attractive and visible. Initial problems were the late visibility for car drivers, the sometimes too long waiting times and the lack of information about where to go. In order to make the offer generally more visible and to increase the attractiveness of the bench with its functionality, the group designed an induction sensor for the bench, which signals to approaching drivers that someone is sitting and waiting on the bench. In addition, a display with a timer was intended to increase the awareness of passing cars to the waiting ridesharer. In addition, extensions to the bench's range of functions, such as QR codes for information about the communities and their bus schedules, which would also be accessible without the network, were also considered. This further developed idea of the mobility project won a call for proposals after the Digital.Labor, so that it can be turned into reality.

In Baden-Baden the topic of volunteering and the digital flow of information was addressed. Associations and voluntary institutions should achieve more visibility. Therefore, the participants came up with the idea of a "digital flow", i.e. to install a media installation of screens in public space, on which Instagram or Twitter feeds, for example, 'flow' along. Associations and institutions can be added to the stream and thus send their own current Twitter or Instagram content on its journey through the digital flow. The aim is to raise awareness of the associations and their content among Baden-Baden's passers-by, regardless of age, and to create broad accessibility with an artistic installation.

In Constance, the Digital.Labor with the participants dealt, among other things, with the topic of concept development of a multimedia communication of urban development and urban planning processes. A concept was developed to visualize urban development projects and to follow their progress virtually. In the first virtual step, Constance should be considered in its entirety, the second level then leads into the district which is currently planned and/or already under construction and provides more detailed information and descriptions of the district design. It should offer the citizens of Constance and all interested parties the possibility to inform themselves about individual concepts and to observe their progress virtually and digitally visually. This concept will now be implemented in the city of Constance and made possible for citizens who are interested in this media communication.

In the municipal administration association of Illertal, consisting of the municipalities of Erolzheim, Berkheim, Kirchberg a.d. Iller, Kirchdorf a.d. Iller and Dettingen a.d. Iller, the Digital.Labor with its mobile modules focuses on mobility in the context of digitization and rural areas. Four ideas could be presented as a result, the autonomous local bus, the RegioMove App, the crawlways and the traffic evaluation, one of which, the idea of the local bus, is to become more permanent. The idea of the "autonomous local bus" developed from the desire to have a more "lively" public transport system. The idea of the "autonomous local bus" was born out of the desire to have a more "lively" public transport system, acting like a shuttle service,

travelling the same route every day, stopping at nodal points such as the kindergarten, the shopping center and various residential areas to allow people to get on and off. One should never have to wait longer than 30 minutes for the shuttle. The concept is currently being examined for feasibility, discussed and made realizable with experts from business, science and politics and should be submitted as an idea within an application if the call for proposals is suitable.

Part of the Digital.Labor is not to let ideas and built prototypes be forgotten after the workshop, but to examine their suitability for current and future calls for proposals and to consolidate them within a joint draft proposal. Furthermore, it should be possible to realize individual prototypes directly.

6 CONCLUSION

Digitization offers great opportunities and also serves as an instrument to "overcome economic and social challenges". (HABBEL;2017) It enables all those involved to have easier access to knowledge by making it easier to use information sources and the resulting possibility of simplified networking. The use and generation of data can open up far-reaching options for action at the federal, state and local levels and thus help to prevent and avert problems and change situations. The central element is the citizen, because he is the user and resident of a city. Their interaction with the various systems is significant for an overall urban view. If citizens are the central element of an overall urban view, then their opinions, ideas and fears should play a significant role in planning and development and urban concepts should be developed through citizen participation - including those who will live in the city in the long term (e.g. the younger generation). Just as companies and platform operators have been using personal data for many years to provide "commercial offers based on individual preferences", cities should try to provide citizen-specific offers using new technologies and analysis methods of individual needs. Therefor privacy and data protection must play a central role. Only in this way, as well as by raising citizens' awareness of certain risky issues and by transferring knowledge, can a city achieve its development goals and generate acceptance and support. Citizen participation in times of digitalization should, in addition to the classical participation formats, "take into account alternative forms of participatory urban development with socio-economic relevance". Participation independent of location and time of day - owed to digitization - has a positive effect on this process and should be used even more as an advantage. With this background, the Digital.Labor wants to help cities and municipalities to use digitization as an opportunity and to think about and integrate possible developments. However, since analogue and physical participation procedures should not be completely replaced by digital tools, since both personal and direct exchange will continue to be of high relevance, "multimodal solutions" will be all the more important in the future, as will the case-oriented use of suitable participation instruments. (BBSR;2017)

The Digital.Labor combines both variants. The handling and work with digital tools and the physical and analogue work on the tools, with a group experience as a further factor. In order to be able to continue to generate new knowledge and new insights, the Digital.Labor should not and must not be allowed to rest in its existence and must be continuously developed. This is one of the reasons why the mobile laboratory of the Digital.Labor will be given a stationary counterpart so that this format can also be carried out in the premises of the Fraunhofer Institute with other target groups. The so-called Next.Lab (stationary counterpart) was developed and is currently built with the help of the knowledge generated and the findings of the mobile labs roadshow.

E-Scooter as Environmentally Friendly Last Mile Option? Insights on Spatial and Infrastructural Implications for Urban Areas based on the Example of Vienna

Karin Markvica, Klemens Schwieger, Michael Aleksa

(DI Karin Markvica, MA, AIT Austrian Institute of Technology, Center for Mobility Systems, 1210 Vienna, Giefinggasse 4, Austria, karin.markvica@ait.ac.at)
(DI Klemens Schwieger, AIT Austrian Institute of Technology, Center for Mobility Systems, 1210 Vienna, Giefinggasse 4, Austria, klemens.schwieger@ait.ac.at)
(DI Michael Aleksa, AIT Austrian Institute of Technology, Center for Mobility Systems, 1210 Vienna, Giefinggasse 4, Austria, michael.aleksa@ait.ac.at)

1 ABSTRACT

We recently face an e-scooter hype in Europe. More and more e-scooter sharing offers are provided in cities and towns which are marketed as a last mile option. At the same time, a greater extent of private households has their own equipment. This trend is two-fold as e-scooter offers not only provide benefits (e.g. in terms of accessibility) but also pose certain risks (e.g. in terms of road safety).

To find out about spatial and technical implications and to assess the potential of e-scooters for urban areas, we used a 'triangulation' research strategy using different sources. Based on the insights from a trend and target group analysis and focus groups with users and non-users we conducted 1-week tests with persons using e-scooters on everyday routes (N=51), a survey of users and non-users (N=128) and course exercises carried out with pupils (N=94) in the city of Vienna in Austria.

Against widespread assumptions that e-scooters can use existing infrastructure, we found that the preconditions are not necessarily suitable for e-scooters. Infrastructure elements would have to be adapted to enable a safe use of e-scooters. It was revealed that e-scooter usage should be recommended for the last mile in suburban areas and not the city center as the density and infrastructure (e.g. cubblestone) do not correspond to preconditions essential for a safe e-scooter usage. In addition to that, we found that labeling e-scooters as an environmentally friendly option is the subject of controversial debate.

Keywords: e-scooter, urban areas, infrastructure implications, spatial implications, Vienna

2 PROBLEM STATEMENT

At present, the e-scooter is an indispensable part of the cityscape of many European cities. There has been a e-scooter hype, which has led to an increasing number of suppliers of this trend vehicle. This includes on the one hand sales to private individuals and on the other hand free floating sharing offers in urban areas. No less than eight suppliers have to struggle for acceptance on the market in Vienna (Gruber/Wiederwald 2019); in Germany seven suppliers offer their services in different cities (t3n 2019). The deployment does not stop at smaller city scales or regions with challenging weather conditions (e.g. Nordic countries). In Norway, e-scooter sharing suppliers entered the market in early 2019 providing services in cities such as Trondheim, Oslo or Helsinki (Lime 2019) under the guise of the green transportation trend. Even though a year-round use of rental systems is not planned, the harsh climate itself is a challenge for the material and the safe use on the roads and cycling paths.

The popularity of e-scooters is due to its relatively easy handling, low physical activity required and flexible everyday use. The new means of transport is promoted as an ideal addition to the existing transport network. It is marketed as an environmentally friendly alternative to motorized individual transport or at least as a supplement for the first and last mile in urban areas (Zarif et al. 2019). Therefore, the said potential of e-scooters unfolds above all in the combination with other transport modes, as a first or/and last mile option for short distances and opportunity for the road users' extension of range.

We know from the past that new trend vehicles are regularly entering the market, which are promoted and advertised differently by retailers. Individual vehicles are strongly accepted by consumers, create a long-term establishment and become everyday means of transport (e.g. inline skates, micro-scooters), others have disappeared from the market after a few sales seasons. It is clear by now, that e-scooters not only offer opportunities for road users. There are manifold problems attached to the implementation of the vehicle in the overall transport system. Lack of parking space, problems with handling, lack of a legal basis and excessive speeds are only some of the factors that contribute to the displeasure of the city administration (Hunstable 2019). Furthermore, it remains unclear whether e-scooters will actually be used as a supplement

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

in the transport system or whether they replace footpaths, cycle paths and public transport. The marketing as environmentally friendly must be critically questioned. Not least because of the production of the vehicles and power consumption which receive little or no attention.

3 METHODOLOGY

The complexity of the effects of e-scooters requires further research. To assess the potential of e-scooters for urban areas, we need to find out about spatial and technical implications. First insights could be gained from a trend and target group analysis and focus groups with users and non-users. Based on this knowledge, we used the 'triangulation' research strategy proposed by Robert K. Yin (2003, 2009) using different sources to capture different aspects of the topic. 1-week tests with subjects using e-scooters on everyday routes (N=51), a survey of users and non-users (N=128) and course exercises carried out in a school (N=94) were performed for the city of Vienna in Austria (see Fig. 1).

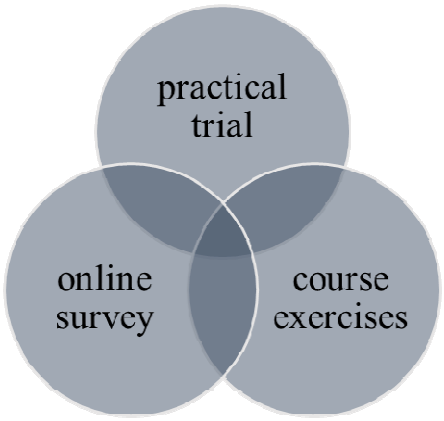

Fig. 1: Triangulation approach covering different aspects.

The approach described provides insights on the usage of e-scooters in terms of spatial ranges and preferred applications, suitability as a last mile option and technical implications (vehicle itself as well as the infrastructure).

3.1 Practical trial

The practical trial took place from September to June 2019 (including a winter break) with no spatial restriction but a focus on the Vienna region. 60 persons participated in the 1-week tests using e-scooters on everyday routes which resulted in complete data sets for 51 participants. The data collection was performed via a Smartphone App called 'SmartSurvey' which collects all the spatial information and offers additional features such as the localization of problem areas, route evaluations, type of infrastructure used as well as requests and proposals.

3.2 Online survey

To obtain a general picture of the population's opinion, an online survey was conducted from May to July 2019. A total of 147 people took part in the survey, which resulted in 128 fully completed questionnaires that were used for an evaluation. In the survey, a broad public was asked about their attitude towards small electric vehicles, their previous experiences and the resulting requirements. Users, non-users and occasional users were interviewed in order to survey the different aspects of road use and to allow different perspectives on this mode of transport. In order to obtain a general opinion, the survey has been advertised via social media, the event 'Radgipfel' in the city of Graz as well as the channels of the LOI partners.

3.3 Course exercises

The course exercise took place on two days in June 2019 in the secondary school "De La Salle" in the north-east of Vienna. Three parcours were designed and placed on an even surface outdoors on the school ground (see Fig. 2):

- straight driving (10 m length; 60/40/20 cm lane width)
- slalom (20 m length, distance between the little hats: 4/3/2 m)

- target braking (speed at least 20 km/h, stop after 4 m, the target area is 1 m long, the front wheel has to stop in this area)

Fig. 2: Examples of the three course exercises: „straight driving“, “slalom” and “target braking”.

The aim of the various tests was to assess the handling of e-scooters in relation to age, gender and previous experience for adolescents. Since it was a closed area, accidents with other road users could be excluded. Furthermore, all tests were explained to the children in detail and special attention was paid to their safety. Their participation was only possible with the consent of the legal guardian and with safety equipment like helmets.

4 RESULTS

The main focus of the study is to investigate the potential of e-scooters as a last mile option for urban areas. Insights on spatial and infrastructural implications were gained using the ‘triangulation’ research strategy described in chapter 3, namely the practical trial, the online survey and course exercises.

4.1 Practical trial

The evaluation included 533 paths and 398 trips which reveal that a combination with public transportation was performed in 53 trips and on 94 paths (see Table 1). A trip implies at least one, more likely several paths.

Category	Trips	Paths
e-scooter	180	200
e-scooter & public transport	53	94
e-scooter & motorized individual transport	2	4
e-scooter & motorized individual transport & public transport	4	6
undefined	159	229
sum with undefined	398	533
sum without undefined	239	304

Table 1: Distribution of trips and paths.

The analysis of the data shows that the participants who drove the 200 e-scooter paths had an average speed of 9.5 km/h during the trial and covered an average distance of almost 2.7 km. Compaired to the second categorie “e-scooter & public transport” were participants drove much shorter distances. If an e-scooter was used in combination with public transport, the average distance of the e-scooter paths were only 1.6 km long while the average of the driven speed is 3 km/h higher. (see Fig. 3).

63% of the respondents stated that their routes had changed as a result of using the e-scooter. 18 respondents (33%) stated that their travel time was shortened by using the e-scooter, while four respondents stated that their travel time was extended. The e-scooter most often replaces cycle and footpaths and in almost 19% of cases it also replaces the use of the private car.

The majority of the test persons (70%) had no experience with e-scooters before the test week. Only 11% said they use e-scooters regularly. About two thirds of all respondents (67%) had a very good or rather good

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

overall impression of e-scooters after the test week. 9% of the respondents rated the experience as "rather bad" or "poor". 78% of the respondents stated that they consider e-scooters suitable for everyday use.

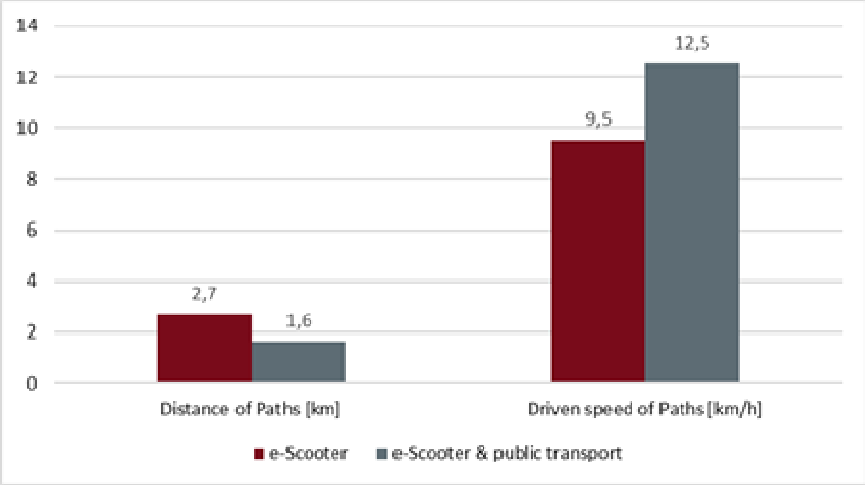

Fig. 3: Distance and speed per category.

With 65%, the majority of problems reported are infrastructure-related. Missing or insufficient infrastructure is classified as serious in only three of 41 cases (7%). In contrast, damage to or defects in existing infrastructure or problems with the vehicle are much more often (14% and 17%) rated as serious. The high speed, as well as damage to the surface of the carriageway or tracks etc. are often classified as a high safety risk. Requests mentioned by the respondents for infrastructure improvement measures mainly concern the surface of the road. On the one hand, this includes the repair of road damage, on the other hand, the avoidance of edges or tram tracks in the direction of travel along cycle routes. It should also be avoided to equip cycling infrastructure with uneven flooring (e.g. paving).

Time saving, flexible use and the possibility to combine with public transport are the three most frequently mentioned advantages of e-scooters. The lack of secure storage opportunities and the weight of the e-scooters were mentioned as the most common disadvantages.

During the practical trial 174 problem areas, including safety relevant issues with the e-scooter itself, were tracked by participants (see Fig. 4).

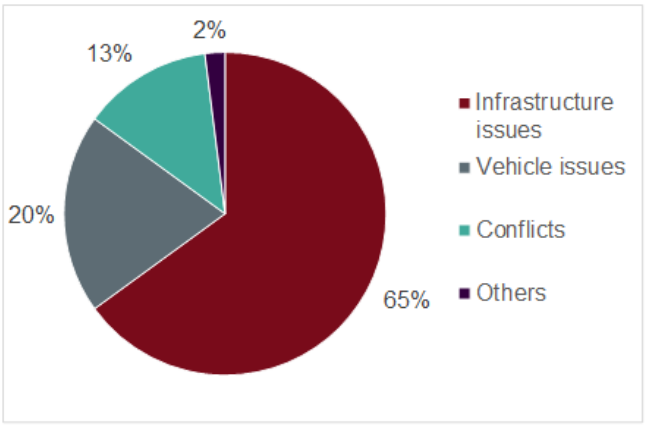

Fig. 4: Problem areas per category.

65% of the problem areas concern infrastructure, of which the majority are missing or insufficient cycling facilities. Reported problems with the e-scooter itself are the second largest category with 20%. Participants mentioned issues with the breaks of e-scooters, as well as the size and weight of the vehicles especially when travelling on public transport. A frequently mentioned problem is giving handsignals. Conflicts with other road users are in third place (13%). Almost two-thirds of them occurred between e-scooter drivers and pedestrians, but none took place on a sidewalk. Conflicts between scooters and motor vehicles have mainly occurred in the intersection area during turning operations, as well as at driveways. Throughout the practical test, no conflict was found between cyclists and e-scooters, although they use the same infrastructure.

The pressure on the infrastructure for cyclists has increased considerably due to the new group of e-scooter riders. On the one hand, this can result in decreased traffic safety, e.g. increase of conflicts. On the other hand, this is also a chance to gain more space as well as more ressources for this road user groups.

4.2 Online survey

With regards to household equipment, it was found that only a few people have access to small electric vehicles. Scooters are owned by only 34 respondents and e-scooters by nine persons. Other small electric vehicles are only available in households to a very limited extent. According to this, the e-scooters are borrowed from various rental providers, with Lime leading the way (20 entries).

After all, 45% have already tried out a small electric vehicle, of which 81% have already been on the road with an e-scooter. Use on everyday routes is still the exception. Only four people stated that they used an e-scooter every day. In contrast, other small electric vehicles are used significantly less frequently. Nevertheless, the predominant purpose of use for e-scooters was still everyday journeys before leisure time activities.

The majority of those questioned stated that the environmental alliance (public transport, cycling, walking) had been replaced by e-scooter driving. Only twelve respondents replaced a car ride with an e-scooter ride. E-scooters were mainly driven on cycle paths/cycle lanes and the road. Sidewalk/pedestrian pathways were also frequently mentioned and only very rarely other surfaces such as play streets. As expected, the survey participants preferred shorter distances with the e-scooter. At the same time, everyday routes hardly differ from leisure routes. 22% of the survey participants use it for a maximum of five minutes on everyday or leisure paths, another 49% and 42% for five to ten minutes respectively.

37% of all respondents perceive e-scooters as an attractive means of transport. The approval among users of small electric vehicles (n=57) is significantly higher here than among those who have not yet had any experience with small electric vehicles (n=71). Among e-scooter users (n=46), e-scooters are perceived as particularly attractive. Here it is 65% who regard e-scooters as an attractive means of transport.

E-scooters are perceived as a very individual, pleasant, fast means of transport. There is a need to catch up on the safety aspect and integration into everyday life. E-scooters are not seen as a cheap means of transport. The previous experiences among all respondents are mediocre to poor. Only 33% of the 128 respondents stated positive experiences. Here again there is a big difference between people with experience in handling small electric vehicles (n=57) and those without this experience (n=71). Only a quarter of the non-users report more or less good experiences. If only the e-scooter users are considered (n=46), 65% have had consistently positive experiences. The fun factor, time savings, flexibility and combinability with other means of transport have been highlighted as particularly positive. The barrier-free access (booking process, availability in the room, etc.) and the driving experience have been highlighted. Critical remarks have been made about mutual consideration and compliance with laws and regulations.

The reasons for switching to small electric vehicles in general were once again cited as alternatives to other means of transport (80 entries), rapid progress (75 entries), taking passengers on public transport (72 entries) and flexibility (70 entries). Coolness, on the other hand, is a secondary topic and received only 19 entries. There is no reason for as many as five people to switch to small electric vehicles.

The main reasons cited against the changeover were the risk of injury (91 entries) and the lack of safe traffic areas (71 entries), followed by other reasons with less than 60 entries. From the point of view of the users of e-scooters (n=46), these aspects also speak against use, followed by the lack of barriers (23 entries). Other reasons given by the users were high weight, lack of battery capacity, the availability of service points, weather dependency, legal aspects and environmental pollution.

22% of all respondents were already involved in a conflict or accident as road users and 4% as e-scooter drivers. 30 people described the conflict situation in detail, often involving pedestrians. 30% of all respondents also stated that they had already observed an accident or conflict. 35 persons described conflicts/accidents caused by reckless driving and/or the combination e-scooter/pedestrian. In contrast, conflicts on the road are rather sparsely represented.

Problems with e-scooters were already experienced by 17% of all respondents. Present topics were speed dosage while driving (14 entries), problems when turning and with uneven ground (10 entries each). Other problems mentioned were lack of equipment due to a change in the law, defective equipment, no

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

homogeneous speeds on cycle paths, not enough power of the rental e-scooter (heavy backpack and gradient) and too slow speed.

More than half of the respondents stated that they were poorly informed about the legal framework of e-scooter use. Only 40% feel sufficiently informed. The legal situation is clearer for users of small electric vehicles (n=57) than for non-users (n=71), two thirds of whom have little knowledge of the legal framework. Among e-scooter users (n=46), more than half of them are largely aware of the legal situation.

When asked about the traffic areas that may be used by e-scooters, cycle path/bike lane received 111 entries, followed by 87 entries of the roadway and 13 entries of sidewalk/pedestrian path. Other areas listed were meeting zones, private ground and approved sidewalks. As a minimum age for unaccompanied use, 44 persons correctly stated 12 years or 10 years with passed bicycle test. If one takes only the 46 users of e-scooters into account, then almost half of them are aware of the minimum age (22 entries).

When asked about the alcohol limit for e-scooter drivers, 58 entries that the 0.5 per mille limit applies and 46 entries 0.8 per mille (actual alcohol limit). After all, there were 15 entries of 0.1 per mille and 14 entries stating that there is no alcohol limit. There are hardly any differences between users of small electric vehicles and non-users answering this question. Among the users of e-scooters (n=46) the level of information was slightly better. 18 entries related to 0.5 and 0.8 per mille and 7 entries to 0.1 per mille. Four e-scooter users assume that there is no alcohol limit.

59% of all respondents see the combination of e-scooters and public transport as an attractive mobility option. This contrasts with 9% who do not like it at all. However, most respondents do not regard the e-scooter as a replacement for a car. Only 44% would assign potential for the e-scooter to replace the car at the first/last mile in the long run. A restriction in the use of e-scooters would be supported by 60%. The regulation of parking areas is particularly present here with 57 nominations, followed by 40 nominations for reducing the existing speed limit. The same tendency can be read for the users of e-scooters. Proposals for other regulations addressed safety aspects, the design of the rental equipment, the regulation of loading responsibility and the areas to be used.

The concluding question about the wishes for the future has been answered extensively by no less than 70 persons. The wishes concerned integration into the transport system, environmental and safety aspects, legal regulations and technical details.

The gender ratio of the interviewees was almost balanced with 45% female persons. All age groups between 14 years and older were represented. 95% stated that they are not restricted in their mobility. The school education of the respondents was above average with 51% holding university degrees. Most of them are employed (69%) and the majority live in households with two persons (45%).

4.3 Course exercises

94 pupils (40% females) took part in the course exercises with a maximum of ten points awarded per course (three attempts per test in order to see their improvement) for comparing the participants and rounds objectively.

After a the welcoming and a general explanation per class giving insights on the project goals, the research questions, the handling of the e-scooter and the tests, the first student was able to start driving.

After performing all exercises, the pupils have been asked about their previous experience with scooters, e-scooters, bicycles and e-bikes, as well as their opinion on e-scooters. After that, they should announce suggestions for improvement to increase safety from their point of view.

The results are evaluated according to age groups and experience with scooters. The course tests show no significant differences in the points achieved between the sexes. Interestingly, the 13- and 16-year-old pupils performed better than their 14- and 15-year-old colleagues (see Fig. 5). A comparison of points between the three courses is not conducive because the criterias for reaching the maximum points were different.

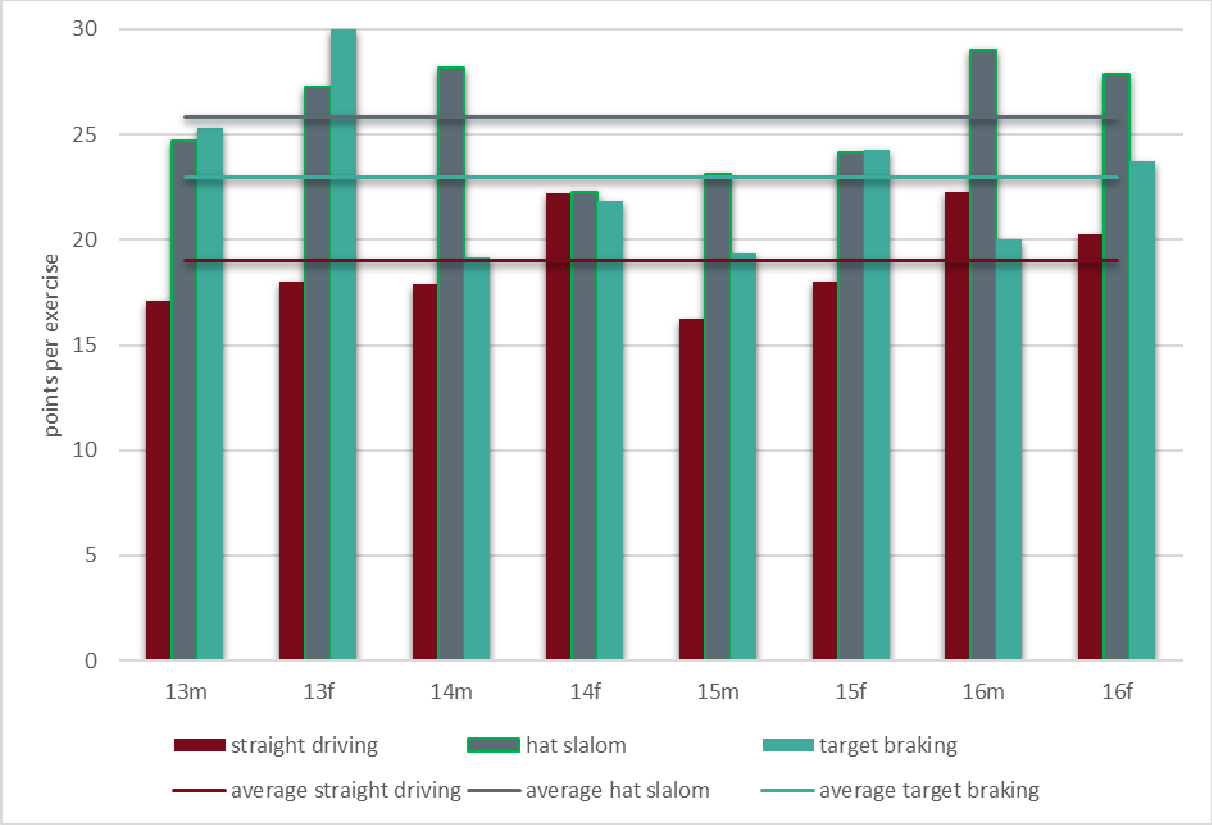

Fig. 5: Points per exercise per age and sex.

The students hardly had any previous experience with electric small vehicles (e-bike and e-scooter), but many of them had experience with normal bicycles and scooters. It was revealed that the experience with e-scooters and normal scooters does not clearly affect the points achieved in the various tests. The students seem to learn how to handle e-scooters very quickly (see Fig. 6).

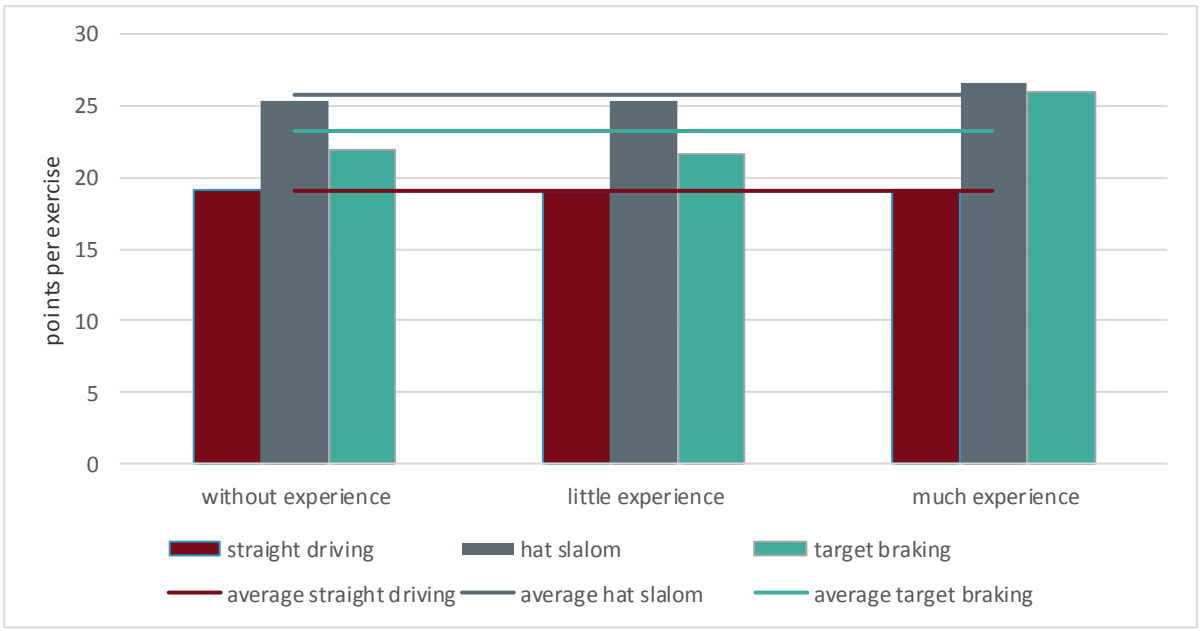

Fig. 6: Points per exercise according to experience with e-scooters.

Only about two-thirds of the total points were achieved in the "straight driving" course. This suggests that keeping a (narrow) track with e-scooters is a challenge. Otherwise the lower value could also be related to the fact that the course was the first to be traversed by the pupils. Slight improvements in the individual tests during the three rounds can be found in "straight driving" and "slalom". During "target braking" the improvement from the first to the third attempt is only visible on average.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The results of the questionnaire show that young people have a positive attitude towards e-scooters, they say that "it is fun". They are aware that driving e-scooters "requires practice" and feel safe riding e-scooters on separate cycle paths, wearing a helmet and after receiving training on the handling of the devices.

5 CONCLUSION

E-scooters are trend vehicles flooding the European market for a few years now. They have proven to be not just a flash in the pan as sales of private vehicles are still high and sharing providers are conquering more and more new cities. So far, they have been treated like bicycles or conventional scooters which means that they share the same urban space. However, they differ considerably in terms of speed and weight. A closer look is necessary to find out which requirements are really needed in urban areas and how suitable they are as an environmentally friendly last mile option.

A more detailed analysis shows that the use of e-scooters in their current form poses several challenges at different levels. Handling the equipment presents difficulties, as do shared areas with other road users and uneven surfaces especially in combination with bad weather conditions. Furthermore, the inner city is a difficult area to use them. On the one hand, decorative surface structures are often used that are not compatible with the small wheel diameters, and on the other hand, these streets are often narrow and very busy areas.

In addition to the infrastructural and organisational (space distribution) challenges, there are major uncertainties regarding the legal aspects. Not everyone is aware of applicable legal regulations. This lack of knowledge can have an impact on traffic safety.

Another striking detail of e-scooter usage is the environmental aspect meaning the perception of the e-scooter as an environmentally friendly alternative for short distances, the promotion of the e-scooters as ‘green transportation trend’ and the users' assessment to that effect. Unexpectedly, many survey respondents pointed out that e-scooters are not environmentally friendly for stating several reasons (e.g. manufacturing, battery, comparison with active mobility).

Measures would have to be taken in different areas (infrastructural, legal, etc.) to promote the positive aspect of use for the last mile focussing on the group of motorized individual transport users. In addition, it becomes clear that it is a much more promising approach to use it as a feeder to public transport stations in poorly developed urban areas than, for example, in a pedestrian-friendly city center.

6 ACKNOWLEDGEMENTS

This work has been partly funded Austrian Federal Ministry for Transport, Innovation and Technology (bmvit) in the “Mobilitaet der Zukunft” programme under grant number 865151 (“e-WALK”).The authors would like to thank all project partners for valuable feedback and their input as well as the surveyand test participants for their time and effort.

1 ABSTRACT

This paper presents Enterprise BIM (EBIM), which is the utilization of Building Information Modeling (BIM) in a holistic organizational aspect structure during the entire life cycle of a building. EBIM acts as a virtual comprehensive representation of the buildings and infrastructure that is aimed to optimize and improve business management, knowledge sharing, digital interaction and connection in the different phases of the building life cycle. This study shows how EBIM could support an organization's core business operationally and strategically. In fact, EBIM is aimed to support the building's entire life cycle and in this approach facility management (FM) is considered as a necessity. This paper demonstrates that FM is not a dedicated or a separate system and it uses exactly the same data as those required for business operations. Hence, we have surveyed the role of EBIM at St. Olavs Hospital as a case study for further consideration. St. Olavs Hospital uses EBIM to realize the goals of better and cheaper construction projects and real estate operations management with the aim of more efficient use of resources. The case study highlights the details and benefits of this approach both with respect to processes, tools and techniques. Furthermore, we demonstrate how EBIM may support interoperability, transparent communication and collaboration among the core business, facility management, the project organization and the different stakeholders throughout the building life cycle.

Keywords: Facility management, IFC, Model server, Enterprise BIM, BIM

2 INTRODUCTION

Digitization, if used wisely, provides a new and optimal way to view business structures and processes. The engineering and construction industry is one of the largest sectors of a country's economy, and real estate is a major economic challenge for any business. Therefore, the present study through describing EBIM as part of the business strategy for digitization, focuses on how to achieve optimum information sharing, collaboration, utilization and management of building-related data across disciplines and systems.

The building configuration and layout constitutes only a small part of the total body of useful information about a building. A really comprehensive and all-embracing building information model should cover and involve not only geometry and properties, but all the information about a building created during its life cycle and its relation to other systems and processes. The building information should be accessible to many different types of users — building owners, builders, operators, administrators, facility managers, portfolio managers and even emergency responders — via user interfaces that are available and approachable to each other (Smith and Tardif 2009). Principally, BIM aims to digitally represent the physical and functional features required to improve and document building designs. Today, BIM applications support walk-through visualizations, collision detection, energy performance estimation, heating-ventilating, air-conditioning systems, lighting design and the assessment of safety and generally issues related to security (Van der zwart 2014). A single building model creation is not only the proper and expected result of BIM; instead, the target is gathering and collecting comprehensive, accessible, reliable and readily exchangeable building information for everyone who requires it during the building lifetime. The value of distinct pieces of data — and with it, the commitment of different parties to compiling and preserving it — varies considerably during the building lifetime. Collecting and maintaining building information and history in a single storage for the whole lifetime of a building is useful and fruitful to individual users only insofar as it supports the many individual business processes during the lifespan. Building information modelling can potentially affect every aspect of business enterprises. Therefore, the implementation of BIM is recognized as an integral part of any business process, and not just as an isolated effort that only relates to a few specific tasks or projects (Smith and Tardif 2009).

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

As will be discussed, while BIM is a method based on digitizing different parts of a building, EBIM focuses on all information management throughout the entire building lifecycle. This paper presents a study utilizing EBIM with St. Olavs Hospital as a case study. The EBIM concept obeys and follows the strategy of the openBIM standard during the building lifecycle and it is aimed to optimize and improve business management, knowledge sharing and digital interaction. Hence, the main objective of this study is to demonstrate how the EBIM can supports decision making during different phases of the building lifespan.

The Central Norway Regional Health Authority (HMN) is a state regional health enterprise that owns and operates hospitals. It consist of three hospitals, in total 700.000m2, where St. Olavs Hospital with approximately 350.000m2, is the biggest one. In 2012, St. Olavs Hospital, together with HMN initiated a project entitled Life Cycle BIM based on facility management. As a result, an EBIM philosophy was adapted where all buildings are an integral part in the entire portfolio of buildings, as well as the aspect structure defined in the hospital business structure. Using such a solution enables the integration of core business and the various processes of the hospital. Today EBIM is an extensive information database at St. Olavs Hospital and Central Norway Regional Health Authority that supports important aspects of the user, such as Facility Management (FM), Virtual Design Construction (VDC) and Property Management (Van der Zwart, Elkhuizen, and Evjen 2016). In this process, St. Olavs Hospital has pioneered using database technology to describe virtual building models according to the openBIM standard. The database is made up of many buildings which both old and new buildings have been incorporated in it. It implies that, the database should be kept updated during the decades of building lifetime and independent of proprietary data systems. The present study describes the transition from BIM to EBIM and indicates how EBIM is used as a digital platform to support building projects, facility management and core business of the enterprises.

3 FROM BIM TO EBIM

3.1 BIM and the Building Lifecycle

BIM acts as a transition of methods and technology from a single traditional consecutive form to a modern multiple parallel form of data integration. BIM is the procedure of data sharing and distribution with the capability to use the data via abundant applications for managing several multidimensional tasks and activities in architecture, engineering, construction, maintenance and different types of operation all along the building lifespan. In fact, utilizing BIM technology is essential for all sized enterprises which are active in the building construction industry and also it is inevitable and imperative for the companies who are seeking to enhance their levels of competitiveness and even their existence in the future cycle of the industry. To mitigate lacking productivity and efficiency in the building industry, BIM plays an efficient role to provide and offer the required information and precise data to be employed for model simulation in different phases in the building industry (Kouch, Illikainena, and Peräläa 2018). In fact, BIM stands at the core of digital transformation throughout the built environment and it provides a vital opportunity and pivotal role to develop and improve performance considerably in innovative ways of delivery and operation. It creates a collaborative method of working that facilitates early supply chain involvement, underpinned by the digital technologies which opens up more effective ways of designing, creating and maintaining assets and resources. It also provides a digital representation of the physical and functional characteristics of an asset to support reliable decisions and information management during its lifetime. For this purpose, at its core, BIM employs three-dimensional model and collective data to access and share information efficiently throughout the supply chain and increase the productivity and efficiency of activities and reduces the risk of errors and maximizes the team capability and potency to innovate (Leader: Cardiff University 2018).

Indeed, BIM makes virtual prototyping as a three-dimensional models and semantic representation of the building for better understanding and comprehension of the project and its components, by all the users and it can be used for the whole lifecycle of the building from the primary design and sketch to the construction, operation and maintenance phases (Lebègue et al. 2013).

3.2 BIM as a Facility Management Tool

Facility management (FM) is an organizational function that supports maintenance of buildings and their services during operation. As such, FM is a multifaceted, complex task that is often challenged by the lack of updated building information. The implementation of BIM can improve facility management tasks by providing related and appropriate data during the buildings operational period. BIM offers a platform for

data exchange between stakeholders in the architectural, engineering and construction fields (Mohanta and Das 2016). However, as a result of rebuilding and partial replacements of building elements on a day-to day basis, FM is continuously faced with the challenge of updating the building information and its quality. Hence, it implies that the FM function may not provide reliable data to building owners for lifecycle management and continuous planning. Therefore, as a emerging technology, BIM is prepared for offering a new level of serviceability and operability to manage buildings and the physical assets in them. (Association 2013). This advantage is a direct result of being able to perform multiple analyses and generate the various documents required by the BIM and information will be more available through increasing the interoperability and collaboration process.

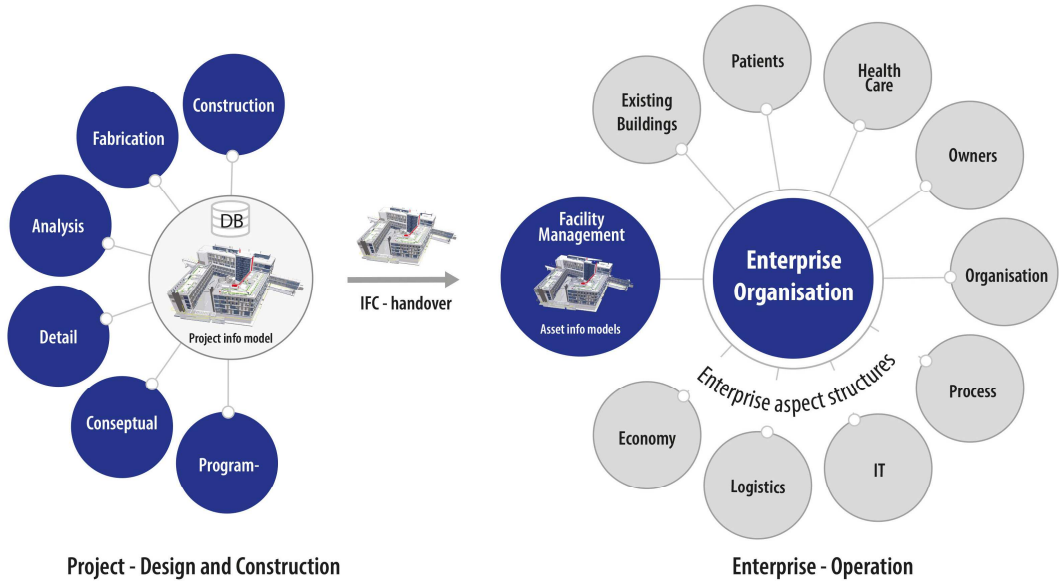

Fig. 1: Description of a classical "BIM-project". The project information model (PIM) developed during the design and construction phase of a project. The asset information model (AIM), IFC files, according to the specifications, are delivered to the Facility Management System.

BIM offers facility managers and building owners/operators a powerful means to retrieve information from a visually accurate, virtual model of a physical facility. BIM also strengthens interactive information improvement and development and has the ability and capability of supporting the full building lifespan from planning through operation and maintenance. However, BIM will not necessarily replace the wide range of information technologies in use by facilities and organizations but it can support, leverage, and enhance these technologies (Association 2013).

The common process for transferring BIM information developed in a building project to FM is illustrated in Fig. 1. The BIM model of a building project is created during the construction phase by applying a Computer Aided Design program (CAD) with product data from various product catalogues. The building owner has to specify the BIM requirements to ensure that the BIM model meets the specifications of the FM system and its applications. During the assignment, the building project exports the BIM model as IFC files as part of the BIM delivery specification to the FM organization. From this point forward, the FM organization is responsible for importing and implementing the IFC files and product documentation into its FM system. This corresponds to the outline of a traditional project delivery and the way of operation was applied before establishment of BIM. This way of organizing collaboration and handover has many difficulties that naturally prohibits the building owner, FM and the core business from participating in the development of the building project as a customer. The project is developed as a virtual building that is disconnected from the enterprise virtual environment and aspect structures such as economy, logistics, FM and IT organizational processes. Therefore, after handover, the customer is faced with conditions that causes significant problems related to insufficient and incorrect data for the operational phase. In addition, the as-built BIM lacks information related to the system tools and aspect structures applied during the building project. These are different from those in use by the enterprise. In addition, there are very few (if any) FM systems on the market that import BIM files for using in FM. As a matter of fact, most of current FM

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

systems only replace traditional 2D/3D DWG files with 3D IFC files. This situation requires other solutions, which Enterprise BIM is an option.

3.3 Enterprise BIM (EBIM)

EBIM is based on the understanding that the world is three-dimensional, holistic, process-oriented and object-oriented. This means that both the real and the digital built environments with all objects and interrelated objects and processes are connected in a complex interlinked network, realized as an Authoritative Data Source (ADS) in a model server. ADS is defined as the repository or system that contains the cohesive set of data and features that are considered as the primary source for this information and it provides reliable, proper, and secure information to support a business process. BIM's major transition to EBIM involves processes and activities as integrated parts of the building's digital life cycle information along with the BIM model. The task of creating a holistic three-dimensional digital representation reflecting the real built environment is daunting and it can not be entirely realistic. EBIM simplifies and clarifies the inherent complexity by creating an enterprise specific aspect structure that is related to other enterprise aspect structures and all end-users, as shown in Fig 2a. As illustrated, this implies that EBIM contains three-dimensional geometrical data and other building information, which in turn are interrelated to other aspects structures, such as economy and facility management.

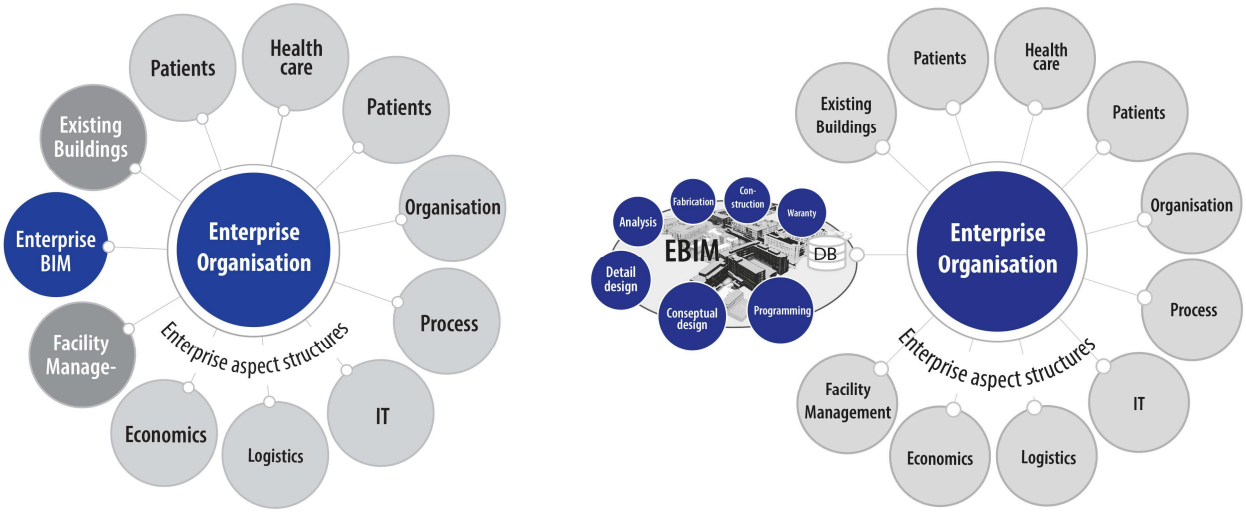

Fig. 2: Enterprise BIM as an authoritative data source aspect structure. a: EBIM is represented as a unique aspect structure in the organization. b:The illustration shows how a building project uses the same data infrastructure as the enterprise itself.

By treating EBIM as a business aspect structure for building information, and as a platform for open project integration with the organization, it is expected to lead to cost efficiency, customer satisfaction and prevention of data loss. EBIM is essential when rebuilding or when major renovation of the physical building requires round-trip of the digital building data. In most cases the builder, owner, managers or employees have little or no access to the BIM building project, despite the fact that the access potential of customers, users and operational organization to the virtual building in all phases of the project will have a major impact on quality, knowledge transfer and user interaction (Helse Midt-Norge 2017).

By considering EBIM as a digital interaction paradigm for all types of documents and properties through all building phases, where all users and stakeholders can initially share and obtain insight through different digital interfaces, the focus is shifted from the project-centric BIM to view EBIM from an enterprise perspective. One of the most important concepts of EBIM is emphasizing the integration, information sharing and openness across business structures that prevents vendor lock-in. Vendor lock-in occurs when a company becomes constrained and restricted due to its relies on a services provided by a vendor or builder. Fig. 2b shows an overall view of the concept and illustrates the relationship between the real building, EBIM and the building processes. In this concept, it means that all information is shared and EBIM reflects the real building complex as far as possible, regardless of phase (Helse Midt-Norge 2017). Collaborative design must support the sharing of data as knowledge rather than just the transfer of data as information in documents associated to business processes. Therefore, EBIM facilitates a new way of digital interaction and is an important step towards creating a future with smart buildings where the enterprise uses realtime

simulation during the construction projects and in daily operation. As a case study, St. Olavs Hospital has established an organization and a technology platform that supports this approach.

4 ENTERPRISE BIM AT ST. OLAVS HOSPITAL

St Olavs Hospital is an integrated university hospital, which means that Faculty of Medicine and Health is located all over the hospital. The hospital provides leading clinical care for Mid-Norway and is organized in a center model, which divides the hospital layout into seven distinct units around an open square (Van der zwart, Elkhuizen, and Evjen 2016). As already stated, St. Olavs Hospital encompasses of many buildings, both old and new, which should be maintained during their several decades of life cycle. Accordingly, a homogeneous standardized open digital platform for developing, improving and maintaining their facilities and amenities efficiently (Øgård Aksnes 2016).

The project life-cycle BIM, established in 2012, aimed for creating a real life-cycle BIM based on a facility management platform of existing buildings (Kristian Jørstad 2017). The EBIM philosophy established during the project, builds on a model server, where each old, new, and future building are integral units in the overall portfolio of buildings (Van der Zwart and Evjen, n.d.). The platform incorporates all old and new buildings, with existing documentation, lease management and work orders from the previous FM system, in a openBIM database platform (Kristian Jørstad 2017). This requires that the health care institution must have full ownership and control of all building-related information throughout the building life cycle, from early phase to demolition. The most important aspect of employing EBIM is the concept that EBIM virtually represents the real buildings, at a sufficiently detailed level and quality, and the relationships with the various stakeholders (Monsen 2017). It also defines which stakeholders can benefit from the information contained in the model. St. Olavs Hospital applied the following definition for EBIM: „EBIM is a virtual holistic representation of buildings adapted for optimized business management, knowledge sharing and collaboration“.

Fig. 3 outlines how stakeholders are related to each other and the physical buildings which are linked again to the virtual environment through the sensors. An important factor in the ownership of the virtual built environment is that the owner of the building must have the knowledge and tools to assist and control properly the entire digital process (EBIM IT).

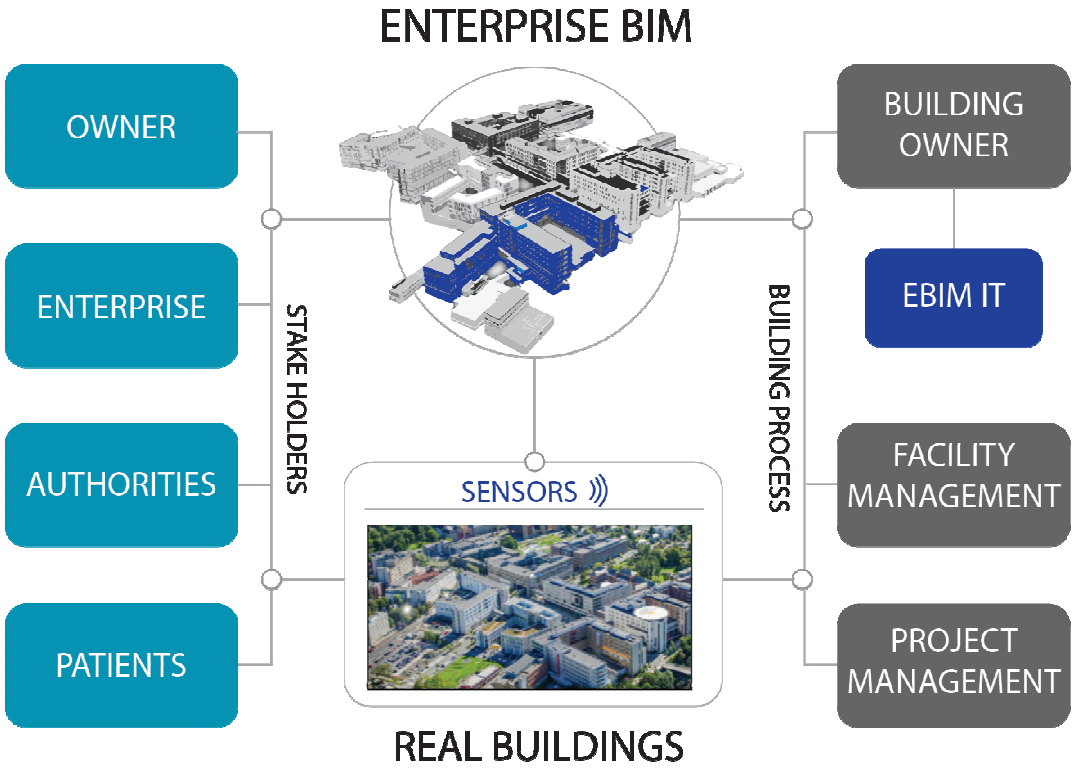

Fig 3: EBIM stakeholders. The relationship between the real building, EBIM and the actors are indicated.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

EBIM is a virtual environment with a common data sharing repository where all stakeholders share and collaborate on the same data in real time.

St. Olav Hospital currently uses EBIM to realize the goals of better and cheaper construction projects and real estate operations management with the aim of more efficient use of resources. Buildings where EBIM is used throughout the process have a better quality of operation and maintenance and they offer a higher level of service for employees and visitors than buildings that have been designed and built traditionally. In this respect, other advantages are proper functionality, easy benchmarking against other projects, faster execution, fewer construction errors, cost reduction, reduced energy consumption and carbon footprint, harmonizing and streamlining of operations (Helse Midt-Norge 2017).

Technically, the model server with all building-related data and embedded systems, shown in Fig. 4, is referred to as the EBIM aspect structure. When the BIM server imports new IFC files and documents from a construction project, the IFC files are validated by the BIM server according to given rules, in such a way that the building owner receives the virtual building model at specified level of detail and quality. In addition, the documentation is also checked against the existing infrastructure of the model server to be compatible with the EBIM aspect structure and internal classification.

EBIM replaces traditional facility management systems through featuring functionality supporting operation, management and maintenance. The end user interface is a web-based real estate portal tailored for the end user disciplines. Moreover, the connection between the three-dimensional models and the sensors and transmitters in the buildings enables and facilitates tracking and retrieval of mobile equipment and people, among other things (Lien and Evjen 2017).

Communication with other aspect structures and systems are primarily done through application protocol interfaces (API). A simple example of such integration, are printers that are used to label patients medications. In this case, the information is held digitally by the IT database, but the printers locations are displayed on the real estate portal. This is a small example of minor improvements in the functional efficiency of daily hospital work.

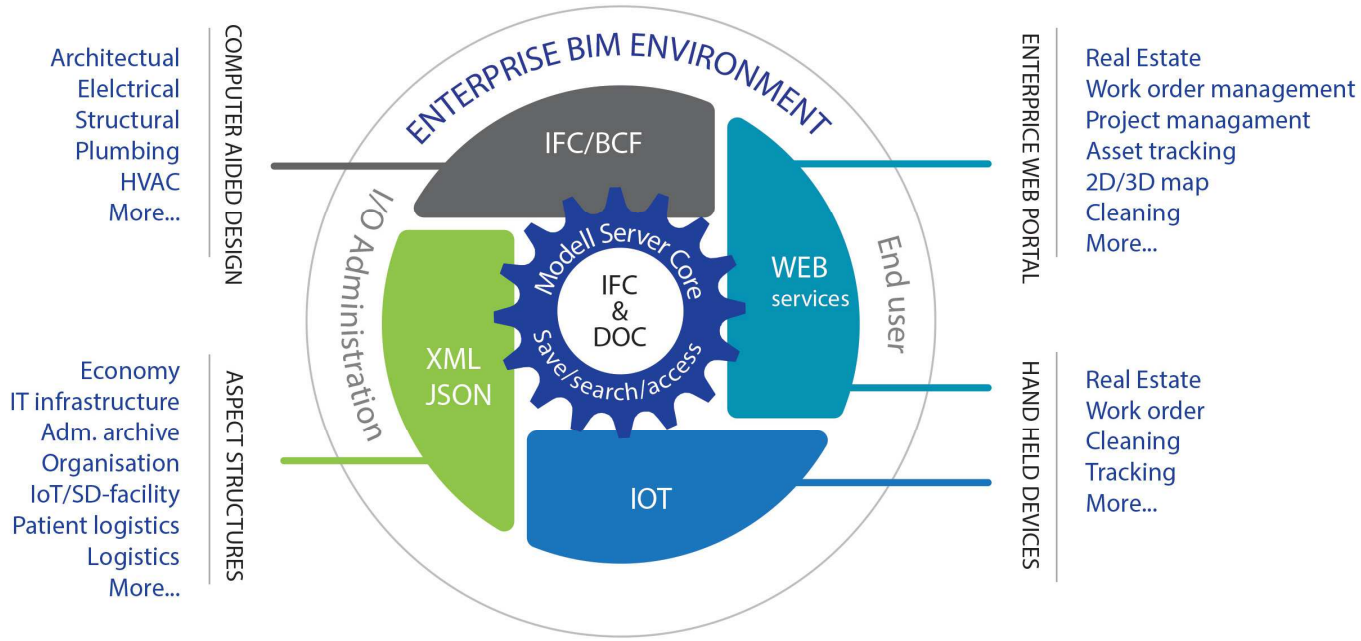

Fig 4: Schematic image of a model server that supports EBIM aspect structure, Web-based real estate portal, wireless and handheld devices.

A model server in itself is a complex digital environment, but the model server client gives the professional staff almost free access to configure and develop new functionality and applications, as shown in Fig. 5. In a hospital with many computer systems, abundance of data and the continuous need for improving and supporting daily routines, a flexible database solution is essential. One of the most complex and challenging tasks is maintaining an existing digital building while different parts of the building are being rebuilt.

Fig 5: The model server consists of a collection of integrated BIM models with property sets, documents, methods for evaluating and checking the models and other turn key functions.

The following two figures show examples of functionality presented to the hospital through the real estate portal. Fig 6 presents a report page where all employees at the hospital can report and follow the status of various working orders from requested repair of a broken door to application for additional space for specific functions. The user only navigates through the map and selects rooms or objects in a 2D/3D map to identify the rooms or objects for the selected task. By entering the data of interest, a work order will be established and submitted to support the designated facility management staff who will execute the work order with all related data. The work order itself is connected directly to the specific rooms or objects in the model server.

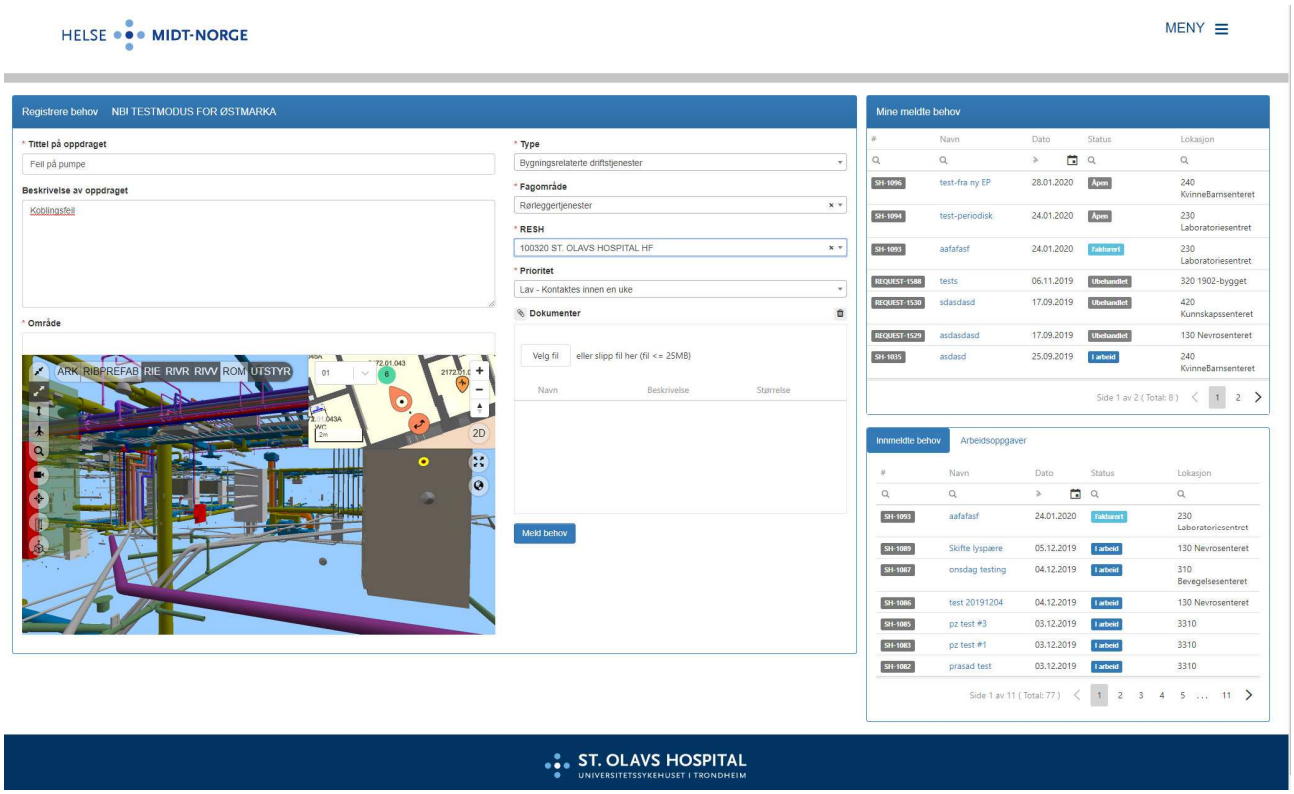

Fig. 6: A snapshot from the real estate portal showing the interface presented for the staff at the hospital for reporting and following up a work order.

Fig 7 displays a 2D view map which demonstrates how the real estate portal presents, in color, different types of room functions in the buildings based on the hospital classification system. The same web page can be used to display rental agreements related to a room.

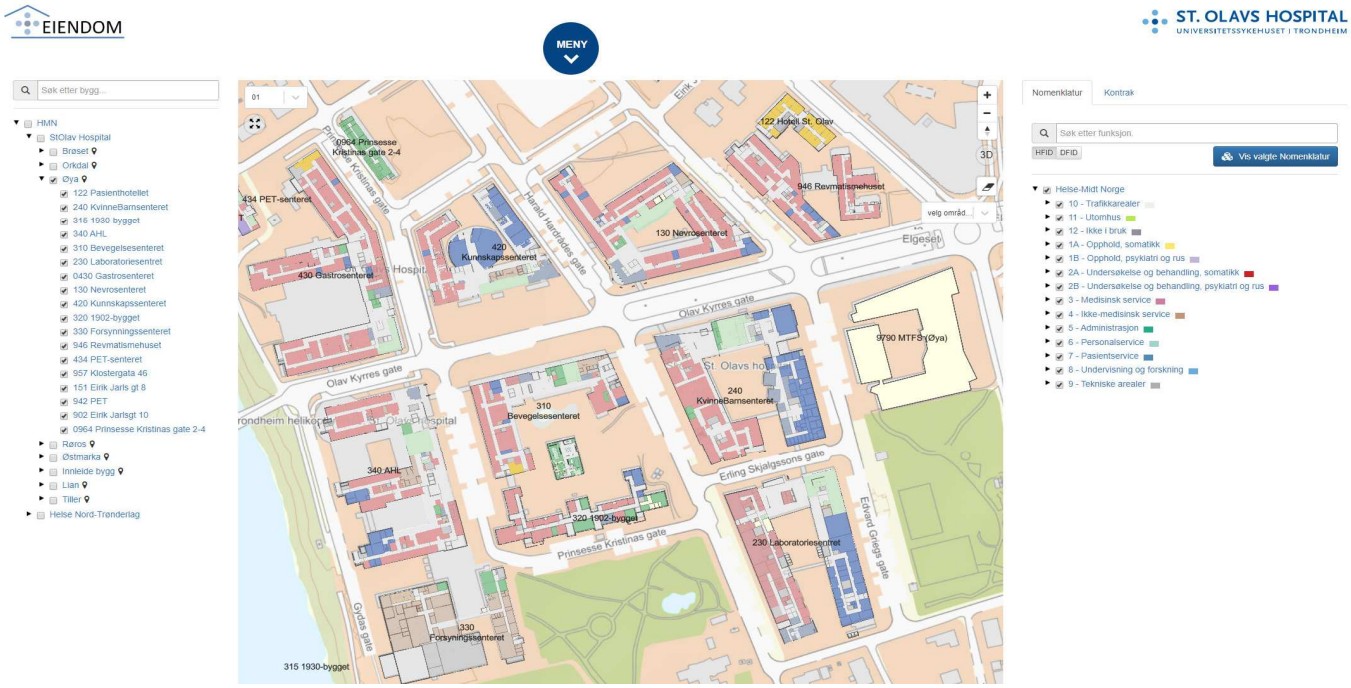

Fig. 7: Visualization of all partial functions in a set of buildings. The different functions are color-coded. Their distribution across the wing and floor is clearly visible throughout the facilities.

5 DISCUSSION AND PERSPECTIVES

As previously noted, EBIM is an extensive information database at St. Olavs Hospital that supports important aspects for the user, including FM, Virtual Design Construction (VDC), tracking and property management. EBIM facilitates essential and major tasks of the core business and is an important source for strategic management analysis in the near future (Øgård Aksnes 2016). In addition, central operations monitoring and sensor technology support EBIM to be more knowledge based. These tools have a significant role in decision making, object tracking, optimizing inventory space and operational costs (Van der Zwart and Evjen, n.d.). In this regard, a common basic information functionality for handheld devices, VR and Web, has been established in St. Olavs Hospital but they are still in the beginning of robotization and automation based on EBIM.

However, the hospital's EBIM platform does not support a user-friendly process modeling tool that supports project planning and other types of workflow.Even though, work order workflow is fully implemented and gantt charts are realized as part of the periodic maintenance, the EBIM platform lacks important and powerful functionality to claim to be a knowledge-based system that supports project planning in full detail with reflective views, roles and tasks (Lillehagen and Krogstie 2008).The implementation of EBIM at St. Olavs Hospital is still in its infancy. The advantage of using a model server based on openBIM standard to obtain all the building data and the capability to develop new functionality is a major competitive advantage, especially for an enterprise of a certain size. New applications and connection to other aspect structure systems are under development. The complexity and the pure size of the data collected makes it necessary to start using technologies like Augmented Reality (AR) to discriminate data in order to provide accurate data delivery to the end user and to apply Artificial Intelligence (AI) to process data.

In fact, the approach and strategy of EBIM is built on its use in organizational processes in the course of the whole building's lifecycle where all buildings will be described and communicated in openBIM standards in relation to other business aspect structures (Lien and Evjen 2017). openBIM is built on workflows and open standards which are used to gain collaborative design, performance and operation of buildings(Øgård Aksnes 2016). Thus, openBIM supports a transparent and open workflow and permits stakeholders and users to take part in and join the project regardless of their software tools. It permits government and industry to obtain

projects with transparent business interaction, ensured data quality and Service evaluation by establishing a common language for extensively referenced processes. (Graphisoft - A part of the Nemetschek Group, n.d.).

The beneficiaries include the owners, managers, users of buildings and all actors that are involved in the project (Kristian Jørstad 2017). Therefore, it expects to achieve EBIM for a better decision based on strategic management, user participation and implementation at all levels. It strives also to get transparent communication and knowledge sharing across the organizational structure (Monsen 2017). Hence, EBIM provides unique opportunities for users as a business to use the available information to manage, operate and develop the buildings throughout their lifetime. The projects must support the business by providing correct information during the planning and construction. Therefore, the projects will be organized so that all relevant information flows to and from the model server. In practice, it is said that the project organization with advisors and contractors will save and develop data (including documents) in the model server.

Introducing new technology that challenges data ownership, existing systems, collaboration, efficiency change, new way of working and motivating to achieve a greater goal, is what that needs to be greatly motivated by the enterprises and organization related to these processes. In this regard, St. Olavs Hospital has a strong focus on how EBIM can support its core business operationally and strategically. At the national level, EBIM supports government and other enterprises in real-time monitoring of demand through web services and it avoids unnecessary reporting and data replication.

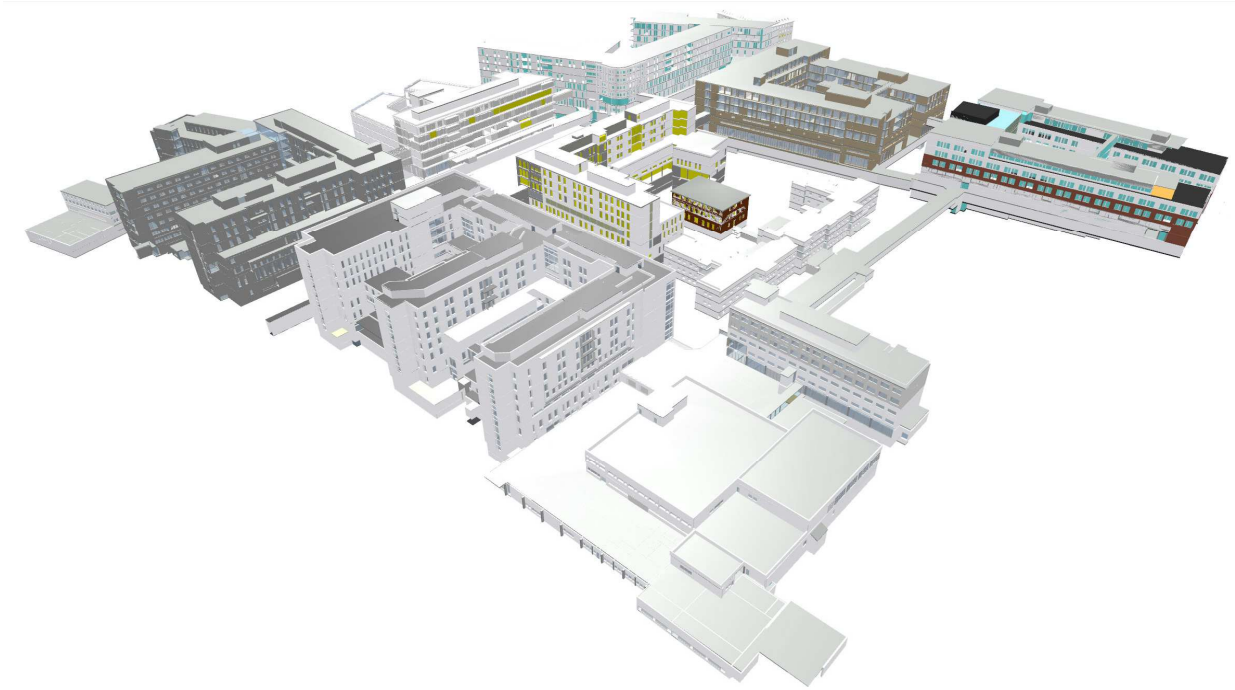

Fig 8: St Olav's hospital site with 220.000 m² – Image taken from EBIM system.

6 CONCLUSION

EBIM obeys and follows the strategy in which all buildings and infrastructure in an enterprise are described and communicated in a uniform openBIM standard during the building lifecycle. EBIM seeks to establish clear and transparent communication and knowledge sharing throughout all organizational structures. Using the EBIM method, the traditional boundaries between project and owner are eliminated by the way in which, the owner implements the project into the digital platform of the enterprise and not as a single standalone building project. This ensures rational and logical digital management of buildings which can reflect engineering structures, performance of buildings and infrastructure from registered demand to demolition. Accordingly, by using EBIM approach, St. Olavs Hospital establishes a virtual building information structure that is capable to support day-to-day maintenance, tracking objects and providing different views to the end user. The work done at St. Olavs Hospital is based on anticipated benefits and so far there is clear evidence of improved data quality and new approaches are emerging. The next step in the advancement of EBIM is to establish additional abilities and capabilities that support the projects in their development towards complete construction in relation to the enterprise aspect structures in real time. EBIM has the

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

potential to become the next step in the process of building business-centric smart buildings that reflects and support the real-world processes, games, social interaction and knowledge sharing across all enterprise disciplines.

Environmental Analysis of the Residential Sector in Cairo

Mohamed Edeisy

(Dr. Mohamed Edeisy, Department of Planning, Design, Technology of Architecture, Sapienza University of Rome, Via Flaminia, 70, 00196, Rome, Italy, mohamed.eledeisy@uniroma1.it)

1 ABSTRACT

Rapid demographic increase and transition in governmental policies influenced the patterns of Egyptian residential sector, services and urban fabric. The housing stock in Egypt is dominated by private owners, informally and high consumption rates. Studies attempted to classify historic periods that created the current urban pattern and led to an uncontrollable expansion of a metropolis. Political and demographic changes had a major role in the city's urban, architectural and legislative transformation, especially after the change of government policies in 1953. The article aims to evaluate the development milestones of the housing stock in Cairo before and after 1953, from an environmental sustainability perspective on a building and urban scale. Based on official statistics, maps from various periods and literature, the urban development of the city is assessed. The impact of governmental policies and strategic plans is analyzed, taking into consideration demographic growth, urban sprawl and environmental aspects. The residential stock is classified in two time phases (before and after 1953) and three dominant typological -urban and architectural- criteria. Based on this classificatory model, representative characteristics of different periods are assessed in terms of morphology, construction materials and environmental design. The results provide a critical analysis of Cairo's environmental and sustainability policies in the second half of the previous century. It provides an evaluation base for comparison with the city's current built environment and offers guidance for future scenarios.

Keywords: Building typology, Informality, Urban built environment, Residential consumption, Housing stock

2 INTRODUCTION

Greater Cairo Region (GCR) is composed of three governorates: Cairo on the east of the River Nile, Giza on the west and Qalyubia in the north. Each governorate has its own administration, governor, and boundaries. According to the national Central Agency for Public Mobilization and Statistics, GCR's surface are is 290km2, its population in 2016 was 22.9 million inhabitants divided as follows: 9.7 million in Cairo, 8.9 million in Giza and 4.3 million in Qalyubia. However, GCR is physically inseparable and it is hard to define a precise barrier that separates the governorates' environmental, physical and social boundaries.

Historically, urban growth started in the core city, Cairo; it is one of the most ancient parts of Egypt. The city's history is long and the region's background goes back to the times of ancient Egypt (31st century BCE) when its capital - Memphis - was not far away from the current location of Cairo, and GCR still hosts the great pyramids of Giza.

Like in many old civilisations, ancient Egyptian buildings were used as a source for construction materials and their stones were adopted to build the houses of Islamic Cairo (Singerman 2011).The first attempt to declare a city with a defined administration and boundaries, after Memphis, goes back to the 10th century. Cairo was founded as a capital for the Mediterranean empire of the Fatimids in 969AD with the arrival of Jawhar Al-Siqilli. Then, the Caliph Al Moizz a few years later made it his basis of rule. Thus, the first city was created according to the urban patterns and features of Islamic architecture (Abu-Lughod 1971).

3 CAIRO BEFORE 1953 | BACKGROUND

3.1 Islamic Cairo

Islamic architecture in Cairo passed through different periods: Fatimid, Ayyubid, Mamluks and Ottomans. In the beginning, the Fatimid architecture combined elements of eastern and western architecture and was strongly influenced by Mediterranean cultures. The city fabric was characterised by a human compact form with low-rise residences and narrow streets, which has the advantage of providing solar shading but minimises wind flows for urban health and social purposes (Sharon L. Harlanan December 2006). Compact cities have environmental, social and fiscal advantages; and in similar climates, the compactness of the city fabric proved to result in lower energy demand for artificial climatisation and have a positive influence on

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

energy savings on a building and city scale (Frey 2003). In Islamic Cairo, the streets were oriented North-South to take advantage of prevailing wind that came from the north; it was characterised by winding streets of different sizes to decrease the potential effect of wind storm carrying dust/sand and provide shaded spaces. Early residential buildings were made with clay brick, which was and still is a commonly used building material in Egypt, then stone gradually took over and it became a major construction material. Morphologically, a typical dwelling apartment in the Fatimid period had a rectilinear plan that revolved around a central courtyard that provided natural lighting and ventilation (Safran 2000). Private houses included a ground floor and one or two upper floors. Exterior windows included sophisticated shading systems – Mashrabeya – that decrease light glare and block visual access from the exterior, providing privacy for households.

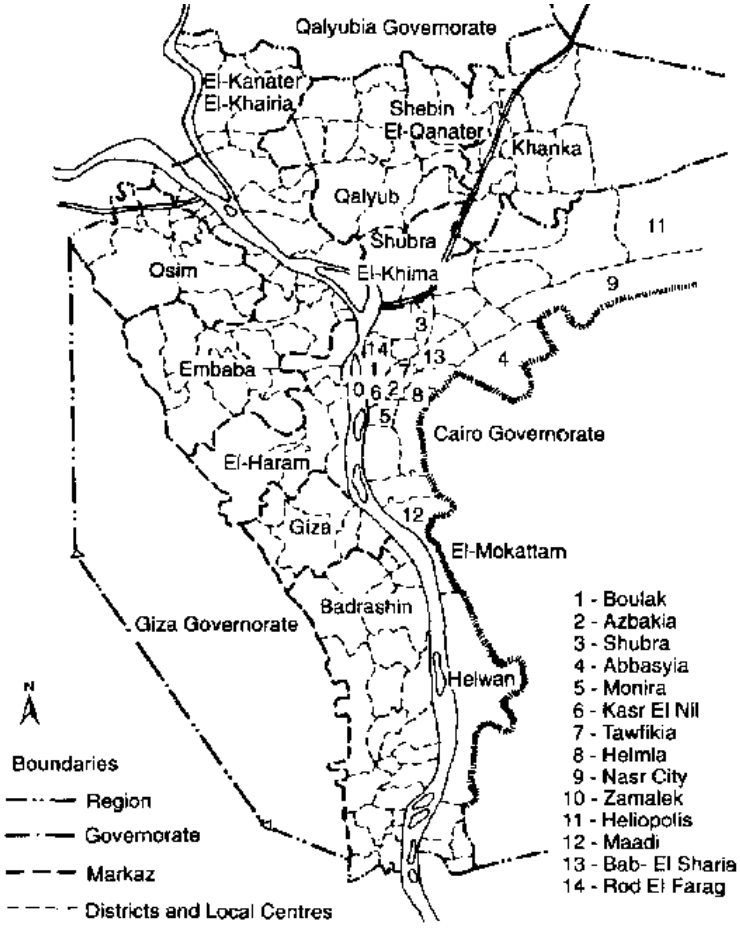

Fig. 1: Greater Cairo Region (Yousry, 1997)

The inexistence of advanced technological tools forced architects to develop solutions that guaranteed thermal comfort without affecting the surroundings negatively. Islamic architecture did not oversee the important concepts of physics and fluid dynamics like air buoyancy and thermal convection. It was based on the use of solar energy, heat conduction and convection, ventilation, evaporation and passive cooling methods to provide high comfort levels for inner spaces (Nermine Abdel Gelil Mohamed 2014) (Yahya Lavafpour 2011); In addition, the correct application of local building materials worked as an efficient way to increase comfort levels and drastically reduce the environmental impact of construction (J.C Morel 2001).

Light-coloured materials with high reflectivity were chosen to decrease the temperature and decrease the dry weather effect. Nermine Abdel Gelil and Waleed Hussein listed the materials commonly used in Cairene Islamic architecture: Stone was a widely used construction material during the Ayyubid and Mamluk eras (12th-16th century), and marble was used by the Mamluks (13th-16th century). Traditionally, limestone was used for the construction of ground floor load bearing walls. External walls were built of at least 50cm thick limestone, which contributed to the thermal insulation of indoor spaces and provided high thermal mass effect. During summer, the heat was stored in the walls during the day and released into indoor spaces at night when temperatures were lower, and spaces could be cooled by natural ventilation (cross ventilation and stack effect). In addition, due to the light colour – and the high reflectivity- of the limestone, it deflected

solar radiation during hot days. Wood was used for building flat horizontal roofs, mashrabeyas, takhtabushes, windows, malqafs, shokhshekhas and scaffolding during the construction of walls; it was also used for shading purposes (Nermine Abdel Gelil Mohamed 2014). Red Brick was used for compact forms, like vaults and domes, which have low surface area to volume ratio and hence provide minimum heat gain and minimum heat loss through the building envelope and imply higher thermal comfort conditions.

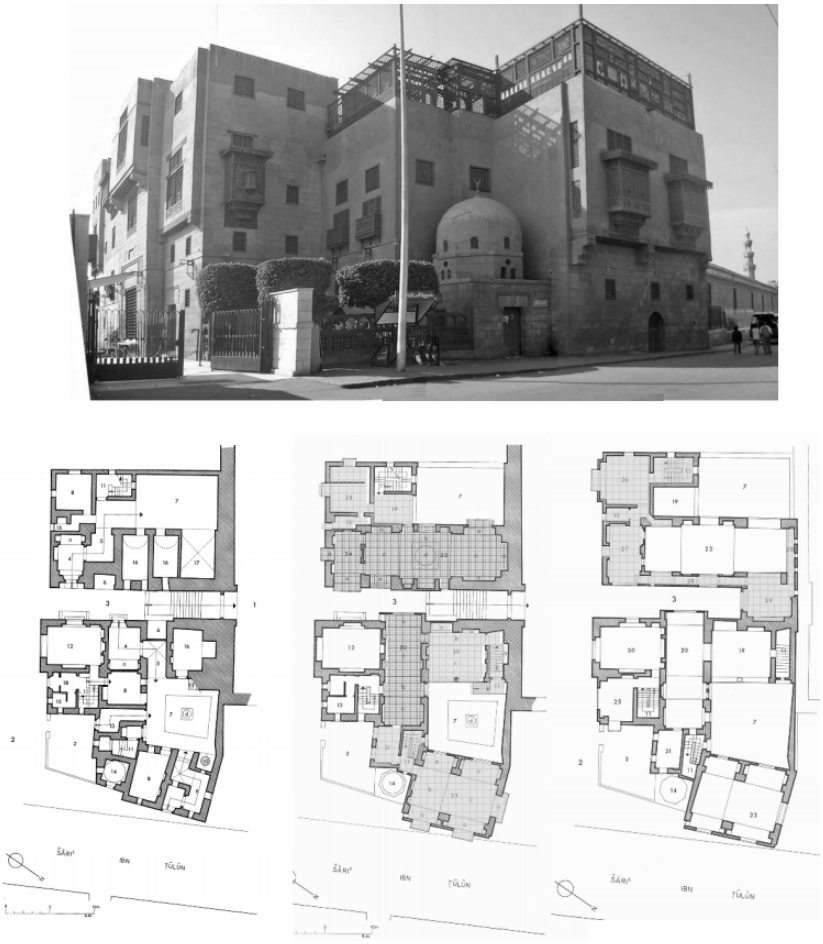

Fig. 2: Manzil Amna bint Salim (back) and manzil al-Kiridliya (front), located adjacent to Ibn Tulun Mosque on Ibn Tulun Street. Above, photo from the street by Nermine Abdel Gelil Mohamed; below, ground, first and second floors (Nermine Abdel Gelil Mohamed 2014)

3.2 European Cairo

The end of the Islamic architecture era in Cairo can be considered to be at the beginning of the 19th century (1805), after the expulsion of the last Ottoman governor by Mohamed Ali, who announced the virtual independence of Egypt from the Ottoman court. This was the beginning of „Modern Egypt“ with comprehensive efforts and mega infrastructure projects to modernise the city and the country in general. In 1863, the Cairene population had barely passed 300,000 (Raymond 2000). Khedive Ismail - who received European education in Paris - showed more effort for social and cultural modernisation of Egypt. A completely modern western city emerged from a small neighbourhood ‘Azbakia’ and the physical and urban patterns of Cairo changed. His famous saying was “My country is no longer in Africa; we are now part of Europe. It is therefore, natural for us to abandon our former ways and to adopt a new system adapted to our social conditions". (Haag 2003)

The first city plan presented by a French architect was inspired by Haussmann’s plans for Paris. It ignored the existing compact patterns of Islamic Cairo and produced new radial grids of large wide streets. English, Italian and Greek architects presented proposals and participated in the construction of a new part of the European city. Cairo was nominated as “Paris along the Nile” and this area – constructed by the Khedive- is now known “Downtown- Wust El Balad”. Utilities and services like water, electricity and trams were developing on a huge scale (Myntti 2000). The new elegant city centre offices, shops, restaurants and cafés gave a new identity to the city. Traditional Islamic architecture was abandoned, and in some cases the use of

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

its elements like mashrabiyya was prohibited and replaced by glass window panes and wooden shutters. Styles ranged from Baroque, Neo-classical and Rococo to Bauhaus, Italian Renaissance and Arabesque until the 1950s (Elshahed 2007).

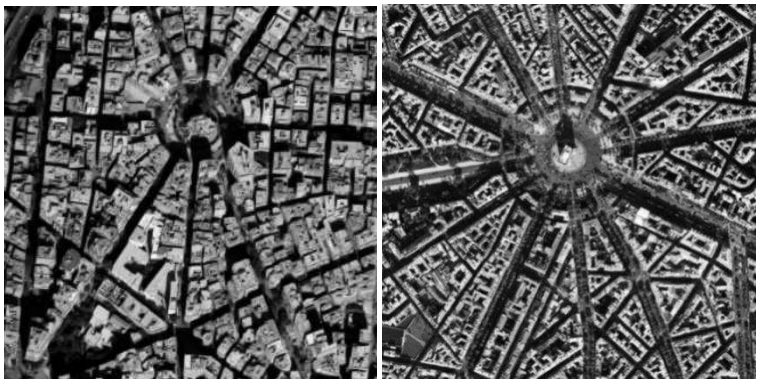

Fig. 3: European Cairo urban fabric (left) vs Paris urban fabric (right)

By the beginning of the 20th century, new lavish neighbourhoods (e.g. Garden city and Zamalek) were already developed. Urban expansion later took place along the north (towards Shubra), then the first satellite cities – like Heliopolis- were designed to host up to 100,000 inhabitants. In the 1940's roads, bridges and water system projects started to take place to provide a solid base for further urban expansions. Cairo became an attractive pole for all Egyptians that came from rural and surrounding areas. The first industrial slums were developing in nearby Boulak, where spot densities reached world records (4000 person/hectare). From 1937 to 1947 the population of Cairo doubled from 1,300,000 to 2,800,000 inhabitants and moving out of the slowly degrading old city centre became a trend by the higher income groups which could afford to buy property in more modern neighbourhoods (Cresti 1987).

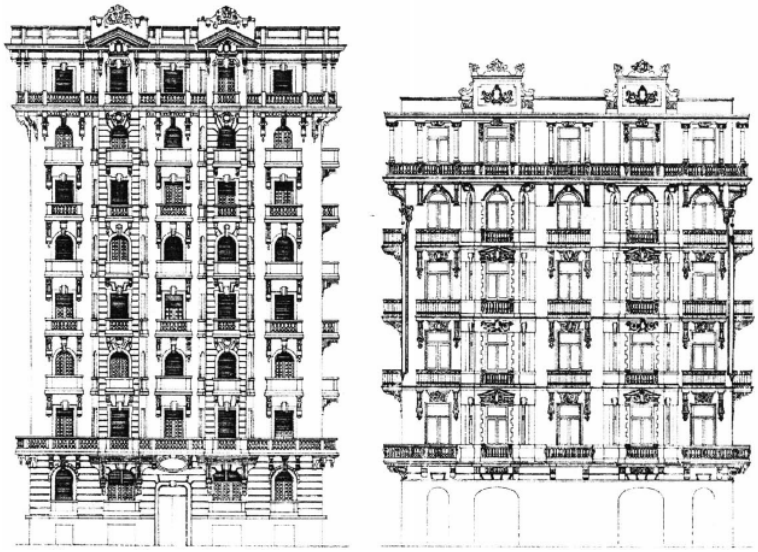

Fig. 4: Change in architectural elements - Downtown Facade from European Cairo 1927 (Elshahed 2007)

Fig. 5: Buildings from European Cairo (photographs by Alain Bonnamy) (Galila El Kadi 2006)

Until today, published work that analyses the architecture of European Cairo from an environmental and passive design perspective is not evident. It is obvious that not until building with reinforced concrete started to take place during the first decades of the 20th century, thick load-bearing stone and masonry walls with high thermal mass was the main building and structural technology used for residential buildings. In addition to the function of articulating the space, load bearing walls ensure the stability of the building to enable it to withstand vertical loads and horizontal thrusts.

This structural function is associated with thermal and acoustic insulation. Therefore, construction materials of poor thermal conductivity were chosen for the construction of thick heavy walls; they provided thermal flywheel effect resulting in a cool environment in summer and a warm environment in winter. This guaranteed higher comfort levels in comparison to slim envelopes of reinforced concrete beam-column structures that started to spread later for residential blocks. Typically, apartment block heights started to be 4, 5, 6 floors. Average floor-to-ceiling height was 4m; this is higher than average floor-to-ceiling height of residential buildings built today – and in the last 40 years- which is typically 3m. This allowed better air movement and higher comfort levels. Through the phenomenon of convection, fluids have a natural movement in which hot air tends to rise allowing the lower part of the room to have lower temperatures that could reach up to 1°C less in warm days. Therefore, in hot climates, a higher floor-to-ceiling distance means a greater distance of the hot air layers from the users, guaranteeing higher comfort levels. (R. P. Guimarães 2013)

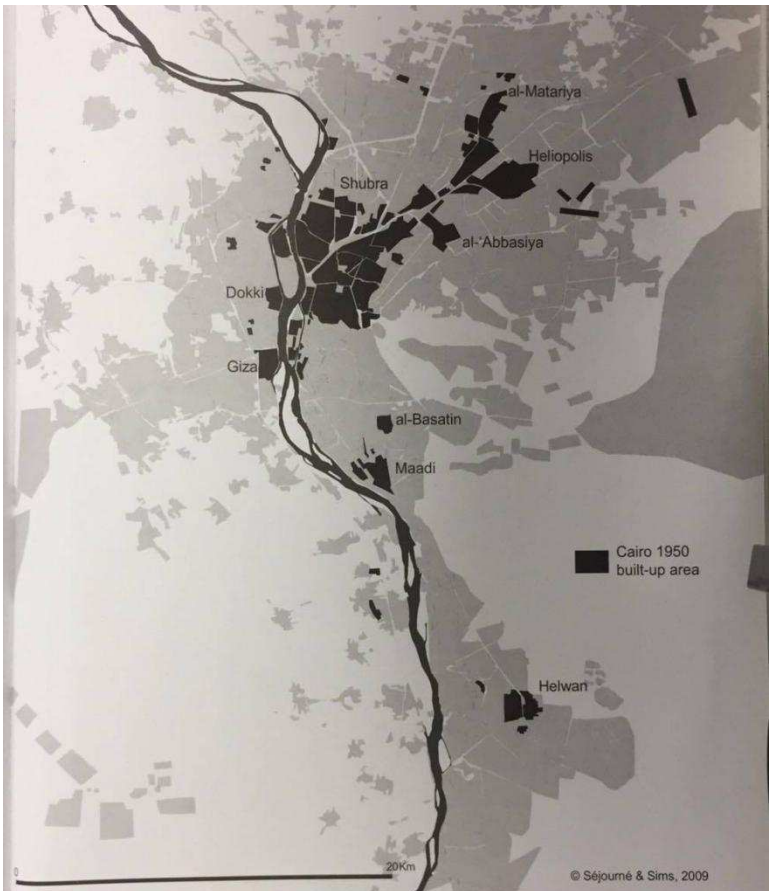

Fig. 6: Cairo built-up area before and after 1950 (Sims, 2012)

Thick wood was used for window frames and shutters on the outside, which worked as a good insulator of solar radiation as wood has low thermal conductivity. Metal was used sparingly for façade ornaments and balcony fences, but it was not a dominant material. Facades included elaborate decorative ornaments, balconies and overhangs which had a shading function that varied in relation to the orientation of the façade. However, the void-to-solid ratio in residential facades of European Cairo was higher than that of the hosues of Islamic Cairo; allowing major solar access through openings and reducing comfort levels during the hot season. Light hues of colours were used to reflect solar radiation, decrease heat absorption and conduction, which guaranteed lower radiant and operative temperature of internal spaces. Many residential blocks included inner courtyards, which permitted higher air cross ventilation between outer façade openings and

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

the ones overlooking the interior courtyard. In addition, weather conditions in Cairo were moderate compared to extreme temperatures reached in the last couple of decades due to global warming, urban heat island effect, and climate change.

4 MODERN CAIRO

4.1 New phase with new policies

In 1949 the Municipality of Cairo was created as the official local administration responsible for managing the city resources and development. The Ministry of Housing, Utilities and Urban Development (MHUUD) issued its first housing and building statutes and laws regarding conciliation, and law amendments. In 1953, the King was deposed by a revolutionary command council and a republic was declared. This was an announcement of a new phase in Egyptian history and led to Cairo's total change. The building sector and the urbanism were directly influenced by those political changes. The new government followed new policies:

- Subsidised public housing
- Applying social housing programmes
- Condominium investments were encouraged to provide the possibility of growth in new areas of Cairo (e.g. Mohandessin neighbourhood)
- New laws were issued regarding improving fees on the real-estate that was upgraded due to the improvement of public utilities and others to reduce rents on housing units
- European Cairo neighboorhoods were Egyptianised (mixed land use and commercial zones were created; elegant villas were replaced by high apartment blocks).

Until 1940, Cairo represented 6-8% of the national population. Between 1950 to 1960, Cairo's percentage of the national population inflated from 11.2% to 18.4%. Rural settlements - of migrants to Cairo - were expanding around the actual city with no planning, architecture or construction reference at all (Yousry 1997); with reinforced concrete as a fast and convenient solution, the city started to grow at a fast pace.

Year	**Cairo**		**Egypt**		**Cairo as % of national population**
	Population ('000)	% growth rate	Population ('000)	% growth rate	
1800	200	2.0	3,000	1.2	6.7
1900	600	2.3	10,000	1.3	6.0
1920	875	3.1	13,000	1.4	6.7
1930	1,150	2.2	15,000	2.3	7.7
1940	1,525	4.1	19,000	1.0	8.0
1950	2,350	4.1	21,000	2.2	11.2
1960	4,784	2.2	26,000	2.4	18.4
1976	6,776	3.5	38,200	2.8	17.7
1986	9,514		50.500		18.8

Table 1 Population growth of Cairo and Egypt, 1800-1986 (Yousry 1997)

4.2 Master plans (1950s -1960s)

In 1956 a master plan that included east and west desert flank expansions was prepared and in the 1960s new industrial zones were identified - Helwan, Shubra, Imbaba and Giza- enhancing the appearance of Cairo as a future mega metropolis. The government financed the design of new settlements like Nasr city (designed to cover 6,300 acres of vacant desert and later extended incorporating additional 14,000 acres) allowing the growth of areas like Abbasiya and Heliopolis. MHUUD issued a new law in 1964 (Law No.6) defining design criteria and rules for structural and building works. It issued ministerial decrees to regulate building execution because of informality; this was followed by other laws and decrees that regulate the restoration, maintenance and elevation of existing buildings (Ministry of Housing 2015). Cairo's population was 6,113,000 inhabitants in 1966 and new master plans had to be created again to include the extension of the industrial area of Helwan and new towns like the 6th of October, Al Badr, El Obour and a West Bank project

that was not realised. Later additions included distant extensions towards the north and east: unsuccessful town examples namely Sadat City and 10th of Ramadan new town. These plans had the objective of sccommodating future population growth until 1990 (Sutton 2001).

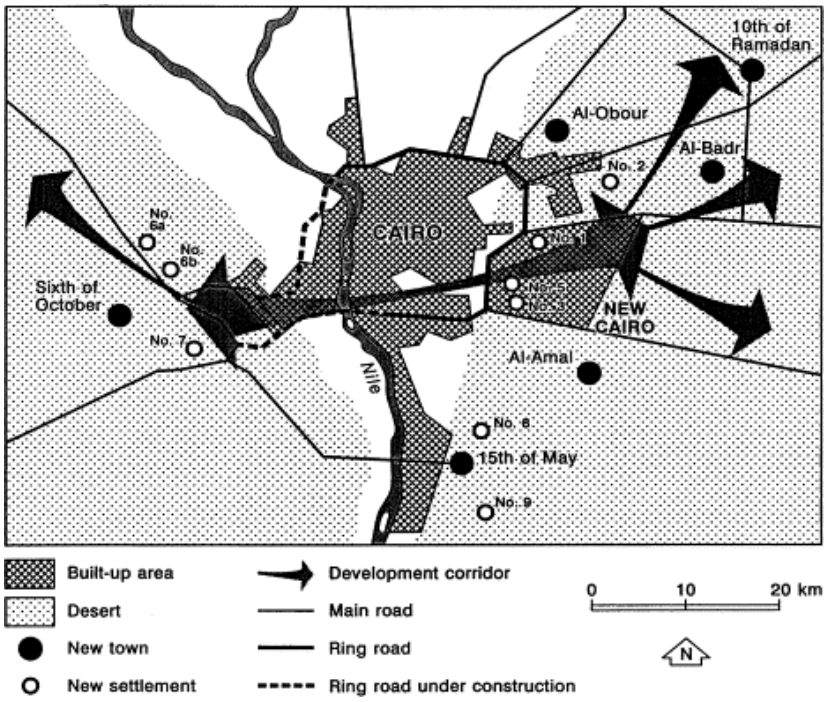

Fig. 7: 1970 and 1983 master plans for Cairo: new towns, new settlements, ring road, and east–west axes of development (Sutton 2001)

4.3 New laws and informal housing (1970s)

In the 1970s the MHUUD issued a new series of laws aiming to regulate the growing building sector and control rising illegality:

1. Law No. 62 of 1974: Provisions for reconstruction, 1974
2. Law No. 66 for in 1974: Establishment of Engineers' Syndicate, 1974
3. Law No. 49 of 1977: Sale and lease regulations between owners and leasers.
4. Law No. 59 of 1979: Indications concerning new urban communities and settlements.

However, the war of 1967 had a negative influence on the national economy and the city's urban development. The government was unable to fulfil the new urban aspiration, shelved the planned projects and turned a blind eye on the illegal growth of the informal sector caused by fast demographic growth. In Greater Cairo, more than 80% of new units built during the 1970s were considered illegal (Sharaf 1999). The official public constructions that started in the 1970s aimed to reach different economic groups and they accelerated the city's expansion towards the east through new settlements and towns like Nasr City and the 10th of Ramadan. Spontaneous urbanisation was promoted west of the Nile towards existing neighbourhoods like Giza, Dokki and Mohandessin. A process of "demolition-reconstruction-densification" was the reason for the transformation of elegant neighbourhoods in the city centre „e.g: Mohandessin". Between 1980 and 1992 a third of the villas and smaller blocks have been demolished and were replaced by tower blocks (Galila El Kadi 2006). Today in neighbourhoods like „Mohandessin", it is hard to find a trace of the old villas or planned low-rise residential blocks built according to regulations. Instead, they have been replaced by tall blocks built by private –mostly the illegal – sector and contractors with a main target: increasing financial profit margins (Sutton 2001). The spread of reinforced concrete as a fast and efficient construction material had a direct influence on the pace of urban growth; new settlements and towns were planned to reach different social groups. High residential blocks of reinforced concrete - column and beam structure and bricks for walls and interior partitions - were built, increasing the average height of residential and commercial blocks. 10-12 story buildings with elevators were starting to become more common and were often built for social housing in the new satellite towns and settlements.

4.4 New city and local divisions (1980s)

In 1982 Greater Cairo was defined by the General organisation of physical planning, located within the jurisdiction of the 3 Governorates: Cairo on the east, Giza on the west and Qalyubia on the north. The total built-up area of GCR was 32,600 hectares with 21,690 hectares for residential use representing 67% of all land use. So, it was necessary to prepare new plans again and one year later a new master plan was made to house 2-3 million people (Luloff 2001). Egyptian authorities confirmed infrastructure development plans and the city was divided into 16 homogeneous sectors for the first time. The division aimed to decrease the suffocating high densities, transfer the population to outer areas of the centre and decrease the pressure on central areas. The census of 1986 had a major impact; the city's ring road plan was changed, and this allowed a better connection with new settlements like 6 October and New Cairo and gave the way for later development outside the centre on both the east and west flanks of the desert.

4.5 Master plans and their impact (1990s)

In the early 1990s, the urban form, size, and fabric of GCR had already developed in a random and spontaneous manner, instead of following a planned strategy. Sutton and Fahmi listed a series of factors behind, what they considered the failure of the previously mentioned master plans and strategies (Wael Fahmy 2008). They observed the following main factors:

- The dominance of the unplanned "spontaneous urbanisation" over three decades (probably referring to the 1960s, 1970s and 1980s).
- Failure of new towns/settlements to attract residents and alleviate overcrowded conditions in central Cairo.
- Financial constraints on government expenditure and growth of the private sector involvement.
- The strengthening of Cairo's polycentricity
- Negative impact of the 1992 Earthquake
- Vacant city dwellings in a situation of housing crisis
- The role of the new ring road and its influence on land use and population.

The impact of the failure of the master plans (made in 1956, 1970, 1982 and 1983) was evident in the 1990s. Since the 1970s till the end of the 1990s, because of a spontaneous rather than a planned land use transformation, central Cairo witnessed a contradictory movement, namely the consolidation of its central place tertiary functions and the fragmentation of these functions over multi centres. Due to the financial constraints on the government expenditure, the government was incapable of providing suitable or economically convenient housing solutions that responded to the fast demographic growth and migration to the capital. Most of the planned new towns failed completely to attract residents and provide them with suitable housing solutions (e.g. 10th Ramadan, Al badr, El Obour, Mobarak housing). It is estimated that in 2006, 25-30% of units were presumably vacant, especially in the new towns ((USAID) 2006). This opened a wide door to the private investment and illegal sector to gain momentum with a market economy approach. Studies propose that up to 84% of constructions over the 1970s and 1980s have been illegal. By illegal, for the most part, studies do not refer to slums or shanty town dwellings. Instead, it is referred to modern formal housing built illegally or without any formal planning permission, possibly with violations of floor plans, land use and construction materials (Sutton 2001).

This led to two main results:

- The spread of informal housing with no design or planning, built by local contractors under no strict administrate control or building regulations of any type.
- The spread of a standard poor construction procedure served to meet people's housing needs. This procedure ignored sustainable or environmental design and produced repetitive minimalistic rectilinear (linear and tower) apartment blocks with no consideration of passive design strategies like quality material selection, shading, natural lighting and ventilation. (Wael Fahmy 2008)

Fig. 8: Residential buildings from Modern Cairo "Mohandessin" and a construction site with traditional technologies (Author)

Due to material availability, common knowledge, easy application, time efficiency, and economic convenience: reinforced concrete column and beam structural system and bricks (slit, clay, cement) for walls and interior partitions is the dominant method used for residential construction since the 1950s and almost exclusively used with the flat slab structural system for residential sector and apartment blocks. Double and triple glazing technologies for windows are not common and single glazed windows with wooden shutters are widely used for openings.

Informal settlements (either semi-legal or illegal residences built on private and public land) are where 70% of the inhabitants of GCR live. Apartment blocks is the dominant housing system in GCR and most of it is owned by the private sector which represents more than 97% in housing construction, with no energy efficiency or renewable energy awareness (Hanna, Sustainable Energy Potential in the Egyptian Residential 2013) (Ahmed Abdin 2006). According to HSE in Greater Cairo, building median height is 5 floors with an average total surface area of the building (building footprint) 157m2. Some structures could reach a height of more than 12 stories, but it is uncommon to find low rise buildings and villas (David Sims 2008). In Egypt, 99% of the households receive electricity and the national demand is on a continuous rise (Singerman 2011).

The 2006 national census showed that the Egyptian building stock comprised about 16.5 million buildings and 11.5 million were used residential purposes in 2006, representing more than 60% of the Egyptian building stock. The Organisation for Energy Planning (OEP) conducted energy surveys between 1998 and 2002 in major cities like Cairo, Alexandria, Port Said and Asyut to represent 2634 apartments in GCR. The research revealed that the average annual end-use energy consumption was 2866kWh/m2 per apartment with 17% as the degree of saturation of air conditioners (Hanna, Sustainable Energy Potential in the Egyptian Residential 2013). The residential sector represented 36% of electricity consumption and about 21% of the total energy consumption nationally in the period 1990-2000 (International Energy Agency 2015). The residential consumption continues to rise 5-10% annually and it is necessary to adopt new efficient policies (Mohamed Edeisy, Energy Efficiency for Egyptian Housing: Code Compliance and Enforcement 2018).

Fig. 10: Buildings (from left to right) Islamic, European and Modern Cairo (Nermine Abdel Gelil Mohamed 2014) (Galila El Kadi 2006)

5 DISCUSSION

The Islamic residential stock represented compact morphological characteristics. On a building scale, this provided minimum heat gain and minimum heat loss through the building envelope and implied higher thermal comfort conditions. On an urban scale, this provided higher shading and lower temperatures. Islamic Cairo is characterised by using local materials. Stone was widely used – especially limestone - (12-16th century) for the construction of thick walls. Wood was used for building roofs, furniture and window shades (mashrabeya). In terms of environmental sustainability, the compactness of the Islamic urban fabric provided more shading and a low surface area to volume ratio – on an urban and architectural scale, which guaranteed higher indoor and outdoor thermal comfort levels.

European Cairo residential morphology is dominated by apartment blocks inspired by European - Baroque, Neo-classical and Rococo to Bauhaus, Italian Renaissance and Arabesque – architecture. On an urban scale, European Cairo witnessed a significant infrastructure development. It is characterised by wide streets for cars, lighting and open space. European Cairo residences were mostly built with thick load-bearing stone and masonry walls and then with the development of the concrete technologies, it started to become widely used. European Cairo residential blocks' thick heavy walls had low thermal conductivity and high thermal mass. Internal courtyards allowed good cross ventilation on hot summer days. On an urban scale, the city's infrastructure was developed significantly.

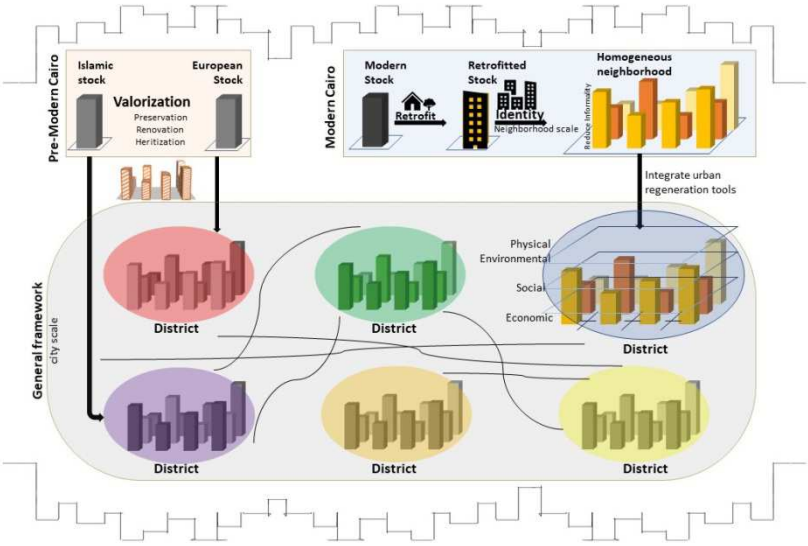

Fig. 11: General framework for future strategies prioritizing the problems of the existing built environment (Author)

After 1953, modern minimalistic apartment blocks - linear and tower – started to become more common gradually and it became the dominating building morphology. The impact of the failure of the master plans was evident and lead to a spontaneous transformation rather than planned land use. The informal settlements (either semi-legal or illegal residences built on private and public land) are where 70% of the inhabitants of GCR live (Hanna, Sustainable Energy Potential in the Egyptian Residential 2013). Modern Cairo blocks were built in a reinforced concrete column and beam structural system and bricks (slit, clay, cement) for walls. Modern Cairo (after the 1950s), is dominated by informality and illegality. Building skeletons of reinforced concrete and red brick filling have high thermal conductivity and thermal bridges are present. In

addition, in the last decades, reliance on artificial acclimatisation is rising accompanied by high consumption levels and greenhouse gas emissions.

6 CONCLUSION

New public policies should take into consideration the factors that led to the failure of previous masterplans. The continuous rapid growth and load on GCR made it extremely complex to manage the numerous actors of physical change of the built environment. The public sector should consider strengthening the attractivity of other Egyptian poles/cities to attract the population there, take advantage of the resources available in unused land – 99% of Egyptians live in 5.5% of land area (Erin H. Foubery 2009)- and decrease the pressure on the capital region.

Future strategies should give priority to solving the problems of the existing built environment through urban regeneration and requalification strategies on urban, neighbourhood and building scale. It is important to valorise the existing building stock of Islamic and European Cairo through urban preservation movements, heritage conservation, and renovation.

Moreover, it is necessary to foresee applicable tools that -while upgrading and maintaining the identity and services of the existing stock- work on upgrading the current state of the informal and illegal existing building stock of Modern Cairo. Passive retrofits have a high environmental potential in GCR; envelope retrofit in Cairo can lead up to lower energy consumption, increase in indoor comfort levels and lower greenhouse gas emissions (Mohamed Edeisy, Envelope retrofit in hot arid climates 2017) (Mohamed Eledeisy 2016); it provides an added aesthetic value through renovating the façade and helps cover gaps or cracks. When applied on a neighbourhood scale, it can be an instrument that contributes to decreasing informality and disorder between buildings in each district. It can be used as a tool to give harmony in the buildings' external aspect (similar colours, materials, etc.) and kick start an urban regeneration movement that begins with the household and expands to reach the neighbourhood within a general framework that integrates the actors of change on a city scale.

The article identified three significant styles of Cairene architecture. It evaluated the development of the housing stock on an urban and building scale before and after 1953. It is obvious that the built-up area of Cairo increased sharply after the 1950s (figure 6). GCR reached an uncontrollable size; the instability of governmental policies and regular change of decisions led to unsuccessful results on the urban and the building scale. The residential sector is mostly informal with a low effort in upgrading. This work presented a descriptive analysis of 3 typologies of a residential building; two of them are from the period before 1953 and the third is after. It analysed the development of housing stock after 1953 with common construction methods and their impact on the current built environment. In terms of technological, environmental and morphological quality of the housing sector -building and urban scale-, it is necessary to apply realistic solutions that reduce informal sprawl of the capital and encourage the private sector to adopt higher construction qualities in design, material selection and energy demand. The work provides an evaluation base and offers guidance in relation to the presented typologies within a general work frame on a wider scale. The indications given can support public policies for future scenarios of GCR and for Cairo vision 2050 strategies.

7 LIMITATIONS AND FUTURE WORK

This work understands that the Cairene housing stock is complex and it cannot be limited to three residential typologies and/or styles. However, the article aims to provide an inclusive overview of the main and most common architectural styles with a focus on their morphological and technological quality before and after 1950. Future work can further analyse the building stock in the period (2000-2020) and propose guiding indications for the vision of Cairo 2050 within the national vision of Egypt.

1 ABSTRACT

Nachhaltigkeitsstrategien im Gebäudesektor fokussieren sich aktuell hauptsächlich auf quantifizierbare Effi¬zienzmaßnahmen. Daneben erscheint es notwendig, die Struktur von Quartieren selbst einer kritischen Analyse zu unterziehen und für die Entwicklung integraler Planungsansätze nutzbar zu machen. Als entscheidend für dessen Wirksamkeit muss die Anwendbarkeit unter Alltagsbedingungen gesehen werden. Dies beinhaltet notwendigerweise Schematisierungen, die sich in der Stadtplanung traditionell im Konzept des Typus reprä¬sentieren. Setzt sich dieser Ansatz – wenn er auf die Perspektive interner räumlicher Organisation beschränkt ist – der Kritik aus, Rückkopplungseffekte zu ignorieren, erscheint die Erweiterung des Typus-Konzepts durch eine Kombination von Nachhaltigkeits- und Raumstrategie als geeignetes Werkzeug das komplexe Bezie-hungsgeflecht nachhaltiger Stadtplanung handhabbar zu machen.

Ein zentrales Element dieses Ansatzes besteht in der Definition relevanter Parameter und deren Berücksich¬tigung in frühen Prozessphasen. Die Bewertung urbaner Räume nach Nachhaltigkeitskriterien stellt Planung vor vielfältige Herausforderungen, deren Ursachen in der Komplexität und der Kontextabhängigkeit des Unter¬suchungsgegenstands wurzeln. Dennoch kann nur ein systemischer Ansatz das notwendige transformative Momentum erzeugen, dass zur Integration von Nachhaltigkeitsaspekten in Planungsprozesse notwendig ist.

In diesem Spannungsverhältnis operieren Analysetools, wie beispielsweise Arups „City-Resilience-Index“. Sie zeigen Möglichkeiten auf, komplexe städtische Systeme zu erfassen und in ein Bewertungssystem zu über¬führen. Dabei liegt der Fokus weniger auf einem linear-wertenden Vergleich, als auf einer ganzheitlichen quantitativen und qualitativen Analyse der Ist-Situation. Diesen Ansatz nicht nur retrospektiv, sondern pro¬aktiv zu nutzen, bildet die Grundlage der im Rahmen des Forschungsprojekts EnStadt:Pfaff entwickelten Strategie zur Entwicklung nachhaltiger Quartierstypologien.

Aus der Überlagerung des skizzierten Analyseansatzes mit dem Konzept städtebaulicher Typologien auf Quar¬tiersebene – das nicht exklusiv, sondern systemisch mit Bezug des einzelnen Moduls zur Quartiersumgebung verstanden wird – lässt sich ein Entwurfstool ableiten, das trotz Schematisierung eine ganzheitliche Betrach¬tung städtischer Systeme und integrale Planung ermöglicht. Unterschieden werden dabei drei Arten von Quartierstypologien: Gebäude, Verkehr und Freiraum. Für jede Typologie wurde ein mehrstufiges Bewer¬tungsschema entwickelt, das für drei Betrachtungsdimensionen – Form, Programm und Kontext – Ziele de¬finiert und über eine indikatorenbasierte dreistufige Bewertungsmatrix Rückschlüsse auf deren Integration zulässt. Die Definition der Zielsetzungen gründet auf den aus den 17 SDGs abgeleiteten Anforderungen ökologischer, ökonomischer und sozialer Nachhaltigkeit, die durch punktuelle Integration von technischen und prozessualen Aspekten ergänzt werden. Die Grundlage hierfür bildet die Analyse erprobter Bewer¬tungs¬strategien der Integration von Nachhaltigkeitsaspekten auf Quartiers- und Gebäudeebene.

Dieses Vorgehen ermöglicht es, das Nachhaltigkeitspotential von Entwurfsvarianten bereits zu Beginn von Planungsprozessen sichtbar zu machen. Es liefert ein Instrumentarium, das Raum- und Nachhaltigkeitsaspekte in Abhängigkeit zueinander als gleichberechtigte Elemente von Planung definiert und für die Realisierung eines integralen Entwurfsprozess nutzbar macht. Daneben bildet es die Basis zur Entwicklung einer Toolbox exemplarischer Quartierstypologien, die in Anlehnung an Christopher Alexanders „Pattern Language“, das Konzept elementarer Bausteine der Stadtplanung durch die Integration von Nachhaltigkeitsaspekten in die Zukunft fortschreibt.

Keywords: Planungswerkzeuge, Quartierstypologien, Quartiersforschung, Planungstheorie, Integraler Planungsansatz

2 EINLEITUNG

„Technology is the answer. But what is the question?“ (Cedric Price)[1]

Es ist aktuell möglich klimaneutrale und energieeffiziente Gebäude zu errichten, weit über die gesetzlichen Standards hinaus. Gleichzeitig klafft eine Lücke zwischen dem technisch Möglichen und seiner Anwendung in der alltäglichen Baupraxis. Dieses Mißverhältnis resultiert zu großen Teilen aus dem − von Price zurecht angemerkten − Fehlen einer hinreichenden Problemformulierung. Nachhaltigkeit bedeutet nicht nur technische Innovation, sondern ganzheitliche Betrachtung, worin ihre kulturelle Dimension sichtbar wird, die auf „soziale Innovation“ zielt.[2] Dieser Imperativ muss zukünftig in der Bau- und Planungspraxis methodisch verankert werden, doch steht diesem Vorhaben die Methodenarmut zeitgenössischer Entwurfsroutinen entgegen, die sich als „iterative trial-and-error process“ verstehen.[3] Wie durch dieses schrittweise Annähern an Planungsprobleme einem ganzheitlichen und methodisch verankertem Verständnis nachhaltigen Gestaltens Rechnung getragen werden kann, erscheint bis dato unbeantwortet.

Architektur wird wirkmächtig, wenn sie Theorie oder Praxis in einem kreativen Prozess verbindet. Dieses Dazwischen-Sein begründet das Ideal architektonischen Entwerfens als „offener Theorie“, die „unvollständig, ständig erweiterbar“ auf kybernetischen Prinzipien der Selbstkritik über Rückkoppelungen aufbaut.[4] Ein idealer Planungsprozess kann als effektive Strategie im Umgang mit Komplexität verstanden werden, dessen entscheidender Erfolgsfaktor − wie Price es andeutet − im „Verbindungspunkt zwischen Zielformulierung, Problemdefinition und Fragen der Gleichheit [zwischen den Projektakteurinnen und Projektakteuren, Anm. d. V.]“ liegt.[5] Neben der Forderungen nach einer offenen Theorie der Gestaltung und der Anwendbarkeit unter Alltagsbedingungen, spielt die Erweiterung der Systemgrenze Gebäude eine zentrale Rolle für die Entwicklung einer Entwurfsstrategie der Nachhaltigkeit. Erst durch die Betrachtung in Quartierszusammenhängen können Wechselwirkungen mit anderen Systemkomponenten erkannt und in den Entwurfsprozess integriert werden. Die Arten von Problemen innerhalb eines solchen Systems-von-Systemen zeichnen sich durch „ihre Einzigartigkeit, […] die Vorläufigkeit ihrer Beschreibung, […] die Unendlichkeit ihrer potentiellen Lösungen, […] die Unmöglichkeit durch Versuch oder Irrtum zu lernen und durch das Fehlen von Überprüfungsmöglichkeiten aus.“[6] Dies verdeutlicht, warum eine umfassende Formalisierung von Planung ins Leere läuft, da sie letztlich für eine gegen unendlich sich erweiternde Variantenvielfalt Lösungen anbieten müsste. Eine Methode nachhaltigen Architekturschaffens muss die Komplexität der sie sich gegenübersieht, effektiv in ihr eigenes Wesen integrieren und als stimulierendes Merkmal kreativer und architektonischer Prozesse anerkennen und nicht versuchen diese durch die Kompliziertheit von Lösungen, die von außerhalb in den Entwurfsprozess getragen werden, auszugleichen.[7]

2.1 Strategieansätze

Ein offener Theorieansatz integriert möglichst viele Teilaspekte des Systems Gebäude und macht diese in einem Planungsalgorithmus handhabbar. Welche Paramater hierbei Berücksichtigung finden können, zeigt der Vergleich von Konzepten zur Entwicklung oder Evaluation von Gebäude- und Stadtplanungskonzepten im Nachhaltigkeitskontext: Im Bereich Gebäude das *DGNB-System Gebäude*[8] der Deutschen Gesellschaft

für Nachhaltiges Bauen, das *Bewertungssystem nachhaltiges Bauen* (BNB)[9] der Bundesregierung, *SNARC - Systematik zur Beurteilung der Nachhaltigkeit von Architekturprojekten für den Bereich Umwelt* (SNARC)[10] des schweizerischen Architeken- und Ingenieurvereins, *SNAP-Systematik für Nachhaltigkeitsanforderungen in Planungswettbewerben des Bundes* (SNAP)[11] und das an der Hochschule München entwickelten *Bewertungssystem nachhaltiger Kleinwohnhausbau* (BNK).[12] Auf der Makroebene Stadt der *Morgenstadt-City-Index* (MCI)[13] des Fraunhofer IAO, der *City-Resilience-Index* (CRI)[14] der Rockefeller Foundation und ARUP und das durch den Stadtforscher Rudolf Giffinger entwickelte *Smart-City-Ranking* (SCR).[15]

Die Analyse der Bewertungssysteme zeigt neben einer prinzipiellen Unvereinbarkeit von Handhabbarkeit und detaillierter Datenerfassung die Problematik in der Analyse komplexer Systeme. Unterscheiden sich die Ansätze primär in ihrem Detaillierungsgrad, zeigt sich eine allgemeine Tendenz, diese nicht mehr ausschließlich auf quantitative Referenzwerte hin auszurichten, sondern im Sinne des Nachhaltigkeitsgedankens eine möglichst umfassende Abbildung des Ist-Zustandes unter Berücksichtigung qualitativer Kriterien anzustreben.[16] Analyse- und Bewertungstools dürfen nicht als abgeschlossene, sondern müssen als anpassungsfähige Systeme verstanden werden, wodurch dem Prozesscharakter von Nachhaltigkeit entsprochen und auf strukturelle und programmatische Innovationen reagiert werden kann.[17] Daneben zeigt sich ebenfalls eine Hinwendung zu einer Ausgewogenheit aller bewertbaren Kriteriengruppen.[18]

Analyseverfahren mit Gebäudefokus integrieren Wechselwirkungen mit dem städtischen System nur unzureichend und *vice versa*. Während sich gebäudezentrierte Analysen überwiegend auf technisch-strukturelle und damit quantitative Aspekte fokussieren, zeigen beispielsweise der CRI und das SCR eine Verschiebung von quantitativen Bewertungsmaßstäben zur Integration von qualitativen Faktoren als Grundlage eines ganzheitlichen Bewertungsansatzes.[19] Die Rolle des Individuums als zentrale Größe in der Analyse eines *Systems-von-Systemen* wird hierdurch entscheidend gestärkt. Ebenso eröffnet die hiermit verknüpfte Denkhaltung einen alternativen und ganzheitlichen Zugang zum Design von Analyse- und Bewertungswerkzeugen für Gebäude- und Quartiere im Nachhaltigkeitskontext, da Nachhaltigkeit zwar durch strukturelle und technische Strukturen (quantitativ) vorbereitet werden kann, aber erst durch die Artefakt-Nutzerinnen-Interaktion und Artefakt-Nutzer-Interaktion (qualitativ) ihre eigentliche Wirkung entfaltet.

2.2 Elemente der Nachhaltigkeit

Ganzheitlichkeit, Vergleichbarkeit (Lesbarkeit), Erweiterung der Systemgrenze, Handhabbarkeit, Abbildung von Komplexität, Prozessintegration und Nutzerzentriertheit bilden die Grundlage eines proaktiv handhabbaren Werkzeug in architektonisch-städtebaulichen Gestaltungsprozessen, die Nachhaltigkeit zum grundlegenden Element entwerferischer Praxis machen.

Das hier sichtbar werdende Paradigma von Entwerfen als „offener Theorie“ lässt sich jedoch nicht unmittelbar in eine undefinierte (generische) Architektur übertragen. Vielmehr muss das Spannungsverhältnis von spezifisch und generisch als *Komplementäre* in eine „spezifisch-generische Architektur“ integriert werden. Dieser Perspektivwechsel verschiebt den Betrachtungsschwerpunkt von Fragen des Raumes zu Fragen der *Temporalität*. Damit nähert sich entwerferische Praxis programmatisch dem Nachhaltigkeitsgedanken an, der Zukunft auf Grundlage von Handlungsentscheidungen in der

Gegenwart denkt,[20] jedoch nicht als in sich geschlossenes Konzept, sondern als Haltung und lernendes System auf Grundlage definierter Handlungsanweisungen. Hierin zeigen sich Parallelen zur städtebaulichen Praxis, die einen Planzustand als Momentaufnahme innerhalb eines Prozesses ohne definierten Beginn und Ende versteht.[21] Durch Übernahme dieser prozessorientierten Haltung und die damit verbundene Integration von Nutzungs- und Programmpotentialen besteht die Möglichkeit Nachhaltigkeitsaspekte in architektonische Prozesse zu integrieren. Parallel forciert die aktuelle klimapolitische Debatte die Hinwendung zu prozessorientiertem Denken. Sie trägt das Potential in sich, die „Gewichte in der Waagschale der Architektur" elementar zu verschieben, indem sich „Gebäudeperformance" als grundlegendes Prinzip ökologischen Bauens und mit ihr der Faktor Zeit zur relevantesten Einflussgröße architektonischer Entwurfspraxis entwickeln wird.[22]

In Planungsprozessen unter Nachhaltigkeitsaspekten gewinnen qualitative Parameter an Bedeutung. Sie repräsentieren ein Verständnis von Planung nicht im Sinne eines Lösens von technischen, sondern von gesellschaftlichen Problemen. Diese Art von Problemen erscheinen von „Natur aus verschieden von den Problemen, mit denen sich Wissenschaftler und […] Ingenieurgruppen beschäftigen. Planungsprobleme sind inhärent bösartig." Diese „Bösartigkeit" beruht auf der Komplexität der Systemzusammenhänge und auf dem Fehlen übertragbarer Lösungsansätze. Dies führt zur Frage, wie ein auf quantitativen und qualitativen Parametern aufbauendes Bewertungssystem, gleichzeitig spezifische und allgemeine Relevanz entwickeln kann. Möglich erscheint eine an verschiedene Kontexte sich anlehnende *iterative Methode*, die durch die Formulierung von Indikatoren einen allgemeinen Handlungsrahmen schafft, ohne den Gestaltungsprozess einzuengen.[23] Zielkonflikte werden hierbei nicht aufgelöst, sondern im Sinne von komplementären Beziehungen bewusst zugelassen und dadurch die Widerstandsfähigkeit des Gesamtsystems erhöht.[24]

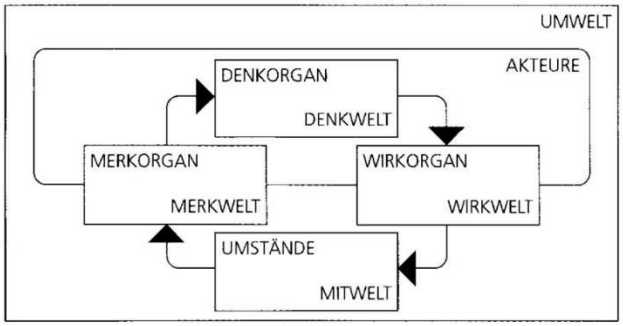

Abbildung 1: Funktionskreis nach von Uexküll 1928[25]

Ein Bewertungssystem der Nachhaltigkeit schafft einen Bezug zwischen Mikro- und Makroebene. Seine Elemente müssen die Wechselwirkung mit dem Gesamtsystem Stadt abbilden, wodurch Planung im hier skizzierten Verständnis ein *Denken in Systemen* und keine Reduktion auf Einzelaspekte repräsentiert.[26] Dennoch bilden bis heute lineare Planungsmodelle – Analyse, Festlegung der Ziele, Entwurf möglicher Handlungen und Beurteilungen der Konsequenzen – vielfach die Grundlage von Planungsprozessen. Einen alternativen Zugang bietet ein auf dem *System-Umwelt-Paradigma* basierender Planungsansatz, nach dem Modell des *Funktionskreises* Jacob von Uexkülls. Nach von Uexküll nehmen Menschen nur bestimmte Umweltreize wahr, auf die sie wiederum in bestimmter Weise antworten. Die Reaktion wirkt zurück auf die Umwelt, woraus ein geschlossener Kreislauf entsteht. Das Modell lässt sich wie folgt beschreiben: „Akteure, mit ihrer jeweiligen Gedankenwelt, agieren (in der Regel in Organisationen) als Systemkern im Kontext einer Umwelt und stehen auf bestimmte Art und Weise in ständigem Austausch mit den für sie relevanten

Komponenten dieser Umwelt."[27] Die durch die Akteurinnen und Akteure manipulierbare Umwelt (Wirkwelt) muss also als Bezugsraum des entwerferischen Handelns betrachtet werden (siehe Abb. 1).

3 TYPOLOGIE ALS METHODE

Eine Hauptforderung die durch die Analyse erhoben werden kann, besteht in der Erweiterung der Systemgrenze Gebäude durch die Nutzbarmachung der Wechselbeziehungen mit übergeordneten räumlichen System. Diese Ausweitung der „Wirkwelt" kann im Sinne Uexkülls bis zu jenem Punkt erfolgen, wie Manipulation der „Umwelt" durch Planungsentscheidungen wirksam sind. Quartiere weisen durch ihre Struktur sowohl eine durch Planung noch handhabbare Komplexität auf, während sie gleichzeitig als Mikrokosmos der sie umgebenden Stadt die Abhängigkeitsverhältnisse eines *Systems-von-Systemen* repräsentieren. In ihnen lassen die Effekte von „kulturellen Identitäten und sozialen Diffusionsprozessen beobachten", bei gleichzeitiger Überschaubarkeit des Untersuchungsraumes.[28]

Quartiere setzen sich strukturell aus den Elementen *Bebauung*, *Freiraum* und *Infrastruktur* zusammen. *Bebauung* umfasst dabei alle Arten von Gebäuden und die mit ihnen verknüpften Anlagen, *Infrastruktur* die Verkehrshierarchie und Erschließungsstrukturen, Entwurfselemente im Straßenverkehr, Entwurfselemente im Rad-und Fußverkehr und Lärmschutz, *Freiraum* die Gestaltung des öffentlichen Raums, technische Aspekte des öffentlichen Raums, Plätze in der Stadt, Grün in der Stadt und Wasser in der Stadt.[29] Diese drei *Quartierstypologien* stehen in wechselseitiger Abhängigkeit zueinander. Sie bilden die Bausteine eines alternativen Analyse- und Bewertungswerkzeugs der Nachhaltigkeit in dem sie es ermöglichen, Nachhaltigkeitsaspekte nicht nur für den Bereich Gebäude zu evaluieren, sondern für alle wesentlichen Bausteine eines Quartiers, worin sich die Forderung nach der Abbildung eines *Systems-von-Systemen* erfüllt.

Durch die typologischen Betrachtung als Grundlage von Entscheidungsfindungen wird auf eine spezifische architektonisch-städtebauliche Strategie zum Umgang mit Komplexität von Entwurfsprozessen zurückgegriffen, die Handhabbarkeit und Bearbeitbarkeit gewährleistet. Die Methode operiert im Spannungsverhältnis von klarem Definitionsrahmen und der Integration individueller und kontextabhängiger Charakteristika, wodurch sie als wirkungsvolles Instrument im Sinne der hier skizzierten Strategie gesehen werden muss.

Mit der Erweiterung des Typologiefeldes von einem (*Bebauung*) auf drei Komponenten (*Bebauung, Freiraum, Infrastruktur*) entsteht die Möglichkeit Wechselwirkungen von Systemen in einen entwerferischen Betrachtungsrahmen zu integrieren, ohne dabei die Handhabbarkeit des Modells durch einen erheblichen Komplexitätszuwachs zu konterkarieren. Gleichzeitig erscheint eine Forderung des uexküllschen Schemas erfüllt, die potentiell manipulierbare Wirkwelt der planenden Akteurinnen und Akteure abzubilden, ohne dabei dem Versuch zu erliegen, Umwelt in einem holistischen Verständnis manipulieren zu wollen.

Zusätzlich muss eine Typologie der Nachhaltigkeit Fragen der Performance und damit ihr Verhältnis zur Zeit adressieren. Dabei werden Typologien nicht als metaphysische Konzepte begriffen, sondern integrieren Lebenszyklusbetrachtung und Zirkularität. Die Erweiterung des Typologiebegriffs in diesem Sinne umfasst Aspekte der Energieversorgung und -produktion, der Soziokultur im Sinne einer Interaktion von Nutzerinnen und Nutzern und gebauter Umwelt, der Ökologie und der Wirtschaftlichkeit, wodurch sich die Möglichkeit eröffnet, Nachhaltigkeit in einem mehrdimensionalen Verständnis abzubilden. Typologie bedeutet in dem hier formulierten Verständnis weniger Form als spezifische Programmierung unter Nachhaltigkeitsaspekten.

3.1 Indizes Bebauung-Infrastruktur-Freiraum

Das *Instrument erweiterter typologischer Betrachtung zur Integration von Nachhaltigkeit in architektonische und stadtplanerische Prozesse* charakterisiert sich durch eine Fokusverschiebung von Objekthaftigkeit zu Aspekten der Zeitlichkeit, durch die Abbildung von Komplexität und deren Handhabbarmachung im Quartierszusammenhang, die Erweiterung der Systemgrenzen zugunsten eines *Systems-von-Systemen* und durch seine niedrigschwellige Verwendung in möglichst diversen Anwendungskontexten. Die kontextunabhängige Verwendung des Werkzeugs wird durch den Verzicht auf gestalterische Vorgaben erreicht.

Dies besonders im Hinblick auf symbolische und auch klimatisch-energetische Unterschiede zwischen Standorten, die eine Zieldefinition nach gestalterischen Kriterien von vorneherein ausschließen. Die drei Nachhaltigkeitsdimensionen *Ökologie*, *Ökonomie* und *Soziokultur* dienen als grundsätzliche Bewertungskriterien und tragen zu gleichen Teilen zur Urteilsfindung bei. Neben dieser programmatischen Synthese verbindet das Werkzeug verschiedene Phasen eines architektonisch-städtebaulichen Entwurfsprozesses und macht als Mittel der *design-control* eine Strukturierung von Entwurfsprozessen möglich, ohne das gestalterische Potential intuitiver und individueller Entscheidungen zu beschneiden.[30]

Die einzelnen Bewertungsräume orientieren sich am Modell der Quartierstypologien *Bebauung*, *Freiraum* und *Infrastruktur*. Jeder Bewertungsraum ist als Index konzipiert, der alle relevanten Parameter zur Realisierung eines ganzheitlichen Entwurfskonzepts im Quartierszusammenhang kombiniert und sichtbar macht. Jeder Index gliedert sich in drei Maßstabsebenen, die drei konzentrischen Kreisen zugeordnet sind, die miteinander in wechselseitiger Abhängigkeit stehen: *Dimensionen*, *Ziele* und *Indikatoren* (Abb. 2). Jede Dimension beinhaltet drei Ziele, deren Erfüllung wiederum anhand dreier Indikatoren nachgewiesen wird. Der Auswahl der drei Dimensionen *Gestaltung*, *Programm* und *Kontext* liegt ein radikal architektonischer Ansatz zu Grunde, in dem drei Grundelemente des architektonischen Entwurfsprozesses als grundsätzlich für die Erfüllung einer ganzheitlichen Problemlösungsstrategie betrachtet werden. Die Grundstruktur des Bewertungsschemas folgt also nicht einem außerhalb der Disziplin entwickelten Ansatz, sondern dockt an die Dynamik von Entwurfsprozessen selbst an.

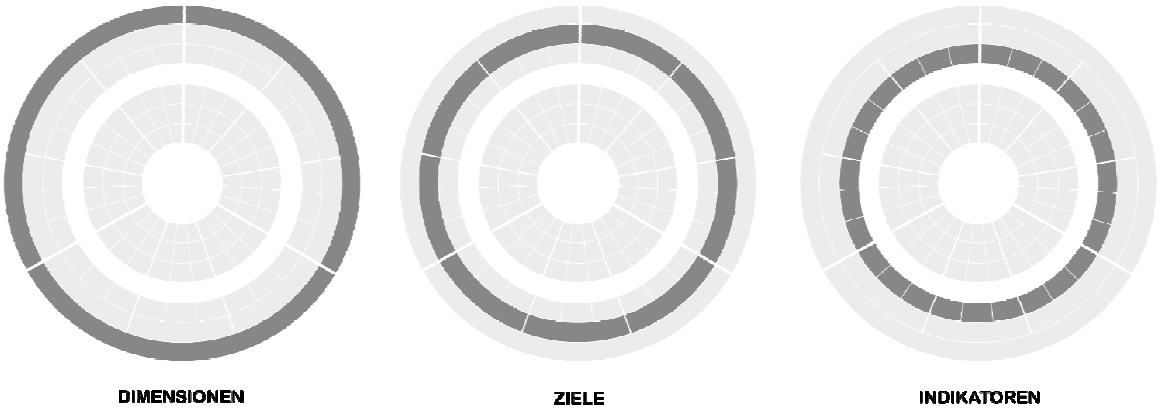

Abbildung 2: Strukturierung der Bewertungsindizes

3.2 Dimensionen der Nachhaltigkeit, Systemgrenzen und Parameter

Zur Abbildung eines ganzheitlichen Nachhaltigkeitsverständisses wurde jedem Index-Ziel eine Dimension der Nachhaltigkeit – *Ökologie, Ökonomie, Soziokultur* – zugewiesen. Es ergeben sich dadurch für jeden der drei Betrachtungsräume Bebauung, Freiraum Infrastruktur drei Ziele und neun Parameter für jede Nachhaltigkeitsdimension. Die gleichmäßige Verteilung und die damit verbundene Parität im Bewertungsverfahren unterstreicht den für die erweiterte typologische Betrachtung zentralen Aspekt der Ganzheitlichkeit. Untergeordnete Aspekte wie prozessuale und technische Nachhaltigkeit, sowie Standortqualitäten wurden als Komponenten einzelner Indikatoren in die Analysematrix integriert.

Die Dimension *Kontext* ist jedem der drei Bewertungsindizes zugeordnet. Sie dient dazu, die Wechselbeziehungen zwischen dem Gesamtsystem Quartier und den einzelnen Modulen – Bebauung, Freiraum, Infrastruktur – innerhalb des Bewertungsschemas zu verankern und für die Analyse fruchtbar zu machen. Die Bewertungsdimension *Kontext* trägt mit einem Drittel zur Beurteilung der Gesamtperformance bei (Abb.5).

[30] Das Ziel von *design-control* besteht in einer „Schritt-für-Schritt"-Kontrolle und der Gewährleistung einer hohen Prozessqualität durch systematische und zielgerichtete Vorgehensweise. Diese kontinuierliche Kontrolle „vom Planungsimpuls bis zur Planerstellung ist ein Muss, um qualitätsvolle, zielorientierte architektonische Lösungen und einen erfolgreichen interaktiven Prozess zu erreichen." M. SCHILL-FENDL: Evaluation der Planungs- und Entwurfsmethode MAPLE/D: Pre-Test eines Evaluationsmodells zur praktischen Überprüfung der Planungs- und Entwurfsmethode MAPLE/D für Architekten komplexer Aufgabenstellungen in interdisziplinären Gruppen Working Paper, Technische Universität Dresden, 2004. pp. 45.

Die in den drei Dimensionen verwendeten Indikatoren und Ziele bilden eine Synthese aus modulspezifischen (*Bebauung*, *Freiraum*, *Infrastruktur*) und systemischen (*Quartier*, *Stadt*) Elementen. Der überwiegende Teil der Parameter wurde nach einem Abwägungsverfahren, das auf Relevanz in frühen Planungsphase, ad-hoc-Bewertbarkeit und Bezug zur Nachhaltigkeitsthematik fokussiert war, aus den im Vorfeld analysierten Bewertungs- und Zertifizierungsmodellen destilliert. Für die Betrachtungsräume *Infrastruktur* und *Freiraum* mussten im Laufe des Analyseprozesses zusätzliche Indikatoren und Ziele entwickelt werden, da diese Quartiersmodule in den untersuchten Bewertungssystemen nur eine Nebenrolle spielten und daher nur wenige Indikatoren für diese Schwerpunkte identifiziert werden konnten.

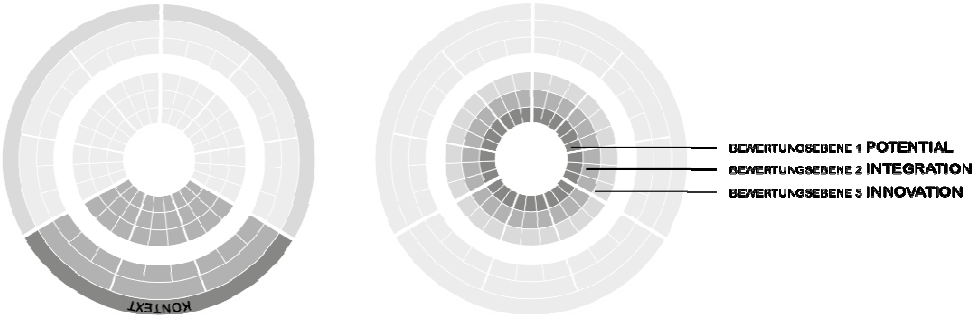

Abbildung 3: Kontextintegration und dreistufiges Bewertungsschema mit Innovationsanreiz

3.3 Bewertungsschema

Die Erfüllung der Indikatoren wird durch Leitfragen überprüft. Diese dienen nicht nur zur Beurteilung des Prozessfortschritts, sondern stellen zwischen Entwerferinnen, Entwerfern und Entwurfsgegenstand eine Rückkopplung her und garantieren eine beständige Auseinandersetzung mit dem behandelten Thema. Das Bewertungsschema ist drei¬stufig aufgebaut und verbindet die Forderung nach Prozessorientierung und nach Integration von Poten¬tialität, in dem es bereits die Möglichkeit zur Erfüllung von Indikatoren bewertet. Die einzelnen Bewertungs¬stufen gliedern sich wie folgt (Abb. 5): Stufe 1: Das Potential zur Erfüllung des Indikators ist vorhanden und kann gegebenenfalls im weiteren Verlauf des Entwurfsprozess aktiviert werden. Es stehen der Erfüllung des Indi¬kators keine Entwurfsentscheidungen entgegen. Stufe 2: Der Indikator ist in die Planung integriert und berück-sichtigt. Stufe 3: Der Indikator wurde auf innovative Weise – über etablierte Lösungsansätze hinausgehend – behandelt. Hierdurch wird zu einer Stimulierung von innovativen Ansätzen im Sinne einer Übererfüllung der Nachhaltigkeitsziele angeregt und gleichzeitig eine Fixierung auf Maximalwerte vermieden, worin sich die Haltung architektonischen und stadtplanerische Entwurfsverfahren als unabgeschlossene Pro¬zesse zu verstehen, manifestiert.

3.3.1 Gebäude

Der Index Bebauung gliedert sich in die drei Dimensionen Gestaltung, Programm und Kontext. Die Dimension Gestaltung umfasst dabei die Ziele „Energiebewusstsein“ (Ökologie) mit den Indikatoren passive und aktive Energienutzung und Graue Energie, „Kostenoptimierung“ (Ökonomie) mit den Indikatoren Lebens¬zykluskosten, Errichtungskosten und Wertstabilität und „Flexibilität“ (Soziales) mit den Indikatoren Aneignungspotential, Umbaufähigkeit und Nutzungsoffenheit der Struktur. Die Dimension Programm gliedert sich in die Ziele „positive Ökobilanz“ (Ökologie) mit den Indikatoren Nutzungssynergien, Flächen¬inan¬spruchnahme und Sicherung von Nachhaltigkeitsaspekten im Planungsprozess, „Produktivität“ (Ökonomie) mit den Indikatoren Digitalisierung, Innovationsfähigkeit und Aktivierung von lokalen Potentialen und „Kohäsion“ (Soziales) mit den Indikatoren Barrierefreiheit, Integration von Nutzerbedürfnissen und Mischnutzung. Die Dimension Kontext in „Mitigation“ (Ökologie) mit den Indikatoren Durchlüftung, Ver¬schattung und Wasserbewirtschaftung, „Zukunftsfähigkeit“ (Ökonomie) mit den Indikatoren Ausstrahlung auf das Quartier, Verkehrsanbindung und Verknüpfung mit städtebaulichen Leitbildern und „Kommunikative Orte“ (Soziales) mit den Indikatoren Aufenthaltsqualitäten, Kontextualität und Symbolische Offenheit.

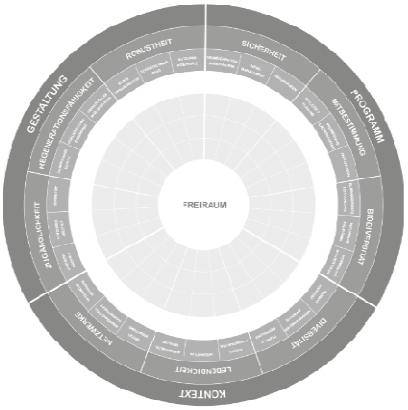
Dimensionen	Ziele	SDGs	Indikatoren	Leitfragen
Gestaltung				
	Energiebewusstsein	13,7	Energienutzung Aktiv	Werden lokale Energiepotentiale (Wind, Erdwärme, Sonne) durch die gebaute Struktur aktiv genutzt?
	ökologisch		Energienutzung Passiv	Berücksichtigen Kubatur, Lage der Fassadenöffnungen und Fassadengestaltung externe Energieeinträge?
			Graue Energie	Finden Materialien Verwendung, die geringe Energiebedarfe betrachtet auf ihren Lebenszyklus aufweisen?
	Kosteneptimierung	11	Lebenszykluskosten	Werden Strategien entwickelt, die zur Minimierung von Lebenszykluskosten und Energieverbrauche führen?
	ökonomisch		Errichtungskosten	Minimiert der Entwurf die Errichtungskosten, durch Materialwahl, Bestandselemente und Terrain?
			Wertstabilität	Gewährleisten Form, Materialität und Struktur zukünftig einen hohen Symbol-, und Gebrauchswert?
	Flexibilität	11	Aneignungspotential	Sind Elemente und Strukturen vorgesehen, die eine Aneignung durch zukünftige Nutzer unterstützen?
	sozikulturell		Umbaufähigkeit	Wird auf zukünftige Nutzungsänderungen flexibel und in der vorhandenen Struktur reagiert?
			Nutzungsoffenheit	Ermöglicht das Konzept programmatische Offenheit und damit vielfältige Nutzungen der Gebäudestruktur?
Programm				
	Positive Ökobilanz	3,13	Nutzungssynergien	Wird ein Miteinander von Nutzungen in ökologischer, energetischer und sozialer Hinsicht realisiert?
	ökologisch		Flächeninanspruchnahme	Ist die Minimierung des Flächenbedarfs durch kompakte Bauform auf Erdgeschossniveau vorgesehen?
			Sicherung von Nachhaltigkeitsaspekten	Integriert die Planung in Ausschreibung und Vergabe Nachhaltigkeitsaspekte?
	Produktivität	8,9,12	Digitalisierung	Reagiert die Architektur auf Anforderungen zunehmender Digitalisierung?
	ökonomisch		Innovationsfähigkeit	Finden innovative Strategien in sozialer, ökonomischer und ökologischer Hinsicht Berücksichtigung?
			Aktivierung von lokalen Potentialen	Stärkt die Programmwahl und die strukturelle Verzahnung mit der Umgebung die Wertschöpfung vor Ort?
	Kohäsion	11	Barrierefreiheit	Ermöglicht die Gebäudestruktur umfassende Zugänglichkeit für ein breites Nutzerspektrum?
	sozikulturell		Integration von Nutzerbedürfnissen	In welcher Weise integrieren die planerischen Entscheidungen die Interessen der zukünftigen Nutzer?
			Mischnutzung	Gewährleistet der Entwurf ein Nebeneinander von Nutzungen und dadurch ein robustes Betriebskonzept?
Kontext				
	Mitigation	3,13	Durchlüftung	Werden Aspekte der Durchlüftung auf Quartiers- und Gebäudeebene berücksichtigt?
	ökologisch		Verschattung	Reagiert die Kubatur auf die solare Einstrahlsituation vor Ort - für sich selbst und seine Umgebung?
			Wasserbewirtschaftung	Werden Strategien entwickelt, um Regen- und Brauchwasser im Gebäudekontext intelligent zu nutzen?
	Zukunftsfähigkeit	8,9	Ausstattung auf das Quartier	Trägt das Gebäudekonzept dazu bei, die stadträumliche Umgebung aufzuwerten?
	ökonomisch		Verkehrsanbindung	Leistet die Konzeption einen positiven Beitrag zur Anbindung der Nutzer an vorhandene Mobilitätsnetze?
			Verknepfung mit Leitbildern	Integriert das Konzept stadtebauliche Leitbilder und/oder schreibt es diese in die Zukunft fort?
	Kommunikative Orte	4,11	Aufenthaltsqualitäten	Stimuliert das Gebäude sein stadträumliches Umfeld und schafft es Orte mit hoher Aufenthaltsqualität?
	sozikulturell		Kontextualität	Findet im Entwurf die stadträumliche Umgebung historisch, sozial und strukturell ihre Entsprechung?
			Symbolische Offenheit	Ist eine symbolische Aneignung des Gebäudes durch unterschiedliche Akteursgruppen möglich?

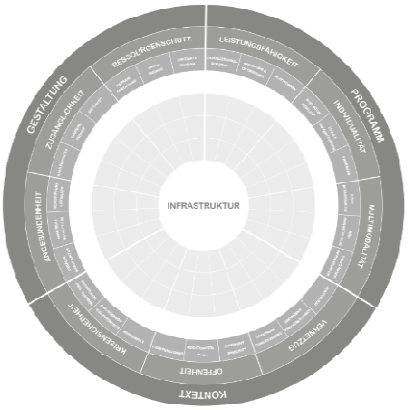
3.3.2 Freiraum

Die Dimension Gestaltung umfasst im Teilgebiet Freiraum die Ziele „Robustheit“ (Ökologie) mit den Indikatoren Blaue Infrastruktur, Versiegelungsgrad und Nutzungspotentiale, „Zugänglichkeit“ (Ökonomie) mit den Indikatoren Barrierefreiheit, Nutzungsvielfalt und Diversität in der Akteursstruktur und „Rege¬nerationsfähigkeit“ (Soziales) mit den Indikatoren Überhitzungsschutz, Resilienz bei Klimaereignissen und individuelles Wohlbefinden. Die Dimension Programm verfolgt die Ziele „Biodiversität“ (Ökologie) mit den Indikatoren Klimaangepasst Bepflanzung, Naturnahe Freiräume und Vermeidung invasiver Arten, „Sicher¬heit“ (Ökonomie) mit den Indikatoren Vermeidung von Angsträumen, Risikomanagement und Redundanzen und „Mitbestimmung“ (Soziales) mit den Indikatoren Begleitete Planungsprozesse, Angemes¬senheit der Flächennutzung und Partizipation. Die Dimension Kontext fokussiert sich auf die Ziele „Netz¬werke“ (Ökologisch) mit den Indikatoren Biotopvernetzung, Anbindung an das städtische Freiraumkonzept und die Etablierung eines Retentionsnetzwerks, Diversität (Ökonomisch) mit den Indikatoren Plurale Identität, Niedrigschwellige Angebote und Flexible Bespielung und „Lebendigkeit“ (Soziales) mit den Indikatoren Soziale Infrastruktur, Interaktion und Aufenthaltsqualität.



Dimensionen	Ziele	SDGs	Indikatoren	Leitfragen
Gestaltung				
	Robustheit	6,13,11	Blaue Infrastruktur	Integriert die Freiraumplanung Aspekte der Wasserbewirtschaftung, -speicherung und -retention?
	ökologisch		Versiegelungsgrad	Existieren Strategien einen möglichst geringen Versiegelungsgrad der Freiflächen zu realisieren?
			Nutzungspotentiale	Ist eine zukünftig Um- und Neunutzung der Flächen, ohne maßgebliche strukturelle Eingriffe gewährleistet?
	Zugänglichkeit	10	Barrierefreiheit	Wird Zugänglichkeit für Nutzerinnen mit eingeschränkter motorischen und geistigen Fähigkeiten ermöglicht?
	ökonomisch		Nutzungsvielfalt	Erfüllt das Freiraumkonzept die Ansprüche an einen möglichst vielfältiges Nutzungsspektrum?
		5	Diversität	Wird die Aneignung durch eine möglichst diverse Akteursstruktur ermöglicht?
	Regenerationsfähigkeit	3,9,11	Überhitzungsschutz	Sieht das Konzept gestalterische und funktionale Maßnahmen zum Überhitzungsschutz vor?
	sozikulturell		Resilienz bei Klimaereignissen	Wird die Widerstandsfähigkeit der Freiräume beim Eintritt selten auftretender Klimaereignisse garantiert?
			Individuelles Wohlbefinden	Gewährleisten die geplanten Strukturen Aufenthaltskomfort für ein breites Nutzerspektrum?
Programm				
	Biodiversität	3,12,13,15	Klimaangepasste Bepflanzung	Trägt die Pflanzenauswahl den sich in Zukunft anderner klimatischen Bedingungen Rechnung?
	ökologisch		Naturnahe Freiräume	Besteht der Anspruch möglichst naturnahe Angebote innerhalb urbaner Kontext zu etablieren?
			Vermeidung invasiver Arten	Legt die Pflanzenauswahl Wert auf die möglichst umfassende Verwendung heimischer Pflanzen?
	Sicherheit		Vermeidung von Angsträumen	Trägt die Gestaltung und Programmierung dem Sicherheitsbedürfnis möglichst vieler Nutzer Rechnung?
	ökonomisch		Risikomanagement	Findet eine Abwägung zur Frage von Risiken statt, dennoch öffentliche Freiräume ausgesetzt sind?
			Redundanzen	Integriert die Planung bewusst redundante Strukturen, um im Falle von Störungen leistungsfähig zu bleiben?
	Mitbestimmung	10,42	Begleitete Planungsprozesse	Verfolgt die Planungsstrategie über Elemente, die die Interaktion von Planern und Nutzern fordern?
	sozikulturell		Angemessene Flächennutzung	Berücksichtigt das Konzept eine möglichst behutsamen Umgang mit den existierenden Flächenpotentialen?
			Partizipation	Auf welchem Wege findet die Einbindung der Stakeholder/Nutzer statt?
Kontext				
	Netzwerke	3,6,13	Biotopvernetzung	Wird blaue und grüne Infrastruktur als Verbund betrachtet, der durch Vernetzung sein Potential entfaltet?
	ökologisch		Anbindung an Freiraumkonzept	Integrieren die Planungen projektbezogen mit den übergeordneten Freiraumkonzept?
			Retentionsnetzwerk	Wird Retention nicht als Einzelmaßnahme, sondern als Verbund verschiedener Elemente gedacht?
	Diversität		Plurale Identität	Ermöglicht die Gestaltung und Programmatik der Freiräume eine inklusive Identitätsbildung des Ortes?
	ökonomisch		Niedrigschwellige Angebote	Sind Freiraumangebote integriert, deren Nutzung an keine besonderen Voraussetzung gebunden ist?
			Flexible Bespielung	Welche Möglichkeiten zur temporären und langfristigen Neuprogrammierung sieht die Planung vor?
	Lebendigkeit	4,10,11	Soziale Infrastruktur	Wie werden Angebote in die Planung integriert, die den Zusammenhalt der Nutzen/Bewohner starken?
	sozikulturell		Interaktion	Welche Planungsentscheidungen tragen zur Erhöhung der Interaktion verschiedener Nutzergruppen bei?
			Aufenthaltsqualität	Bilden Maßnahmen zur Steigerung der Aufenthaltsqualität einen Bestandteil des Entwurfskonzepts?

3.3.3 Infrastruktur



Dimensionen	Ziele	SDGs	Indikatoren	Leitfragen
Gestaltung				
	Ressourcenschutz	12,15	Terraingestaltung	Werden möglichst geringe Terrainbewegungen realisiert?
	ökologisch		Graue Energie	Werden Materialien verwendet, die einen geringen Energiebedarf innerhalb ihres Lebenszyklus aufweisen?
			Effiziente Trassenführung	Wird eine möglichst effiziente und dadurch ressourcenschonende Trassenführung realisiert?
	Angebundenheit		Schnittstelle Gebäude-Infrastruktur	Existieren Konzepte, die Synergien an der Schnittstelle von Infrastrukturen und Gebäuden entfalten
	ökonomisch		Quartiersvernetzung	Auf welche Weise trägt die Infrastruktur zur Vernetzung von Mobilität und Stoffströmen bei?
			Verknüpfung mit Leitbildern	Finden nationale, regionale und lokale Leitbilder ihre räumliche Entsprechung in der Infrastrukturplanung?
	Zugänglichkeit		Shared-Spaces	Integriert die Planung flächen, die von verschiedenen Mobilitätsformen gleichberechtigt nutzen können?
	soziokulturell		Barrierefreiheit	Ermöglicht die Infrastruktur Zugänglichkeit für ein möglichst breites Nutzerspektrum?
			Offenheit	Bietet das Infrastruktursystem Adaptionsmöglichkeiten für zukünftige Technologien?
Programm				
	Multimodalität:	9,3,12,13	ÖPNV-Infrastruktur	Wird eine leistungsfähige und zukunftsfähige Integration von ÖPNV-Infrastruktur garantiert?
	ökologisch		Radinfrastruktur	Wird eine leistungsfähige und zukunftsfähige Integration von Radinfrastruktur garantiert?
			Fußgängerinfrastruktur	Wird eine leistungsfähige und zukunftsfähige Integration von Fußgängerinfrastruktur garantiert?
	Leistungsfähigkeit	9	Erschliessungseffizienz	Wie kann eine umfassende Erschließung mit einem minimalen Trassennetzwerk realisiert werden?
	ökonomisch		Steuerung und Optimierung	Integriert das Planungskonzept Möglichkeiten zur dezentralen Steuerung und potentieller Optimierung?
			Plattformen	Bieten sich Integrationsmöglichkeiten für zukünftige Nutzungen durch Energie- und Mobilitätsplattformen?
	Individualität		Innovative Mobilitätsangebote	Auf welche Weise finden innovative Mobilitätsformen und Angebote ihren Weg in die Planung?
	soziokulturell		Lokale Anforderungen	Reagiert das Konzept auf die spezifischen Anforderungen vor Ort?
			Freiräume	Können trotz Effizienzgebots Freiräume für Redundanzen und zukünftige Nutzungen integriert werden?
Kontext				
	Krisensicherheit	9,11,13	Starkregen	Sind Maßnahmen vorgesehen, die es ermöglichen Starkregenereignisse zu bewältigen?
	ökologisch		Redundanz der Verkehrssysteme	Gewährleisten redundante Strukturen während einer Störung ein Funktionieren des Betriebsablaufs?
			Robuste Trassenführung	Kann die Trassenstruktur auch unter Extrembedingungen ihre Funktion aufrecht erhalten?
	Vernetzung	9,8	Zentralität	Wird die Herausbildung eines Funktionsverbunds mit Ausstrahlung in die räumliche Umgebung gefördert?
	ökonomisch		lokale und regionale Anbindung	Wie ist die Infrastruktur an regionale und lokale Verkehrs- und Versorgungsinfrastruktur angeschlossen?
			überregionale Anbindung	Wie ist die Infrastruktur an die überregionale Verkehrs- und Versorgungsinfrastruktur angeschlossen?
	Offenheit	9,12	Leistbare Infrastrukturnetzwerke	Ermöglicht das Planungskonzept durch Kostenminimierung einen möglichst breiten Zugang?
	soziokulturell		Neue Technologien	Integriert das Konzept Potentiale zur Integration experimenteller Technologien?
			Erweiterbarkeit	Beinhalten die Planungen Möglichkeiten die Leistungskapazitäten des Netzwerks je Bedarf zu erweitern?

Der Index Infrastruktur verfolgt in der Dimension Gestaltung die Ziele „Ressourcenschutz“ (Ökologie) mit den Indikatoren Terraingestaltung, Graue Energie und Effiziente Trassenführung, „Angebundenheit“ (Ökonomie) mit den Indikatoren Schnittstelle Gebäude-Infrastruktur, Quartiersvernetzung und der Ver¬knüpfung mit übergeordneten städtebaulichen Leitbildern, „Zugänglichkeit“ (Soziales) mit den Indikatoren Shared-Spaces, Barrierefreiheit und Offenheit. Die Dimension Programm fokussiert sich auf die Ziele „Multi¬modalität“ (Ökologie) mit den Indikatoren Infrastruktur des öffentlichen Personennahverkehrs, Radinfra¬struktur und Fußgängerinfrastruktur, „Leistungsfähigkeit“ (Ökonomie) mit den Indikatoren Erschließungs¬effizienz, Steuerung und Optimierung und Plattformen und „Individualität“ (Soziales) mit den Indikatoren Innovative Mobilitätsangebote, Lokale Anforderungen und Freiräume. Die Dimension Kontext beinhaltet „Krisensicherheit“ (Ökologie) mit den Indikatoren Reaktion auf Starkregenereignisse, Redundanzen der Verkehrssysteme und Robuste Trassenführung, „Vernetzung“ (Ökonomie) mit den Indikatoren Zentralität, lokale und regionale Anbindung und überregionale Anbindung und „Offenheit“ (Soziales) mit den Indikatoren Leistbare Infrastrukturnetzwerke, Neue Technologien und Erweiterbarkeit.

4 FAZIT

Das hier skizzierte System ist primär als Methode zur Selbstkontrolle für Akteurinnen und Akteure in architektonisch-stadtplanerischen Gestaltungs- und Entscheidungsfindungsprozessen entwickelt worden. Es bietet die Möglichkeit zur Strukturierung von Entwurfsprozessen und individueller *design-control*, die verhindert, dass durch eine einseitige Fokussierung auf intuitive Entwurfsansätze die zur Etablierung von Nachhaltigkeit in Planungsprozessen notwendige ganzheitliche Arbeits- und Denkweise aus dem Fokus gerät. Der zentrale programmatische Aspekt des Ansatzes besteht in der Verschneidung von Analysetools der Makro- und Mikroebene im Quartiersmaßstab durch ein, in die Praxis des architektonisch-städtebaulichen Entwurfs selbst integriertes, *proaktiv nutzbares Planungswerkzeug*. Die Handhabbarkeit des Ansatzes in frühen Planungsphasen wird durch die Fokussierung auf die typologische Betrachtung als etablierte Methode architektonisch-stadtplanerischer Praxis erreicht, die durch eine programmatische Erweiterung ihrer tradierten Definition für die produktive Verwendung im Nachhaltigkeitskontext aktiviert wird. Die Struktur des Werkzeugs beruht auf der Annahme, dass ein Evaluierungssystem keinesfalls „hochkomplex“ sein muss, um eine effektive Bewertung von architektonischen Problemstellungen zu ermöglichen.[31]

In einem nächsten Schritt soll die *Methode erweiterter typologischen Betrachtung* zur Entwicklung beispielhafter Quartierstypologien beitragen, um die Praxistauglichkeit des Ansatzes theoretisch zu überprüfen. Ziel

[31] DRAEGER, Vergleich des Systems des Deutschen Gütesiegels Nachhaltiges Bauen mit internationalen Systemen. pp. 255.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

ist die Entwicklung eines Katalogs nachhaltiger Quartierstypologien, die weniger objekthaft, als im Sinne eines Sets von Programmen und Prozessen verstanden werden können.

Die *Methode erweiterter typologischer Betrachtung* bietet Ansatzpunkte für eine systematische Analyse und Weiterentwicklung der Begriffe Nachhaltigkeit in stadtplanerischen und architektonischen Kontext, Untersuchungen zur zukünftigen Rolle von Architektinnen, Archtikten, Stadtplanerinnen und Stadtplanern, die Weiterentwicklung einer methodenbasierten Entwurfsstrategie der Nachhaltigkeit, die Integration von Strategien aus anderen Disziplinen und die Entwicklung von Evaluationsmethoden zur Bewertung von Bewertungsmodellen selbst. Ebenso wirft die erweiterte typologische Betrachtung die Frage auf, ob die heute geltenden städtebaulichen und architektonischen Leitbilder auch weiterhin ihre Berechtigung haben werden oder ob sie durch Konzepte ersetzt werden müssen, die beispielsweise energetischen und soziokulturellen Entwurfsparametern eine wesentlich größere Bedeutung zumessen.

Die Forschung zeigt, dass der Einfluss früher architektonischer und struktureller Entscheidungen als wesentlich für die Realisierung nachhaltiger Gebäude gesehen werden kann.[32] Im Gegensatz zur Stadt der Moderne, die auf Entflechtung von Nutzungen setzte, wird die Stadt der Zukunft vermehrt aus Komponenten bestehen, die sich durch eine Überlagerung von Nutzungen und Synergieeffekte charakterisieren. Dieses Verständnis steht tradierten Planungsverfahren und Instrumenten entgegen und führt zu einer Komplexitätszunahme auf allen Maßstabsebenen. Produktiv mit dieser Situation umzugehen, muss künftig das Hauptkriterium von Architekturentwurf und -ausbildung sein. Letztlich kann sich hieraus eine Denkhaltung entwickeln, die Zielkonflikte in entwerferischen Prozessen bewusst nicht auflöst, sondern als komplementäre Bausteine eines Prozesses betrachtet, der Komplexität nutzbar macht. In diesem ganzheitlichen Denkansatz liegt eine Möglichkeit zur Beantwortung der von *Cedric Price* erhobenen Forderung nach einer hinreichenden Problemformulierung: ein der Nachhaltigkeit verpflichtet Verständnis architektonischen Entwerfens muss einer einseitigen Fokussierung von Entwurfsaufgaben durch Narrative, Sachzwänge und politische Einflussnahme entgegentreten und im Gegensatz dazu bewusst Möglichkeitsräume eröffnen und das eigene Handlungsfeld erweitern.

1 ABSTRACT

HARA is a land-use model that uses a search algorithm to find the optimal spatial allocation of new housing demands in an urban plan area. In the model, the plan area is represented as a grid of cells. A core element of the algorithm is a function that is used to evaluate the value of a cell for each possible land-use given its location. The value function is specified as the net value of a (housing) development given the land costs, the construction costs, and the market value of the development at a location. Specified in that way, the solution generated represents an optimum as well as a market equilibrium (maximum net value for developers). A critical prerequisite for this is, however, that the value-function is specified such that it accurately represents buyers' willingness-to-pay for dwelling and location characteristics in the housing market. In this paper, we show how the value function can be estimated using hedonic price analysis. The analysis is carried out based on a large housing transaction data set focusing on two medium-sized cities in The Netherlands combined with detailed land-use data of these areas. Although a full set of land-use types is taken into account, special attention is paid to the classification of urban green space, given the purpose to analyze scenarios for developing urban green space. The results indicate that land-use effects on housing prices differ considerably between housing types as well as city. We conclude therefore that it is important in the estimation of land-use models to take the specific local conditions of housing markets and housing segments into account.

Keywords: Land use allocation, Hedonic price method, Housing, Urban planning, decision making model

2 INTRODUCTION

Urban green space (UGS) attracts more and more attention as a means to release urban area climate problems given its variety of climate functions. Many studies have proved that UGS has great potential to deal with heat, hydrology, biodiversity and air quality problems. Also, UGS can improve the quality of the living environment for inhabitants by providing open space for relaxation, exercise and pleasant scenery. The value of UGS (e.g., as park or lake) for creating a pleasant living environment is also reflected in the value of real estate properties in the neighborhood. Purchasers of residential properties, for example, are willing to pay more for dwellings that have an attractive green neighborhood environment as shown by many studies (Engström & Gren, 2017; Huang & Yin, 2015; Jim, 2013; Kong, Yin, & Nakagoshi, 2007; Baranzini & Schaerer, 2011; Diewert, de Haan, & Hendriks, 2015). Given these advantages, urban planners generally seek proper ways to make current cities more climate adapted by using UGS as a tool. How to develop green space wisely in the city context is, however, not straight forward. Specifically, two main challenges need to be addressed. One is the costs of development and maintenance of UGS or, when retrofitted in buildings, of green vegetation on roofs or facades. Due to these costs a conflict may arise in the urban area development process between stakeholders who are seeking financial benefits and inhabitants or planners who care about living quality. The other is the scarcity of space to develop UGS especially in high-density urban area due to demands for other land-uses that must be met. The scarcity is reflected in land-prices and, therefore, also responsible for the high costs. These challenges may limit the amount and spatial flexibility of developing UGS.

Spatially, both the UGS climate (cooling effect) and (housing) property market value effects are strongly affected by their spatial allocation pattern (Li et al. 2018). Furthermore, the climate characteristics of urban green vary based on vegetation species. Spatial allocation of UGS therefore should be optimized considering their climate and land economic characteristics and effects. To support land-use decisions taking into account these objectives, in earlier work, we extended and refined the HARA[1] land-use allocation model system (Li et al. 2018). The model focuses on housing development. Using a function that determines the impact of locations on the net value of properties, the model generates allocation plans that have maximized housing

[1] HARA is an acronym for Housing-type Allocation in Residential Areas

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

net value while meeting given demands for different housing types. In the process, the model considers a full range of urban and non-urban land-uses, including different green land-use types and mixing of green and built-up area (e.g., green building decorations). In Li et al. (2018) it is demonstrated how the model can be used in combination with a climate effect model to evaluate housing development strategies to release the climate pressure.

Land-use models have a long history in urban and spatial planning. A variety of modeling approaches has received attention including CA (cellular automata), regional economics (Lowry models and derivations) and optimization models. Invariably, the models use a classification of land-uses and a particular value function to evaluate the suitability of a location for a particular land-use taking into account interactions between land-uses and accessibility of locations. Obviously, for creating useful solutions the validity of the value function is of critical importance. Yet, the empirical estimation and validation of value functions have only received very little attention in land-use modeling. Usually, the models are manually calibrated based on face validity of the land-use plans generated. An exception is Ligmann-Zielinska, Church, & Jankowski (2008) who use an empirically estimated land–use allocation model to explore feasible land use possibilities. Hedonic price analysis offers a possibility to estimate the value function in a more rigorous way. A hedonic price model is able to predict the price level of a real-estate object based on characteristics of the object itself and location characteristics, and can be estimated based on transaction data.

In this paper, we consider the empirical estimation of the land value function used in the HARA model. We propose a specification of the value function that enables an empirical estimation of the parameters based on hedonic price analysis. To create a tool that is suitable for evaluating urban green scenarios, the sensitivity of the value function for urban green receives special attention. Next, we use a large transaction data set from the Netherlands to estimate the model for two cities in the Netherlands - Eindhoven and Almere. These two cities differ largely in terms of housing market and green land-use characteristics. They were chosen as cases to see whether parameter estimates show local differences between cities. Occurrence of such differences would indicate that local estimation (and application) of land-use models is needed.

The remainder of the paper is structured as follows. First, in the next section we explain the methodology used in terms of the land-use model and the hedonic price analysis. Next, in the third section, we describe the study area and data. Then, in the section that follows, we discuss the results of hedonic price analysis to estimate the value functions of the land-use allocation model. Finally, in the concluding section, we summarize the major conclusions and discuss remaining problems for future research.

3 METHODOLOGY

To provide a background for the empirical analysis that follows, in this section, we will briefly explain the HARA model, the value function that is to be estimated and hedonic price modeling as an estimation approach.

3.1 The HARA land-use model system

HARA implements an algorithm to generate optimal land-use plans, given demands for particular land-uses in a delineated plan area. The algorithm assumes that the plan area is represented as a regular grid of cells where each cell corresponds to a piece of land that has a particular land-use. Land-use allocation decisions concern decisions to develop current unbuilt-land (so-called Nature cells) for a particular urban land-use. Both the value function and allocation algorithm are focused on housing developments, so that the model can be used to generate housing development plans for a given plan area. The user specifies the size of (new) demand for each relevant housing type (e.g., stand alone, terraced houses, apartments, etc.) as well as the zones available for new housing development. Given the demands and zoning regulations, Hara determines which cells are to be developed for which housing type such that the best use for each location is realized, given the land-value function. Below we describe the function used to evaluate land developments and a method to estimate the parameters based on housing transaction data using well-known hedonic price analysis.

The value function used in Hara has the following form:

$$V_{ijk} = Vcon_{ijk} + Vnbh_{ijk} + Vacc_{ijk} \quad (1)$$

where V_{ijk} is the (market) value of housing of type *k* in cell *ij*, *Vcon* is a constant, *Vnbh* is a value component related to the direct neighborhood of the cell and *Vacc* is a value component related to accessibility of particular other land-uses from the cell. The neighborhood component is specified as:

$$Vnbh_{ijk} = \sum_{h \in H} \alpha_{kh} \cdot N_{ij0h} \quad (2)$$

where *H* is the set of all land-uses (nature, the housing land-uses and other land-uses), N_{ij0h} is the number of cells with land-use *h* in the neighborhood of cell *ij* and α_{kh} are parameters representing the marginal value of *h*-cells in the neighborhood for a housing land-use *k*. The neighborhood of a cell consists of the 8 adjacent cells. The accesibility component is specified as:

$$Vacc_{ijk} = \sum_{h \in H} \sum_{m} \beta_{khm} \cdot I_m(D_{ijh}^{min}) + \sum_{h \in H} \sum_{q} \gamma_{khq} \cdot N_{ijqh} \quad (3)$$

where *H* is defined as above, D_{ijh}^{min} is the distance to the nearest cell with land-use *h* from cell *ij*, I_m is a binary variable indicating whether the distance falls in the *m*-th distance band (= 1, if it does and 0 if it does not), β_{khm} is the value of having land-use *h* within distance band *m* for land-use *k*, N_{ijqh} is the number of *h*-cells within distance D_q from cell *ij* and γ_{khq} is a parameter representing the value of the accessibility of *h*-cells within that distance for a housing land-use *k*. Thus, accessibility is measured in two ways - availability of land-uses in distance ranges from the cell and distance to nearest cells with particular land-uses. Which of these two methods is most appropriate may depend on the land-use under concern.

The constants and coefficients $Vcon_{ijk}$, α_{kh}, β_{khm} and γ_{khq} are parameters that need to be estimated. We propose to use hedonic price analysis to estimate the parameters. The impact of urban green on value of residential property comes to expression in the alpha parameters (green land-uses in the direct neighborhood) and possibly also in beta and gamma parameters (accessibility to recreational green). As the subscripts indicate the values of all parameters are housing type (*k*) specific.

3.2 Hedonic price analysis

Hedonic price analysis uses multiple regression analysis to estimate the contributions of housing attributes on the total value (or price) of a dwelling (Rosen, 1974). When demand and supply of dwellings are in equilibrium, the estimated marginal values represent willingness-to-pay values of buyers for the specific attributes (Maslianskaïa-Pautrel & Baumont, 2016). Since the analysis of urban green scenarios is a special aim of the land-use model (HARA), the impact of UGS on housing values is of special interest in the hedonic price model we develop here. Therefore, in this section, we briefly review existing studies that have aimed to model UGS and measure its impact on housing values through hedonic price analysis.

Melichar & Kaprová (2013) investigate the distance ranges in which UGS have positive effects on housing prices. Tyrväinen & Miettinen (2000) finds that buyers have to pay more to obtain a dwelling with a green space view, which depends on the natural environment quality and amount. Conway, Li, Wolch, Kahle, & Jerrett (2010) show that each additional percentage of greenery coverage significantly increases the housing price. GIS has been used as a tool to determine a wide range of spatial factors in a hedonic pricing model to explore the urban green spatial configuration impacts on residential building prices (Asmawi, Norzailawati, & Tuminah, 2016). Diversity of urban green vegetation types and spatial landscape has also been shown to have added value on dwelling price (Panduro & Veie, 2013; Franco & Macdonald, 2016) . However, existing research has mostly focused on one single type of urban green (e.g., a park). In the present study, we extend existing literature by considering a broader range of urban green types that can be taken into account in land-use models. Furthermore, in our analysis, we make a comparison between two regions, in order to see whether local land-use configurations and housing market conditions have an influence on price relationships.

3.3 Estimation approach

A complication for hedonic price analysis is that structural, neighborhood and accessibility variables relate to different levels of scale - the plot and building, the direct neighborhood and the wider area of the dwelling, respectively. A robust and well-known way of estimating the parameters in such a multi-level case is to estimate fixed effects for locations in a first step regression analysis which are then used as dependent

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

variable to estimate the effects of the location factors in a second-step regression (Helbich, Brunauer, Vaz, & Nijkamp, 2014). Formally, the regression models for the two steps are specified as follows. For the first-step regression analysis, the model is specified as:

$$\ln Y_{ij} = \beta_{01} + \beta_1 H_j + \beta_2 L_i + S_i + \varepsilon_{ij1} \quad (4)$$

where Y_{ij} is the transaction price of a dwelling j at location i, β_{01} is an intercept, H_j is a vector of value-relevant dwelling characteristics (volume, lot size, construction year, maintenance condition, etc.) and β_1 is a vector of related coefficients, L_i is a vector of neighborhood characteristics (urban green and other land-use types) and β_2 is vector of related coefficients, S_i represents the *fixed* effect of location i, and ε_{ij1} is random error term. By using the natural log of price as dependent variable, which is a commonly used approach, the coefficients represent effects as a percentage price increase. In this model, S_i captures the price effect of the location after having taken into account the dwelling and neighborhood characteristics.

In the second step, the fixed effects are regressed on accessibility factors to identify the marginal effects of location characteristics. The regression equation for the second step can be written as:

$$S_i = \beta_{02} + \beta_3 D_i + \varepsilon_{i2} \quad (5)$$

where β_{02} is an intercept, D_i a vector of location accessibility characteristcs, β_3 is a vector of related coefficients and ε_{i2} is a a random error term.

This two-step hedonic price model allows us to estimate the parameters of the HARA value function: the *Vcon* term (Eq. 1) corresponds to $\beta_{01} + \beta_1 H_j + \beta_{02}$, the alpha parameters (Eq. 2) to β_1 and the beta parameters (Eq. 3) to β_3 with proper handling of the log transformation of price. Since all parameters in the HARA model have housing type specific values, the regression models (Eqs 4 and 5) must be estimated housing type specific. Given limited space, we will only consider the first-step regression analysis in the application described in the next section.

4 STUDY AREA AND DATA

Figure 1 shows the location of the Eindhoven and Almere cities in the Netherlands. Almere is a planned city with 208,000 citizens (2019) in the province of Flevoland, Netherlands. Eindhoven is the fifth-largest city of the Netherlands with 231,000 citizens (2019) and located in the south of the country. Eindhoven is an industrial city in the center of a region that houses a lot of high-tech companies.

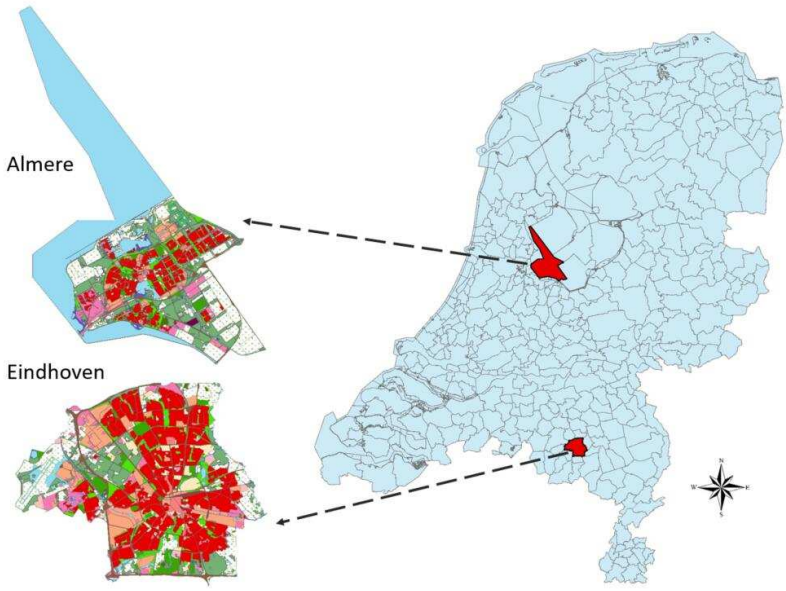

Figure 1: Research areas location (the cities Almere and Eindhoven)

The spatial land-use data used for the analysis are provided by the CBS (Central Bureau of Statistics) in the Netherlands. The transaction data used are provided by the NVM, the largest real estate market agency, in the Netherlands. For the present study NVM-data of transactions that took place in Eindhoven and Almere

from 2014 to 2018 were used. The data-set consists of 18813 geocoded housing transactions. Table 1 shows the dwelling characteristic variables Hj and neighborhood land use variables Li that entered the hedonic regression model. Of interest here is the estimation of location effects on housing price on the level of the neighborhood land-use variables. The land-use data include all land-use categories that are potentially relevant for housing value and land-use planning. The classification of UGS is extensive compared to earlier studies. This allows us to estimate housing value effects of UGS in a more detailed way than have been done so far. Also on the level of other land-uses, we are not aware of other hedonic price analysis studies that have modeled neighborhoods in this level of detail. The dwelling characteristics are included as control variables.

Dwelling characteristics			
Variable	Description	Measure	Expected sign
Log of transaction price		Number	DV[a]
Area		Number	+
Number of rooms		Number	+
Volume of the dwelling		Number	+
Construction year	Old to new (0-9)	Categorical	-
Lift	House has a lift (0/1)	Binary	+
Heating system	No; simple; advanced (0/1/2)	Categorical	+
Parking space	House has a parking space (0/1)	Binary	+
Facing direction	Good to normal (0-4)	Categorical	+
Maintenance inside	Excellent to bad (1-9)	Categorical	+

Neighborhood land use variables			
Variable	Description	Measure	Expected sign
Shopping area	Retail; restaurant; shopping mall, etc	%	+
Industry and office	Industry area; business offices	%	-
Public buildings	Museum; city hall; school; hospital	%	+
Road traffic area	Road traffic area	%	-
Park and sports field	Parks, sports field	%	+
Day recreational area	Day recreational area	%	+
Agricultural	Agricultural land use	%	+
Forest	Forest	%	+
Open wet natural terrain	Open wet natural land use	%	+
River and lake	River and lake	%	+
Other water body	Other inland water	%	+

[a] Dependent variable

Table 1: Definitions and descriptive of variables entering the hedonic model

The land-use variables related to each transacted dwelling are determined based on the HARA land use modeling framework. Each spatial observation is located by its postcode on a six-digit level and overlayed by a 100 by 100 meter cells grid. After this, the land-use characteristics of each cell's direct neighborhood (eight cells) are calculated as the percentage of cells covered by the land-use (Figure 2). The 4-digit postcode to which each transaction belongs are entered as dummies in the regression equations to estimate the fixed effects, Si. Eindhoven counts 47 4-digit postcode areas and Almere 52.

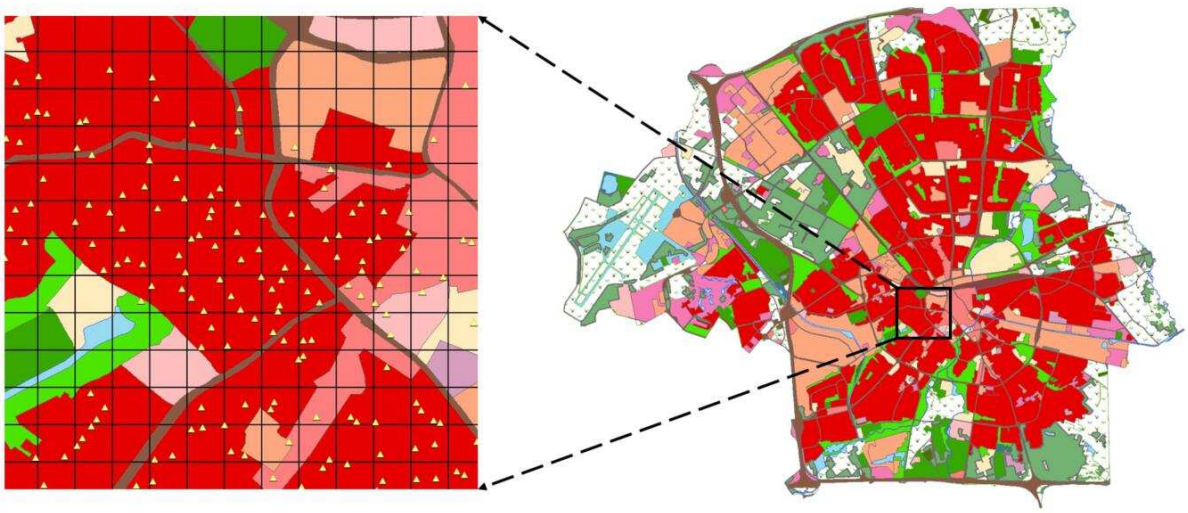

Figure 2: Transaction cases plotted on the grid map in Eindhoven

5 RESULTS AND DISCUSSION

Housing types are classified into four categories: apartments, row house, semi-detached and detached. The hedonic regression model is estimated separately for the four major housing types and the two study areas Eindhoven and Almere. The Enter method was used and non-significant variables were removed to obtain a final model specification in each estimation using 5% alpha level. Table 2 shows summary statistics of the eight models.

Model	City	Adjusted R Square	N
All	Almere	.735	8115
Apartment	Almere	.582	1738
Row	Almere	.462	4804
Semi-detached	Almere	.583	1036
Detached	Almere	.603	491
All	Eindhoven	.784	10698
Apartment	Eindhoven	.718	3894
Row	Eindhoven	.638	4944
Semi-detached	Eindhoven	.718	1211
Detached	Eindhoven	.820	559

Table 2: Summary statistics of the eight models

Given the purpose of the present study, we will focus on the estimation results on the level of the land-use variables. For these variables, Table 3 shows the estimation results for Almere, and Table 4 for Eindhoven.

	Variable	Mean	Std. Deviation	Unstandardized Coefficients B	Standardized coefficients Beta	sig
All	Shopping area	2.523	11.322	.001	.040	.000

Table 4. Hedonic price regression results for the land-use variables in Eindhoven

We will discuss the results of Tables 3 and 4 with regard to the question whether there are differences between the two cities and within cities between housing types regarding the neighborhood land-use effects. First, for the question whether differences exist between cities, we consider the estimation results for all housing types together. In both cities, shopping area, park and sports field, day recreation area and water all have significant positive effects on housing price. For the other land-uses, however, there is no correspondence between the cities indicating that land-use neighborhood effects are dependent on the existing local landscape and housing pattern.

Second, regarding the question whether there are differences in the valuation of neighborhood land-uses between housing types we will consider Eindhoven as case. We consider the different land-uses in turn.

Shopping area has positive effects on housing price for apartments and semi-detached housing and no significant effect for row houses and detached houses. Since the pattern is different in Almere (shopping area only positive for apartment and row), the specific local pattern of housing facilities probably plays a role so that it is hard to generalize the finding.

Similarly, Park and sports field has positive effects on semi-detached housing and detached housing. There is no significant influence on the apartments and row houses. From the overall regression result, the park and sports field land use have positive effects. The possible explanation is that the low-density expensive housing buyers (high-income or family with children segment) are more concerned about the open urban green space for sports recreation compared to the market segment living in apartments and row houses.

Other water body has a low standard deviation in Eindhoven, reflecting the fact that relatively few transaction cases concern dwellings that possess water land-use in the direct neighborhood. In segments where the standard deviation is higher the effect is positive. Therefore, it is plausible that overall water land-use has positive impacts on the housing price. The same holds for day recreational area.

Public buildings have a positive effect on the price of row houses, but a negative effect on the price of apartments in Eindhoven. Since there is no common finding for both two cities, we didn't find significant effect of public buildings. This may be because the public buildings land use type includes so many different types, such as city hall, hospitals, museums, schools and so on. And we didn't specify the type of public facilites. Therefore, since mutiple funtional facilities may affects housing value differently, it is difficult to find a common effect regarding public buildings as a single land use type.

Industry and office has a positive effect on the price of apartments. This land-use mainly refers to business and commercial land-use, including creative business offices and small-scale industry, which are typically located near the city center. Given the nature of this industry negative externalities such as noise and pollution is not in play. That may explain the positive influence on the housing price. The positive influence does not have significant influence on other housing types (based on the overall results in Eindhoven). So the explanation could be that for owners of apartments on average the creative business activities add to the quality of the environment in or around the city center locations.

Road traffic land use has a positive impact on apartment prices and a negative impact on price of semi-detached houses in Eindhoven. In Almere, road traffic has a positive effect on price of row houses. Based on the results of both cities, we can conclude that, to some extent, from row house to semi-detached house, there is a negative effect. This indicates that the balance between convenience and quietness may differ between housing types.

Agricultural and forest are mostly located at the edge of a city. Only the neighborhoods located near the border of the city have agriculture and forest land-use in the direct neighborhood. Agricultural land-use has a positive effect on the price of row houses. This may be an edge-of-the-city effect. Unexpectedly, forest has a negative effect on row and semidetached housing types. However in Almere, all the natural environment land use, including open wet natural terrain, agricultural and forest all have a positive effect. In Almere the allocation pattern of these nature elements is much more evenly distributed compared to Eindhoven. Hence, the negative effect of forest in Eindhoven may not be a generalizable effect.

In conclusion, shopping area and park and sports field are two types of land-use environment that have a positive impact on house purchasers' preferences. Housing buyers' evaluations of industry and office, public buildings, and traffic land use depend on housing type, which may be related to differences in family situations between housing types. Apartment owners prefer industry and office and road traffic area in the

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

neighborhood possibly due to convenience and a city like atmosphere, while house owners of lower density housing assign more value to public buildings in the neighborhood such as schools and hospitals. Agriculture and forest are located at the edge of the city and may reflect how isolated the housing locations are.

6 CONCLUSIONS

In this paper we have proposed and illustrated the use of hedonic price modeling to estimate parameters of a land-use allocation model. The model focuses on housing. Although all land-uses are taken into account, UGS receives special attention given the intended use of the model to analyze urban green scenarios. We showed how a hedonic price model can be specified to fit the framework of the land-use model. A large housing transaction dataset was used and the analysis was conducted for two medium-sized cities in the Netherlands. Hedonic price models were estimated separately for different housing types and a full range of land-uses was taken into account.

The results indicate that UGS indeed has a positive influence on residential real estate prices to some extent. Different UGS types have different impacts on dwelling prices. Comparing the two cities - Eindhoven and Almere - the results indicate that local differences exist that are related to specific characteristics of the spatial land-use arrangement in the two areas. Especially, some UGS types do not occur in both municipalities. We also found structural differences in the way land-use affects housing prices between different housing types that may be related to differences in socio-demographic and socio-economic characteristics. Therefore, the findings indicate that land-use models should be estimated locally and housing market segment specific. The parameter estimates can be transferred to the HARA model system. In a follow-up we plan to develop an application of the estimated model to analyze UGS scenarios to support the development of urban greening strategies.

1 ABSTRACT

The Fourth industrial revolution has created new realities on the spatial growth of urban areas. One interesting phenomenon is the innovative public transportation systems that have emerged in the developing world. Developing countries such as South Africa have seen a rapid improvement in mobility systems, with the introduction of innovative public transport systems such as bike sharing services, bus rapid transport and high speed trains. Building on these innovations is the concept of big data, which has enhance the development of information dissemination systems. The objective of this paper was to review innovative public transportation systems and develop an index to determine the sustainability of these systems. Using an explorative approach the innovative public transportation systems were assessed in relation to the spatial development of land parcels within their proximity. Preliminary results reveal locations within close proximity to the high speed train stations are highly accessible, as there are connected to more one or two other traditional mobility systems which has increased the rate of multi-modal trips in these zones. Although bike sharing services are present in major metropolitan cities, few commuters utilise these services for commuting trips. In conclusion the innovative public transportation systems have improved mobility in the city, however, currently interchange zones between these modes are still limited which has adversely affected the rate of multi-modal commuting. Also economic opportunities over time for citizens have increased in location within close proximity to routes of these innovative mobility systems.

Keywords: Innovative public transportation, Connectivity, Multi-modal, Sustainability, South Africa.

2 INTRODUCTION

Public transportation has over the past decade evolved. Notable examples inlude the introduction of high speed trains, bus rapid transportation and ride sharing servies. In developing world there has been a growth of interest in the concerpt of innovative urban public transport systems. Innovative public transportation uses optimal efficiency to improve the communting experience as a whole. Within the innovation sector of transportation planning, literature focuses on implementation and dissemination of transportation infrastructure and service delivery. However, there is a large gap in the literature related to empirically evaluating the outcomes associated with public transport innovation (Novak, 2015). Whilst there is literature on how innovation can guide policy development, there is still a need for more research that evaluates the impact of innovation on mobility trends. To address this city authorise have developed models to ensure sustainability within the transportation sector (Geurs & van Wee, 2013; Yatskiv & Budilovich, 2017).

With the urban population growing at such a rapid rate, transportation planning is consequently faced with challenges of optimisation of services and infrastructure. Improving the commuting experience is essential in bridging the inequality gap in most developing countries. Developing countries have set a sustainable urban public transport (PT) trend, through the adoption of improved urban PT standards which facilitates transformation through initiatives such as using non-motorised transport, improved urban PT and mobility systems and providing pedestrian walking zones in cities previously dominated by automobiles (Veeneman, 2016; Pojani & Stead, 2015).

3 LITERATURE REVIEW

PT is an essential means of mobility for any city and it‘s dwellers (Potter & Skinner, 2000). Public transport provision provides for the needs of the urban dwellers while providing functionality to a city and it‘s economy (Cardinale et al., 2014; Ryser, 2014; Schwaberger, 2014). Central to urban public transport is the ability to be accessible, reliable, convenient and affordable to the commuters, making movement from one location to another possible (Scoppetta, 2014; Szczech, 2014; Tan et al., 2008; Zhou, 2014). In this regard,

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

urban public transport paves a way for economic, social, health and environment aspects of a city and its dwellers to thrive providing better livelihoods. Significantly, urban public transport plays a crucial role in reducing private motor vehicle use, traffic congestion and environmental pollution in cities across the world. (Tanahashi et al., 2012; GMA, 2013; Tillner, 2014).

Urban PT has vastly evolved into a concept of better possibilities. Moreover, it has become the theatre of innovative ideas, opportunities as well as a platform to collaborate with different sectors in development. Although there is no common definition for innovative, there are still many concepts surrounding the term (Cobbinah et al, 2015). The concept needs to be unpacked as it has elements lined to being smart and the Fourth industrial revolution (4iR). Countless authors have exhausted meaningful means to epitomize the concept of innovative public transportation systems and many cities in the global north and south are in the process of implementing the concept as thorough and best as they can (Zhukova & Smirnova, 2014).

Emerging research studies on mobility have focused on factors which have historically reflected the various levels of accessibility such as distance or time between points of origin to destinations (Castillo & Benitez, 2012; Nil & Naciye 2004). In this interplay of public transportation provision, innovation is not limited to creating new services and improving existing ones. Innovation is also required to reduce transactions costs, enabling commuters to reach their target destinations. Improved travel time, connectivity and information dissemination are a few of the innovations that have been introducted to improve the commuting experience (Legara et al, 2014; Novak et al, 2015; Perl & Goetz, 2015).

In an international context, different methods have been created to obtain new knowledge to develop innovative urban PT, with some researchers focusing on smart cities (Giffinger et al., 2007), transport economics and urban geography (Miller, 2013; Gao et al, 2013). Agostino et al., (2014) have articulated in developing urban public transportation for an agglomeration, technology can be instrument for improving mobility. Currently, the state of urban public transport in most developing countries is gradually improving as evident in South Africa and Ethiopia that have implemented innovative public transport systems namely high speed railway systems and bus rapid transporation sytems in their metropolitan cities (Wilkinson, 2009; Yatskiv & Budilovich, 2017).

Building on such innovations over the years have been new phenomena such as the concept of big data, which has enhance the development of information dissemination systems. Big data has also been described as “datasets whose size is beyond the ability of commonly used software tools to capture, manage and process the data within a tolerable elapsed time. The integration of urban public transport and big data has significantly enhanced the manner in which authorizes manage and monitor spatial interests. Nonetheless, though the potential merits of implementing urban public transport are vast, most African cities are still to integrate them into their daily practice, as most do not have the required mechanisms to do so (Ambrosin et al, 2014; Cardinale et al, 2014).

Given such a background, the physical structures of PT systems encompass the road networks, railways, routes and stops represented by a multifaceted network of spatial and temporal data (Ceder, 2007; Hadasa et al, 2014). Kittelson & Associates et al., (2003), hence have expressed that in order to measure or analyse the connectivity of PT systems, one needs to focus on three key factors: Firstly, the geographic location, that is area where the service is offered. Secondly, the temporal aspects, that is the time factor associated with the service and lastly focus must be given on information that is how accessible is information regarding the service.

Contemporary, information and communication technologies (ICTs) allow public transportation providers to tap into previously inaccessible sources of demand by establishing an instantaneous connection with the city (Geurs et al, 2013; Małeckia et al, 2014). This opens up new possibilities in origin and destination (O-D) analysis as people move around with various mobile devices which are constantly sending information to the internet, such as cell phones, tablets and smart watches. This will allow for more accurate location of trip distribution and also trace the various movement networks. As internet of things (IoT) has led to nearly every device and human being locatable and interlinked (Farooq, et al., 2015). This has greatly made man’s life simpler and transformed how decision making is done, as information is now shared almost instantaneously and at times automatically. However with this interconnectivity concerns of information security have arisen and a call for new means to ensure data is secure arises (Farooq, et al., 2015). With the right capabilities, technology-driven structural change in public transportation systems, greatly reduced trave-times for

commuter. Notable examples have been the high-speed trains, ride-sharing services, and bus rapid transportation.

4 STUDY AREA

Recognising that developing cities are different, we assess the metropolitan cities namely Johanesburg, Pretoria, Ekurhluleni and Cape Town in South Africa (see figure 1). All the four cities are run by an elected executive mayor from a political party. The Gauteng economic hub is made up of three metropolitan cities namely Johannesburg, Tshwane and Ekurhuleni. The innovative public transportation connecting the Gauteng economic hub is the Gautrain, a high speed train (figure 2). Johannesburg is the commercial capital of South Africa with a population of 957 441 people and a surface area of 1,645km2 (Stats S.A, 2011). The Rea Vaya is a rapid bus transporation which connects commuters from the south of the city to the central business district of Johannesburg (Figure 3). Pretoria is located to the north of Johannesburg as is known as the administrative capital of South Africa with a surface area of 687,5 km2 and a population of 741 651 people (Stats S.A, 2011). A Re Yeng is a rapid bus transporation, which connects commuters within central Pretoria (figure 2). Ekurhuleni lies to the east of Johannesburg and is known as South Africa's manufacturing hub with a population nearly 3.2 million and a surface area of 1,975 km² (City of Ekurhuleni, 2013). Harambe is a bus rapid transporation currently being implemented in Ekurhuleni, which is still at the initial stages of operations. Cape Town, located in the Western Cape province of South Africa has a population of 433 688 people and a surface area of 400,3 km2 (Stats S.A, 2011). MyCiti is a rapid bus transporation which connects commuters in central Cape Town (figure 3).

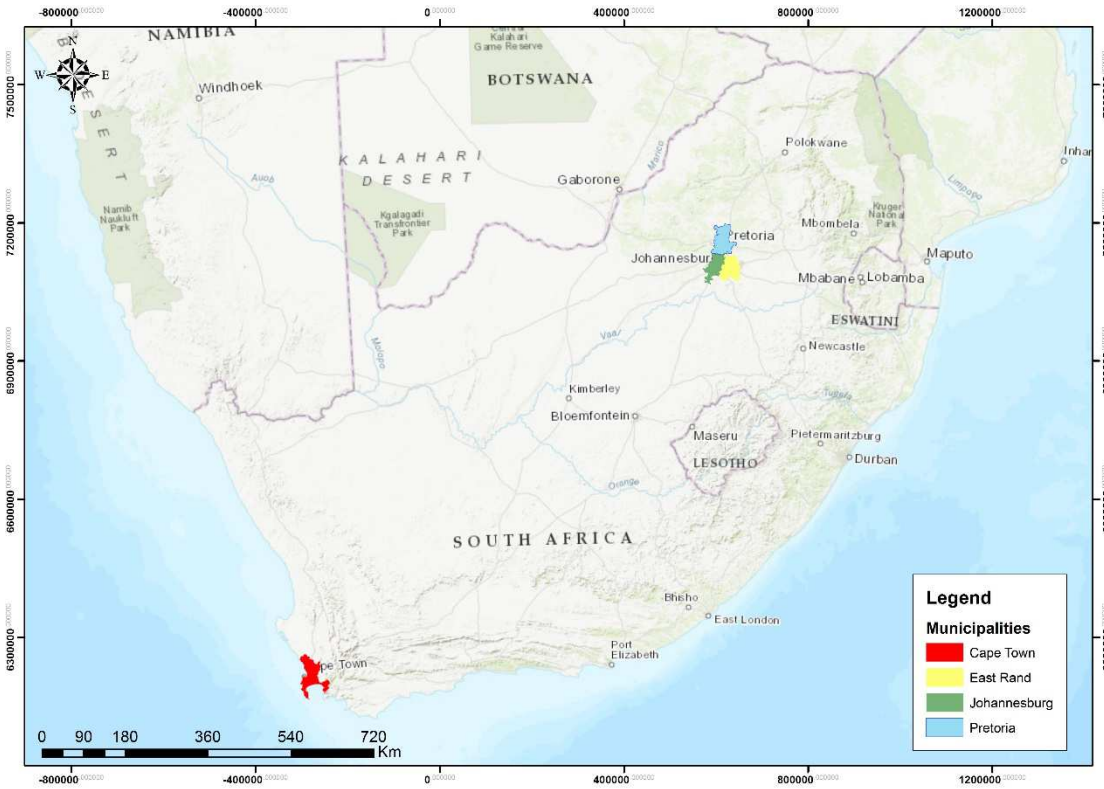

Figure 1: Study Area

5 METHODOLOGY

Using an explorative approach the innovative public transportation systems in the metropolitan cities were assessed in relation to the spatial development of land parcels within their proximity. Key informant interviews were also used to unpack the status quo of urban public transport systems; while spatial data (GIS Shapefiles) are used to visualize rail and road route networks of the urban public transport systems. Consequently a workshop was conducted with a group consisting of four spatial planners (i.e., urban and transport planners) from the four metropolitan cities and 16 masters students from the University of Johannesburg. An index was developed that ranked the public transportation in the cities (see figure 4). For

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

the various mobility systems each was ranked using the developed Index factors and was given a score from 0 to 100.

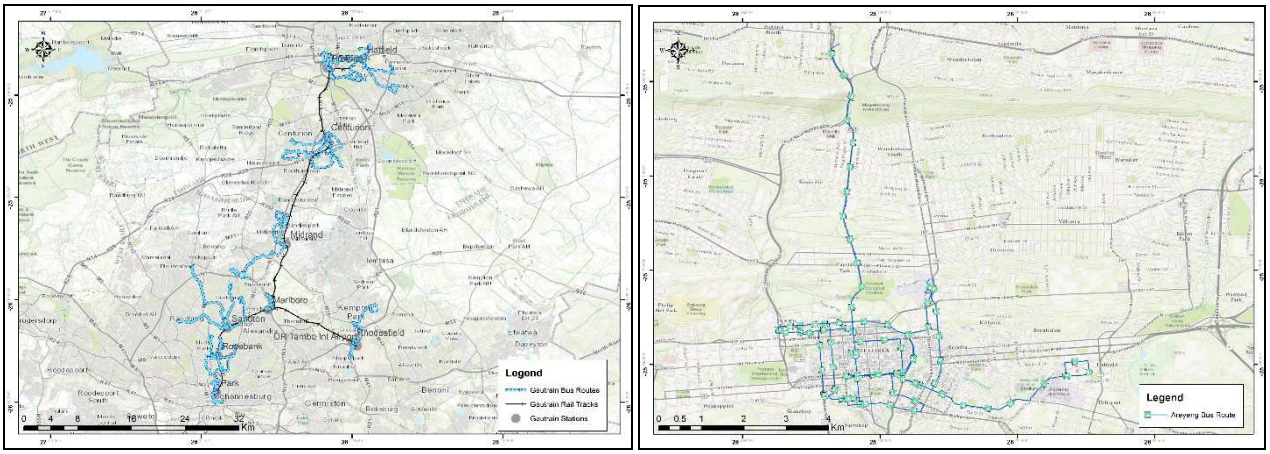

Figure 2: Gautrain (Johannesburg, Pretoria and Ekurhluleni) and A Re Yeng (Pretoria)

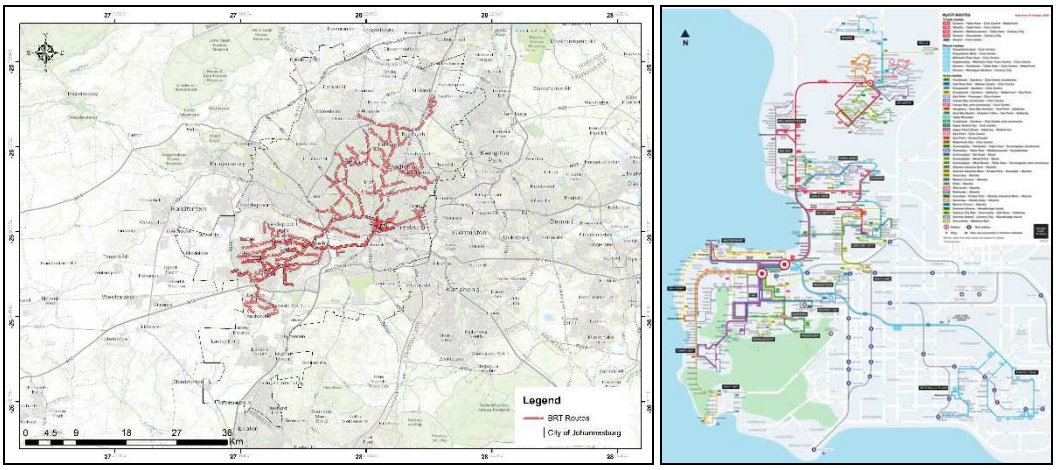

Figure 3: Rea Vaya (Johannesburg) and MyCiti (Cape Town)

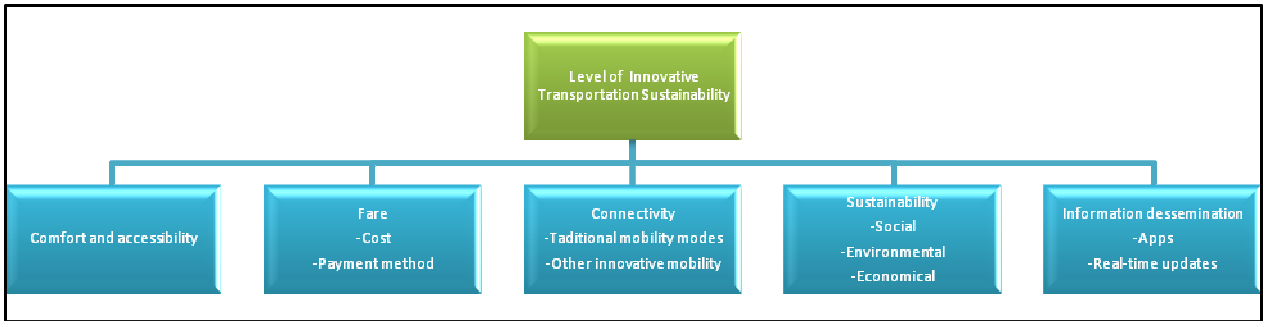

Figure 4: Index factors

6 RESULTS AND DISCUSSION

The results from the inital discussion concerning spatial connectivity of within the metropolitain cities (see figure 5) reveal certain locations along the innovative public transportation routes namely Braamfontein, Rosebank CBD, Sandton CBD in Johannebsurg, Pretoria CBD and Kempton Park in Ekurhuleni are highly accessible, as there are connected to more than two or three traditional mobility systems (mini-bus taxi and other bus services) this which has increased the rate of multi-modal trips in these locations. Regarding connectivity to alternative mobility modes bike sharing services are present in major metropolitan cities, few commuters utilise these services for commuting trips. This has led to most commuting trips in these cities being undertaken either using road or railway based public transportation systems. The innovative mobility modes were then assessed using the index factors as shown in figure 5. The results reveal variations on the utilisation of technology by the varies public transportation providers such as the payment method, with A

Re Yeng and Rea Vaya yet to develop a mobile payment method. Also there are variations in the target groups with the Gautrain targeting commuters within the middle to upper class, whilst all the three rapid transportation targeting all income groups, however with jey focus on the middle income group.

Figure 5 : Innovative mobility modes in relation to Index factors

	Connectivity	Information dessemination	Multiple Fare Payment Method	Comfort	Sustainability
Moderate	60	70	40	30	35
High	65	85	60	50	45
Low	30	35	20	10	5
Medium	40	40	50	34	20

Figure 6: Gautrain

In Gauteng the initial intention for investment in innovative mobility was to improve the economic efficiency of the rail system and consequently enhance the market share of the rail public transportation system compared to road public transportation services. A second goal was to reduce travel time between and within the metropoliatn cities. The creation of high speed train was the innovation introduced. The ineffectiveness of the existing rail public transportation required an introduction of a new railway line, in the form of the Gautrain. Using the index (figure 6), the Gauteng has a high connectivity level to numerous public transportation networks. Investment into social media applications has greatly enhanced information dessemination, which has led to many commuters utilising the Gautrain app, to obtain fare rates, timetables and also to plan their commuting trips. Commuters have also welcomed the tag-in and tag-out system, which can be done with either the train card or bank card. With regards to comfort, the train is reasonable comfort however commuters have expressed the need for more comfortable seats at the train station. Lastly with regards to sustainability over-time, the high speed train has the potential to be the backbone to introduce more innovation into the existing public transportation system.

Medium	25	38	50	34	18

Figure 7: Rea Vaya

In the city of Johannesburg, the Rea Vaya (bus rapid transportation) connects commuters from the south of the city to places of economic interest, namely the Central business district in Braamfoentin, Rosebank and parts of Sandton. The route network connects commuters from Soweto (which has a population of over 1,2 million) to their work places. With such a high demand, this has led to the municipality investing on infrastructural upgrades to support the system. Commuters can either use cash or bank cards to load money on a smart card, which allows them to pay for commuting trips and tag-in and out of the bus stations (see figure 7). Regarding comfort and sustainability, commuters have highlighted concerns with the payment system as the online payment network is unrealiable which has led to commuters seeking alternative commuting modes. However given the high demand for connecting from Soweto to the CBD, the continued investment into the Rea Vaya would greatly improving the commuting experience in the region.

	Connectivity	Information dessemination	Multiple Fare Payment Method	Comfort	Sustainability
Moderate	25	20	25	30	20
High	30	35	30	35	40
Low	5	2	2	3	5
Medium	20	15	20	20	15

Figure 8: A Re yeng

In Pretoria the A Re yeng was recently introduced to improve mobility within the city's CBD. The bus rapid transportation, is within close proximity to tranditional public transportation networks, however more A Re yeng bus routes are still required (figure 8). Information dessemination is currently based on traditional means, namely signage at bus stops and little socia media useage. Fares can be made at disgnated stations, however commuters cannot tag-in with other means. There is still a need to expand the route network to ensure sustainability of the system.

	Connectivity	Information dessemination	Multiple Fare Payment Method	Comfort	Sustainability
Moderate	30	25	40	50	40
High	60	57	60	70	55
Low	10	12	10	5	5
Medium	20	38	30	20	30

Figure 9: MyCiti

Technology utilization in current public transporation systems, promises to increase commuter ridership. In the city of Cape Town, MyCiti (bus rapid transportation) is a notable example of innovative public transportation. The route network is well connected to other existing public transportation systems, namely train, ships and road based public transportation systems (figure 9). The smart card used for boarding the bus can be utilised to make purchases at select shopping centres. Regarding comfort and sustainability, commuters have outlined the seats are funtional and comfortable. The smart-card has over the years been praised for the multi-useability, this which has lead to an increase in commuting trips undertaken using MyCiti.

7 CONCLUSION

In this paper from a spatial prespective, we observe that transportation routes are along commuter points of interest which as some advantages but is not always the best solution to ensure decentralitation of development. Moreover, the preferred solution for one operator does not necessarily coincides with the national public transportation system's best solution. In conclusion the innovative public transportation systems have improved mobility in the city, however, currently interchange zones between these modes are still limited which has adversely affected the rate of multi-modal commuting. Also economic opportunities over time for citizens have increased in location within close proximity to routes of these innovative mobility systems.

1 ABSTRACT

Living in the era of digitalization shapes more or less all the aspects of one's life. The multitude of available technologies extends the range of tools, established processes, and available affordances in many spheres. Cities of the future will not only impact the living patterns of their inhabitants but also require special conditions and requirements for their planning and design. Virtual reality as an interactive tool for visualization and urban planning is no more tomorrow's technology, as it can be seen from the appearance of cheaper and portable virtual reality devices. However, we still lack established routine and multidisciplinary best practices for designing VR educational applications. There are also not enough "visionary approaches" attempting to cross-sectoral exploitation of technologies. In this paper we will try to extrapolate and extend learning use cases of construction and mechatronics to the broader areas of construction and planning sector. We will discuss our experiences and use-cases of integrating innovative visualizations tools in the learning context of construction and planning related fields. Based on this, we will discuss potential applications and links to other disciplines and their integration into the construction and planning sector.

Keywords: Digitisation, Digital Reality, Construction, Education, Virtual Reality

2 INTRODUCTION

Virtual reality as a special type of digital reality attracts steady interest from both the general public and scientific community. People have long been drawn to alternative realities (e.g., storytelling), but physically and technically it has become possible to plunge into another world relatively recently. Though the term "Virtual reality" was coined about 30 years ago, the technology itself has not reached its technical peak yet; neither has been it widely accepted by the community and unleashed its full potential.

Challenges arise starting from the definition of the basics. The majority of definitions given to VR are rather descriptive: digitally generated 3D environment (see e.g., KAVANAGH, LUXTON-REILLY, WUENSCHE, & PLIMMER 2017), as the terminology around the technology also still young and being used inconsistently. A common definition being used in urban planning sciences is the one highlighting the essence of VR as a visualization and simulation technique (PORTMAN, NATAPOV, FISHER-GEWIRTZMAN 2015). Sherman & Craig (2018), the authors of one of the most seminal and comprehensive works about virtual reality, gave their definition of VR emphasizing its integral characteristics as an interactive immersive (both mentally and physically) medium of communication providing synthetic sensory stimulation. We would also delineate our understanding of VR in a narrower and broader sense: the former includes completely immersive (and interactive) instances of VR (frequently referred as those being used with a head-mounted display), whereas the latter brings together under its wing all the other forms of VR (as, e.g., less immersive screen-based ones; MAKHKAMOVA, EXNER, GREFF, & WERTH 2020).

Virtual reality research (as any other research) can be outlined as two general approaches: fundamental, focusing on the VR as it is - as the end target of research and on the understanding on how it works, especially which effect it has on living creatures (e.g., cognitive and behavioural changes when being exposed to VR), including usability concerns, sense of presence, technology advancements etc.; or as a tool - as a utilitarian approach of its application to various domains in form of proof of concept (e.g., what are the effects of using VR as a marketing tool).

Some of the virtual reality features have determined a certain interest in it as a learning tool and medium, and because it is believed to be improving the quality of learning. Scenarios of its application to education has a

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

very wide range, and vary from surgery skills training (GURUSAMY et al. 2009) to basketball tactics (TSAI et al. 2017), from ecosystem science (DEDE et al. 2017) to robotics and kinematics (FLANDERS & KAVANAGH 2015). Among some of the positive results of using VR for learning, researchers reported learners' enjoyment, increased motivation, and long-term retention. However, some systematic studies showed that the results are less obvious and optimistic (e.g., SITZMANN 2011) indicating that the use of VR is rather favourable in terms of enjoyment than in terms of learning.

E.g., one of the advantages of integrating VR into curriculum is commonly discussed in the literature (e.g., WOLFARTSBERGER 2017) is that it enables reality-like natural interaction with 3-dimensional objects and intuitive in operation. Putting aside the question of how intuitive the typical VR input devices really are, let us focus on VR as a medium that delivers decent 3D-output. That is why VR is being used in such domains as construction and adjacent fields, providing great potential for planning, design, and construction management.

3 VR AND CONSTRUCTION

Virtual reality has been recognized as a promising tool to use in the construction and planning industry. Possible implementation are seen especially in the conceptual phase and also in the light of vizualizations for participation purposes, but also for education and training, as well as for adopting it for just widely connected further purposes. This could include, for example, vehicle and utility communications simulation, urban design and planning, as well as digitization and model making of virtual twin-cities.

Thomson, Horne, and Fleming (2006) provided an overview of using VR for urban modeling. Based on the interests of various stakeholders of urban models (e.g., city authorities) and their motives (e.g., attract more tourists), they presented an extensive list of use cases where VR city modeling can be beneficial. Besides, they discuss some important reasons for the practical adoption of VR modeling and some obstacles when doing so. Particularly interesting is the voiced concern about the ownership of the city model.

Wang et al. (2018) conducted a systematic review of 347/66 journal articles published between 1997 and 2017 on the use of VR in construction engineering education and training (CEET). They found that the most adopted approach to VR systems was Building Information Modeling (BIM)-enabled VR. They point out that the possibility to reflect real-time changes in a model may be the biggest advantage of that, but at the same time also the challenge needs to be overcome due to compatibility and connection issues (also discussed in XIE, SHI, & ISSA 2011).

Portman, Natapov, and Fisher-Gewirtzman (2015) focused on the showcasing VR because of the inaccessibility reason (e.g., yet not existent places) in the context of learning architecture, landscape architecture, and environmental planning. They also raised the question of how realistic visualization should be for these purposes (as always: context matters).

Regarding educational purposes, the most common scenario at first glance seems to be safety training. E.g., Sacks, Perlman & Barak (2013) compared construction site safety training in a traditional classroom settings with visual aids and VR training, and found positive effects of VR over baseline for the courses of stone cladding work and for cast-in-situ concrete work, but not for general site safety training, in terms of recall and attention. Rüppel & Schatz (2011) describe the process of the creation of an environment to practice fire emergency evacuation based on a serious game approach. Discussing the capabilities of BIM for data-driven design, they also propose to increase the realism of simulation in a way that affects the human senses, such as binaural and 5.1 surround sound, olfactory exposure (smell of smoke), and feelings of heat and movement. By doing so, it is expected to make the simulation from only "visually satisfying" to more "real", immerse the users to evoke a greater sense of presence - which, in turn, critical to performance in case of emergency.

Nonetheless, the amount of critical papers addressing VR specifically in application for construction and planning purposes in the urban context, seems not to be great. E.g., a cursory search (as of January 2020) conducted in REALCORP database resulted just in 7 papers total with term "Virtual Reality" in their names. In the following sections we will present 2 use-cases from adjacent areas of construction and mechatronics which results could inspire and provide an impulse for further discussion of VR use for broader urban-scale planning context.

4 USE CASE 1: D-MASTERGUIDE - DEVELOPMENT AND TESTING OF DIGITAL LEARNING STATIONS FOR THE ACQUISITION OF MEDIA COMPETENCE IN THE FINISHING TRADE

The research project D-MasterGuide aims to prepare apprentices of crafting professions for the world of future work, where many processes are digitized. Digital visualization tools will influence the planning and construction process more in the future and hence also non.-research-related branches are using these methodologies more frequent in the project work and especially in the training for ongoing experts. Based on Germany-located vocational training centers of the building and renovation trade, it focuses on the encouragement of the apprentices not only to gain required expert knowledge but also methods expertise, media literacy, and self-competence when working with new digital technologies. In order to achieve that, eight domain-specific digital learning stations (DLSs), based on the essence of processes of plastering trade, were created and integrated into master preparatory course framework, with help of a learning management system. DLSs contain anchored instructions, work orders or exercises in order to augment blended learning lessons with a situated learning experience. Apprentices and trainers switch between digital learning sequences and activities in the workshop to review and discuss their results afterward in meetings. This scenario enables new learning dynamics and competence development of the participants. Moreover, lessons are enriched with virtual reality experiences, video animations of the working area, role-playings, open exercises and a self-organized learning environment. Finally, self- and external assessments are the basis for deeper discussions as well as for an increase of self-reflection.

Technical basis of the approach is the Smart Guided Learning System (SGLS) which combines a learning management system with a process guidance component. The architecture is enhanced by various devices, applications and services providing optimal tools depending on task and place of action. Apprentices and trainers are involved in a participatory development process to give direct feedback and derive improvements for the next implementation stage.

Theoretical basis of the approach is Anchored instructions (AI) representing a situated learning content in the form that “anchors” a problem-solving task into a short story or adventure. Every DLS starts with a narrative describing an authentic problem behind the learning content, which was supposed to familiarize the prospective masters with the content of DLS and motivate them by providing also contextualized essence of their future work (e.g., client consultation, agreeing upon the end result of plasterworks). VR experience pieces of training here were conceived as a special type of AI aimed to provide the utmost “reality-like” grounding. That would allow the apprentices to solve real-world problems actively and independently. The relation of those narratives with further knowledge acquisition helps to apply new knowledge in practise. Assuming the apprentices to be novices to that technology, the experience were designed to tailor lack of experience with peripherals etc.

The VR experience is grounded in the story of a house on-site inspection. The learners make a virtual walkthrough around a house that was filmed with help of a 360° camera. The end goal is to identify scope of further work and plan necessary repairs and finishing. In order to achieve that, the apprentices start by outlining all the problem spots on the exterior of the house. Every correctly identified spot was gamified as an question-answer sequences in order solidify the obtained knowledge and also reduce the chance of false positives answers. Figure 1 gives a glance of the VR user interface and snapshot of its use. This used methodologies enables a transferability in related use cases, such as education of architects or also on the job training for building inspectors.

Fig.1: VR experience of a house inspection

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

4.1 Results of evaluation

During continuous evaluation of the approach, we were focused on the user experience and acceptance of the apprentices, as well as their motivation (SCHMIDT et al. in press; SPILSKI et al. 2019). The Proof-of-Concept results indicate that the scenario has a potential of integrating that form of learning into curriculum. The evaluations involving more than 60 prospective masters mostly did not reveal discomfort, motion sickness, low motivation or low acceptance in the target group.

An additional thesis study compared the learning outcomes of on-site house inspection with that one in virtual environment. The apprentices who learned within the VR environment overperformed the control condition in terms of correctly identified problem spots (d = 1.15) and correctly answered questions (d = 0.85). All in all, the usability of the VR environment can be considered as above average (M = 72.85, SD = 10.79).

4.2 Implications for practitioners regarding learners acceptance and integration VR into class

It is specifically important to note that the didactic setting depicts specific work processes. To this end, a virtual learning environment was implemented in such a way that it enables action-oriented learning in a vocational training institution, including for planning tasks. This includes, for example, recording the building structure of an existing old building facade and planning the necessary next steps.

So far, we have focused on the learners perspective: However, during our studies we found that the actual gatekeepers for the acceptance and integration it into the practice are the teachers and lecturers. If they do not translate the value of accepting the technological innovations even when using them and propagating their use in the class, the use of the technology and the acceptance of those by their students will be rare. The problem is that teachers often do not get the time resources to develop expertise with these new methods, or has not developed self-competence, i.e., confidence in use and believe that it can be beneficial.

We also noticed during our evaluations that when using VR application instructors seem to feel a break in regular dynamics between instructors and apprentices. The common routine instructing method in the craftsmanship environment is obviously the three-step-method: Demonstrating – Imitating – Exercising. Therefore instructors tend to adopt the same frontal presentation method in a typical classroom setting where they reinforce their subjectively self-experienced learning from their own learning history. This scenario is one that traditional handcraft instructors would intuitively choose. Nevertheless the VR-application under consideration encourages learners to experience the VR-application on their own, individually. This kind of individualized learning results in a massive loss of control at the instructors side on the one hand and with the chance of compensating looking at the learners as unique persons following their specific learning challenges and having the patience to answer their numerous feedbacks in the learning process being on a par with young people on the other hand. Whereas learners obviously enjoy the kind of new experience an educational institution is saving time-consuming excursions by the VR-application as a substitute a comparable learning sequence would exist in the analog world. Presumably repeated use of VR-glasses will lower this existing motivational effect but strengthen the demand of effectiveness of learning. Consequently, the instructors would have the need as in other typical autonomy fostering environments to improve their own 4C-competencies (4C-didactical model) - communication, collaboration, creativity and critical thinking – in order to cope with the unfamiliar accompanying of the learning process. Nevertheless if the VR-interactions at the frontage seem from the professional point of view to be incomplete the building expert would judge it´s not more than a play and could lose his interest. That is why for sustainable implementation in a VET-course realistic and complete work through by the authoring editors for VR environment is necessary in advance enabling in this case VR-interaction to replace traditional visuals-aided way of teaching.

Although the trainers are very experienced in training small groups of about 15-20 apprentices, they focus mainly on improving manual skills. Therefore, mainly facade construction techniques are taught. In contrast, little or no consideration is given to preparatory and follow-up cognitive work processes (e.g., planning).

Furthermore, vocational training institutions are currently still investing predominantly in analogue, "tangible" technologies. Even for relatively small 4-digit amounts, it is often not greatly affordable. However, current funding policy trends could bring about a change in the investment culture.

5 USE CASE 2: INKRAFT – INCLUSION IN VOCATIONAL TRAINING IN THE CONCRETE CASE OF AUTOMOTIVE MECHATRONICS USING VIRTUAL REALITY TECHNOLOGY

In the project InKraFT, a VR application was developed and used for the training of prospective automotive mechatronics engineers. The virtual environment enables students to learn practical skills as a part of the official training course. Prior to integration, the practical activities and sequence of processes and actions were recorded and documented in detail by an experienced mechanic. Then, the sequence of the individual steps was transferred to the VR environment and embedded in an overarching didactic concept. Specifically, that includes processes of dismantling and assembling an engine and a brake system, measuring and testing the cylinders and performing a compression pressure test. First evaluation results show a strongly increased motivation of the users as well as an increased knowledge transfer into practice. A distinguishing feature of the project is the barrier-free design and the development of alternative input methods and assistance systems in order to match special needs the target learning audience has. Thus, the additional focus of the project is inclusion of people with disabilities into vocational learning. Though this tailor-made solution is designed for the automotive context, the theoretical concept could be transferred also to the planning context because an disassemble engine model could be a disassemble architectural model in another context and the shown principles as well as partly the study results could be transferred in another domain.

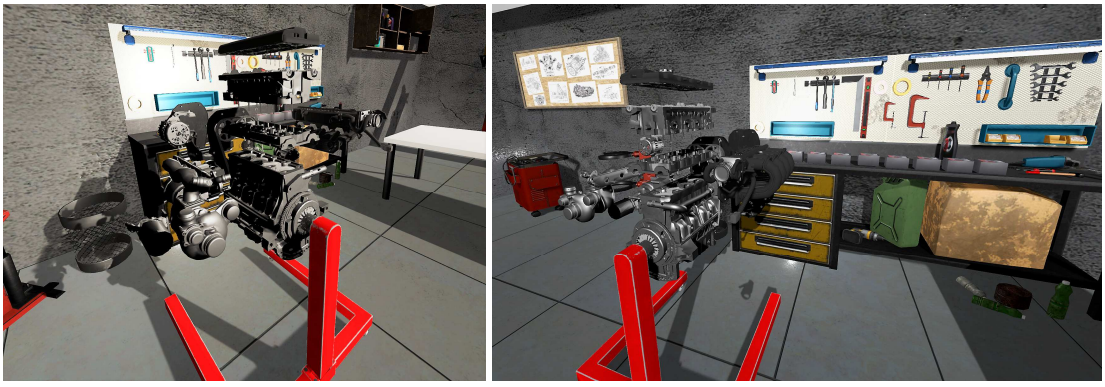

Fig.2: VR experience of an engine dismantling

In addition to the virtual work environment where students can train their practical skills, the VR application is also equipped with a learning room where 360-grad videos with theoretical content can be watched. The videos have been created by other students and provide small learning nuggets on various topics related to the basic course as well as content that builds on this with more advanced topics. The combination of a theoretical, immersive environment and the practical workshop showcases how digital technologies can be used in order to enhance the learning and motivation and at the same time give people with special needs access to the job market, as e.g., as prospective masters with strong diagnostic or teaching orientation.

Fig.3: Use of the VR app and a snapshot of explanatory 360-grad video

5.1 Results of evaluation

A total of 20 subjects (1 female, 19 male) were tested an interim version of the VR environment between March and April 2019. The participants' age ranged between 16 and 56 (M = 29.10; SD = 14.55), with 14 (70%) of participants either working as car mechanics or currently training to become one. Education had a

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

similarly broad range with 8 participants not having a certified vocational education yet, 8 participants with a finished vocational education and 4 participants with either a Bachelor or higher university degree. Participants reported no major visual, auditive or physical 5 impairments, 7 wore prescription glasses due to hyperopia or myopia and one participant reported Tinnitus. Therefore, no participant had to be excluded from participation. All twenty subjects volunteered to participate in this study and either received work time compensation for their participation or participated on their own accord as part of a roadshow, where the VR environment was showcased to the public.

In the pre-questionnaire participants reported some experience with VR (M = 2.40, SD = 0.99; on a scale from 1-4) with 5 people reporting no previous experience with VR systems at all and two participants reporting having their own VR headset at home. No participant reported experiencing major feelings of dizziness during or after interacting with the VR environment with one participant feeling "everything was spinning" during their interaction in VR, possibly due to a technical problem, which was resolved quickly. We used an adapted German version of the igroup presence questionnaire (IPQ) where items were changed to be tailored towards our specific VR use case (exemplary item: "How real did the virtual mechanic workshop seem to you?"). As these are preliminary results without a comparison group, participant scores for the IPQ were taken as single factor and a mean was calculated from all 13 items without the use of the standard three factor structure. Participants overall reported a tendency towards a sense of presence (M = 4.14, SD = 0.65; on a scale from 1-6). We added an open space for feedback and comments on the VR environment at the end in which participants particularly noted the realistic engine and that they had fun while doing the task, while some wished more detailed visualisation for the future. One participant with several years of expertise as mechanic noted "A large step into the right direction. Needs more time & refinement" (translated from German by the authors).

5.2 Implications for design of VR

Virtual Reality applications pose a great challenge for developers when concerned barrier-free design as a priority, because the use of the hardware often requires a strong physical effort. Experience has shown that there are no perfect settings that fits everyone, and the most important thing is to offer alternatives that the user can use to individually adapt the 3D application to his needs. Two essential features of every VR environment are movement and interaction. A barrier-free implementation of these features depends also on the question on which target system the software should run on, since the hardware can be very different. The tasks in a virtual learning environment are versatile and often very complex. For this reason, the tasks should be divided into small steps and always be presented in a way that the user can perceive them with at least two of his senses. In InKraFT all sub-steps are read out aloud by the system, so that people with reading disabilities still have a chance to understand the next necessary steps. All text content and audio instructions are implemented in several languages , so that language barriers can also be avoided. If the user completes a partial step, this is confirmed with a positive sound feedback. If he completes a whole task, he receives an achievement to increase the motivation and the perseverance of the learners. The removal and fitting of crucial screws usually also requires some physical effort, which mechanics with more work experience get a "feeling" for (SPILSKI et al., 2019), which might be difficult to replicate in a virtual space. Since our environment was designed as an out-of-the-box solution for usage in the field of vocational education, we did not include specific forms of haptic feedback and will rely on the HTC Controller or Knuckles as available. For possible solutions to this problem, see e.g. the work of Choi and colleagues (2017) as well as Lee and colleagues (2019) for manual manipulation and haptic controllers. In addition to a solid theoretical foundation it is important to get feedback from the population which the environment is designed for.

This approach towards more participatory and compensatory designing processes is crucial to guide action to meet the needs and preferences of various groups of people. This particular use-case can be extrapolated to the sphere of public participation in planning. The well-known in the software development user-centered approach can be particularly applicable here. Individuals from various stakeholder types should be involved into the planning, designing and decision making processes from the very beginning, not only when the model is ready and needed to be validated on the final steps with finishing touches. Only that can ascertain the hearing real-human concerns and needs.

An important highlight here to takeaway is also possibility of transferring regular processes and procedures in the digital world, as well as replication of "feeling" the place and object in the virtual world.

Though spatial representation of information and certain special abilities was not primarily considered during our approaches when designing and evaluating both VR applications for D-MasterGuide and InKraFT, we could not help but notice that users need additional contextual information for orientation in space. This was especially noticeable in D-MasterGuide, when subjects could not immediately understand that they were moving around just one object in space. For them, it was difficult to combine many mosaic projections from different perspectives into one full-fledged cognitive model.

6 SO HOW TO DESIGN & USE VR FOR URBAN PLANNING AND CONSTRUCTION?

Based on the lessons learned, in this section we will outline our vision when designing and integrating VR experience into practice. We chose the mentioned projects because they represent from a technological point of perspective two different settings with different technological solutions which concepts could be transferred in respective use case in the construction and planning sector. This studies tries to assess the potential fields of application with an evaluation of the potential use. Advocating the “problem first” approach, it would be ideal to start the development of VR application with the questions "Do we actually need VR here?" and "What goals we want to achieve with it?" to gauge whether VR is appropriate medium for that. In the context of such disciplines relying heavily on spatial representation of information as design, construction and urban planning sciences, the utmost reason to integrate VR is to improve ability to examine and explore 3D data.

The main reason for using VR in the first project D-MasterGuide was essentially to have positive effect on the motivation of apprentices but also to bring more authentical practice to the learning without necessity to leave the class. The relevant in that regard is also the emphasis of planning activities, starting with the inspection and determination of weak spots for identification of scope of work. The added value in the long term is the better acceptance and self-competence when using the technologies of such type. As we can imagine, the today’s apprentices will be the practicing professionals in the future, and their ability to be confident with the technologies will determine the ease of which they would integrate them to their daily working routine, e.g., to plan and communicate the vision of project with clients.

Another feature of the project is use of 360-grad VR. We can extend this use-case to the 360-grad construction documentation and also for “digitizing” entities bigger in scale than regular buildings, as in our case. Google Panoramas actually has done a vast amount of work capturing virtual tours of incredible amount of places on Earth (and even further). However, this does present challenges such as problems with wayfinding/navigation and constructing a mental map of the area/object. Although it involves more computational power, using this type of virtual reality to reflect the fourth dimension (i.e., time) in a virtual model is potentially of a big interest, as this could bring up capturing “real” development of the entity. This, obviously, would be more appropriate for the domains where this “reality-likeness” has significant importance. Especially the use for collaborative Virtual Environments (CVEs) is very promising in this field, because they support the non-local communication between planners and public (HÖHL, BROSCHART 2015). This can be used for either greater urban master plans as well as detailed architectural questions with respective level of detail. Especially if planners is personally affected by a project, the visualization techniques can make use of their potential during communication with the general public. In this way, citizens can be sensitized to thoroughly serious urban planning issues in a playful way and form their own opinion, which they can then express in further planning phases.

The focus of the second project InKraFT was, on the other hand, on the acquisition of procedural knowledge with bringing potentials created by the VR application to a very special category of users. Though the latter is not the main focus of this use case in that context and that work, it is still can be reasonable to consider that when applying VR to other areas. Designing with inclusiveness in mind however is not that easy even nowadays, especially for those use to leave without special needs. We can imagine including VR into curricula of urbanists in order to, e.g., familiarize them with daily challenges individuals with special needs face living in various environments. Specifically, some studies have shown that “walking in someone else's shoes” (i.e., perspective-taking induced by means of VR) can lead to a boost in empathy towards special ones (VAN LOON et al. 2018,), especially on the long-term scale (HERRERA et al. 2018).

Turning back to the question of procedural knowledge, the potentials of VR-technology can be supported in a application to such highly complex modelling and problem-solving oriented areas as urban planning,

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

especially what concerns the possibilities to interact with the virtual world in the way it is not possible in real, e.g., scaling up and down, implementing various perspectives, even at once. Virtual reality, as any other technologies, for sure will not substitute all the processes and routines - architects still use 2D blueprints to convey the necessary details without over cluttering the things, but the it can help to go where no one else has gone, to add and to reduce details to the visualization as we wish, experiment in the safe environment and play "what if scenarios".

The main lesson that we learned from the D-MasterGuide is basically the importance of transportation of theoretical knowledge and skills into virtual word, making them testable in real practice, aside from open-mind attitude toward technologies. InKraFT raised some further questions regarding interactive conceptual participatory design. The results from both ongoing projects show that practice and integration them into real-world for sustainable use surely raises subsequent problems that could not be foreseen from the theoretical positions. Here that can be mitigated by involving expertise from other disciplines, e.g., psychologists and pedagogues in order to observe behavioural and cognitive challenges and phenomena going deeper than mere acceptance and enjoyability of the experience. This is especially important to reflect that from the stances of environmental psychology. Churchman (2002) voices those issues and convincingly discusses that such important things as concepts and perceptions of places, territoriality, people in these places, their feelings are not always intuitively or obviously relevant to urbanists. This interdependences and dualism posits indeed demanding and sophisticated mission to solve when we adding into the equation the Unknown "X" in the form of digital technologies.

7 CONCLUSION

Even though the use of VR seems promising for learning purposes and usually receives positive feedback from participants, it is uncontroversial that the research on VR in education and its further integration into practice is still limited. There range of possible applications in the sector of construction and urban planning is considerably wide and can embrace the stages from early planning and concepting to the construction itself, as well as showcasing and validation on later levels. Though, what can be said for sure is, that the variety of fields in these sectors will grow and together with it, the requirements for training and further education. In this paper we argued that exploratory dip in adjacent areas can enrich and revive the veins of VR for UP research. We tried to give a brief overview of state-of-art research focusing on the use of virtual reality in construction and urban planning context, and discussing some of the interesting use-cases as e.g., integration of human senses other than vision for better sense of presence. Based on our experience of two projects that are adjacent to the areas discussed, we broadly outlined some implications that we consider to be fruitful to deepen further, i.e., more interdisciplinary focus involving pedagogical and psychological perspectives; more critical view considering which added value the use of such technologies can bring and what actual ultimate goal is to achieve (and not just integration of those for integration's sake); once more voiced necessity of the user-centered iterative design; bridging the gap between research and actual incorporation of its results into the practice and curriculum, where the main driver in acceptance and digital transformation is still the person who translates them as valuable as a teacher and tutor. Besides, we outlined some problematic areas which are worth further investigation: i.e., question of wayfinding and construction of cognitive models when using the complex VR models; and potentials of VR not only for inclusion but also for empathy and perspective-taking reasons. The given results indicates, that a deep practical integration of the mentioned approaches will always bring up new obstacles for implementation, which cannot be foreseen in the theoretical frameworks. Though, using the visualization methods not only helps for the respective project (public participation of 3D-city models, BIM-analysis etc), but it also could help to improve the willingness of people to be open to new technologies. To achieve this mindset will be crucial for urban planners in the coming decades.

8 ACKNOWLEDGEMENTS

The results are based on the works within the projects "D-MasterGuide" and "InKraFT" which were funded under the project references 01PZ16010 and 01PE17003A-E, correspondingly, by the Bundesministerium für Bildung und Forschung. The authors would like to express their gratitude as well to the European Social Fund (ESF) by the European Union for co-funding.

Feeling Safe in Urban Estates: Learning from Riverwood, Sydney

Samaneh Arasteh

(PhD Candidate Samaneh Arasteh, University of New South Wales, Department of Built Environment, Sydney, Australia, s.arasteh@unsw.edu.au)

1 ABSTRACT

Feeling safe is a necessity for quality of life. Conversely, feeling unsafe has a substantial impact on residents' quality of life. How does design impact on the perception of safety, and moreover, how can design reduce incidences of crime? Safety is influenced by many social, economic, and wellbeing factors that affect residents' experiences of their built environments. Neighbourhood and urban design – which are liable to be affected by the perceived quality of local spaces – are likely to be significant factors influencing broader residents' feelings of safety.

To these ends, this paper reviews recent literature on how design processes have influenced perceived and actual safety in public spaces. This paper focuses on different aspects of urban safety, including planning, management, and design in a mix-tenure neighbourhood. The paper selected Riverwood, a social housing renewal neighbourhood located in southwest Sydney, as the study area. Data collection methods used by the author for this paper include direct-observation and a cross-sectional survey of 62 households, aimed at shedding light on what are residents' preferences to improve safety perception in public spaces.

The paper finds that, for greater safety of neighbourhoods in urban estates, design approaches need to consider both physical and social-cultural factors; and that to achieve this, practical and realistic mechanisms are required to improve existing estates and to design future estates better. The findings of the study reveal that, addressing the concerns revolving around the trust-deficit in the community, will be the cornerstone to promote residents feeling of safety.

Keywords: Feeling of safety, urban estates, safety perceptions, Riverwood, Social housing renewal.

2 INTRODUCTION

Cities are the places where people with various backgrounds mingle with each other, and it is also the place where we can witness a higher intensity and complexity of social life, culture creation, palpable economic development and also strides in science. Globalisation has brought, along with all its virtues, certain negative impacts on the society – which we cannot deny. The apprehensions about safety, the increase in crimes and an ever-increasing feeling of insecurity among the residents were the ultimate downsides of all the development sagas. Due to the constant growth of cities, provision of urban safety, thus become one of the most important pre-requisite to achieve a sustainable development of an urban system; which is reflected in the renewed interest towards urban safety in recent literature (Kudryavzev et al., 2011; Rastyapina and Korosteleva, 2016).

One of the prominent factors, which contribute towards achieving sustainable urban safety, is to experience a feeling of safety in residential areas (Chandola, 2001; Jesus et al., 2010; Whitley and Prince, 2005; Ziersch, 2005). Various studies and observations have indicated that, when citizens are asking for higher safety, they will refer not only to criminal behaviours of the fellow citizens but also to planning and design issues that make a sense of insecurity. Safety perception about a neighbourhood depends on various aspects, such as the location of the neighbourhood, the social, cultural and religious composition of the community which reside in it, the economic disparity among the neighbourhood, as well as the physical design. Therefore, incorporating the residents' idea into the adaptive planning, design and management strategies pertaining to the neighbourhood can lead to increased satisfaction among its residents. Thus, the policymakers at local levels should address urban safety by considering these novel ideas and local governments should make provisions to implement these in existing neighbourhoods and the planning of future establishments.

3 URBAN SAFETY: URBAN PLANNING, URBAN DESIGN AND URBAN MANAGEMENT

Urban planning, urban design and urban management are three crucial attributes for achieving urban safety (Abbott, 2013). Urban planning strategies for creating a safe city should consider factors such as typology of urban spaces, the function of the desired city, its density, its inhabitants and their day to day activities. Thus, urban planning contributes to the improvement of urban safety via managing the distribution of function and

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

activity, the layout of infra-structures, location, and characters of commercial sectors. These strategies play a role in urban safety as well as the quality and liveliness of the cities.

Structures and design of spaces highly affect the actual safety, as well as the perception of safety among its inhabitants. Some places are enjoyable and energetic and convey a sense of well-being, while certain others create anxiety and fear. The urban design addresses the structure of spaces, location of the buildings, the use of the building, layout of green areas and public spaces, street patterns, location of transit stops, and parking areas. Good designs result in a neighbourhood with higher vitality, whereas, bad urban designs may lead to empty spaces, uninteresting environments, fearfulness, unsociable behaviour and higher incidence of crimes.

Good management provides opportunities for neighbours to be familiar with each other and generate Neighborhood Watch programs. Neighbourhood Watch programs are intended to educate the people in these neighbourhoods regarding the security and safety aspects of the neighbourhood, and also it teaches them how to achieve this (Fennelly, L. and Perry, M., 2018). A good space management in the neighbourhood will send a clear message of care and safety, which reassures the residents and discourage the offenders. It also advocates community participation which is an effective solution to improve urban safety (Abbott, 2013). Moreover, managing a place in terms of safety includes maintenance, surveillance, regulation of its use, communication with users, and provision of suitable standards for vulnerable groups (Fennelly, L. and Perry, M., 2018; Fennelly, L. J. and Perry, M. A., 2018). Each of the above activity requires a complicated interaction between the various providers and the beneficiaries in the community. The owners and contracting authorities of a project have to engage these stakeholders in their decisions for considering their jobs and requirements. Similarly, As Carmona (2008) suggests: “in order to manage public space more efficiently, there has been a tendency to carve up the field into smaller units of responsibility, sometimes contracted out to a multitude of private contractors”

Thus, it is necessary to consider these safety strategies in various aspects of urban settlement, right from the initial phases of planning like decision-making, master plans, and urban renewal plans. The following figure shows a blueprint of the possible urban safety strategy that can be achieved by urban management, design and planning.

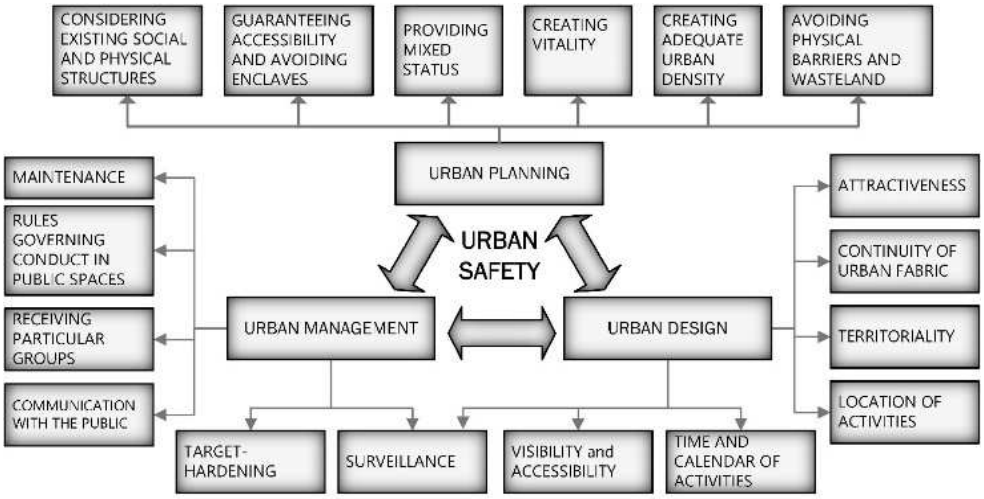

Fig. 1: possible urban safety strategies by urban management, design and planning

4 SAFETY PERCEPTION

One of the prominent factors, which contributes to the sense of health and wellbeing, is to experience a feeling of security and safety in residential areas (Chandola, 2001; Jesus et al., 2010; Whitley and Prince, 2005; Ziersch, 2005). Safety perception can be influenced by environmental and design components, including poor lighting, presence of graffiti, absence of sightlines, other individuals and seating or recreational spaces. It also depends on various factors such as the age and gender, the social position, economic status, personal characteristics, health and political views of the members in the community (Koskela, 1997; Koskela and Pain, 2000; LINDGREN and NILSEN, 2012; Madge, 1997; Pain, 2001; Valentine, 1989). For instance, the above-mentioned factors cause variable perception about safety and security in the neighbourhood among the residents during situations like the re-location strategies in urban

renewal programmes by the government. Research conducted on U.S. tenant relocation plans constantly demonstrated that some residents from public housing, who moved out of their congested neighbourhoods with poverty, feel a higher sense of personal safety in their new settlements (Goetz and Chapple, 2010; Popkin et al., 2009). On the contrary, certain people who were relocated from public housing districts to new neighbourhoods, experienced a higher degree of insecurity in their new establishments (Brooks et al., 2005; Popkin et al., 2009). A meta-analysis conducted by Goetz and Chapple (2010) between 1995 and 2010 revealed that there is no statistical relationship between these individual perceptions and the actual benefits of the migration like mental or physical health. On the contrary, interviews with the participants of large-scale Scottish research among the tenants re-housed in a novel social rental neighbourhood showed less anxiety among the participants while getting out of their house in the new neighbourhood. These feelings of safety and security in their newer neighbourhoods can lead to better social behaviours among the residents (Forrest and Kearns, 2001).

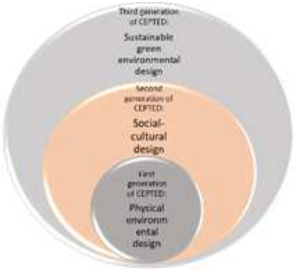
5 URBAN SAFETY AND CRIME PREVENTION THROUGH ENVIRONMENTAL DESIGN (CPTED)

Crime prevention through environmental design (CPTED) is one of the branches of spatial practices that address interventions by focusing on the place-based approaches to reduce crime, and enhancing spatial cognition, as there is a relationship between a place and perception of being safe and secure at that particular place (Fennelly, L. and Perry, M., 2018). Brantingham and Brantingham (1981) mentioned that four dimensions should be considered for any approach towards crime prevention; which are locations, targets, offenders and the prevailing laws in that region. Similarly, Erdoğan (2010) asserted that place-based approaches to reduce crimes and fear of crimes are based on the theory that there is a relationship between spatial features of a particular place, which can support or encourage criminal activities. Thus, crime location is one of the most prominent dimensions of a crime, as crimes are not randomly dispersed in modern urbanised regions.

Particular areas are found in cities, which are identified by the public and administrations as 'hot spots' of crime which are not safe (Eck et al., 2005). In these scenarios, suitable designing and efficient application of the fabricated environments may result in the decline of fear and the occurrence of crime and thus improves the safety and quality of life among its residents (Crowe, 2000). Various studies have proved the efficacy of design options in the reduction of crime and emphasised the role of CPTED (Jacobs, 1961; Lynch, 1984; Stiles, 2009).

The CPTED theory has evolved over time and we can broadly categorise them into three generations (Fig. 2 and Table 1):

- First-generation: Physical Environmental design
- Second-generation: Social- Cultural design
- Third-generation: Sustainable Green Environmental design



Physical environmental design	Natural surveillance Natural access control Territorial Reinforcement	Image management Target hardening
Social-cultural design	Social cohesion Connectivity	Community culture Threshold capacity
Sustainable green environmental design	Energy crisis Natural energy	Recycling and minimizing waste

Fig. 2: A dynamic integrated model for CPTED (Adapted from Cozens and Love (2015)), Table. 1: The principles of Crime Prevention Through (CPTED) (Adapted from Cozens and Love (2015)

Each generation is a guideline to create a mixed-use and walkable communities that have numerous benefits from a crime prevention point of view; which can be created by proper urban design, management and planning (see Fig. 2). The 1st generation of CPTED was a set of approaches to prevent crimes which are related to urban design. The 2nd generation of CPTED concentrates on the approaches for eliminating the root causes of criminal behaviours through sustainable and rich environments which are related to urban planning and management. Similarly, urban planning and management play a major role in the 3rd

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

generation of CPTED, which concentrates mainly on the security and consider it as a universal problem. The 3rd generation CPTED attempts in providing a guideline that can be applied in social, political, and geopolitical divisions (Fennelly, L. and Perry, M., 2018).

6 METHODOLOGY

The research started with a review of literature and direct-observation (by using drawings, note-taking, photography, and mapping), followed by a field study. The data collection in the field was using household survey questionnaire (Table 2). The questionnaire sample included 62 adolescents, both genders and aged 18 or over.

Data collection methods	Target area or population	Purpose
Direct-observation	Social housing renewal projects	Finding criteria to measure safety in public spaces. Selecting a case study area
household Survey questionnaire	Residents	Residents' perception of safety Residents' expectations for safe public spaces. Residents' needs Residents' experience about safety What are the existing safety problems in the area?

Table 2: Stages of data collection.

A case-study approach was chosen to gain a detailed understanding of the context. Table 3 shows the criteria to determine Riverwood as a case study area.

Criterion	Reason
Social housing neighbourhoods with different socio-economic level	To enable safety development to be investigated in different socio-economic contexts.
Social housing renewal projects	To explore safety issues before and after renewal.
Medium to high-density estates	Potential for future urban model
Crime rate	Potential for safety improvement

Table 3: Case study selection criteria.

6.1 Case study area

The neighbourhood chosen as the study area is part of the Local Government Area (LGA) of Bankstown and state suburb of Riverwood (Fig. 3). Riverwood today is an established residential suburb with its commercial centre focused around the intersection of Belmore Road and the East Hills railway line. The suburb is located approximately 18 kilometres (km) south-west of the Sydney CBD and is situated within the municipalities of Canterbury and Hurstville.

The study area consists of two urban renewal projects undertaken by the NSW state government and has been held up as a model for the future; where one site has already been re-developed and the other one is under re-development. The former is the Washington Park Development which was renewed by Payce developer and the latter one is currently being redeveloped by the Communities Plus (Fig. 3). Riverwood is an integrated housing neighbourhood consisting of social housing, affordable housing and private housing. These dwellings comprise a range of housing types from single cottages to high rise residential apartments. The age of the housing stock ranges from buildings built in the mid-1950s through to relatively recent projects from the mid-2000s. The Riverwood estate is within a 1100m radius of Riverwood Station and the Riverwood shopping centre is located to the south (NSW Government, 2018). Figure 4 shows a pictorial overview of Riverwood study area.

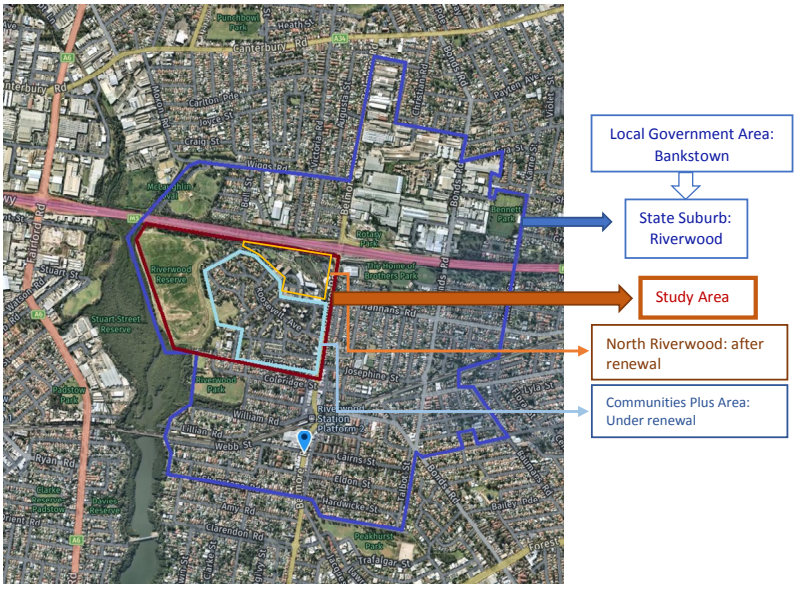


Fig. 3: Map of Riverwood study area (Nearmap, 2019)

Fig. 4 Pictorial overview of Riverwood study area (Researcher, September 2018)

According to the Australian Bureau of Statistics (ABS) household and family projections, between 2006 to 2016, the Riverwood estate residents came from a diverse set of countries and had various racial backgrounds. Many of its residents born in China, Taiwan and Lebanon has declined, and those from other countries such as Australia, Philippine and Sudan showed a sharp increase. The population of listed races in Riverwood in 2006, 2011 and 2016 were 1620, 1484 and 2356 respectively. The largest number of people immigrating to Riverwood from 2006 to 2016 were from the south and southeast Asia and New Zealand. The immigrants from India grew at 833.3%, followed by those from Sudan at 683% and those from New Zealand at 104.1%.

Statistics relevant to the understanding of crimes at Riverwood were obtained from the NSW Bureau of Crime Statistics and Research (BOCSAR). The hotspot map depicts the density of incidents of non-domestic assault and domestic assault crimes in Riverwood estate (see Fig. 5: a and b). The five most common offences reported in the estate in 2006, 2011 and 2016 were theft, malicious damage to property, transport regulatory offences, assaults and the offence of 'Against Justice Procedure'. 'Theft' was the major crime in Riverwood in 2006 and 2011 and the second major crime after 'transport regulatory offences' in 2016. Four offences with the highest incidents were the same in 2006, 2011 and 2016 but with different varying incidence (see Fig. 5: c). Except for malicious damage to property, which was reduced from fifth to the sixth place in the most reported offence's list in 2016, the other four stated offences held their positions as the top crimes. Drug offence was placed in the fifth place in the list of the first five offences in 2016, which has linearly increased from 31 incidents in the year 2006 offences to 101 incidents in 2016.

6.2 Data Collection

Household surveys were conducted in the study area using the questionnaire method. The residents were provided with a questionnaire having five closed questions (with 10-13 sub-questions) about the relationship between the quality of the neighbourhood and public spaces, and the perceptions of safety in public spaces. The scale or measures of public spaces quality and safety perception were selected based on the first and second generation of CPTED (See table 1).

The household surveys were conducted on random days between 10:00-17:00 from February 2019 to June 2019. The inclusion criteria to choose participants were their age (age should be more than 18 years) and their residential area (the participants should be from the study area).

7 RESULTS

7.1 The Perceived Safety of the Residents

The response by the participants about the perception of safety was categorized into three groups:-

(1) Safe (includes Very Safe and Fairly Safe)

(2) Unsafe (includes Very Unsafe and Fairly Unsafe)

(3) No opinion (Neutral)

The public areas considered for the study included the immediate area around the individual house/ apartment, playgrounds, public gathering spaces, shopping areas, resting areas and community gardens.

Out of the 62 participants, 87.09% of the respondents said that the public spaces in these neighbourhoods were safe during the day time, whereas during the night time only 46.77% felt these areas are safe (either Very safe or Fairly safe). 6.45% among the respondents had no opinion about the safety of public spaces during daytime and 4.83% during nighttime safety. 54.83% of the participants were females. The gender variation regarding the perception of safety is shown in Table 4. Among night-time safety, 82.14% of the males felt the public spaces in the neighbourhood safe, whereas it was only 17.64 % for the females.

Participants	Daytime			Nighttime		
	Safe	Unsafe	No opinion	Safe	Unsafe	No opinion
Female (34)	28 (82.35%)	3 (8.82%)	3 (8.82%)	6 (17.64%)	26 (76.47%)	2 (5.88%)
Male (28)	26 (92.85%)	1 (3.57%)	1 (3.57%)	23 (82.14%)	4 (14.28%)	1 (3.57%)
Total (62)	54 (87.09%)	4 (6.45%)	4 (6.45%)	29 (46.77%)	30 (48.38%)	3 (4.83%)

Table 4: Gender-wise comparison of the perception of safety in public spaces during the daytime with that of nighttime.

Among the public spaces, the immediate surroundings near to each one's house or apartment was found to be the most unsafe area among the respondents (58.06%), followed by playgrounds (50%) and community gardens (35.48%). None of the respondents felt shopping areas to be unsafe. The opinion of the residents towards safety in various public spaces in the neighbourhood is depicted in Figure 6.

Fig. 6: Perceived Safety of specific locations inside the neighbourhood.

The next group of questions in the questionnaire were related to the general factors in the neighbourhood, which made the residents feel safe or unsafe. The factors considered for the study were:

(1) Impact of criminal offences in the surrounding neighbourhoods

(2) Impact of lack of activities in their neighbourhood, especially in the evenings.

(3) Effect of trees and vegetations that might create blind spots or hiding places

(4) Presence of high-density residential areas in the neighbourhood.

(5) Presence of Wastelands in the neighbourhood

(6) The effect of unattractive public spaces in the neighbourhood

(7) The impact that can be caused by the presence of Police in the neighbourhood.

(8) Winter weather.

Figure 7 clearly shows the residents reaction towards each of the above factors and their impact on their feelings of safety in the neighbourhood. 30% of the participants felt that criminal offences in the surrounding neighbourhoods negatively affect safety in their neighbourhood. The large majority of the participants indicated that the presence of police force in the neighbourhood would help in controlling the crimes. An interesting fact was that, for a small proportion among the participants (20%), feelings of unsafety tend to have seasonal variation, with winter weather increasing their fear and making them feel insecure.

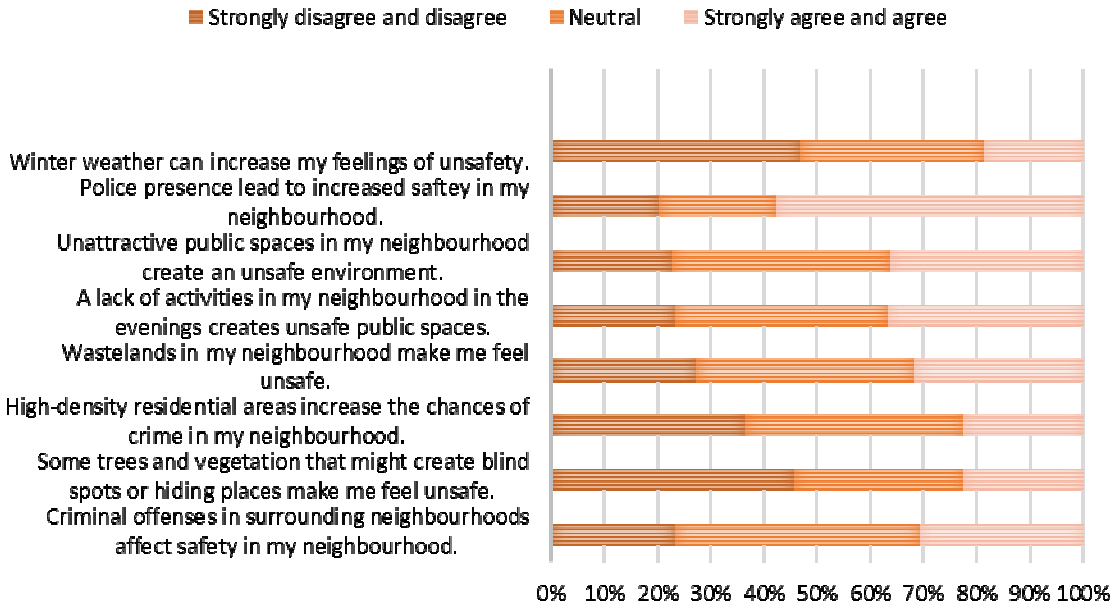

Fig. 7: Residents opinion regarding various factors and their effect on the perceived safety in the neighbourhood

Within the respondent group, drug abuse or dealing with drugs was the most important factor which made the participants feel unsafe in their neighbourhood (100%), followed by alcohol-related issues (90%), anti-social and nuisance behaviour (85%), robbery (85%), and Graffiti and vandalism (47%) (Fig. 8).

7.2 Residents' suggestions for improving safety conditions

This part of the survey was designed to understand the importance of physical, social and cultural factors for feeling safe in the neighbourhood according to residents' suggestions. The scale or measures of these questions were defined based on the first and second generation of CPTED principles. All the questions in the questionnaire were close-ended.

This part had 2 sections:

PART 1: Suggestions for improving the neighbourhood using the Physical Environmental Principles, and

PART 2: Suggestions for improving the neighbourhood utilising the Social- Cultural Principles.

Table 5 shows the suggestions by the residents for improving the safety perception in their neighbourhood by physical environmental factors.

Table 5: Residents' suggestions for improving the perception of safety in their neighbourhood by modifying the Physical Environmental factors

A summary of the main social-cultural principle to improve safety, indicated by the respondents are presented in Table 6.

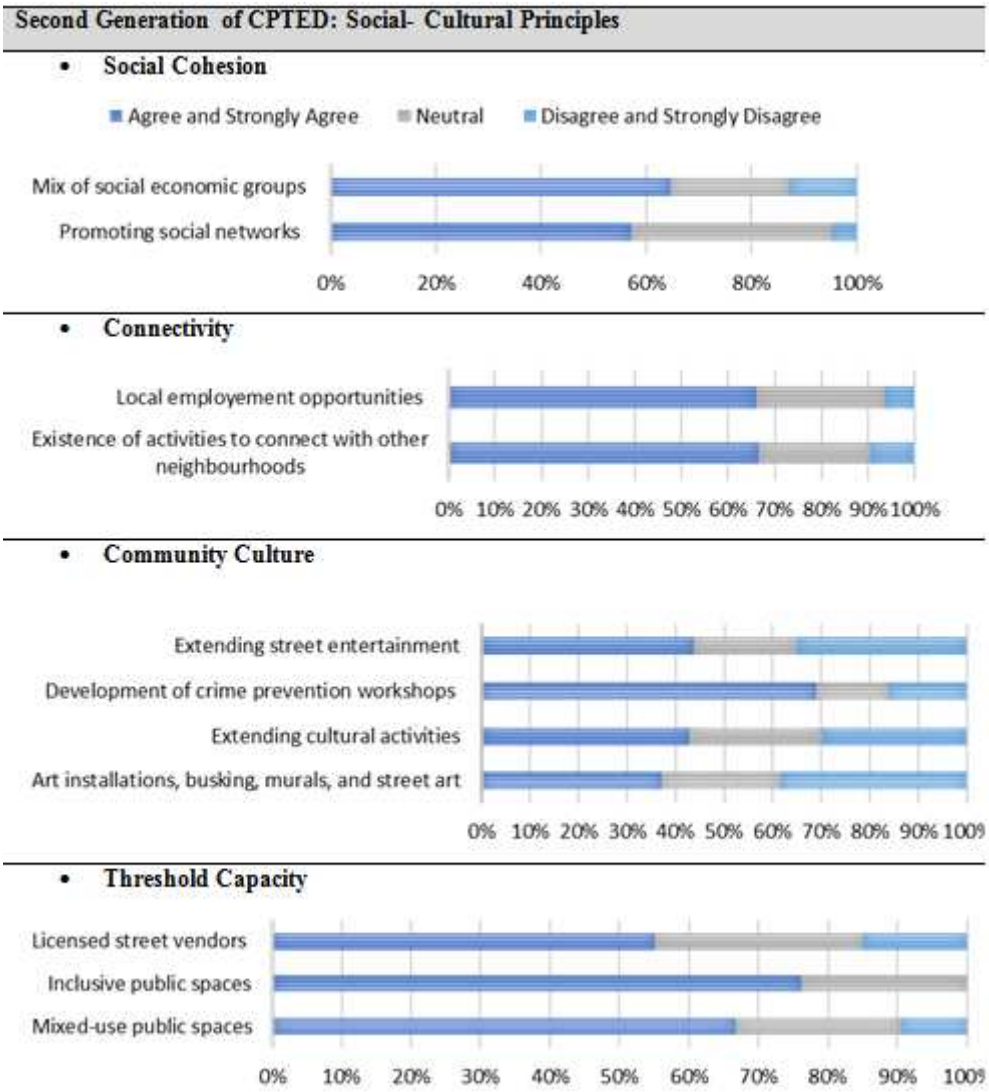

Table 6: Residents' suggestions for improving the perception of safety in their neighbourhood by modifying the Social Cultural factors

8 DISCUSSION OF THE RESULTS

Perception of safety is one of the most significant factors in livable public spaces, which is influenced by various social, cultural, and environmental factors. Residents' perception of safety is a subjective measurement and it is influenced by their preferences.

Safety feelings can impact people's quality of life as well as the social and economic wellbeing of a community (Cai and Wang, 2009, pp. 221–222; Klima et al., 2016; Michalos and Zumbo, 2000; Sugiyama et al., 2009). The social and economic wellbeing of a community is a vital element for the success of a city because these principles help build a sense of community among its residents (Cai and Wang, 2009; City of Sydney, 2018; Fennelly, L. and Perry, M., 2018)

According to the aspiration model proposed by Campbell et al. (1976), there is a relationship between residential preference, perception, and satisfaction. His model shows that residents assess their neighbourhood characteristics, and they compare their expectations to what they really have. Lang (2010) has opined that - "Fundamental to any understanding of human activities within the built environment and feelings about it is an understanding of the processes of perception". In his study, very often residents would declare feeling generally safe in public spaces located in their neighbourhood (87.09%) but still would point out that some public places during the night trigger unsafe feelings. The high rate of safety feeling among the residents can be due to the fact that, they sometimes adopt their preferences with their actual life situations.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

By comparing the incident records and residents' perceived safety, it can be noted that there is a discrepancy between the types of commonly perceived crimes and that of actually recorded ones; which can be attributed to individual experiences. For example, if a particular person had a bad experience of drug abuse within themselves or in their family, then they tend to implicate drug abuse as the most important crime which makes them insecure. Jackson (2004) has pointed out that the gap between the perception of crime and the actual crime rate can be because of the different cultural meaning of crime prevalent in different communities. The perception of the public towards crime has an important effect in making policy decisions addressing crimes (Cohen, 2000). The results of this study are in accord with the recent studies, indicating that, policymakers should consider the perception of crime as well as actual criminal records when they make decisions related to law enforcement.

Overall, the residents' perception of safety is important to understand which factors are more effective in terms of providing a feeling of safety. They have different suggestions in terms of both physical and social principles, to improve the safety environment in the public spaces located within their neighbourhood. A possible explanation for this might be that, in a neighbourhood environment that is well planned, well designed and well managed; residents will feel comfortable and have a sense of belonging. This sense can be achieved not only by improving the physical environmental design but also by implementing a favourable social-cultural design. The recommendations for the estate of Riverwood is certainly to engage residents in the Neighbourhood Renewal Process in all the different stages - design, planning and management; in order to create a sustainable development.

9 CONCLUSION

The present research reveals that the feeling of insecurity increased at night for the female residents in a significant amount, in comparison with day-time, but this pattern could not be observed with similar strength in males. To improve the feeling of safety in their neighbourhood using physical environmental principles, close accessibility to public transportation, developing pedestrian-friendly streets and installing physical security devices were the suggestions which were supported overwhelmingly by the residents; whereas the distribution of parking areas and the ownership of the residence could not gather much support. With regard to utilisation of socio-cultural principles in improving the feeling of safety, development of crime prevention workshops, inclusive public spaces and connectivity were the most supported ideas, but there were few takers for the suggestion of installing artworks to improve safety. The findings of the study reveal also brings out that, addressing the concerns revolving around the trust-deficit in the community, will be the cornerstone to promote residents feeling of safety.

To summarise, the paper finds that, for greater safety of neighbourhoods in urban estates, design approaches need to consider both physical and social-cultural factors; and to achieve this, practical and realistic mechanisms are required to improve existing estates and to design better estates in the future.

Flächenkonflikte urbaner Mobilität – mit Flexibilisierung zu mehr Raumpotenzial?

Antonia Stratmann, Sina Diersch

(M. Sc. Antonia Stratmann, RWTH Aachen, Wüllnerstr. 5b, 52062 Aachen, stratmann@staedtebau.rwth-aachen.de, Forschungskolleg Nachhaltige Energiesysteme im Quartier)

1 ABSTRACT

Dieser Artikel ist eine literaturbasierte Analyse des Konzeptes der Flexibilisierung in der Planung von Verkehrsflächen zur Schaffung von mehr Raumpotenzial. Bei der Aufteilung des öffentlichen Raumes mit seinen dominierenden Verkehrsflächen wurden jahrzehntelang nicht die Verkehrsmittel des Umweltverbundes bevorzugt, sondern vor allem flächenintensive Verkehrsarten wie den privaten Pkw: Das ist das Ergebnis der einseitigen Orientierung am autogerechten Paradigma der 1960er und 70er Jahre. Um Räumen in der Stadt im Sinne der aktuellen Debatte um ‚Flächengerechtigkeit' neue Nutzungen zuzusprechen, braucht es zeitgemäße Ansätze unter Zuhilfenahme neuer Planungsphilosophien. Dabei müssen innovative Wege der infrastrukturellen und regulativen Gestaltung gefunden werden.

Vor diesem Hintergrund soll in dieser Publikation der Fokus auf die Flexibilisierung von Verkehrsinfrastrukturen gelegt werden. Flexibler Städtebau zeichnet sich durch seine Fehlertoleranz aus. Es wird eine Basis bereitgestellt, die den Aus-, Rück- und Umbau zulässt. Sowohl für aktuell bestehenden Flächenkonkurrenzen als auch für die sich stark wandelnden und noch schwer kalkulierbaren Entwicklungen urbaner Mobilität können flexible Verkehrsinfrastrukturen ein Lösungsweg sein. Daher lautet die Forschungsfrage dieser Arbeit: „Ist der Ansatz von Flexibilisierung der Verkehrsflächen ein Lösungsweg, um im Kontext städtischer Mobilität aktuellen Herausforderungen der Flächenkonkurrenz zu begegnen?" Mit Hilfe einer Literatur- und Dokumentenanalyse soll die Fragestellung beantwortet und diskutiert werden.

Im Rahmen der Publikation werden zunächst die aktuellen Herausforderungen städtischer Flächenkonkurrenz im Kontext der urbanen Verkehrswende dargelegt. Darauffolgend wird der städtebauliche Ansatz der Flexibilisierung definiert und abschließend auf die Gestaltung städtischer Verkehrsflächen angewandt. Als Untersuchungsbeispiel dient die Seestadt Aspern, welche in ihren Planungsdokumenten Flexibilität berücksichtigt. Die Publikation wird literaturbasiert eine Übersicht über die Möglichkeiten und Chancen sowie die Schwächen des Konzepts gegenüberstellen. Abschließend folgt die Diskussion der Frage, inwiefern sich Ansätze der flexiblen Raumplanung im Sinne der Herausforderungen der Verkehrsinfrastrukturplanung als zielführend erweisen können.

Keywords: Flexible Verkehrsflächen, Urbane Mobilität, Flexibilisierung, Verkehrsplanung, Nachhaltigkeit

2 FLÄCHENKONFLIKTE URBANER MOBILITÄT: HERAUSFORDERUNGEN AN URBANE VERKEHRSINFRASTRUKTUREN

Die Vielfalt der Nutzungen des urbanen Raums in seiner Funktion als Verbindungs-, Erschließungs- und Aufenthaltsraum (vgl. Brilon 2005) nimmt stetig zu. Die Diversifizierung des Nutzerinnen- und Nutzerverhaltens stellt dabei vielfältige (versorgungstechnische, wirtschaftliche, ökologische, verkehrliche, soziale, kulturelle und gestalterische) Anforderungen an die Straßenräume einer Stadt (Notz 2016). Angesichts des immensen Bedeutungszuwachses, den die Verkehrsplanung im Laufe der Zeit gegenüber der Stadtplanung erlangt hat, geraten nicht-verkehrlichen Nutzungsformen allerdings zunehmend in Vergessenheit (vgl. Bendiks/ Degros 2019: 14). Denn, bedingt durch starre Infastrukturen, etablierte Verkehrsträger und einflussreiche Akteurinnen und Akteure, wie Automobilunternehmen, zeichnen sich Verkehrsräume durch ein hohes Maß an Pfadabhängigkeiten aus (Butzin/Rabadjieva 2018: 9). Dabei zeigt sich die Infrastruktur gerade in wachsenden Städten und Städteregionen mit steigenden Einwohnerinnen- und Einwohnerzahlen sowie Pendlerinnen- und Pendlerzahlen tendenziell als überlastet. Im Zuge dessen verschärfen sich auch die Flächenkonflikte im und um den endlichen urbanen Raum (vgl. Agora Verkehrswende 2019). Die wachsenden Ansprüche an räumliche Qualitäten, starre Nutzungsrechte und die mangelnde Kompatibilität einiger Nutzungsformen können dabei verkehrssektorintern und -extern zu Zielkonflikten und Flächenkonkurrenzen führen (vgl. BMUB 2015). Im von einer unsicheren sowie unberechenbaren Entwicklung geprägten urbanen Raum, gilt es daher neuartige Ansätze in der Verkehrsplanung zu fokussieren. Darüber könnten neue Raumpotenziale generiert werden, die sowohl den

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Verkehrsträgern des Umweltverbundes als auch vielfältigen nicht-verkehrlichen Nutzungsansprüchen Rechnung tragen.

Vor dem Hintergrund seiner gesamtgesellschaftlichen Relevanz, ist die Qualität des Straßenraums von essentieller Bedeutung für urbane Lebensqualität. Gleichzeitig ist eine leistungsfähige, bedarfsgerechte und moderne Verkehrsinfrastruktur eine wesentliche Grundvoraussetzung für Wettbewerbsfähigkeit, Wachstum und Wohlstand der Städte. Neben öffentlichen Gebäuden und Freiflächen besteht der öffentliche Raum einer Stadt anteilsmäßig zu großen Teilen aus Straßenraum. Zumeist wird dieser Straßenraum allerdings „gemeinhin eher als technisches Artefakt oder als Verkehrsfläche für zumeist motorisierte Fahrzeuge wahrgenommen und weniger als Freiraum für Menschen." (Notz 2016: 4) In seiner Rolle als Allmendegut, das allen Nutzerinnen und Nutzern und ihren Ansprüchen gleichermaßen zur Verfüng steht, wird er oftmals vernachlässigt. Das Straßenrecht, das die Nutzungsrechte für öffentliche Straßen im Allgemeinen regelt, unterstützt diesen Effekt: Der Auffassung einer ‚Konzeption des Gemeingebrauchs' wird prinzipiell nicht widersprochen. Allerdings spiegelt sich die historisch gewachsene Auffassung, nach der „der öffentliche Raum in erster Linie ein verkehrlicher Transitraum ist" (Ruhrort 2019: 203). Dieses Postulat, das sowohl in der öffentlichen Wahrnehmung als auch im Recht reproduziert wird, und das dem Verkehr eine Vorrangstellung in der Nutzung des Straßenraums einräumt, führt in autogerechten Strukturen dazu, dass urbane Flächen faktisch vom motorisierten Individualverkehr dominiert wird, da er mit Abstand die meisten Flächen und Nutzungsprivilegien beansprucht und zugesprochen bekommt (ebd.). Demzufolge wird je nach absoluter Flächenverfügbarkeit, sowohl die Nutzung alternativer, flächen-, raum- und energieeffizienter Formen der Mobilität als auch die Befriedigung anderer Nutzungsbedürfnisse durch die Dominanz des motorisierten Individualverkehrs konterkariert und Flächenkonkurrenzen produziert.

Trotz erheblich geringeren Flächenanforderungen werden die Verkehrsmittel des Umweltverbundes faktisch benachteiligt, indem gesamtgesellschaftliche Ressourcen (Parkraum) für bestimmte Nutzerinnen und Nutzer reserviert oder sogar privatisiert werden, wobei gleichzeitig die Kosten für die Bereitstellung eben jener Flächen der Allgemeinheit angelastet werden (vgl. Kühne 2018). So konstatiert Notz (2016), dass endliche „Kapazitäten, Nicht-Ausschließbarkeit der Nutzung und Rivalität im Konsum" dazu führen, dass Flächenkonkurrenzen entstehen, da „Allmendegüter in der Praxis oftmals übernutzt werden, gerade wenn ihr Verbrauch ungehemmt möglich ist" (vgl. Brezina et al. 2008: 293).

Für eine langfristige Neubewertung urbaner Straßenräume im Rahmen von Stadtentwicklungsperspektiven braucht es daher zeitgemäße Ansätze unter Zuhilfenahme prozessorientierter Planungsphilosophien, die in ihren Bestandteilen flexibel agieren können (BMVBS 2013). Neue Planungen dürfen dabei nicht zu neuen Flächenkonflikten und Rebound-Effekten führen (Stadtentwicklung Wien 2014).

3 DER ANSATZ VON FLEXIBILISIERUNG

Ein innovativer Ansatz in der infrastrukturellen Planung und regulativen Gestaltung von Verkehrsflächen ist daher Flexibilisierung. Flexibilität beschreibt ein Bindeglied zwischen dem Raum und den in Konkurrenz stehenden Funktionen, Aufgaben, Akteurinnen, Akteuren, Nutzerinnen und Nutzern (Ardeshiria et al. 2016). Vermehrt ist der Ansatz von Flexibilität bei der Planung und Gestaltung unserer Städte aufgetaucht. Grund dafür sind die sich wandelnden Bedürfnisse der Gesellschaft, der politische und soziale Druck auf Klimaanpassungstrategien in Zeiten von Unsicherheiten und unvorhersehbaren Naturereignissen. Und zu diesen Herausforderungen des 21. Jahrhunderts zählt Flexibilität und neue Anforderungen an die Erschließungsqualität (Wien 3420 aspern development AG 2009).

Die Untersuchung, die der vorliegenden Publikation zugrunde liegt, erfolgte methodisch durch eine qualitative Literaturrecherche. Mit Hilfe von zentralen Begriffen, wie Flexibilisierung und Infrastrukturplanung, flexibler Städtebau, Raumpotenziale durch Flexibilität, wurden Literaturdatenbanken durchsucht. Die Recherche wurde dabei induktiv vorgenommen, die zu gewinnenden Erkentnisse sollen theorieentwickelnd sein. Zwar ist das Messniveau der qualitativen Literaturrecherche niedrig, jedoch ist der Planungsansatz von Flexibilisierung in der Literatur noch nicht ausreichend repräsentiert, um quantitativ vorgehen zu können. In einem ersten Schritt wurde zunächst ein Überblick von nationalen und internationalen Literaturen generiert. Anschließend sind die Erkenntnisse zusammengefasst auf die Potenziale der Flexibilisierung für urbane Verkehrsinfrastrukturen bezogen worden. Zuletzt wurden die gewonnenen Erkenntnisse zur Frage, ob Flexibilisierung ein Ansatz zur Lösung von Flächenkonkurrenzen ist, auf die aktuellen Herausforderungen der Schaffung von Raumpotenzialen für urbane

Verkehrsinfrastrukturen übertragen. Mit Hilfe einer explikativen Datenanalyse wird der Forschungsfrage „Ist der Ansatz von Flexibilisierung der Verkehrsflächen ein Lösungsweg, um im Kontext städtischer Mobilität aktuellen Herausforderungen der Flächenkonkurrenz zu begegenen?“ nachgegangen.

In der Literatur sind bereits Planungsansätze von Flexibilisierung der Verkehrsinfrastruktur zu finden, jedoch sind diese noch nicht bezüglich ihrer Wirkung auf Raumpotenziale untersucht worden. Aus diesem Grund werden nachfolgend Erkenntnisse aus wissenschaftlichen Dokumenten zum Ansatz von Flexibilisierung in der Infrastrukturplanung beleuchtet und anschließend auf die zu gewinnenden Raumpotenziale übertragen.

3.1 Was ist Flexibilisierung?

Starre, permanente zeitlich und im Kontext unveränderbare Lösungen sind nicht mehr Konsens und es wird nach innovativen Strategien gesucht: auch für vermeintlich starre Verkehrsinfrastrukturen. Flexibilität muss aber nicht als rein physisch, gebautes Werkzeug verstanden werden. Neben physischen Handlungsmöglichkeiten sollten auch weiche Faktoren, wie beispielsweise digitale Infrastrukturen, Berücksichtigung finden (Moroni et al. 2018).

Flexibilität kann verstanden werden als ein dynamisches, prozessbasiertes Planungsinstrument, welches sich zeitlich und räumlich auf die gegebenen Umstände anpassen lässt. Definieren lässt sich Flexibilität als „ein Gestaltungsmittel, um eine ressourcenschonende Raumplanung zu erreichen. Flexibilitätsmaßnahmen sind: reversibel, abnehmbar, anpassungsfähig, verstellbar und/oder ausbaufähig.“ (Stratmann 2019: 1) Dabei gibt es Kriterien, welche den Grad der Flexibilität bestimmen und beeinflussen. Dazu zählt der Grad der Veränderungs- und Umbaumöglichkeiten, das Potenzial der Erweiterungsmöglichkeiten und der Grad der Wiederverwendung (ebd.). Ziel von Flexibilität ist es für neue Nutzungen und Funktionen Räume zu schaffen mit niederschwelligen Eingriffen und strukturellen Veränderungen (Sanei et al. 2018). Auch Infrastrukturen sind städtische Strukturen und bedüfen durch die sich ändernden Anforderungen einer näheren Betrachtung, denn Flexibilität kann wesentliche Zielqualitäten in der Planung erfüllen.

3.2 Flexibilisierung von Verkehrsflächen: Von Flächenkonflikten zu Raumpotenzialen?

In den Städten nehmen Verkehrsinfrastrukturen einen wesentlichen Flächenanteil im öffentlichen Raum ein (vgl. Agentur für clevere Städte 2014). Mit einer flexiblen und dynamischen Planung können diese Flächen einen wesentlichen Beitrag zur Nachhaltigkeit eines Quartiers, einer Stadt, einer Region, eines Landes und über die Landesgrenzen hinaus leisten. Neben ökonomischen und sozialen Vorteilen ist dabei insbesondere der ökologische Nutzen einer flexiblen Infrastrukturplanung, in Bezug auf ihre Wirkung auf die Nachhaltigkeit urbaner Verkehrsinfrastrukturen, zu betonen.

3.2.1 Der Ansatz von Flexibilisierung in der Literatur

In der Literatur sind bis dato nur wenige Ansätze von Flexibilisierung der Verkehrsflächen zu finden und diese sind nach Meinung der Autorinnen bislang unzureichend zusammengetragen worden. Aus diesem Grund wird nachfolgend beleuchtet, was Flexibilisierung der Verkehrsflächen bedeutet, welche Elemente und Umsetzungsmaßnahmen notwendig sind und welche Kriterien es in Bezug auf die Planung flexibler Verkehrsflächen zu beachten gilt.

Moroni et al. (2018) betonen, dass es bei dem Ansatz von Flexibilisierung der Verkehrsinfrastruktur nicht allein um das physisch Gebaute geht. Auch die rechtliche Ebene, digitale Strukturen und der Prozess an sich Bedürfen einer Einbindung. Auf dieser übergeordneten Ebene stellten Moroni et al. (2018) heraus, dass bevor neue Infrastruktur gebaut wird zwei Optionen geprüft werden sollten: zum einen soll nichts getan werden, die Verkehrsinfrastruktur soll bestehen bleiben wie sie bis dato ist, und zum zweiten sollte die bestehende Infrastruktur effizienter gemacht werden (ebd.). Wie schon vormals erwähnt bekräftigt Kötter (2005) dieses Argument, laut dem insbesondere die bauliche (Neu-) Gestaltung der Flächen einen Interessensausgleich zwischen Nutzerinnen Nutzern, Aktuerinnen, Akteuren und Funktionen schafft (ebd.). Um Raumpotenziale schaffen zu können ist es wichtig, dass jene Infrastrukturen priorisiert werden, welche nicht nur für eine Nutzung bestimmt sind (Moroni et al. 2018). Monostrukturen müssen vermieden und polyzentrische bevorzugt werden (ebd.). Damit der Ansatz von Flexibilität in der Infrastrukturplanung greifen kann, sollte dieser im kleinen Maßstab Anwendung finden. Begründet ist der kleinräumige Eingriff durch weniger Kostenschätzungsfehler, weniger finanzielle und technische Risiken, es kann in kürzeren

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Phasen und zeitlichen Abschnitten gedacht und umgesetzt werden und einer der Hauptgründe: Der Eingriff ist anpassungfähiger an den Raum (ebd.).

Neben der Mobilität können Straßenräume auch als Spiel- und Aufenthaltsorte programmiert werden (Lewis/Schwindeller 2014). Eine Bevorzugung von Funktionen kann durch viele Kombinationen von Strategien angepasst werden, um eine vielfältigere Nutzung zu erreichen (ebd.). Lewis/Schwindeller (2014) fassen dementsprechend zusammen, welche Elemente Vekehrsflächen flexibel und anpassungsfähig machen. Ein oft genanntes Element ist das städtische Mobiliar. Die Ausweisung von Flächen durch Schilder für oder gegen bestimmte Nutzungen lassen Räume flexibel werden. So können beispielsweise Straßen für Feste temporär abgesperrt und anderen Nutzungen zugesprochen werden. Sanei et al. (2018) bekräftigen, dass multifunktionalen Stadtmöbel die Flexibilität der Verkehrsflächen positiv beeinflussen.

Da Verkehrsflächen öffentliche Räume sind, betonen Ardeshiri et al. (2016) die Wichtigkeit diese Flächen unterschiedlich nutzbar zu machen. Flexible Stadträume sind demnach multimodale Räume (ebd.). Ziel der flexiblen Räume ist es, auf die Bedürfnisse der Nutzerinnen und Nutzer reagieren zu können. Es wird herausgestellt, dass sich durch flexible Straßenräume unterschiedliche Nutzerinnen und Nutzer und Funktionen gleichzeitig derselben Fläche bedienen können. Somit stellen flexible Räume eine optimale Raumnutzung dar (ebd.).

3.2.2 Einfluss von Flexibilisierung: Vortheoretischer Ansatz zu Raumpotenzialen

Zusammengefasst kann der Ansatz von Flexibilisierung dann zu einer Minderung von Flächenkonflikten auf Verkehrsflächen führen, wenn Flexibilisierung als ein Planungsinstrument verstanden und angewandt wird, das statt einem ‚Nebeneinander' der unterschiedlichen Verkehrsträger und Nutzungen zu einem ‚Miteinander' beiträgt (Stadtentwicklung Wien 2014). Durch die Offenheit für diverse Flächennutzungen im Raum werden Resistenzen gemildert, sodass Konflikte nicht entstehen müssen. Dabei ist ein Hauptargument für Flexibilisierung, dass bei ihrer Umsetzung Ressourcen eingespart werden können. Dieser Vorteil greift vor allem in urbanen Gebieten, wo der Boden hart umkämpft ist und Flächenkonkurrenzen bestehen. Diese Konkurrenzen werden durch Flächen, die sich durch multiple Nutzungsmöglichkeiten auszeichnen, gemildert. Im Zuge dessen kann Flexibilisierung in Kontext urbaner Verkehrsflächen neue Raumpotenziale aufdecken.

Flächenkonfikte im urbanen Mobilitätskontext können durch den Ansatz von Flexibilisierung reduziert werden. Grund dafür ist, dass prinzipiell die Offenheit der Gesellschaft für anderweitige Nutzungen auf öffentlichen Flächen gefördert wird. Der Ansatz, Flächen mehrfach und zeitgleich zu bespielen und offen für (temporäre) diverse Nutzungen zu machen, ermöglicht, dass der Flächenverbrauch sinkt. Durch multifunktionale Räume können daher neue Raumpotenziale ausgeschöpft werden (vgl. Ardeshiri et al. 2016). So können Verkehrsmittel dieselben Flächen nutzen. Wie herausgestellt werden konnte, bedarf es nicht nur der phyischen Gestalt des Raumes zur Schaffung von Raumpotenzialen (vgl. Moroni et al. 2018), sondern ebenso der Wechselwirkung von dem Gebauten und den wahrgenommenen Optionen (vgl. Deffner et al. 2014). So können durch Veränderungen der Nutzungen, Anforderungen und Umstände (steigende Pendlerinnen- und Pendlerzahlen, neue Mobilitätsmuster und Verkehrsmittel) neue Zielkonflikte entstehen (vgl. Zandvoort et al. 2019; Carr/Dionisio 2017) die zu einer weiteren Überlastung der Verkehrsräume führen. Ein Beispiel hierfür sind neue Verkehrsmittel, wie E-Scooter, die zuvor nicht dagewesene Flächenkonflikte auf urbanen Verkehrsflächen verursachen. Hier kann Flexibilisierung eingreifen und beispielsweise durch das Aufstellen von Schildern das Fahren mit neuen Verkehrsmitteln auf bestimmten Flächen freigeben oder untersagen (vgl. Lewis/Schwindeller 2014). Für die Planung urbaner Verkehrsräume ist es daher ebenso relevant, dass die „… sie durchfließendenVerkehrsströme eine gewisse Flexibilität aufweisen …" (Bendiks/Degros 2019: 26). Das flexible Freigeben von öffentlichen Flächen für Nutzungen, beispielwesie auch nur in bestimmten Zeiträumen, kann dabei eine Entlastung der Verkehrsflächen addressieren. Laut Bendiks/ Degros sollte daher trotz spezifischer Gestaltung die Anpassung der gemeinschaftlichen Nutzung des Raums auch an den „Rhythmus des Quartiers" erfolgen. „Ein Parkplatz wird (Jahr)markt, Stellplätze vor Schulen werden tagsüber für Räder von Eltern und Schülerinnen und nachts für die Autos der Anrainer (Flexparking) genutztsowie variable Höchstgeschwindigkeiten vor Schulen" (ebd.: 88). Technologische Hilfsmittel, wie bspw. in Form von Verkehrsleitsystemen, können dabei entscheidend zu einer flexibleren Teilung des Raums beitragen (ebd.).

Der Herausforderung, den gesellschaftlichen Ansprüchen an die Qualität der Straßenräume generell gerecht zu werden, kann ebenfalls durch eine Form der Flexibilisierung begegnet werden, die mit städtischem Mobiliar und Inventar qualitätvolle Aufenthaltsräume schafft und so zu neuen Raumpotenzialen beiträgt (vgl. Lewis/Schwindeller 2014; Sanei et al. 2018; Ardeshiri et al. 2016). Neben dem Potenzial Qualitäten zu sichern, begegnen Mobiliar und Inventar auch der Herausforderung Zielkonflikte in den Nutzungen zu lösen: Durch das verschieben, aufstellen und abnehmen von Mobiliar werden städtische Flächen nutzbar. Beispielsweise können durch Fahrradabstellanlagen an neuralgischen Punkten neue Räume erschlossen werden, Sitzmöglichkeiten können zum Aufenthalt einladen oder Beschilderung zum Spielen einladen.

Für solche unvorhersehbaren Nutzungen plant Flexibilisierung und ist damit fähig auf akute Bedarfe zu reagieren. Da nicht in jeder Stadt und jedem Quartier die gleichen Flächenkonflikte herrschen, ist der kleinräumige Ansatz zur Schaffung von Raumpotenzialen essentiell. Eine optimale Raumnutzung kann im kleinen Maßstab erfolgen (vgl. Moroni et al. 2018). Die Nutzungen und die daraus resultierenden Konflikte ändern sich mit der Zeit. Flexibilisierung kann durch eine kurzfristige Reaktion auf Ereignisse Potenziale schaffen. Gleichzeitig können Zielqualitäten eine langfristige Planung sichern. Neben der Generierung von Raumpotenzialen, begegnet der Ansatz allerdings auch Herausforderungen. Ein wichtiger Punkt ist, dass Flexibilisierung auch politisch gewollt sein muss (vgl. BMVBS 2013). Dafür ist ein adäquater und flexibler Rechtsrahmen unabdingbar. Die mangelnde rechtliche Verankerung könnte einer der Gründe sein, wegen derer es noch kaum Umsetzungsbeispiele gibt.

In der Literatur finden sich Ansätze, die Flexibilisierung und ihre Umsetzung in der Planung fossieren. Jedoch mangelt es an Beispielen, die das theoretische Konzept in der Praxis verwirklichen. Daraus ergibt sich die Frage, ob Flexibilisierung in der Realität umsetzbar ist oder welche Faktoren einer Umsetzung entgegenstehen (Ardeshiri et al. 2016). Über die Gründe lässt sich bis dato nur spekulieren, da die Literatur hierüber bisweilen nur wenig Aufschluss liefert. Mögliche Ansatzpunkte für die mangelnde theoretische und praktische Auseinandersetzung mit Flexibilisierung könnten sein, dass das Konzept bislang zu abstrakt scheint, die bisherigen wissenschaftlichen Beiträge nicht ausreichend gebündelt und fundiert dargestellt sind, die Schwelle zwischen Forschung und Praxis zu groß ist oder die Strukturen in den jeweiligen Planungseinheiten der Länder und Städte in ihrem System zu starr erscheinen.

4 ENTWICKLUNGSKONZEPTE SEESTADT ASPERN: EINBINDUNG VON FLEXIBILITÄT IN DIE VERKEHRSPLANUNG

Die Seestadt Aspern ist eines der wenigen Beispiele, welche in einer städtebaulichen Entwicklung den Ansatz von Flexibilisierung sowohl in der Planung (in den Entwicklungskonzepten) fest verankert als auch praktisch umgesetzt haben. Die Seestadt Aspern ist ein Stadtteil im Außenbezirk der Millionenstadt Wien in Österreich. Aufgrund der hohen Nachfrage nach Wohnraum in der Hauptstadt Österreichs wurde auf dem ehemaligen Militärflughafen außerhalb der Kernstadt ein neuer Stadtteil ‚auf der grünen Wiese' entwickelt. Diese räumlichen Gegebenheiten bietet bei der Planung und Entwicklung das Potenzial traditionelle Stadtstrukturen zu überdenken und bezüglich der Verkehrsinfrastrukturen losgelöst vom Autogerechten Paradigma zu bewerten. Für ein qualitativ hochwertiges städtebauliches Konzept hat die Stadt einen Wettbewerb ausgelobt.

Anhand der in Kapitel 2 dargestellten Methodik, sind im Rahmen der vorliegenden Publikation die städtebaulichen und planungsrelevanten Konzepte und Entwürfe der Seestadt Aspern auf den Ansatz von Flexibilisierung untersucht und hinsichtlich der daraus resultierenden Raumpotenziale beleuchtet worden.

Nachstehend werden zunächst die relevanten Planungskonzepte vorgestellt und die Passagen mit Aussagen und Festsetzungen zur Planung flexibler Verkehrsflächen erläutert. Darauffolgend werden die in den Planungsdokumenten gefundenen Elemente mit den zuvor dargestellten Raumpotenzialen verschnitten. So kann ein erster Eindruck generiert werden, wie und in welcher Form es möglich ist, in Planungsdokumenten Flexibilisierung festzusetzten, sodass diese in der Realwelt Anwendung finden und Potenziale im Raum freisetzen können.

4.1 Die Planungskonzepte

Das theoretische Fundament für den Bau der Seestadt besteht aus mehreren (Teil-)Konzepten. Diese bauen aufeinander auf oder stehen nebeneinander. Nachstehend werden die zentralen Planungsdokumente zur Schaffung von Flexibilität der Verkehrsflächen vorgestellt. Der Masterplan ist dabei als das übergeordnete

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Konzept zu verstehen, dem alle Fachkonzepte untergeordnet sind - Der Masterplan gibt den Rahmen vor. Des Weiteren wird die Partitur des öffentlichen Raums beleuchtet. Die Partitur ist eines der wesentlichen Planungsdokumente, das insbesondere international Aufmerksamkeit erlangt hat und zehn Jahre nach seiner Aufstellung evaluiert wurde. Diese Evaluierung (lessons learned), wird im Rahmen des vorliegenden Artikels ebenfalls analysiert. Auch das Fachkonzept Mobilität sowie der City Lab Report werden hinsichtlich ihrer Bezugnahme auf Flexibilität in der Verkehrsinfrstrukturplanung näher betrachtet. Begründet ist die Auswahl der vormals beschriebenen Planungsdokumente darin, dass diese insbesondere die Planung von Verkehrsflächen fokussieren. Die hier aufgeführten Konzepte der Seestadt Aspern sind allerdings als nicht abschließende Planungsgrundlagen zu begreifen, sondern evaluieren das theoretische Konzept der Flexibilisierung in Bezug auf Möglichkeiten seiner Umsetzung. Zudem soll die Analyse keine Wertung darüber abgeben, ob die Seestadt Aspern eine Flexibilität von Verkehrsinfrastrukturen erreicht hat. Der Umfang der zugrunde liegenden Analysen reicht hierfür nicht aus.

4.1.1 Masterplan

Der Slogan des Masterplans ist: “Grundlage für die intelligente Stadt bildet eine gründliche und flexible Planung“ (wien 3420 aspern development AG 2017: 1). Die räumliche Planung zu Flexibilisieren ist somit ein Leitziel der Stadt. Der Masterplan soll kein starres Planwerk sein und sich auf Veränderungsprozesse während der jahrelangen Entwicklungslaufzeit anpassen können. Aus diesem Grund ist Flexibilität im Planungswerk verankert. Dies soll auch dazu führen, dass Qualitäten vorgegeben und gesichert werden können (ebd.). Die Planung der Verkehrsinfrastruktur soll sich demzufolgen ebenfalls an den Grundsätzen flexibler Planung orientieren. Flexibilität bietet das Potenzial auf Bedarfe zeitlich angemessen zu reagieren. Dieser Vorteil kann beispielsweise beim Bau von Parkmöglichkeiten zum Tragen kommen. Dazu heißt es: „Hochgaragen sollen so gestaltet sein, dass sowohl Erweiterungen und Rückbau als auch Umnutzungen möglich sind, um auf den zukünftigen Bedarf flexibel reagieren zu können“ (ebd.: 30). Zudem sollen Straßen einen hohen Grad an Nutzungsflexibilität und Weiterentwicklungsmöglichkeiten aufweisen (ebd.). Damit bietet das übergeordnete Konzept des Masterplans erste Richtlinien, welche Flexibilisierung in der Verkehrsinfrastrukturplanung beinhalten. Beispielhaft aufgegriffen werden soll an dieser Stelle das Konzept der Quartierswege. Wie Abbildung 1 zeigt, können diese Wege mehrere Funktionen gleichzeitig miteinander verknüpfen. Sie sind zugleich Verkehrs-, Aufenthalts- und Parkraum (ebd.).

Abb. 1: Quartiersweg, Mischprinzip (eigene Darstellung nach Wien 3420 aspern development AG 2017: 24)

4.1.2 Partitur des öffentlichen Raums

Die ‚Partitur des öffentlichen Raums‘ wurde 2009 vom Planungsbüro gehl architects aufgestellt. Ebenso wie der Masterplan gilt die Partitur als ein „prozessbasiertes dynamisches Planungswerkzeug“ (Wien 3420 aspern development AG 2009: 18). Dieses dient als Planungsgrundlage für die Seestadt. Die Partitur bündelt mehrere Konzepte mit Fokusbereichen, wie beispielsweise den Mobilitäts- und Bebauungsleitfaden (entwickelt in Zusammenarbeit mit Wien3420 AG) und der Strassenplanung und -gestaltung (entwickelt in Zusammenarbeit mit MA28). Die Themen um die Entwicklung und Gestaltung der Verkehrsinfrastrukturflächen sind vielseitig. Bedacht worden sind u.a. Räume wie die „Savanne“, ein flexibler und multifunktioneller Ort mit interaktivem Charakter (Wien 3420 aspern development AG 2009). Berücksichtigung fand auch das Stadtmobiliar, welches flexibel und situationsbedingt anpassungsfähig ist

(ebd.). Zu diesem Inventar zählen u.a. Fahrradabstellanlagen, Pöller und auch Lichtsignalanlagen, die dem öffentlichen Straßenraum zuzuordenen sind. Jedoch ist auch festzustellen, dass der motorisierte Individualverkehr auch in diesem Konzept weiterhin priorisiert wird. Nichtsdestotrotz hat sich die Partitur den zeitlich anpassbaren Charakter von Flexibiliserung in der Festsetzung von temporären Nutzungen und Infrastrukturen zu Nutze gemacht. So ist während der Entwicklung und des Baus der Seestadt u.a. ein temporäres Wegenetz zum Einsatz gekommen. Dieses Wegenetz passt sich den Bedürfnissen der Bewohnerinnen und Bewohner an und reagiert flexibel auf die Entwicklungen im Raum (ebd.: 104). Die „Savanne“ soll zu einem multifunktionellen und flexiblen Ort werden, d. h., dass der Ort in längeren zeitlichen Perioden interaktiven Charakter erhält. Ähnlich ist mit unbefestigten Wegen umgegangen worden, welche sich zu einer Straße entwickeln konnten (ebd.). Diese Wege dienten temporär in den Bauphasen der Seestadt zum Verbinden von neuralgischen Punkten und Schaffung von kurzen Wegen, in der zeitlichen Entwicklung haben sich die Wege etabliert und sind zu Straßen ausgebaut worden. Neben dem Verkehrsinfrastrukturbereich ist der Ansatz der Flexibilisierung auch im Bereich Wohnen verankert worden (ebd.). Hier liegt der Fokus vor allem auf flexiblen Nutzungen der Gebäude.

4.1.3 Lessons learned

Das Dokument ‚Lessons learned‘ entstand aus der Evaluierung der Entwicklungsziele der Partitur. Dass sowohl die Partitur als auch ihre Evaluierung vom Planungsbüro gehl architects durchgeführt wurde, hat in der Vergangenheit vermehrt zur Kritik geführt, da eine Evaluierung der eigenen Planung nie objektiv erfolgen kann und demzufolge vermieden werden sollte. Aus diesem Grund muss kritisch hinterfragt werden, inwieiweit die folgenden Ergebnisse valide sind.

Die Relevanz von Flexibilisierung kommt in den ‚Lessons learned‘ (Gehl 2019) besonders zum Vorschein. Im Gegensatz zur Partitur ergeben sich hier einige Änderungen in den Entwürfen: Aus der Partitur folgte die Straßengestaltung respektive die Verteilung der Straßenräume an die unterschiedlichen Nutzungen anders: „im endgültigen Design wird Fußgängerinnen großzügig Raum gegeben. Dies spricht für die verantwortlichen Verkehrsplanerinnen und Verkehrsplaner, die den gesamten Planungsprozess im Sinne einer Vision von Straßen“ (Gehl 2019: 5). Besonders hervorzuheben ist, dass die Partitur Überschneidungen von Nutzungen vorgesehen hat. Die Analyse hat gezeigt, dass dies in der Realität gut funktioniert (siehe Abbildung 2; ebd.: 8). Sowohl der Masterplan als auch die Partitur sehen Überschneidungen von öffentlichen Räumen und Funktionen vor, um eine lebedige Stadt zu schaffen (ebd.). Die Evaluierung hat jedoch auch gezeigt, dass die multifunktionellen Flächen bis dato nicht genutzt werden. Als Grund wird neben einer Überdimensionierung der Flächen auch die bislang zu geringe Anzahl an Nutzerinnen und Nutzern genannt. Wie diese ungenutzen Flächen sich in den nächsten Jahren entwickeln werden, bleibt abzuwarten.

Abb. 2: Lebendige Freiräume durch Überschneidung von Aktivitäten (eigene Darstellung nach Gehl 2019: 8)

4.1.4 Citylab Report

Wie bereits zuvor beleuchtet, greift auch der Citylab Report (Wien 3420 Aspern Development AG 2011) die Potenziale des Ansatzes von Flexibilisierung auf. „Die Schaffung einer neuen Gemeinschaft muss die Veränderungen über kurze und lange Zeiträume reflektieren und berücksichtigen, sie muss einerseits die Ziele und Bestrebungen präzise formulieren, andererseits aber auch flexibel und offen bleiben“ (Wien 3420 Aspern Development AG 2011). Im Report wird hervorgehoben, dass das Zusammenspiel von Identität und

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Flexibilität konzeptionell verankert sein muss, damit eine Entwicklung gelingt (ebd.). In dem aufgestellten Katalog zu Kriterien einer nachhaltigen Entwicklung wird das Thema Flexibilität aufgeführt (ebd.). Flexibilität ist Teil des Plans, so der Report (ebd.). Freiräume müssen bereitsgestellt werden, in welchen flexible Nutzungen zugelassen werden. Dafür bedarf es an flexiblen Rahmenvorgaben, welche trotz Anpassungsfähigkeit ihre Zielqualitäten nicht verfehlen (ebd.).

4.1.5 STEP 2025 Fachkonzept Mobilität

Das Fachkonzept STEP 2025 Mobilität fokussiert ein neues Element von Verkehrsflächen, die insbesondere durch ihre Möglichkeiten der flexiblen Nutzung auffallen: die Multifunktionsstreifen. Dieses Element weist deshalb einen hohen Grad an Flexibilität auf, weil es so angelegt ist, dass es auf sich rasch ändernde Nutzungen und neue Verkehrsträger reagieren kann. Dazu heißt es: „Die Flexibilität ergibt sich aus einer entsprechenden baulichen Gestaltung des Raumes zwischen Gehsteig und Fahrstreifen. Diese erfolgt so, dass Multifunktionsstreifen als eigenes Element im Straßenraum wahrgenommen werden. Sie sind Teil des Gehweges, und nicht Teil der Fahrbahn. Die Befahrbarkeit, beispielsweise um Fahrzeuge abzustellen, wird durch sanfte Niveauübergänge gewährleistet. Keinesfalls dienen Multifunktionsstreifen dem fließenden Fahrzeugverkehr“ (Stadtentwicklung Wien 2015: 78). Mit Hilfe dieses Entwurfselementes möchte das Konzept mehr Flexibilität in der Planung und Durchführung umsetzen. Der Multifunktionsstreifen lässt, wie der Name schon sagt, verschiedene Funktionen zu und ist damit anpassbar.

Geminderte Flächenkonflikte und mehr Raumpotenziale durch Flexibilisierung

Die vormals besprochenen Konzepte zur Entwicklung der Seestadt Aspern greifen den Ansatz von Flexibilisierung von Verkehrsflächen auf. Das Beispiel Aspern zeigt dabei auch, dass Flexibilität eine konzeptionelle und rechtliche Verankerung braucht, um Umsetzungsfähig zu sein: Der Masterplan als übergeordnetes informelles Planungsinstrument hat Flexibilität zum Leitziel, sodass die darauffolgenden Konzepte, wie die ‚Partitur des öffentlichen Raums‘, der ‚Citylab Report‘ und das ‚Fachkonzept STEP 2025‘ sich daran orientieren und die Planungsziele weiterführen konnten. Dem Kritikpunkt einer mangelnden rechtlichen Grundlage von Flexibilisierung in Planungsdokumenten, konnte in Aspern von Beginn an begegnet werden. Sowohl der Masterplan als auch der Citylab Report betonen, dass ein flexibles Planwerk Grundvoraussetzung ist, um Flexibilität in die Praxis zu transferieren. Ohne Rahmenvorgaben und Zielqualitäten ist der Ansatz von Flexibilisierung nicht möglich. Mit diesen Festsetzungen kann das Potenzial der Umsetzung von Flexibilisierung geschaffen werden. Die Literaturrecherche hat zwar ergeben, dass direkte räumliche Potenziale bis dato nicht erreicht werden, jedoch hat die konzeptionelle Verankerung hohe indirekte Auswirkungen auf die Schaffung von Raumpotenzialen.

Durch eine zeitlich versetzte Abfolge der Erstellung und Ausführung der Konzepte ist das Festsetzen von Flexibilität im Prozess ein weiterer wichtiger Baustein. Der Masterplan und die ‚Partitur des öffentlichen Raums‘ verstehen sich als ein dynamisches Planungswerkzeug. Das hat zum Vorteil, dass ein flexibler Prozess generiert wird. Dieses Potenzial hat die ‚Lessons learned‘ (vgl. Gehl 2019) herausgestellt.

Wie in der Literatur zusammengetragen worden ist, spielt das städtische Mobiliar eine zentrale Rolle zur Schaffung von Raumpotenzialen. In den Planungsgrundlagen und der anschließenden Umsetzung sind flexibles Inventar und Stadtmobiliar zu finden. Dadurch sind unterschiedliche Nutzungen im Raum möglich. Ebenso ist der kleinräumige Maßstab der Umsetzung von Flexibilisierung, wie es in der ebenso in der zugrunde liegenden Literatur dargestellt wurde, beachtet worden. Der flexible Ansatz ist auf kleinem Maßstab umgesetzt worden und erreicht somit einen hohen Grad der Anpassungsfähigkeit.

Neben übergeordneten Zielen zur Flexibilisierung sind auch bauliche Umsetzungen festgehalten. So wird beispielsweise im Masterplan der Rückbau, Umnutzung und die Erweiterung von Hochgaragen festgesetzt, damit auf Bedarfe flexibel reagiert werden kann und das Potenzial der begrenzt zur Verfügung stehenden Flächen genutzt wird. Diese Nutzungsneutralität von städtebaulichen Strukturen kann Konflikte lösen und Raumpotenziale für anderweitige Nutzungen generieren. In der ‚Partitur des öffentlichen Raums‘ werden Raumpotenziale durch das temporäre Wegenetz eröffnet. Durch das Bereitstellen von temporären Wegen, können Konflikte auf bestehenden Verkehrsflächen vermieden werden; gleichzeitig können diese Flächen zu einem späteren Zeitpunkt für andere Nutzungen bereitgestellt werden. Damit nicht jede Nutzung eine eigene Fläche braucht sieht das ‚Fachkonzept STEP 2025‘ eine flexible Fläche im Sinne des Masterplans vor. Mit der Etablierung von Multifunktionsstreifen sollen mehrere Nutzungen gleichzeitig ermöglicht werden. Neben baulich-räumlichen Aspekten werden den Nutzerinnen und Nutzern die Möglichkeiten des flexiblen

Bespielens der Flächen zugesprochen. Die ‚Partitur des öffentlichen Raums' hat gezeigt, dass durch mehr Flexibilität im Planungswerk letzendlich in späteren zeitlichen Abschnitten flexibler auf die sich wandelnden Bedürfnisse der Gesellschaft reagiert werden kann. Es bleibt nicht aus, diesen Prozess weiterhin zu evaluieren und ein stetiges Monitoring zu betreiben, um zu prüfen, inwieweit das theoretische Konzept um Flexibilisierung, Auswirkungen auf den Raum und den Mensch in der Stadt hat.

Trotz der dargestellten positiven Aspekte müssen sich die Konzepte und ihre Umsetzung auch einiger Kritiken stellen. So lässt sich feststellen, dass es noch keine ausreichende wissenschaftliche Datengrundlage zu vielen der in den Konzepten genannten Ansätze gibt. Dazu zählt beispielsweise der Multifunktionsstreifen, zu welchem es bis dato sowohl an wissenschaftlicher Evaluation als auch erfolgreichen Umsetzungsbeispielen mangelt. Eine Evaluation wäre unter anderem deswegen von großer Bedeutung, da erst auf dieser Grundlage erörtert werden kann, welche Raumpotenziale im Vergleich zur herkömmlichen Planung freigesetzt werden. Dasselbe gilt für eine Evaluierung sinkender Flächenkonflikte. Dennoch lässt sich sagen, dass die Seestadt Aspern als ein gutes Beispiel voraus geht, einen innovativen Ansatz praktisch umzusetzten, um flexibel auf sich ändernde Ansprüche einzugehen.

Abb. 3: Seestadt Aspern. Straßenraum mit Mischprinzip (eigene Darstellung).

5 MIT FLEXIBILISIERUNG ZU MEHR RAUMPOTENZIAL?

Im Rahmen der vorliegenden Publikation wurde der Frage nachgegangen, inwiefern sich Ansätze der flexiblen Raumplanung im Sinne der Herausforderungen der Verkehrsinfrastrukturplanung als zielführend erweisen können. Die in diesem Kontext vorgenommene Literaturanlyse hat gezeigt, dass über die Flexibilisierung von Verkehrsflächen einer Transformation urbaner Mobilität positive räumliche Effekte und dementsprechende Raumpotenziale geschaffen werden können. Flexibilisierung kann einen Beitrag leisten, Unsicherheiten in der städtebaulichen Entwicklung aufzuheben und Konflikten durch flexible Lösungen zu begegnen. Flexibilisierung bietet zudem das Potenzial, die Aufenthaltsqualität durch die städtebauliche Aufwertung der Straßenräume immens zu steigern. Das Konzept muss allerdings auch dahingehend gedacht werden, dass derartige flexible Gestaltungen nicht in jedem städtischen Raum Sinn ergeben oder angewandt werden können. Das Beispiel Aspern zeigt, dass ein Konzept mit dem Ansatz von Flexibilisierung die Bedürfnisse der Gesellschaft in Entwicklungszeiten gerecht werden kann. Obwohl in der Literatur bislang nur wenige theoretische Ansätze der Flexibilisierung von Verkehrsflächen bestehen und trotz Mangel an Umsetzungsbeispielen hat sich die Stadt Wien hier dem Ansatz von Flexibilisierung angenommen und von Grund auf während der Entwicklung mitgedacht. Dabei wurde berücksichtigt, dass die unterschiedlichsten Elemente, vor während und nach der Planung maßgeblich die Flexibilität von Infrastrukturen und Planungsabläufen beeinflussen. Dieses Beispiel zeigt, wie wichtig es ist, Flexibilität nicht nur aus einer infrastrukturellen Perspektive heraus zu denken, sondern in den Konzepten und Rahmenbedingungen festzusetzten, um eine spätere Durchführung und Umsetzung zu gewährleisten. Daraus lässt sich ableiten, dass Regelwerke und Richtlinien in der Raum- und Infrastrukturplanung so angepasst werden müssen, dass Flexibilisierung rechtlich verankert und ein Planungsleitsatz ist.

Der vorliegende Artikel zeigt allerdings auch, dass Flexibilisierung in der räumlichen Planung nicht trennscharf von anderen stadt- und verkehrsplanerischen Ansätzen abzugrenzen ist. Flexibiliserung von Verkehrsflächen setzt vielmehr gleichzeitig im Entwurf (des öffentlichen Raumes), einer flexiblen

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Anpassung der Verkehrsträger und -ströme sowie den daraus resultierenden Nutzungsmöglichkeiten gleichermaßen an. Flexibilisierung muss daher als ein Konzept verstanden werden, dass wie in Kapitel 2 dargestellt, einem systemischen Gedanken folgend als Bindeglied zwischen Raum und den in Konkurrenz stehenden Funktionen, Aufgaben, Akteurinnen, Akteuren, Nutzerinnen und Nutzern (Ardeshiria et al. 2016) agiert.

Zwar fokussiert die Publikation den städtebaulichen Ansatz der Flexibilisierung auf und von Verkehrsflächen, jedoch sollte dieser nicht nur sektoral behandelt werden. Vielmehr ist im Kontext der Flexibilisierung im Kontext urbaner Mobilität eine ganzheitliche Betrachtung unterschiedlichster Disziplinen notwendig, woraus auch Synergieeffekte entstehen können. Bei der Planung von Verkehrsinfrastrukturen müssen auch soziale Aspekte eine Rolle spielen. Es gilt daher in Bezug auf Raumpotenziale auch Aspekte der Sicherheit für vulnerable Gruppen zu bedenken: So ist es nicht selbstverständlich, dass alle Verkehrsteilnehmerinnen und Verkehrsteilnehmer in der Lage sind, mit flexiblen Veränderungen der Flächennutzungen umzugehen. Denn, in komplexen Verkehrssituationen brauchen beispielsweise ältere Menschen oftmals mehr Zeit zur Verarbeitung und Reaktion. Für Personen mit Geh- und Sehbehinderungen gilt es zu bedenken, dass festgelegte, taktile Leit- und Warnelemente oder eine kontrastreiche Gestaltung von elementarer Bedeutung zur Orientierung im Raum ist. Über eine Flexibilisierung könnten daher erneute Zielkonflikte und eine Benachteiligung mobilitätseingeschränkter Personen generiert werden. Die Frage ist außerdem, ob flexibilisierte Verkehrsinfrastrukturen dafür geeignet sind, den Verkehr leistungsfähig abzuwickeln oder vielleicht sogar Einfluss auf das Mobilitätsverhalten und die Verkehrsmittelwahl hat – beispielsweise durch Parkverbote bei hohem Parkdruck und gleichzeitiger Förderung einer multimodalen Infrastruktur.

1 ABSTRACT

For the European Union, smart cities are cities socially, environmentally and economically sustainable, preparing to be the catalysts of innovative changes for the world. Accordingly, the European Commission (EC) has a series of programmes to support the transition from cities to smart cities, such as the Horizon 2020 programme for research and innovation. The Triangulum project is one of the first projects in this programme, which trusts on the idea of replicating solutions to reduce the risks for decision-makers and business alike. The goal of replication within these projects is to enable the Follower Cities to replicate the implementation of smart solutions done in the Lighthouse Cities.

Triangulum developed the concept and framework of an extensive replication process that relied on workshops, city assessments, on-site visits and other tools, with dedicated personnel, time and budget. Through the funding possibilities of these programmes, the EC mobilises the smart city policy, providing the chance for cities to embark on the smart city world.

Leipzig (Germany) is currently a Follower City within the project. It has changed from a shrinking city to the fastest growing city in Germany and now faces the challenges to accommodate the growing population, secure a new economy while improving its liveability and sustainability, with its ageing infrastructure and financial limitations. By seizing the momentum of growth, Leipzig seeks to overcome its restraints, especially the limited financial resources, exploring its potentials and thus following a new sustainable path through the smart city idea.

This paper aims at identifying the real benefits of the 'replication' process designed within the project. By looking closely at Leipzig as a Follower City in Triangulum, it is possible to reflect on the meaning of replication in the European smart city context.

Keywords: Triangulum, Follower cities, Replication, Leipzig, Smart City

2 INTRODUCTION

The concentration of the majority of the world population in urban areas, a relatively new and fast-paced phenomenon, has conveyed the recognition of the duality and undeniable importance of cities in the face of environmental, economic and social challenges. With the concentration of population, cities concentrate the use of resources and emissions, but also concentrate money, knowledge generation, and innovation potential, creating a duality of being part of both the problem and solution (UN Environment Programme, 2018; UN-Habitat, 2016; United Nations, 2019).

The concept of smart cities arose amidst this recognition of the duality of cities and aims at unlocking the potential of cities to tackle the environmental, economic and social challenges. The concept evolved beyond solely digital technologies and is being embraced by cities worldwide. However, the smart city concept has a multitude of definitions and real-life implications. The technological, efficiency, and connectivity idea of smart cities corroborate with the processes of looking elsewhere, with the search for best practices and continuous benchmarking. As a result, mobilisation, transfer and replication of policies and ideas between cities are increasingly part of urban policymaking and planning. Different actors engage in these processes, in the hope of finding quick-fix solutions. For cities, belonging to this abstract space of globalisation, this signifies unlimited access to the flows of ideas, knowledge, money, people and possibilities, connoting a sense of relevance and attractiveness. Nevertheless, there is still the need to ground policies and solutions in the territoriality of cities and with social and institutional contexts, showing the duality of the fixity-mobility in these processes. That is relevant especially when considering the smart and digital technologies, that already denote a less localized and more abstract idea (Boulanger & Nagorny, 2018; Calzada, 2016; Cochrane, 2007; Cochrane & Ward, 2012; Dolowitz & Marsh, 1996, 2000; Gudmundsson et al., 2005;

Hollands, 2008, 2015; Macário & Marques, 2008; Macmillen & Stead, 2014; McCann, 2011; McCann & Ward, 2011; Peck & Theodore, 2010; Stead, 2012; Vandevyvere, 2018).

2.1 The Triangulum project

The EC published an open call within the Horizon 2020 work programme at the end of 2013 called 'Smart Cities and Communities (SCC)'. The aim was to identify, develop and deploy replicable, balanced and integrated solutions in the sectors of energy, transport, and information communications technology (ICT) actions through partnerships between municipalities and industries.[1] The Triangulum Project was one of the first three projects from this call and is composed by the Lighthouse Cities (LCs) of Manchester (United Kingdom), Eindhoven (Netherlands), and Stavanger (Norway), with three Follower Cities (FCs) – Leipzig (Germany), Prague (Czech Republic), and Sabadell (Spain). The consortium is made up of 22 partners and is coordinated by the Fraunhofer Institute for Industrial Engineering (IAO). This innovation and demonstration project integrates and deploys smart city solutions in the area of energy, mobility, and ICT to face societal challenges. Moreover, it contributes to sustainable and eco-friendly urban development, reduces CO2 emissions and promotes the use of renewable energy. At the same time, FCs are learning from the concepts, processes and reflecting on these for their own smart city strategies. Triangulum has received a 25 million euro grant from the EC and lasted five-years (2015-2020).

2.2 Follower City of Leipzig

Leipzig is one of the most dynamic cities in the heart of Germany with more than 590,000 inhabitants (2017). From the end of the former German Democratic Republic and reunification of Germany, this city faced numerous challenges, with losing population, deindustrialisation and high unemployment, to cite a few. However, since 2005 the population in Leipzig has been increasing steadily, and projections anticipate that the population growth will continue, making Leipzig one the fastest growing city in Germany (City of Leipzig). After years of population decline and an above-average unemployment rate, Leipzig started to regain popularity during the last years and is successfully turning from a post-industrial into a modern, knowledge-based economy, with a high concentration of small and medium enterprises and a lively start-up scene (City of Leipzig, Triangulum, D6.5 – Revised implementation plan Leipzig).

Leipzig, as a FC, takes advantage of the experiences gained and lessons learnt from the implementation processes in Manchester, Stavanger and Eindhoven respectively. As part of the project, each FCs has to develop a smart city implementation strategy based on the tools and lessons learned from witnessing the implementation in the LCs. Within their strategy, Leipzig´s main objective focuses on setting an integrated approach, understanding the importance of using renewable energy sources and designing a new plan of multimodal traffic/logistics/ICT system solutions.

By taking the case study of Leipzig as a FC in Triangulum in the context of European smart cities through the EC funding programmes, it is possible to get an insight into the processes of mobilisation, transfer and replication and their influence on the implementation of smart city solutions.

3 METHODS

This research is based on extensive desktop research and in-depth expert interviews, supported by literature review. The literature review covered the topics of smart cities, its definition, characteristics, benefits and criticism, and the topic of mobilization of policies, transferability, replication and best practices in the field of urban planning and development. The desktop research comprised the analysis of documents, websites, publications, reports and deliverables from the European Union (EU) and the EC to the Triangulum Project and the municipalities. Semi-structured expert interviews were conducted with experts from the Follower City of Leipzig, the Lighthouse Cities of Manchester and Eindhoven, the Fraunhofer FOKUS, IAO, University of Stuttgart and the University of Manchester covering topics specific from their practice.

4 RESULTS

Subchapter 4.1 will present the results of the desktop research. It is an assessment of the settings that allowed the case study, Triangulum Project, to happen. By analysing the different documents, it was possible to

[1] Work programme: https://ec.europa.eu/research/participants/data/ref/h2020/wp/2014_2015/main/h2020-wp1415-energy_en.pdf

understand the narrative from the different institutions and agencies and the methodologies and processes of their work and results from the project itself. Subchapter 4.2 will present the results of the interviews. From the interviews, it was possible to compare the narrative, objectives and results with the perceived practical experiences and details from the processes, work dynamics and relationships resulting from the project.

4.1 The case study

4.1.1 The Lighthouse and Follower Cities concept within the European smart city scenario

Triangulum is one of the projects that is part of the European Innovation Partnership on Smart Cities and Communities Lighthouse Projects (EIP-SCC). The EIP-SCC was an initiative by the EC as part of the targets of the EU 2020 Strategy, which accounts "for smart, sustainable and inclusive growth"[2], and also aimed at the European targets for climate and energy for 2020. An initial Strategic Implementation Plan (SIP) for the EIP-SCC was developed to guide and "speed up the transformation of European Cities into 'smart cities'" and is intended to set the necessary actions to create a framework so that cities can be improved for life and business, and to be able to reduce energy use, emissions and congestions. Moreover, it outlined the EIP-SCC ideas "on how to best harness innovative technologies, innovative funding mechanisms and innovative public private partnerships" (EIP-SCC, 2013, p. 2). One of the activities proposed in the SIP to ensure its implementation and therefore consolidate the aims of the EIP-SCC was the creation of several 'Lighthouse Initiatives'.

Even though the purpose of these 'Lighthouse Initiatives' suggested the idea to group the participant cities, it was never indicated clearly in the initial bid (2013), as no resources were explicitly allocated for these purposes. Nevertheless, the project coordinators of the first three SCC projects (Triangulum, REMOURBAN and GrowSmarter) identified the need of coming together to discuss common challenges and issues in Berlin at the Fraunhofer Urban Futures Conference in 2015. In the next years, the projects founded the SCC1 Board of Coordinators (BoC) and a Manifesto[3] to ensure cooperation across the projects. After the formation of the BoC, the EC saw the potential of this growing community (2-3 projects per year with a duration of 5 years each) to achieve their goal of scaling up the implementation of smart cities solutions in Europe. Thus, "creating scale and reducing risk for political decision makers as well as investors, to progressively support wider implementation across the EU" (EIP-SCC, 2019), which would also serve as a way to demonstrate the competitiveness of the European industry.

The concept of LCs and FCs works in a way that innovative pilot projects can be tested and demonstrate at the LCs and later replicated in the FCs. The pilot projects focus on sustainable mobility, energy, smart buildings, ICT and business opportunities. The concept creates a diverse experience that covers the main typologies of European cities. All the current seventeen European SCC Lighthouse Projects have the same structure of Lighthouse and Follower Cities, relying heavily on the replication idea, including partners from industry and academia (EIP-SCC, 2019; Smart cities Information System, 2019). In general terms, Triangulum aligns with the EC EIP- SCC SIP across the LCs, so recommendations can be made to the EC in the broader replication process of real solutions for smart cities and hence boosting the transition from cities to smart cities in the European context.

4.1.2 Replicating the experiences from Lighthouse Cities in the project of Triangulum

The LC in Triangulum are Manchester (UK), Eindhoven (NL) and Stavanger (NO), the FCs are Prague (CZ), Sabadell (ES) and Leipzig (DE), so the project reflects urban populations between 100k and 1,2m within six countries, aiming at the different typologies of European cities.

Within the project, a dedicated team from Fraunhofer (FOKUS, IAO), University of Stuttgart IAT and TÜV Süd was responsible for developing and facilitating the replication process. It consists of two different approaches, the technology transfer, and the customer centric approach. Simplistically, these two approaches depart from different poles to try to achieve the same goal, to support replication of smart city solutions.

The technology transfer approach is set on what the EIP-SCC programme has established as an agenda. It structured the learnings and information of the implementation of solutions in the LCs, and supplied it to the FCs, or any other city interested in replicating them. The customer centric approach departs from the other

pole, from the FCs. It is a supportive process to achieve a smart city implementation plan, through an assessment of the FCs needs so it can be linked with the LCs solutions.

The technology transfer approach outcome was addressed by the development of a replication tool (or Decision Making Tool, the names are used interchangeably), a public excel-based tool that can be downloaded from the site of the project and be used by anyone.[4] It is a user-friendly interface where filters can be applied to search for the smart city use cases from the LCs from Triangulum, and thus find the most suitable one depending on whether the user is a city or industry or if it has a specific goal or challenge. The 'use case' is defined as the unity of replication, employing technology to achieve a specific goal in a defined setting.

Collecting data from the LCs was necessary to develop the tool. During this process, the refinement of the necessary data occurred, where the team responsible for the technology transfer received feedback from the partners, from the LCs and FCs sides, on the type of information that was relevant and interesting for them, as well as making the template for the use cases more user-friendly. .

The second approach, the customer centric approach, was designed to support the FCs in a personalised way to process and develop their smart city implementation plan. The first step had the Morgenstadt City Lab in each FC, where the Morgenstadt Methodology[5] was applied, and a complete assessment of the cities was conducted. With the city assessment cities could identify their strengths, weakness, and the current state of the cities and where lays the smart city potentials. That was made through site visits to the FCs by the team responsible for replication. From that, different formats of activities were used to connect the FCs with LCs smart city solutions, but also to connect all stakeholders within the project. These formats included on-site visits, workshops and webinars with different topics at different stages of the project, where the data collected in the LCs could be shared, and the FCs could develop their implementation strategy gradually. The activities and the respective topics were based on the FCs specific training needs, which the replication team matched with the right partners, so that knowledge exchange could happen.

Both approaches of the replication process fed each other with information, so they were always adapting and transforming throughout the project. The activities and tools that were part of the process were designed with different levels of personalization, some being more directly linked with specific FCs than others, allowing a level of adaptability when necessary. They had ultimately the goal of linking the FCs, and other interested cities, to the implemented solutions of the LCs. Part of the replication process of Triangulum were regular evaluations of the activities by the different partners of the project, what facilitated improvements and adaptations by the replication team when necessary.

4.2 Replication for the FC of Leipzig

As presented before, Leipzig has been experiencing changes in its urban environment in recent years. While most changes are positive, they still bring new challenges for the city. Leipzig has benefited of European and national funds to support urban regeneration projects, and together with active civil engagement has been successfully strengthening its urban development.

The commitment of Leipzig with environmental goals has been on the agenda for a while, yet it gained more relevance over the years. Leipzig was invited by Fraunhofer to be a FC in Triangulum, matching the intentions of the city of exploring the smart city world. The participation of the city within a larger European programme was perceived as an excellent approach to deal with their sustainable goals, decarbonization and promotion of local business. The EU funding possibility and the central role that EU and national funding plays in urban development in Leipzig were relevant in the decision to join the project. Even though there was the intention to pursue a smart city approach, Triangulum gave the city a place to start their smart city process, as there was no institutional or political configuration for that. The work for the Triangulum project in Leipzig initially was done by a team that was allocated in the Office for Urban Renewal and Housing Construction Subsidies. The budget for the team came exclusively from Triangulum and there was no additional budget allocated for smart city solutions within the municipality.

4.2.1 Challenges within the project

The replication process inside Triangulum was perceived from different angles by the team from Leipzig. When considering replication in a direct way, meaning solution to solution, the process was perceived as laborious for them, with various factors presented as reasons for that. Moreover, as being part of a consortium, they had to comply with the scope of the project and the agreed proposal. The scope of the project determined that they have obligations to follow, such as deliverables, which are concrete documents and actions. Because of the project´s replication scope at the beginning, the city felt a pressure from the coordination side to choose within the implemented solutions in order to comply with the project plan. However, this risk was identified by the replication team and incorporated into the abovementioned replication customer centric approach.

The mismatch between the timeline of the project and the smart city/digitalisation process of the city was perceived by Leipzig as one of the reasons why replication was difficult for them. The project was structured in a way so that the first 36 months the LCs were dedicated to implementing the solutions, having the last 12 months to monitor them. By having to wait for the LCs to implement their solutions, Leipzig had time to start developing their understanding of smart city, but they also did not have anything to show for the city council and other city agencies about the solutions on the LCs, which was essential for them to communicate the possibilities of smart cities. For Leipzig, this had both negative and positive impacts. It was not a linear cause-effect, because they used the experience from the LCs as a best-practice scenario in different ways.

4.2.2 Challenges of replication

Another perceived reason by Leipzig on the difficulty in replicating was concerning the various context-related different conditions from the LCs to Leipzig. For example, the institutional structure of the public utility companies that were involved from the beginning in Leipzig was different in the LCs. Not only in terms of the institutional structure but also in terms of involvement and cooperation. Another example was the distinction between the legal system from Leipzig and Eindhoven, especially in the aspects of data protection, which can hugely influence and determine smart cities solutions. Other context-related differences were recognized between Leipzig and the LCs, in different levels from infrastructure to policies, regulations and cultural. These differences did not facilitate the direct replication of solutions as well.

Leipzig has a tradition with civic engagement in the planning process (Triangulum, D6.5 – Revised implementation plan Leipzig), and during Triangulum, they had different participation formats, like future labs, discussion evenings, series of lectures, where they invited the inhabitants of Leipzig West to discuss specific topics, e.g. mobility, energy. It was relevant for them to collect orientation regarding potentials but also the fears of the inhabitants with the whole smart city discussion. However, Leipzig as a FC had no funds for implementation of smart city solutions within the project of Triangulum, so the participation process stopped due to the lack of concrete results from the inhabitants' perspective. Even though their efforts did not stop; Leipzig had to partially stop the participation process and start to focus on other concrete actions, such as institutional restructuring or applying for new funding opportunities in order to proceed with participation in future projects and re-gain the credibility and approval of smart cities among the citizens.

4.2.3 Achievements

When deploying the replication customer centric approach, it became evident to the Leipzig's team that it was necessary to have structural changes in Leipzig to advance in the topic of smart city. The replication process of Triangulum indicated that every city has its own smart city timeline in mind, they might be facing different challenges in specific moments. That was the case with Leipzig. Their timeline was different from the project because they need to deal with other challenges first.

Triangulum created conditions so that Leipzig could develop new guidelines and evolve in the smart city process. By being part of this pioneering initiative, the city administration needed to commit with the process, and gain legitimation within the municipality to support this new challenge. Inspired by the experience from the LCs, Leipzig realised that they needed structural changes to address these topics. Thus, at the beginning of 2019 a new division, the Digital City Unit was created inside of the municipality responsible for smart city and digitisation issues. Leipzig's team from Triangulum developed together with other departments this new division. Besides being responsible for the final steps of Triangulum, they will consider new guidelines for smart city to have a more city-wide coordination role. Leipzig could also

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

determine that they needed first to advance and consolidate the city digital transformation to be able to support the smart city idea, retaking the participation processes. As funding is still a crucial aspect for the implementation of smart city projects, the Digital City Unit also seeks for suitable funding options, as well as managing the two new EC funded projects that they are now part of SPARCs (SCC1) and EfficienCE (Interreg Central Europe Programme).

Both are direct results from Leipzig being part of Triangulum, from the knowledge gained by the team, and from the need for funding to implement smart city projects. It is relevant to emphasize that within SPARCS Leipzig changed from being a FC to become a LC, signalling their smart city development. Within their implementation strategy, Leipzig planned projects that can be linked in their majority to solutions implemented in the LCs from Triangulum. Some of the projects are now part of either SPARCS or EfficienCE, others are under evaluation. Nonetheless, their implementation is still in process.

4.2.4 Lessons Learnt

For Leipzig, the know-how exchange was of utter significance. The different activities and tools of the replication process allowed them to have access to the know-how of the LCs in their smart city pathway. They were able to have contact with relevant stakeholders of the LCs in this process, such as the private partners, which offered them different perspectives. In this way, they could also improve their relationship and create new connections with private partners in Leipzig. The neutral learning environment of the process relieved some of the pressure that such connections can create, and allowed the city of Leipzig to be more prepared in their setting. Nevertheless, to be able to do so, it is essential to have the right people to participate in such process since it will determine their level of engagement. The activities that had a higher level of customization, that were more specific to Leipzig's needs, facilitated the involvement of some partners, allowing a higher level of engagement and better outcomes for the city.

5 DISCUSSION

As previously stated, the EC intended with this new LCs mission, to speed up smart city implementation across Europe by having a programme where smart city implementations could be tested, recognized and validated, thus reducing risks for decision makers and investors. Despite promoting and relying on the idea of transferability and replication in their smart cities' programmes, the EC does not establish a clear framework or concept about how and what is replication means for them. In this way, EC leaves these tasks to be defined and shaped by each project consortium that needs to re-invent the wheel again and again. In their study, Boulanger and Nagorny say that "replication is not a 'natural' process but requires strategic planning and continuous mentoring" (Boulanger and Nagorny, 2018). The replication process of Triangulum exhibit that, indeed, replication requires planning, continuous mentoring, and dedicated time and personnel. That goes against the premise from the EC of having this programme to accelerate smart cities transition, even though the Triangulum process had beneficial outcomes, it is clear that replication is not an easy process.

The literature suggests that these processes (mobilising policies and ideas, transferability and replication) are not fast or straightforward and are subjected to different influences of the different actors. The literature also defends that these processes are complex, strongly dependent on context, and demand a high level of commitment (Dolowitz & Marsh, 2000; Macário & Marques, 2008; Macmillen & Stead, 2014; McCann, 2011; Peck & Theodore, 2010; Stead, 2012). They can be onerous processes. That might be especially true for cities that are trying to follow the 'best cities', trying to be part of the global networks, struggling to have budget and capacity to do so.

The way that the replication process was developed in Triangulum implies that replication cannot happen without having a 'mediator'. The amount of work and data that needs to be handled and the steps that need to be followed cannot take place between different cities outside the boundaries of specific projects or without someone exclusively dedicate to it. Both approaches of the replication process, the technology transfer and the customer centric approach have a setting that demands dedicated personnel and resources. That can be overwhelming to the ones involved and could undermine the learning process, which is perceived as the beneficial part of these processes (Boulanger & Nagorny, 2018; Gudmundsson et al., 2005; Macário & Marques, 2008; Macmillen & Stead, 2014; Stead, 2016). Most of the activities from the replication described here are part of a social process of the mobilisation of policies. Still, McCann (2011) also calls attention to

the fact that these activities can be time and budget dependent, what can limit who engages on them. In Triangulum, these limitations were not present, on the contrary, the project allowed partners to be part of them, and especially for municipalities such as Leipzig that have limited financial resources, this might represent unique opportunities. However, the experience showed the importance of having these cross-learning processes among not only these projects, but to promote urban transformations in general.

The know-how transfer that the replication process of Triangulum supported was what allowed Leipzig to engage in the two new projects SPARCs and EfficienCE. From the know-how, or process learning, where the LCs could show how was their process, it was possible to realise where the organisational and skill blockages are, and how to get around them. From that, it is possible to make a connection with the identification of different actions resulting from the use of best practices made by Macmillen and Stead (2014), even though their study was about sustainable mobility, the parallel is possible. More than heuristic learning, where the practitioners could perfect their understanding and the daily practice of smart cities and the processes that the LCs went through to make the implementation possible, they also did strategic articulations with the examples of the LCs. The strategic articulations motivated a change in the institutional structure of the municipality, thus securing smart city and digitisation in the city's agenda for urban planning. Not only for Leipzig did Triangulum serve as a way of doing strategic articulations. The LCs also saw the value of the demonstration in Triangulum, something similar to an advertisement campaign for smart cities. Even as LCs, they still need to foster the idea within their cities.

For Leipzig, however, most of the actions on the topic are still pilot projects as there is no suitable business model yet. Leipzig still depends on funding from other EC programmes or the national governments. The EIP-SCC, a smart city marketplace promoted by the EC, was developed to showcase the solutions from these 17 SCC1 projects and to display their bankability, as proven risk-free solution so other cities could simply implement them. However, each solution should be adapted to each city's reality, as it is not an easy and fast way, as it was shown in the case of Leipzig. Despite the unlocked smart city process, the commitment and progress that the city did on the topic of smart city, they still depend on funding to do so and the EC realised the importance of developing the business models of each solution rather than seeking for replication. As Leipzig became a LC within the SPARCs project, they could continue in receiving EC funding for their implementation of smart city solutions. Thus, there are no guarantees that demonstrated LC's solutions are risk-free. Leipzig's smart city projects are still considered from their perspective as pilot projects.

Triangulum unlocked a series of possibilities for Leipzig in the path to achieving CO2 reduction and a more sustainable future. However, the gains they had by being a FC were not because they managed to replicate any given smart city solution, but because they managed to identify their organisational blockages. What is possible to conclude is that for Leipzig as a FC, replication meant first, the already mentioned access to the flows of knowledge and capital, access to a global network where now they can actively engage. Secondly, it meant identifying their challenges and being able to define their framework to become a smart city, with a new institutional rearrangement. Finally, it meant learning and knowledge that they shared and exchanged with the other partners, and will continue to do. Triangulum allowed the city to start a new process; nevertheless, a process, not packages or solutions.

6 CONCLUSION

The findings of this research explore the influences in Leipzig of a smart city replication process, promoted by the EC and developed and applied within the scope of Triangulum. What could be perceived from the analyses of data and interviews is that the implementation of smart city solutions was not the direct outcome of Triangulum for Leipzig. Triangulum and the replication process unlocked a smart city process in the city, where they could engage in a network that allowed access to knowledge, ideas and capital. The knowledge sharing, especially concerning the processes of implementation, served as a way of promoting the idea of smart cities within the city government and amongst citizens so that the organisational and skill blockages could be overcome and the necessary changes could happen. The concept of smart cities and digitisation can still be so abstract that being part of such projects helps to foster the idea of what it could be and what can be accomplished through it, both for LCs and FCs.

Different literature, from the social science to the sustainable urban mobility perspective, imply that processes of transferability and replication can be overwhelming and onerous for the ones involved, demanding continuous attention. The findings here corroborate with the argumentation of the literature.

Triangulum replication process required work from Fraunhofer and the University of Stuttgart even from before the project to be able to take place. They had dedicated personnel, budget, different approaches, several activities, and a considerable amount of data. The process also required careful design and constant guidance. Regardless the name 'replication process', what seemed more relevant while engaging in the replication activities for the practitioners of Leipzig was to learn the know-how, the processes of how to do it and what is behind the solutions. Hence, learning about the processes was more relevant than replicating technologies or solutions per se.

Leipzig is now fully engaged in a smart city agenda. This was just possible through Triangulum. Nonetheless, they still depend on funding to accomplish that agenda. Within the next years, Leipzig will have the opportunity as a LC to implement pilot projects and engage with their citizens again. Despite the learnings from Triangulum, its replication and its deployed solutions, Leipzig still does not have bankable solutions as implementations are not coming in a quick-fix risk-free way. This is not necessarily undesirable, but it is just not what was envisioned by the EC.

The local context of Leipzig was not appropriate for simple replication of Triangulum solutions. The context differences between Leipzig and the LCs of Triangulum were perceived as a hindrance to replication at various levels and for different aspects, including legal, institutional, financial, and cultural. Reduction of CO2 emissions, sustainable development, new economy, digitisation and technology, are and will probably continue to be vital aspects for the future of Leipzig. However, the city will progress these objectives according to its own time, capacities and needs. The relevance of placing and grounding activities in the specificities of a city, the fixity of policies and cities cannot be underestimated, even when digital technologies seem to put everything into a more mobile or abstract place. Reflecting on the intentions of the replication concept might show that they need to be reconsidered. The challenges that persist, such as the lack of bankable solutions and funding opportunities other than EC and the faster pace for changes that might be needed for the environmental goals, should be considered in a new perspective. The network that was formed as one of the outcomes of the programme has the potential to divert from this established concept and explore innovative ways to address these challenges.

The success of smart cities or sustainable cities that can comply with environmental, social and economic goals should not be delimited by replication. Replicating for the sake of replicating will not bring benefits and will not be effective. Replication may not be the solution, but it may help bring the 'smartness' topic into the agenda of a city.

What the experience in Leipzig shows, is that replication was not the action that occurred during Triangulum. Access, rearrangements, changes, redefinition, exchange, learning, etc. occurred as part of a broader process, and technological solutions did not determine that.

Therefore, despite the recent efforts by the EC to hold working groups amongst SCC LC projects to exchange experiences on topics such as replication, this research proposes that it is also essential to recognize the value of knowledge gain as one of the main and key outcomes of such projects. Instead of focusing on replicating specific solutions amongst cities within projects, the EC should focus on using the favourable settings created by these projects to strengthen the competencies of FC to become smart. Moreover, it suggests to dissociate from the terminology replication and redefine what the real process is, balancing the expectation that the terminology could bring. That might be more profitable for the process and the actors involved.

The moment is opportune for this reflection since the projects from the first call of the SCC LC programme are close to conclusion and the evaluation of the actual outcomes of these projects can contribute with valuable insights. On the positive side, these projects might provide detailed sources of data that can generate in-depth understandings for European cities.

(Prof. Dipl.- Ing. Oliver Hall, Technische Hochschule OWL, Emilienstraße 45, 32756 Detmold, oliver.hall@th-owl.de)

1 ABSTRACT

Städte befinden sich in einem stetigen Transformationsprozess und aktuell rückt die Kreativwirtschaft als Schlüsselbereich und Innovationsmotor für die Gesamtwirtschaft vermehrt auch in das Blickfeld der Stadtentwicklung. Während dieses Themenfeld in Metropolen und Großstädten schon mehrfach städtebaulich und wissenschaftlich untersucht wurde, besteht in Mittelstädten noch Forschungsbedarf. Die zugrundeliegende Forschungsarbeit „Potenzialstudie Kreativ Quartier Detmold“ hatte das Ziel Erfolgschancen, Potenziale, Herausforderungen und Anforderungen an die (Weiter-) Entwicklung der Kultur- und Kreativwirtschaft in der typischen Mittelstadt Detmold und ihrer Bedeutung in einer polyzentralen Region zu untersuchen. Hierfür wurde ein Methodenmix angewendet, der sich in Form einer Umfrage mit den Anforderungen der Akteure auseinandersetzt; den Stadtentwicklungsprozess zweier erfolgreicher Fallstudien untersucht; Detmold städtebaulich auf geeignete Orte zur Ansiedlung von Kreativen analysiert und schließlich in Szenarien vergleichend bewertet. Im Ergebnis zeigt sich, dass die Kultur- und Kreativwirtschaft der Mittelstadt Detmold ein starkes Bedürfnis hat sich zu vernetzen und insgesamt mehr wahrgenommen zu werden. Es zeigen sich starke Wertschöpfungsketten untereinander und besondere Anknüpfungspotenziale im Umfeld von Hochschulen. Die räumliche Analyse offenbart, dass auch in einer Mittelstadt wie Detmold ausreichend Potenzialräume vorhanden sind. Gleichwohl existiert nicht ausreichend Eigendynamik, dass sich diese Räume selbst und in verdichteter Form entwickeln. Das kreative Potenzial ist also auch in Mittelstädten vorhanden. Es braucht aber gerade in einer Mittelstadt einen gesteuerten Stadtentwicklungsprozess der zusammen mit Förderimpulsen gezielt Entwicklungen in diese Richtung stimuliert.

Keywords: Stadtentwicklung, Mittelstadt, Kreativwirtschaft, Innovationsmotor, Kreativquartier

2 EINFÜHRUNG IN DAS THEMA KREATIVWIRTSCHAFT

2.1 Kultur- und Kreativwirtschaft als Schlüsselbereich für die Gesamtwirtschaft

Die Kreativwirtschaft wird vom Bundesministerium für Wirtschaft und Energie als Schlüsselbereich und ein Innovationsmotor für die Gesamtwirtschaft eingeordnet (Bundesministerium für Wirtschaft und Energie 2019). Sie ist ein wichtiger volkswirtschaftlicher Faktor und Impulsgeber für die gesamte Wirtschaft. Die Kultur- und Kreativwirtschaft fungiert mit ihren kreativen und innovativen Ideen als zentraler Impulsgeber von der viele traditionelle Wirtschaftszweige in NRW profitieren (Ministerium für Wirtschaft, Energie, Industrie, Mittelstand und Handwerk des Landes Nordrhein-Westfalen 2013). Insgesamt erzeugen die Unternehmen der Kreativ- und Kulturwissenschaft mit ihren individuellen, vielfältigen, kreativen Leistungen und Nutzungen einen Mehrwert in verschiedenen gesellschaftlichen sozialen und ökonomischen Bereichen. Die wirtschaftlichen Kennzahlen der Kultur – und Kreativwirtschaft haben sich stets positiv entwickelt. Die Zahl der Kernerwerbstätigen, Selbstständigen und sozialversicherungspflichtige Beschäftigte, sowie der Umsatz sind weiter gestiegen und konnte im Jahr 2018 neue Spitzenwerte erreichen. Insgesamt ist die Umsatzentwicklung in der deutschen Kultur- und Kreativwirtschaft ist seit dem Jahr 2014 positiv. (vgl. Bundesministerium für Wirtschaft und Energie 2019)

Trotz der hohen Bedeutung der Kultur- und Kreativwirtschaft werden die Teilmärkte und Wirtschaftszweige immer wieder unterschiedlich definiert. Sowohl Teilmärkte als auch Wirtschaftszweige sind nicht scharf umrissen und weisen zahlreiche Überlappungen auf. Um eine möglichst hohe Vergleichbarkeit zu den Monitoring-Berichten des Bundes und des Landes NRW sicherzustellen, zieht die Forschungsarbeit die Definition des Bundes bzgl. der Teilmärkte heran und erweitert diese um die definierten Wirtschaftszweige innerhalb dieser Teilmärkte des Landes NRW (s. Abb. 1).

Abbildung 1: Teilmärkte & Wirtschaftszweige der Kreativwirtschaft (Cardinali et al. 2019, nach BMWE 2017 & MWIDE NRW 2016)

2.2 Kultur- und Kreativwirtschaft im Fokus der Stadtentwicklung

Richard Florida beschäftigte sich früh mit dem Zusammenh¬ang zwischen der kreativen Klasse und der Anziehungskraft des städtischen Raums. Er zeigte, wie sich die Wettbewerbsfähigkeit der Städte steigern lässt, indem sie aktiv um die kreative Klasse werben und so neue wirtschaftliche Aktivitäten und Impulse erzeugen (Florida 2002). Dazu wiesen Eckert et al. für europäische Städte nach, dass die kreative Klasse eine hohe Mobilität aufweist und stets auf der Suche ist nach Städten in denen die Bedingungen mit ihren Idealen zusammenpassen (Eckert et al. 2010). Darüber hinaus zeigt sich, dass sich die Unternehmen der Kultur- und Kreativwirtschaft räumlich gesehen nicht gleichmäßig verteilen, sondern regionale Cluster ausbilden (Bundesministerium für Wirtschaft und Energie). In der Folge führt das zu einem Wettbewerb der Städte, die jeweils für sich eine möglichst hohe Sichtbarkeit des kreativen Milieus erzeugen müssen, um auf sich als Standort aufmerksam zu machen. Dies gelingt bisher fast ausschließlich Großstädten und Metropolen. So dass Klein- und Mittelstädte tendenziell Schwierigkeiten haben, ihre oftmals selbst ausgebildeten Kreativen zu halten. Auf Grundlage der Erkenntnisse Richard Floridas liegen zahlreiche weitere Studien vor. Die Publikationen befassen sich mit europäischen Großstädten (Eckert, et al. 2010), den deutschen Bundesländern (Berlin-Institut für Bevölkerung und Entwicklung 2007), deutschen Kreisen und kreisfreien Städten (Martin 2015), aber auch dem gesamten Bundesgebiet (Fritsch, Stützer 2007). Klein- und Mittelstädte werden in den bisherigen Forschungen noch nicht auf der städtebaulichen Ebene untersucht. Dazu bleibt aktuell offen, ob die Kultur- und Kreativwirtschaft in Mittelstädten wie Detmold vor besonderen Herausforderungen steht oder schlicht andere Anforderungen an Standorte stellt. Mehr als die Hälfte der deutschen Bevölkerung lebt jedoch in Klein- und Mittelstädten. Insbesondere durch die Digitalisierung wird dem ländlichen Raum von vielen Kultur- und Kreativschaffenden ein besonderes Entwicklungs- und Wachstumspotenzial zugesprochen. Die anhaltende Digitalisierung führt dazu, dass Hemmnisse durch räumliche Distanzen an Bedeutung verlieren. Eine verbesserte Sichtbarkeit des Innovationspotenzials nach außen und nach innen ist für die Kultur- und Kreativwirtschaft in diesen Räumen essentiell (Bundesministerium für Wirtschaft und Energie).

Als Schlüsselakteur für die Wirtschaftsförderung einer Stadt und als Impulsgeber für die Stadterneuerung von Transformationsräumen innerhalb der Stadt, steht die Kultur- und Kreativwirtschaft in einem besonderen Fokus. Vielerorts ist die Kreativwirtschaft eine Art Vehikel für die Implementierung von neuen Strategien in der lokalen Wirtschaftspolitik geworden (Overmeyer et al. 2014).

Insbesondere in Zeiten der Reurbanisierung und doppelten Innenentwicklung fungiert die Branche auch als Impulsgeber und Nährboden für Stadterneuerung. Sie ist nicht nur in der Lage wohnverträgliche Arbeitsplätze zurück in die Innenstadt zu bringen. Sie wirkt sich auch wertsteigernd auf das gesamte Viertel aus und befördert Investitionen. In der Gestaltung urbaner Transformationsprozesse wird die Wieder- bzw. Neuentdeckung der kulturellen und ökonomischen Kreativität der Stadt und deren Fähigkeit zur Erneuerung eine zentrale Aufgabe geworden, die auch die Mittelstädte erreicht hat. Es existieren jedoch in sehr wenigen Kommunen Praxiserfahrungen mit ressortübergreifenden Strategien und dem Zusammenspiel zwischen Wirtschaftsförderung und Stadtentwicklung für eine verdichte Entwicklung von Kreativclustern im Besonderen oder Wirtschaftsclustern im Allgemeinen.

Dabei können solche Agglomerationsvorteile auch abseits der großen Städte generiert werden, wie Danielzyk et al. in ihrer Veröffentlichung zu erfolgreichen metropolenfernen Regionen gezeigt haben (2019). Netzwerke aus Wissenschaft, Dienstleistungen und Unternehmen tragen dazu bei, innovative Impulse in die Praxis umzusetzen. Innerhalb eines Verbundes sind neben Unternehmen in der Regel auch staatliche Behörden, Forschungsinstitutionen, Bildungs- und andere Einrichtungen angesiedelt. Aufgrund des netzwerkartigen Zusammenwirkens aller Clusterteile kann die Produktivität und Innovationsfähigkeit gestärkt werden. Cluster üben einen starken Anreiz auf Unternehmensgründung aus, da das Markteintrittsrisiko gesenkt wird und durch die Bündelung eine hohe Sichtbarkeit erzeugt wird. Diese innovativen Milieus machen deutlich, dass nicht nur ökonomische Faktoren für die regionale Innovationskraft entscheidend sind. Insbesondere städtebauliche, soziale und kulturelle Aspekte sind wichtige Kriterien für eine hohe Sichtbarkeit und Anziehungskraft. Insgesamt messen Danielzyk et al. der Förderung der regionalen Innovationsfähigkeit in der Regionalentwicklung eine zentrale Bedeutung zu (2019). Unter ganz ähnlicher Prämisse entstanden in Deutschland viele Hochschulen in Mittelstädten im letzten Jahrhundert, abseits der Metropolen, in der Hoffnung auf Anwesenheits- und Aktivitätseffekte der Hochschulen für die regionale Entwicklung (Pasternack, Zierold 2018).

Detmold besitzt mehrere Hochschulen und Berufsschulen die Akteure aus der Kreativ- und Kulturwirtschaft ausbilden. Seitens der Stadt Detmold, Kreis Lippe Wirtschaftsförderung, Hochschule für Musik sowie der Technischen Hochschule OWL wurde der Forschungsschwerpunkt urbanLab beauftragt zu untersuchen ob die Mittelstadt Detmold geeignet ist und entsprechende Voraussetzungen mitbringt um den Wirtschaftszweig der Kreativ- und Kulturwirtschaft zu stärken und im städtebaulichen Raum zu konkretisieren. Demzufolge lautete die zugrundeliegende Frage der Studie, wie der Transfer zwischen Bildung, Forschung, Wirtschaft und Gesellschaft im Bereich der Kultur- und Kreativwirtschaft in Detmold durch gezielte städtebauliche Entwicklungen zu einem Cluster und lokalem Innovationsökosystem verdichtet werden kann.

3 METHODIK

Um sich dem hochkomplexen Thema und seinen Entwicklungsanforderungen, den Steuerungsnotwendigkeiten und den städtebaulichen Möglichkeiten in einer Mittelstadt wie Detmold systematisch zu nähern, wurden verschiedene Methoden eingesetzt.

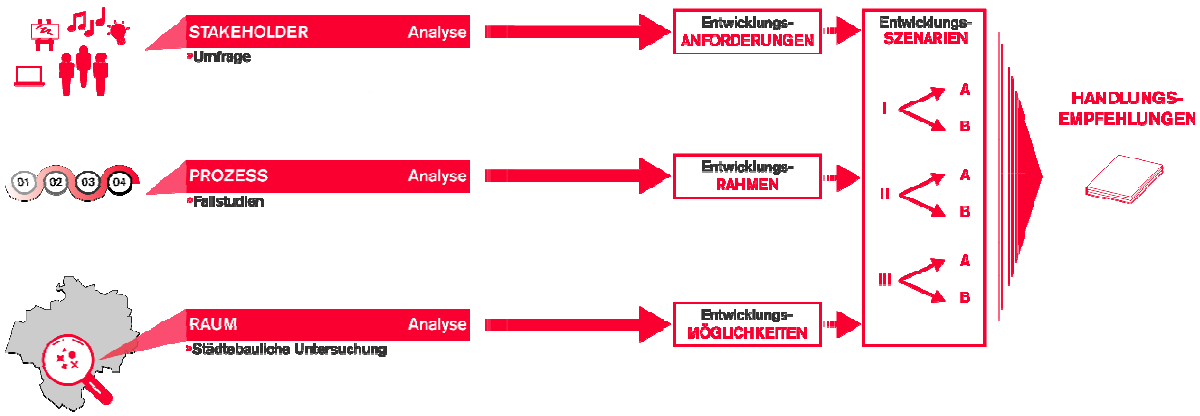

Abbildung 2: Methodik (Cardinali et al. 2019)

3.1 Stakeholderanalyse

Als Grundlage fungierte eine Stakeholderanalyse, welche Informationen zu Bedürfnissen, Anforderungen und Vernetzungspotenzialen der Kultur- und Kreativwirtschaft generierte. Die Stakeholderanalyse wertete vorhandene statistische Erhebungen auf Bundes-, Landes- und Regionaler Ebene aus. Zusätzlich erfolgte eine Recherche nach Berufsbildern sowie übergeordneten Begriffen der Kreativbranche anhand der obengenannten Definitionen der Teilmärkte. Mit dieser Methodik konnten ca. 1100 Akteure der Kultur- und Kreativwirtschaft in Ostwestfalen-Lippe ermittelt werden, die dann um Beteiligung an der Umfrage gebeten worden sind. Die Akteure lassen sich in Kreativwirtschaft, freischaffender Künstler und Kulturinitiativen

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

unterteilen und bilden die erste Säule der Adressaten. Der Fragebogen war in acht verschiedene Kategorien eingeteilt und hat folgende Themen abgefragt:

(1) Einschätzung der KuK Allgemein,

(2) Beschreibung Unternehmen/Organisation,

(3) Standortfaktoren,

(4) Mitarbeiter/Mitglieder,

(5) Infrastruktur & Arbeitsformen,

(6) Kooperation & Wertschöpfungsketten,

(7) Fortbildung,

(8) Allgemeine Angaben

Eine zweite Säule ist der Bildungs- und Ausbildungsbereich der Kreativwirtschaft, der durch bestehende Verteiler an den teilnehmenden Hochschulen in Detmold (Hochschule für Musik Detmold und Technische Hochschule OWL - Fachbereich Architektur & Innenarchitektur, Fachbereich Medienproduktion, Fachbereich Bauingenieurwesen) sowie den teilnehmenden Berufsschulen in Detmold breit unter Absolventen, Studenten und Berufsschülern gestreut werden konnte. Dieser Fragebogen hatte ebenfalls acht Kategorien, die allerdings teilweise nur an Absolventen adressiert wurden (mit A gekennzeichnet):

(1) Einschätzung der KuK Allgemein,

(2) Angaben zu Studium & Ausbildung

(3) Standortfaktoren,

(4) Ambitionen zur Selbstständigkeit,

(5) Übergang in den Arbeitsmarkt (A),

(6) Beschreibung Unternehmen (A),

(7) Beschreibung Tätigkeit (A),

(8) Allgemeine Angaben (A),

Insgesamt haben 278 Akteure an der Umfrage teilgenommen: 51 Vertreter eines Unternehmens, 15 Vertreter eines Vereins/Initiative, 24 Freischaffende Künstler, 60 Absolventen, 97 Studenten, 31 Berufsschüler. Im Verhältnis von Stichprobe zur Gesamtpopulation der Kultur- und Kreativwirtschaft in Ostwestfalen-Lippe ergibt sich eine Fehlertoleranz der Ergebnisse von 10%.

3.2 Fallstudien

Das Instrument der Fallstudien gab einen Einblick in bestehende Kreativquartiere in Deutschland und ihre Umsetzungsstrategien. Mit 306.000 Einwohnern diente die Stadt Mannheim als Best-Practice Beispiel für die Folgeeffekte einer Kreativquartierentwicklung. Die weit fortgeschrittenen Entwicklungen zeigen Möglichkeiten und Impulswirkungen öffentlicher Förderungen im Bereich der Kreativ- und Kulturwirtschafts auf. Die Voraussetzungen im Vergleich zu Detmold sind durchaus unterschiedlich, dennoch zeigen sich wichtige Einblicke in den Prozess zur Entwicklung eines Kreativquartiers und in mögliche Folgewirkungen. Die Fallstudie der Mittelstadt Coburg analysiert einen Prozess der mit der Mittelstadt Detmold und seinen Hochschulen gut vergleichbar ist. Allerdings ist hier der Prozess noch nicht so weit fortgeschritten. Mit Hilfe der Untersuchung von Fallstudien entstand das Bild eines möglichen Entwicklungsrahmens und notwendigen Steuerungsprozessen.

3.3 Städtebauliche Analyse

Eine städtebauliche Analyse identifizierte schließlich Neubau- Umbau- Umnutzungs- und Aneignungspotenziale zur Etablierung eines Kreativquartiers in der bestehenden Stadtstruktur. Dazu wurde der Stadtraum nach den vier von Overmeyer et al. definierten Raumkategorien (2014), die von den kreativen Milieus nachgefragt werden, untersucht:

(1) Transformationsräume,

(2) Leergefallene Erdgeschosslokale,

(3) Leerstehende Büroimmobilien,

(4) Neubaugebiete

Neben der Vorortung von Potenzialräumen sind die bereits bestehenden Standorte von Kultureinrichtungen und Akteure der Kreativwirtschaft wichtig um potenzielle Synergieeffekte zu identifizieren. Dazu wurden weitere flankierende Nutzungen und Wegebeziehungen von Studierenden, Berufsschülern und Kunden des Einzelhandels analysiert. In der Folge wurden auch die weichen Faktoren und die Belebtheit bestimmter öffentlicher Räume sichtbar.

3.4 Städtebauliche Szenarien

Um abschließend zu validen Entwicklungsschritten zu gelangen, wurden drei städtebauliche Szenarien entwickelt und anhand der vorher in der Stakeholderanalyse geäußerten Standortfaktoren der Kultur- und Kreativwirtschaft miteinander in einer Bewertungsmatrix verglichen. Die Bewertungskriterien teilten sich in vier Themenblöcke auf:

(1) Sichtbarkeit und Identität,

(2) Entwicklungsstufen und Realisierbarkeit,

(3) Erreichbarkeit und Anbindung,

(4) Gemeinschaft und Netzwerk

Die einzelnen Faktoren wurden dabei nicht weiter gewichtet. Das Ergebnis ist eine Gesamtsumme von möglichen 110 Punkten, die schließlich gegenüber gestellt wurden, um zu einer abschließenden Bewertung zu gelangen.

4 ERGEBNISSE

4.1 Stakeholderanalyse

Die Verteilung der einzelnen Unternehmen der Kreativwirtschaft zeigt deutlich, dass Detmold gemessen an der Einwohnerzahl ein überdurchschnittlich ausgeprägter kreativer Hotspot der Region ist. Die kreative Dichte Detmolds ist hoch. In der Region OWL weisen die Städte einen Wert von unter 1 Einrichtung pro 1.000 Einwohner auf, Detmold hingegen erreicht einen Wert von 2,5 Einrichtungen pro 1.000 Einwohnern. Gleichzeitig äußern die Befragten aber, eine geringe Wahrnehmbarkeit der kreativen Dichte in der Stadt. Es zeigte sich außerdem, dass die Teilmärkte untereinander starke Wertschöpfungsketten aufweisen, aber nur 32% in Netzwerken organisiert sind. Dabei ist die Bereitschaft sich gemeinschaftlich zu organisieren ausgesprochen ausgeprägt. Als Standortfaktor erscheinen urbane und nutzungsgemischte Räume vorteilhaft, um die nachgefragten flankierten Dienstleistungen und den Kontakt zu Endkunden sicherzustellen. Das Interesse an einer generellen Zusammenarbeit mit Hochschulen ist mit 68% stark ausgeprägt. Noch deutlicher wird der Zugang zur technischen Infrastruktur der Hochschulen, wie z.B. 3D Drucker, Tonstudio oder Veranstaltungsequipment nachgefragt. Hier äußern durchschnittlich über 80%, dass sie davon (sehr) profitieren würden. Als Gegenleistung für diesen Zugang ist mehr als die Hälfte der Befragten bereit Arbeitsstunden für die Gemeinschaft zu leisten oder Ausleih-/Nutzungsgebühren zu bezahlen. Immerhin 41% wären bereit dafür einen Mietaufschlag zu zahlen. Für die Implementierung der Wertschöpfungskette zwischen Bildung und Wirtschaft kann Nähe und Zugang ein wesentlicher Schlüssel sein. Daneben ist die Ausbildung der angehenden jungen Fachkräfte und das Halten dieser in der Region eine wichtige Säule für eine dynamische starke Kultur- und Kreativwirtschaft. Auf Grundlage der Stakeholderanalyse wurde deutlich, dass Detmold einige der Absolventen aus der Region dazu bewegen kann in Detmold zu bleiben. Bezogen auf die gesamte Region OWL wandern derzeit jedoch noch ca. die Hälfte der jungen Fachkräfte aus Detmold in das übrige Bundesgebiet ab. Nicht zuletzt das sehr hohe Gründungsinteresse der Befragten Studierenden (55%), Absolventen (47%) und Berufsschüler (26%) und der hohe Bedarf nach Fortbildungsangeboten unter den etablierten Unternehmen, weisen auf einen hohen Unterstützungsbedarf und eine bisher nicht ausreichende Sichtbarkeit bestehender Angebote hin (siehe Abb. 3).

Abbildung 3: Gründungstendenzen (Cardinali et al. 2019)

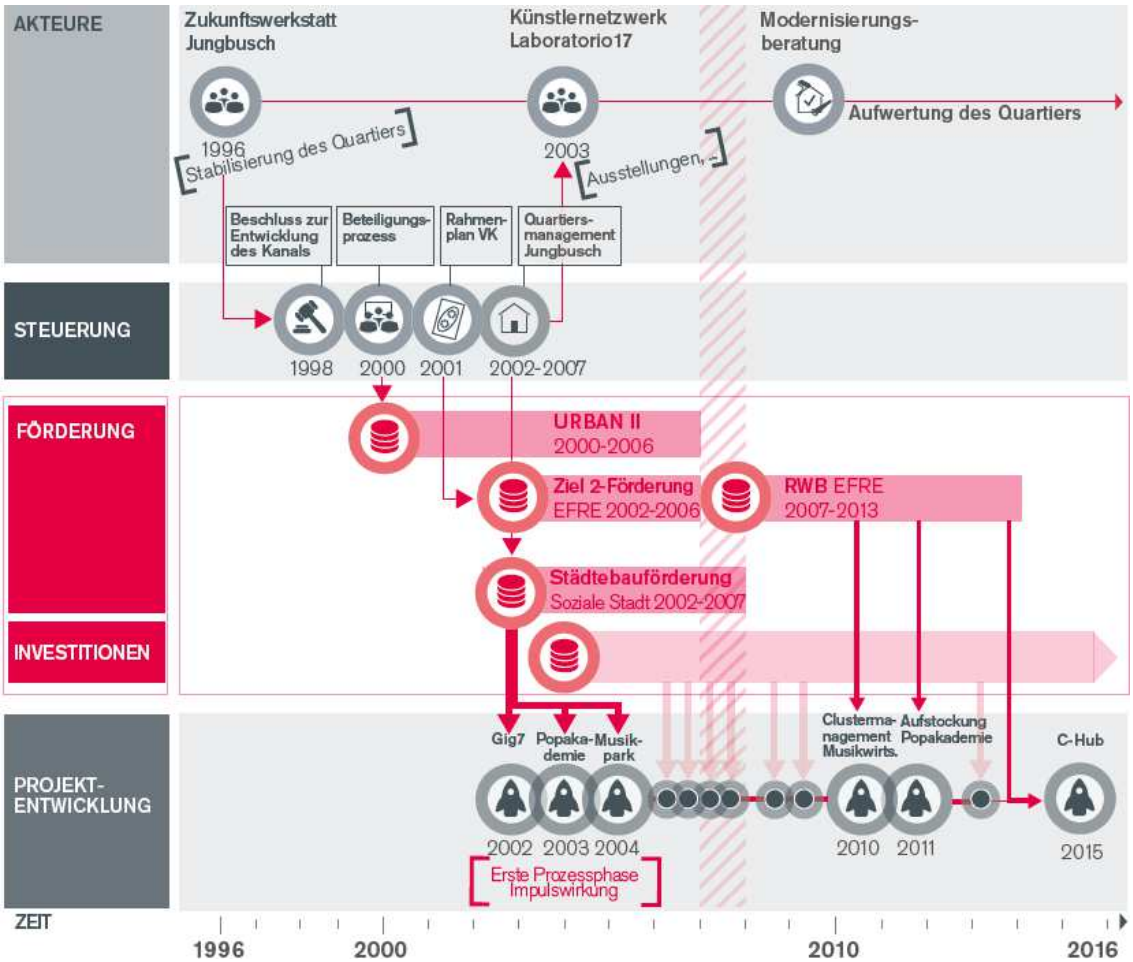

Abbildung 4: Prozess „Kreativquartier“ Mannheim-Jungbusch (Cardinali et al. 2019).

4.2 Fallstudien

Die Untersuchung der Fallstudien in Mannheim-Jungbusch und Coburg zeigte auf, wie aus einzelnen Hochbauprojekten und verschiedenen Akteuren ein integriertes Stadtentwicklungskonzept entstehen kann, das in der Lage ist einen attraktiven Standort für die Kreativ- und Kulturwirtschaft in der Stadt gebündelt zu entwickeln (siehe Abb. 4). Die Nähe zu den Hochschulen sorgte für eine messbar erhöhte Gründungsrate.

Integrierte Stadtentwicklungskonzepte sowie Rahmenpläne sind in Bezug auf die Entwicklung eines Kreativquartiers nicht nur dazu geeignet Synergieeffekte zwischen einzelnen Projekten herzustellen, sondern auch um eine tragfähige Gesamtentwicklung zu erreichen. Gründungszentren stellen in den Fallstudien eines der ersten wichtigen Leitprojekte dar, gerade unter der Einbeziehung der Hochschulen besitzen sie eine starke Impulswirkung und Anziehungskraft. Mit Hilfe von Gründungszentren entsteht ein erster Kommunikationskanal zwischen Hochschule und Wirtschaft. Neben den Gründungszentren sind offene Werkstätten Teil erfolgreicher Konzepte und Treiber für das Ansiedeln kreativer Unternehmen im Umfeld. Die offenen Werkstätten sind darüber hinaus ein Unterstützungsangebot für angehende Gründer. Viele der Maßnahmen sind Einzelimpulse die aufeinander aufbauen, kombiniert und eingebettet in einen attraktiven gut erreichbaren öffentlichen Raum wirken sie am besten. Vervollständigt wird der Nährboden für die angehende Kreativwirtschaft mit gemeinschaftlich nutzbaren Räumen. Eine räumliche Nähe zu den Hochschulen erleichterte die Etablierung von Dienstleistungen durch eine größere Nachfrage. Regelmäßige Veranstaltungen ergänzten das Maßnahmenpaket und förderten den Ort im Bewusstsein des lokalen und regionalen Umfelds.

4.3 Städtebauliche Analyse

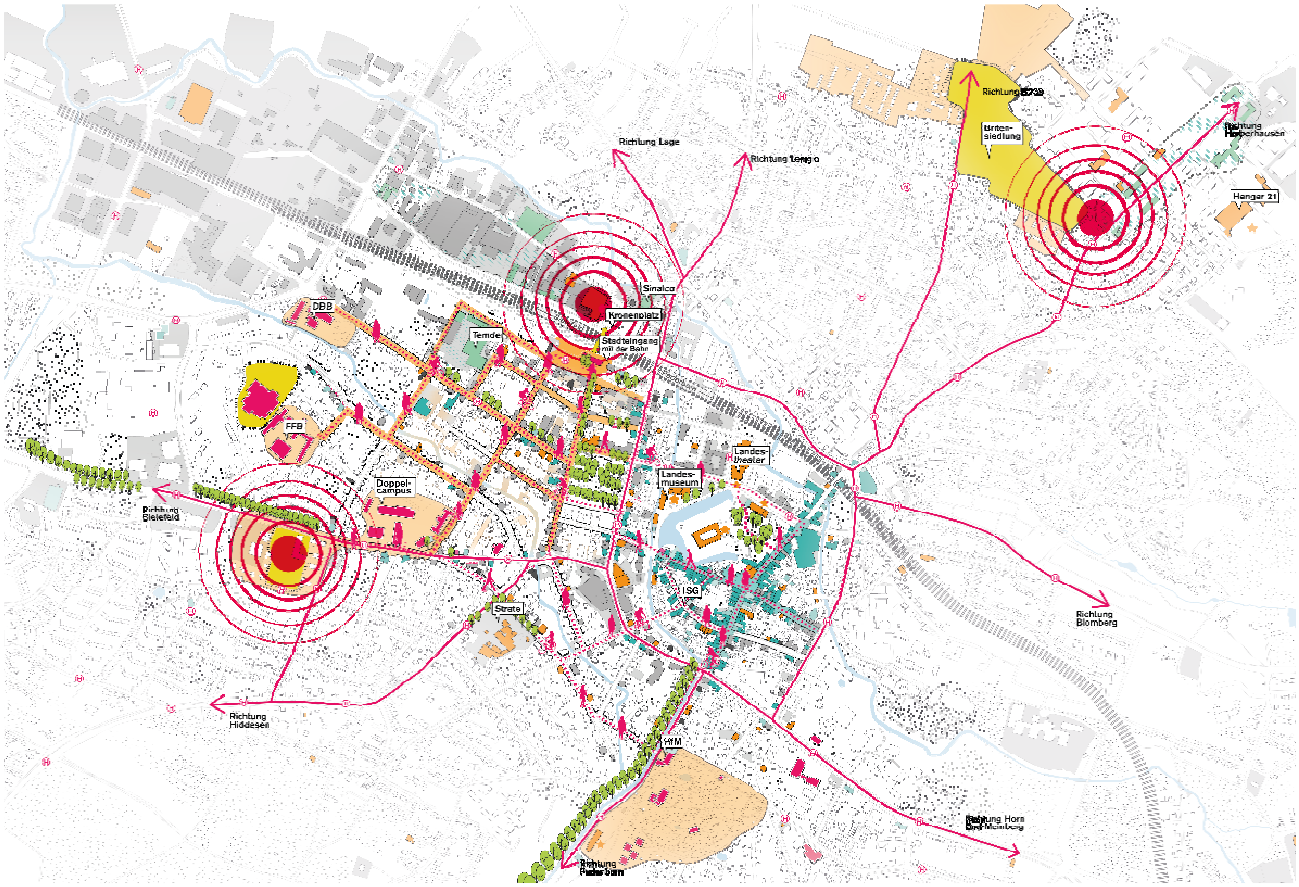

Abbildung 5: Entwicklungsräume (Cardinali et al. 2019)

Die räumliche Untersuchung zeigt, dass die nachgefragten Räume auch in Mittelstädten vorzufinden sind. Alle Kategorien der Transformationsräume in Detmold sind in den klassischen Lagen rund um den Bahnhof und darüber hinaus in den Kasernenarealen und der Nähe der Hochschule zu finden (siehe Abb. 5). Im Umfeld des Bahnhofs sind leerstehende oder mindergenutzte Gewerbeimmobilien, welche Potenzial für die Nachnutzung von Kreativen aufweisen. Neben dem Transformationsraum am Bahnhof befindet sich ein großflächiger am ehemaligen Standort der britischen Streitkräfte. An diesem Standort hat die Transformation

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

bereits begonnen. Einige Kasernen wurden bereits in eine neue Nutzung überführt, vereinzelt auch durch die Kreativ- und Kulturwirtschaft. Das Areal und die Kasernen bieten darüber hinaus viel Raum zur Aneignung und Nachnutzung. Die westlich befindliche Britensiedlung hingegen ist aufgrund ihrer Wohntypologien nicht ohne weitere Maßnahmen durch die Kreativwirtschaft nutzbar. Des Weiteren liegen westlich des Kronenplatzes weitere Neubaupotenziale, als möglicher Impuls für eine weitere Transformation des Gewerbeareals und der Leerstände im Umfeld des Bahnhofs, sowie an der Bielefelder Straße. Im Zentrum Detmold befinden sich leerstehende Erdgeschosslokale, sowie im angrenzenden Westen und Süden der Innenstadt. Im Untersuchungsraum befinden sich zudem ehemalige Büroimmobilien. Demzufolge sind ehemalige Gewerbeareale, leerstehende Büroimmobilien aus der Nachkriegszeit und leere Erdgeschosslokale in Detmold zu finden, welche für Kreative besonders attraktiv sind. Ungenutzte Brachflächen mit Neubauentwicklung sind ebenso denkbar. Auf Grundlage der Untersuchung von den Potenzialflächen, mit der Überlagerung von bestehenden Akteuren und Standorten sowie den Bewegungen von Studierenden und Berufsschülern werden im Raum vier potenzielle Entwicklungsräume erkennbar. Die bereits angesprochenen großflächigen Entwicklungsräume wie der Kreativ Campus an der Bielefelder Straße, Bahnhofsareal und Britensiedlung inklusive der Kasernen besitzen jeweils eigene Herausforderungen und Potenziale. Die Entwicklungsstandorte besitzen ihre eigene Identität. Der Standorte des Kreativ Campus an der Bielefelder Straße fällt unter den Typus Neubau mit Campusflair. Die direkte Nähe zur Hochschule ist sehr auffällig. Das Bahnhofsareal ist ein Mix aus geschichtsträchtigen Transformationsräumen sowie leerstehenden oder mindergenutzten Gewerbehallen. Der historisch bedeutendste Ort ist hingegen das Kasernenareal. Angrenzend im Westen befindet sich zudem die Britensiedlung. Die gründerzeitliche Struktur im Detmolder Westen ist der vierte Entwicklungsraum. Leerstände und Bewegungslinien weisen auf ein großes Potenzial des Detmolder Westens hin, der insbesondere in den Erdgeschosszonen absehbar kleinteilige privatwirtschaftliche Folgenentwicklungen aufnehmen kann. Im Ganzen wird deutlich, dass eine bauliche Entwicklung in den drei größeren Entwicklungsräumen am Kreativ Campus, im Umfeld des Bahnhofs und im ehemaligen Areal der Briten möglich ist. Die potenziellen Entwicklungsräume weisen jeweils eigene Stärken, Herausforderungen und Entwicklungschancen auf. Die Räume bieten zudem unterschiedliche Flächenverfügbarkeiten und Potenziale für weitere Entwicklungen.

4.4 Städtebauliche Szenarien

Die städtebauliche Analyse legte mögliche Entwicklungskerne offen und gab Aufschluss über die räumlichen Qualitäten. Zusätzlich ermöglichten die untersuchten Fallstudien Einblicke in mögliche Konzepte und Strategien in der Entwicklung von Kreativquartieren. Die Umfrage verdeutlichte Anforderungen, Notwendigkeiten und Bedürfnisse der Kreativen. Darauf aufbauend wurden drei städtebauliche Szenarien entwickelt und anhand der identifizierten Anforderungen und räumlichen Potenzialen bewertet. Die Szenarien orientieren sich an bereits beschlossenen baulichen Entwicklungen an der Bielefelder Straße, dementsprechend nehmen alle Szenarien die Impulse der Entwicklung auf und versuchen sie weiterzuentwickeln. Das Szenario „Kreativ Campus+“ beschreibt eine verdichtete Neubauentwicklung rund um den bestehenden Campus der TH OWL. Folglich wird der bestehende Campus erweitert. Der Entwurf nimmt die vorhandenen Strukturen und Campi auf und integriert sie in eine neue städtebauliche Entwicklung und entwickelt ein gemeinsames Cluster. Das Ergebnis zeigt hochwertige öffentliche Platzsituationen, die eine hohe Aufenthaltsqualität bieten. Das Szenario „Kreativ Rahmen“ setzt zusätzliche Impulse am Bahnhof und platziert sich mit maximaler Sichtbarkeit in der Stadtmitte. Die Impulse des Fachbereiches Medienproduktion an der Bielefelder Straße und den Anschluss des Detmolder Nordens durch eine Unterführung am Bahnhof werden genutzt. Das Szenario weist eine geringe Anzahl an notwendigen Neubauten auf, da viele Bestandsgebäude umgenutzt werden. Das Szenario „Kreativ Hotspots“ nutzt die Große Flächenverfügbarkeit der leergefallenen Kasernen im Stadtteil Hohenloh und die Impulswirkung an er Bielefelder Straße. Beide Impulse werden verknüpft. Der Detmolder Norden wird dabei großflächig neustrukturiert.

Das Szenario verfolgt einen integrativen Ansatz mit Bestandsnutzungen und Inwertsetzungen in Kombination mit Neubauten. Der Vergleich dieser drei städtebaulichen Szenarien zeigt, dass das Szenario „Kreativ Campus+“ aufgrund seiner kurzen Wege und die maximale Nähe zu einigen Konsortialpartnern besticht (siehe Abb. 6). Die Vernetzung der Wirtschaft mit den vorhandenen Bildungs- und Forschungseinrichtungen wird dadurch voraussichtlich positiv beeinflusst. Das Szenario „Kreativ Rahmen“ ist ansprechend durch die starke Impulswirkung am Kronenplatz und seine Positionierung in der

Stadtgesellschaft. Besondere Stärke dieses Szenarios ist die große Flexibilität und die Nutzung vieler Leerstände. Die Offenheit wiederum birgt die Gefahr vieler Einzelentwicklungen, die nicht als Kreativquartier wirken und keine Gemeinschaft oder Netzwerk erzeugen können. Das Szenario „Kreativ Hotspots“ weist eine große Flächenverfügbarkeit auf. Die Neugestaltung des Raums zwischen den beiden Kasernen als neue Platzspange und Mittelpunkt des Kreativclusters kreiert zudem einen hochqualitativen öffentlichen Raum und bietet die Möglichkeit für einen Open-Air Makerspace. Der Vergleich zeigt auf, dass die Szenarien vor unterschiedlichen Herausforderungen bzgl. Flächenverfügbarkeit, Impulswirkung und Anbindung stehen. Deutlich wird, dass eine größtmögliche Nähe zur Innenstadt erstrebenswert ist um ohne Mehraufwand eine hohe Sichtbarkeit in der Stadtgesellschaft und eine höhere Nutzerfrequenz für angebotene Dienstleistungen zu erhalten. Darüber hinaus wäre eine räumliche Dichte vorteilhaft um die Gemeinschaft unter den Akteuren zu fördern.

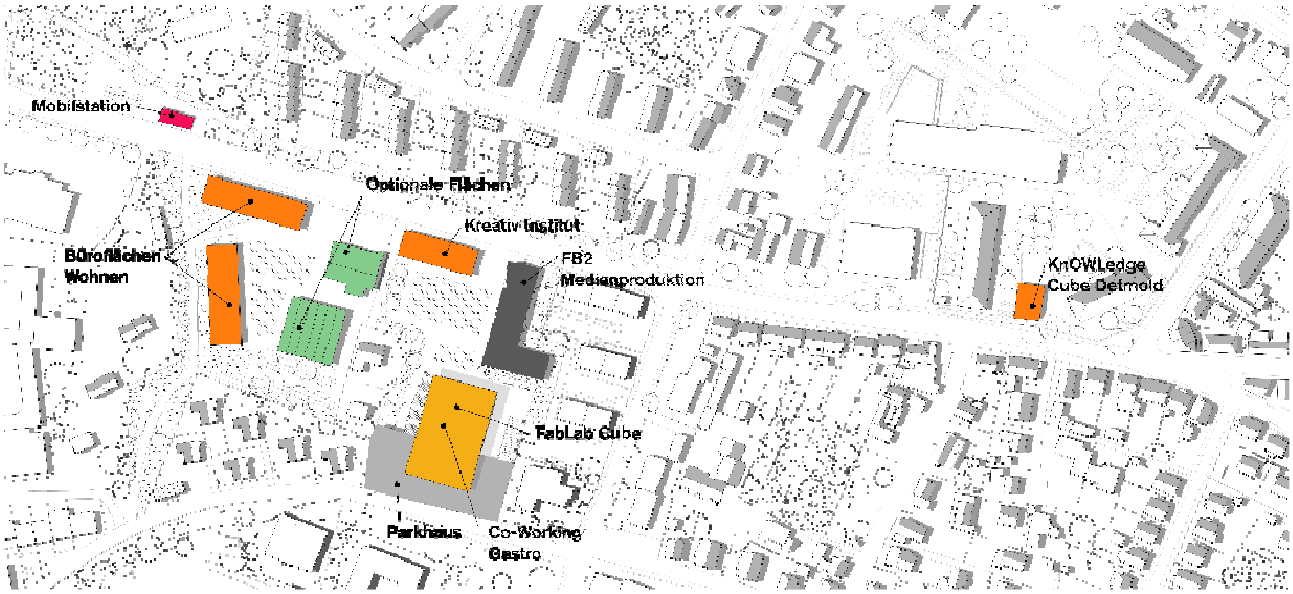

Abbildung 6: Szenario „Kreativ Campus+“ Nutzungen ohne Maßstab (Cardinali et al. 2019)

5 CONCLUSIO

Auf Grundlage der Forschungsarbeit ist erkennbar, dass gerade in einer Mittelstadt wie Detmold der Bedarf der Akteure der Kultur- und Kreativwirtschaft ausgesprochen hoch ist, sich untereinander zu vernetzen. Es lässt sich außerdem ableiten, dass diese Cluster und Netzwerke eines gesteuerten Prozesses bedürfen, da die eigenen Marktkräfte hierfür in einer Mittelstadt nicht ausreichen. Um eine entsprechende Sichtbarkeit und Impulswirkung zu erzeugen, sind urbane stark frequentierte und nutzungsgemischte Räume zu entwickeln, die ausreichend Sogwirkung erzeugen. Es hat sich gezeigt, dass insbesondere die Hochschulen in den Mittelstädten dafür ein entscheidender Akteur sind. Die Öffnung der technischen Infrastruktur ist ein entscheidender Schlüssel zur Implementierung der Wertschöpfungskette zwischen Bildung, Forschung und Wirtschaft. Durch Formate wie OpenLabs kann auch eine gesteigerte Wahrnehmung in der Stadtgesellschaft erreicht werden. Zusätzliche Fortbildungsangebote und flankierende Dienstleistungen, wie z.B. Gastronomie, sind zudem in der Lage zusätzliches Publikum in das Quartier zu ziehen und so die Vernetzung der Akteure untereinander zu fördern.

Zudem hat sich gezeigt, dass eine Mittelstadt wie Detmold genauso wie eine Großstadt urbane Transformations- und Entwicklungsräume aufweist, die sich als potenzielle Entwicklungsräume eignen. Gleichzeitig zeigte sich aber auch, dass nicht genügend Entwicklungsdruck auf den Flächen liegt und sich eine verdichtete Entwicklung nicht aus den inhärenten Kräften der Branche einstellt. Insbesondere in Mittelstädten wird so die Notwendigkeit eines gesteuerten Prozesses deutlich, der durch (Förder-)Impulse in Gang gesetzt wird und einzelne bauliche Entwicklung zu einem städtebaulichen Gesamtkonzept zusammenführt. Rahmenplanungen und Stadtentwicklungskonzepte erscheinen als notwendige Grundlage für eine solche Entwicklung und sind darüber hinaus in der Regel notwendige Fördergrundlage. Neben der städtebaulichen Entwicklung empfiehlt sich eine strategische Unterstützung durch eine Vereinsstruktur als strategischer Unterbau, der es erlaubt Unternehmen eine aktivere Rolle in dem Netzwerk zu übertragen.

Besonders anspruchsvoll erscheint vor diesem Hintergrund die Herausforderung, dass Kreativität nicht planbar ist. Entsprechend müssen bei der Planung dieses Prozesses die höchst dynamischen und kaum mit konventionellen Planungskategorien zu fassenden kreativen Nutzungen behutsam integriert werden. Demgemäß steigt die Bedeutung indirekter Einflussnahme in Form von Möglichkeitsräumen und einer Strategie der Befähigung. Gerade solchen Räumen kommt in der Nähe der Hochschulen als kreativem Nährboden und Schlüsselakteur im Innovationsökosystem eine besondere Rolle zu, die städtebaulich urban und öffentlich sichtbar umgesetzt werden will.

Die zugrundeliegende Studie macht insgesamt deutlich, dass auch abseits der Großstädte und Metropolen eine ausgesprochene Dichte dieses urbanen Wirtschaftsbereichs vorhanden sein kann und dass die Bedarfe und Anforderungen an eine verdichtete Entwicklung eines Clusters – zumindest im Fallbeispiel Detmold - ausgesprochen hoch sind. Eine städtebauliche Entwicklung eines Kreativquartiers ist dabei nicht nur ein Konzept für eine Stadterneuerung, sondern richtig platziert ein wesentlicher Hebel für die Wirtschaftsförderung der Mittelstadt. Gerade in metropolenfernen Regionen und mit der Hochschule als Nährboden vor Ort können Mittelstädte mit einer solchen Entwicklung absehbar auch ausreichend Sichtbarkeit und Nachfrage erzeugen, die eine solche Entwicklung benötigt. Weiterer Forschungsbedarf besteht sicher in der Frage, ob eine solche Entwicklung generell in Mittelstädten auf ausreichend Nachfrage stößt, oder ob zum Beispiel eine Hochschule mit kreativen Studiengängen vor Ort eine notwendige Grundlage für eine solche Entwicklung ist. Die Potenzialstudie für ein Kreativ Quartier Detmold zeigt in jedem Fall, dass es auch in einer Mittelstadt ausreichend Potenzial für eine solche Entwicklung geben kann.

1 ABSTRACT

Toronto is known as a city of neighbourhoods, many of which are defined by the cultural origins and traditions of immigrant groups. Examples of official or unofficial neighbourhood names include Chinatown, Koreatown, Little Tibet, Gerrard India Bazaar, Corso Italia, Little Portugal, Greektown, and more. Other major immigrant groups such as Scandinavian, German, and French are notably absent from the place names in Toronto and other major global cities, and we wanted to examine whether this reflects different patterns of residential clustering and dispersion. We chose to analyze the Francophone population in the Toronto metropolitan area, since French is an official language of Canada as well as being spoken by a number of different immigrant groups, which allows for comparisons of both, language and culture as a factor in settlement decisions. We found that French speakers, including those born in Toronto as well as intra-Canadian migrants, tend to live in clusters, while none of the individual Francophone immigrant groups examined in this research are clustered at a statistically signifcant level. Based on this finding, language rather than culture is a key factor in residential location decision-making.

Keywords: Language, Clustering, Spatial Analysis, Settlement, Immigration

2 INTRODUCTION AND RESEARCH CONTEXT

Cluster analyses of the settlement patterns of specific ethnic groups within cities are few and far between. However, analyses of populations at larger scales and relating to concentrations rather than clustering are more common. Ethnic neighbourhood analysis has been conducted in many of the world's most notable cities, including Toronto. This field of study tends to concentrate on the factors that lead to settlement decisions. Factors such as pre-existing concentrations (Gross & Schmitt, 2003), mnemonic institutions (Harold & Fong, 2018), economic standing and resources (Fong & Chan, 2010) have all been covered in Toronto. Gross & Schmitt found that pre-existing ethnic clusters of settled immigrants were considered strongly in settlement decision-making of newly landed immigrants. Another study identified mnemonic institutions (institutions which related to collective memory) such as religious centres of gathering, to contribute to ethnic cluster growth. For example, Harold & Fong found that higher concentrations of Jewish residents were found near synagogues and Jewish community centres. More traditional schools of thought on ethnic settlement, such as the spatial assimilation model developed by the Chicago School of Ecology tied settlement patterns uniquely to economic opportunity. The model indicates "that immigrants first concentrate spatially in older, less-expensive housing close to the centre of the city and, upon improving their economic status, move outwards through increasingly higher-status residential zones, ultimately ending up at the urban periphery" (Murdie & Ghosh, 2010). Fong and Chan's study expands on this model, suggesting that economic opportunity is one of three main factors, the other two being ethnic information sources (ethnic community centres and real estate agents) and ethnic resources (help and advice from community members).

In contrast to spatial assimilation, the heterolocalism model sees "communities without propinquity" as a possibility (Zelinsky & Lee, 1998). This model infers that a community does not need to live together spatially as their interactions could happen at ethnic centres between communities. The Price et al. (2005) study of Washington DC found that ethnic groups did not always follow the traditional spatial assimilation concept. They noted instead that cities exemplified numerous paths to settlement with different results, ranging from the traditional perspective to a new one where ethnic community members could relate to each other via ethnic institutions. This echoes Qadeer and Kumar's (2006) sentiment that "mere living side by side...does not make an ethnic neighbourhood". In all of these scenarios, the study subject were distinct ethnic groups. In the present study of French-speaking people, there may be a variation of both models at play, perhaps depending on other factors. Literature regarding French-speakers in Toronto and their spatial

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

residential distribution is scarce. Francophones in Toronto come from various ethnic backgrounds, income levels, religions, etc. so it is expected that their spatial relationships will be complex and multifaceted.

On the other side of the spectrum, cities, rather than people, have been analyzed to understand how they accept newcomers. Gateway cities in immigrant-receiving countries like Canada, the US and Australia have all been studied to understand why these cities attract mass immigration (Gross & Schmitt, 2003). Each city, province/state and country are different in their immigration history and policy (Bauder & Sharpe, 2002). These may govern how settlement patterns at every level of geography may manifest themselves. The city of Washington had a simple colonial cultural makeup until the late 20th century (Price et al. 2005). Thus it would not be surprising that its immigrant population composition and spatial distribution differs from that of e.g. New York and Los Angeles in the US (Logan, Zhang, & Alba, 2002) or Toronto in Canada. New York's demographic distribution has emerged over several hundred years. Like Toronto, it has been the home of various European immigrants (Italians, Irish, Dutch, etc.), but more recently, it received more diverse migrants. Los Angeles, on the other hand, like Vancouver, has been built more on a foundation of Asian immigration but differs from the Western Canadian city in its massive acceptance of Latin Americans, due to its proximity to the Mexican border (Logan, Zhang, & Alba, 2002). Unlike the aforementioned cities, Toronto is located in Eastern Canada, which has French and English as official languages. As the largest city in the country, it is not surprising that it has a sizeable French-speaking population, but it is still dwarfed by Ottawa's and Quebecois cities' Francophone populations. According to the Ontario Office of the Commissioner of Official Languages, 42,7% of Francophones in Ontario resided in Ottawa in 2016, while only 19% were in Toronto, and another 20.7% were spread across Northeastern Ontario in smaller communities like Timmins. Ottawa's Francophone population is twice the size of Toronto's, despite Toronto's CMA total population being almost 5 times that of Ottawa (Statistics Canada, 2019a). So despite, Toronto's size, the influence of the French language on the city is felt far less than other Canadian cities. This could possibly push Francophones residing in Toronto to stay together, as they are a minority.

While similarities exist between large American and Canadian cities, research shows vast differences as well. Many studies focus on the segregation of minorities in the US, most notably blacks (Price et al., 2005). Even though in Canada such segregation does not occur to the same extent, many Canadian cities like Toronto are home to large ethnic enclaves (Bauder & Sharpe, 2002). The terminology used to designate ethnic neighbourhoods relates to the freedom that people have in regard to their housing situation, and what the future may hold for them. Ghettoization refers to the residential segregation of populations who are not be able to relocate. Enclaves, on the other hand (following the rationale of the spatial assimilation model), act as a place for an ethnic group to remain until they inevitably attain the economic capital to move on to better housing (Logan, Zhang, & Alba, 2002). When analyzing a group like Francophones in Canada, this is important to keep in mind as lower-income Francophones may reside in enclaves but will likely be able to move away eventually. On the other hand, higher-income Francophones may have enough capital to choose their residences more freely. Thus, economic differences between different subgroups of Francophones may result in spatial clustering or the lack thereof, with some subgroups living in ageing, more affordable housing and others in better kept, more expensive housing. Another significant difference between large American and Canadian cities, and more specifically Toronto, are the areas in which different income classes settle. In the US and some Canadian cities, the suburbs are usually more affluent and homogenous, while inner cities are typified as less safe, cheaper to live in, and dominated by minority groups (Logan et al., 2002; Bauder & Sharpe, 2002). In contrast, some of Toronto's highest value property is just outside of the Central Business District (CBD), like in the Rosedale neighbourhood. Furthermore, many ethnoburbs have sprouted along the edges of Toronto, such as Indian neighbourhoods in Brampton and Chinese in Markham (Murdie & Ghosh, 2010). While these suburbs are often middle-income neighbourhoods, the majority of Toronto's lower-income neighbourhoods are found outside of the CBD in the inner suburbs. Gentrification has also played a large part in changing the traditional view of settlement patterns in cities. Immigrant enclaves across the city of Toronto, which were once settled due to being cheaper housing opportunities, are being filled with educated high-income professionals. Murdie & Ghosh (2010) have found that this has led certain immigrants to avoid the traditional settlement patterns and to settle directly into the suburbs. Some studies found similar results in the US, declaring that in some cases, lower-income residents were forced to relocate as a result of increasing costs in their own neighbourhoods (Vicino, Hanlon, & Short, 2011). As a result of these processes, higher-income Francophones such as native-born Canadians or immigrants from industrialized

countries may settle in different areas than those from developing nations, who may not have the resources to live with other Francophones. Poorer Francophones may thus find themselves clustered together in ethnic enclaves, away from more affluent Francophone communities.

Within the Francophone community are many ethnic variations. An infographic from the Office of the Commissioner of Official Languages (2019) revealed that 58% of Franco-Ontarians were born in the province, that 25% came from other Canadian provinces or territories, and the remaining 17% was comprised of foreign-born immigrants. Within this immigrant population was a relatively even split between continents, with 17% coming from the Americas, 27% coming from Europe, 20% coming from Asia and a slightly larger 37% coming from Africa. Many of the immigrants coming from outside of Europe are immigrating from former French colonies. These include but are not limited to Algeria, Djibouti and the Democratic Republic of the Congo (DRC) in Africa, Vietnam and Syria in Asia, and French Guyana, Haiti and the state of Louisiana in America. One can notice that these various countries may vary significantly in race, culture, language and religion, even within the same continent. As observed by Fong & Harold's (2018) analysis of mnemonic institutions, and more specifically, institutions tied to religion, we can assume that different Francophone people may distribute themselves spatially based not only on race and language but also religion. The religious beliefs of some Francophone subgroups may draw them to churches, mosques, synagogues, temples or community hubs associated with their beliefs like community centres. Some may even prioritize minimal distances to these institutions over proximity to other settlers with a common language or geographical origin. Furthermore, specific subgroups may conscientiously avoid each other due to religious beliefs. In their analysis of Jews in Toronto, Fong & Harold (2018)found that Jews and Muslims would not be found in large concentrations in the same neighbourhoods, instead choosing to co-exist with other groups such as Catholics. This effect may be more apparent between two groups from different regions like Israeli Jews and Saudi Muslims but could also occur to different religious groups coming from the same country. North African countries, in particular, have seen a mass exodus of a large Jewish population following independence movements and their newly installed Muslim governments (Gruen, 1994).

In other cases, the existence of established language-based communities may separate people rather than cluster them. The city of Montreal is well known to have established French-speaking and English-speaking neighbourhoods . Because of this, Hiebert (2000) discovered that specific immigrant populations would unintentionally segregate themselves from one another upon arrival in Canada, even if coming from the same regions. In Montreal, Jamaican immigrants, who speak English, moved into established English-speaking neighbourhoods while Haitian immigrants, who speak French, moved into French areas (Hiebert, 2000). Algerians, one of the test groups for this study, were also observed to move into French-speaking parts of the Quebecois city, possibly due to fewer language barriers and thus better integration (Manaï, 2015).

As previously mentioned, 83% of Francophone residents of Ontario are born within Canada. Unfortunately, there are no detailed data on the birthplaces of this population for recent time frames. While Toronto is very often seen as a gateway for international immigrants, it could also be one for inter-provincial migration. Langlois's 1993 study on Quebec and Ontario's inter-provincial migration revealed that in 1986, 672 Ontarians emigrated to Quebec, consisting of 271 Anglophones, and 305 Francophones, with an additional 39 being bilingual. However, 1616 Quebecers moved to Ontario in that same year; 862 Anglophones, 492 Francophones and 50 bilingual individuals. A few fundamental pieces of information can be pulled from this observation. Francophones are actively leaving Ontario for Quebec, most likely to find a home with an official language they speak, but more Francophones are still leaving Quebec for Ontario, perhaps due to Ontario's economic pull. Also important is to understand that almost twice as many Anglophones leave Quebec compared to Francophones. Langlois cites a 1986 study by Baillargeon in which he writes that Anglophones are 17 times more likely to leave Quebec compared to Francophones, yet the province's Francophone migration patterns reveal a deficit of Francophone migration. In addition to this, Langlois found that two-thirds of the Francophones leaving Ontario for Quebec were born in Quebec. This shows that while Quebec is known to be the French-speaking hub of Canada, non-Quebecois French speakers still make up the vast majority of Ontario's Francophone population (roughly 72% based on Langlois' findings in 1986) (Langlois, 1993). Unfortunately, until data that detail place of birth by province, are publicly available, the detailed spatial distribution of Canadian-born Francophones will remain unexplored.

3 DATA AND METHODS

3.1 Case Study Data

The data for this study were obtained from the SimplyAnalytics (2020) tool. The spatial unit of analysis is the census tract (CT) defined by Statistics Canada, as this is a commonly used level of geography for similar studies and related data would also be available at this level. While the finer dissemination area (DA) level contains more detail, it can also create a mosaic effect that is visually deceptive. Such a high level of detail could also be difficult to map. We do, however, acknowledge that census tract level data average out differences within the tracts, which may increase clustering. The case study data include a Shapefile of the CT boundaries for the Toronto Census Metropolitan Area (CMA).

As shown in Table 1, three categories with several variables from SimplyAnalytics' (2020) Demographic Estimates and Projections (DemoStats) for 2018 were analyzed. The variables obtained were already normalized using total CT populations as the denominator. The first variable is the proportion of population in private households who indicated French as their mother tongue. This variable represents people exclusively based on their common language. If clustering only occurs at this level, we could conclude that the study population clusters based on language.

The second group of variables represent the proportions of household population who are immigrants from a specific country. The countries of origin included in the study are France, Switzerland and Belgium for French-speaking populations from Europe, Morocco and Algeria from (Northern) Africa, and Haiti from the Caribbean. These variables test whether immigrants from the same country cluster together, with other populations from a specific geographical region or not at all.

The third variable aggregates the previous six immigrant groups into a new category that identifies French-speaking immigrants. This variable differs from the first because it does not consider Canadian born French speakers (native Franco-Ontarians or Quebecers). This variable is imperfect as it may miss Francophone countries not included in the specific country variable (such as Cameroon, Americans, etc.), but no pre-existing Francophone immigrant data is currently available.

Also included are two control variables: Chinese immigrants and total immigrants. Chinese immigrants have been shown to cluster in Toronto (Murdie & Ghosh, 2010), so the inclusion of this variable will allow for validation of the methodology as well as aid in the visual comparisons with the study populations. Clustering of all immigrants will be compared with areas in which Francophone immigrants settle to determine whether Francophones simply settle in a similar manner as other immigrants.

Variable	Category	Purpose
French mother tongue % of CT population	Language	Test for clustering based only on language
French immigrant % of CT population	Immigrant country of origin	Test for clustering based on country of origin, immigrant status or language
Swiss immigrant		
Belgian immigrant % of CT population		
Algerian immigrant % of CT population		
Moroccan immigrant % Of CT population		
Haitian Immigrant % of CT population		
Chinese immigrant % of CT population		Control variable
Francophone immigrant % of CT population (combination of first five variables above)	Aggregate immigrant population	Test for clustering based on immigrant status and language
Total immigrant % of CT population		Control variable

Table 1: Normalized variables used in the analysis. Data source: SimplyAnalytics.

3.2 Cluster Analysis Methods

Clustering was analyzed in two stages, at a broader scale and a narrower scale. Using the Spatial Auto-correlation (Global Moran's I) tool in the Spatial Statistics toolbox in ArcGIS, we determined whether there are significant clusters of Francophones, Francophone immigrants and/or immigrants from specific French-speaking countries in the Toronto CMA. The tool returned a report, which included the Moran's I index

score and corresponding p-values. Positive index scores indicate clustering of similar values, and the strength of this clustering, while negative index scores indicate spatial dispersion of similar values. A p-value < 0.05 indicates that the spatial distribution is not random, i.e. it is either clustered or dispersed.

We used contiguity to conceptualize spatial relationships in a way that polygons that share an edge or at least a corner with the target polygon are included in the calculations. The ArcGIS software help recommends this method for scenarios, in which the analyst is "dealing with continuous data represented as polygons," which applies to this study. However, inverse distance weighting was also tested to see how much the results would be affected by the conceptualization of spatial relationships. Row standardization was enabled in order to avoid polygons with more neighbours being treated differently than those with fewer neighbours (such as those on the edge of the study area).

The second stage of the analysis employs the Hot Spot Analysis (Getis-Ord Gi*) tool to visualize clustering at a local level. While Anselin Local Moran's I could have been used for this task, that tool is more suited to finding outliers, a goal that is less relevant to this study. The combination of the two stages of analysis will answer the question of whether any French-speaking groups cluster in Toronto, and if so, where they do.

Since clustering depends on the spatial and numeric distribution of the data, we also provide the total number of people in each group along with the total population of the Toronto CMA for reference. Table 2 reveals that some of the immigrant groups are quite small in comparison to all Francophones as well as the Chinese and total immigrant control variables.

Variable	**Number of People in Toronto CMA**
# Household Population by Mother Tongue | Household Population For Mother Tongue | Total Single Response | **French, 2018**	77,049
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Western Europe | **France, 2018**	9,551
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Western Europe | **Switzerland, 2018**	1,888
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Western Europe | **Belgium, 2018**	2,151
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Northern Africa | **Algeria, 2018**	1,761
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Northern Africa | **Morocco, 2018**	4,008
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Caribbean And Bahamas | **Haiti, 2018**	3,317
# Household Population by Total Immigrants and Place of Birth | Total Household Population | Total Immigrant | Eastern Asia | **China, 2018**	302,468
# Household Population by Total Immigrants and Place of Birth | Total Household Population | **Total Immigrant, 2018**	3,066,986
# Basics | **Total Population, 2018**	6,419,713

Table 2: Case study population groups in relation to total population of Toronto Census Metropolitan Area. Data source: SimplyAnalytics.

4 RESULTS AND DISCUSSION

4.1 Global Cluster Analysis

The results obtained using the contiguity conceptualization can be classified into a few different outcomes. Immigrants from Belgium and Algeria do not cluster in a statistically significant manner. Both groups exhibited very small negative index scores, suggesting a minimally dispersed spatial distribution. French and Swiss immigrant populations were found to cluster at a 95% confidence level (meaning there is a 5% chance that this pattern is not significantly different from random). However, the strength of clustering indicated by the Global Moran's I score is again minimal. Moroccan and Haitian immigrants were shown to cluster at an above 99% confidence level. However, the level of clustering is still very small with an index score around 0.12 and 0.16. The same applies to the variable that aggregates all immigrant groups into French-speaking

immigrants, with a statistically significant (99%) yet very small index score of 0.08. By contrast, the general French-speaking resident group clusters at the 99% level with a clustering intensity of 0.68, only surpassed by the total immigrant and Chinese immigrant control groups with I = 0.76 and 0.82, respectively.

Groups		**Contiguity**	**Inverse distance**
Language	French mother tongue	0.684934**	0.453577**
Countries	French	0.036183*	0.052183**
	Swiss	0.034149*	0.015265**
	Belgian	-0.006484	0.008898
	Algerian	-0.002174	-0.002669
	Moroccan	0.162411**	0.034573**
	Haitian	0.116389**	0.046939**
	Chinese (control)	0.818422**	0.490387**
Immigrant status	French speaking immigrants	0.086070**	0.040065**
	Total immigrants (control)	0.764930**	0.530928**

Table 3: Results of global cluster analysis using contiguity and inverse-distance for spatial neighbourhood definitions. Asterisks mark statistically significant Global Moran's I scores, with * representing a 95% confidence interval and ** representing a 99% confidence interval. Higher positive scores indicate a greater degree of clustering.

These results were mostly consistent with those found using the inverse distance conceptualization. The notable differences include markedly lower index scores for the French mother tongue and the Chinese and total immigrant variables, yet with values of 0.45, 0.49, and 0.53 these groups are still highly clustered at a 99% confidence level. Clustering of French and Swiss immigrants is significant at a 99% level rather than 95% using the inverse distance method, although the index scores remained in the same order of magnitude. Lastly, the score for Belgian immigrant clusters changed from negative to positive, but since it remained extremely close to zero, like the score for Algerian immigrants, this change does not have practical significance.

4.2 Local Cluster Analysis

The results of local cluster analysis are shown on the maps in Figure 1. The output feature classes for the Getis-Ord Gi* tool highlight clusters of high values and low values, known as hot spots and cold spots, respectively. While hot spots of the highest significance (the 99% confidence level) are perhaps of more interest than other ones of lower significance, we will discuss all hotspots above 90% for this analysis, unless they are not part of bigger clusters.

While clustering did not necessarily occur in the same areas for each group, each group did cluster in one or multiple areas of the Toronto CMA. In the six country-specific immigrant variables, clustering occurred in downtown areas as well as suburban areas. However, the mix of clustering between these two areas varied from group to group. Algerians, Moroccans and Haitians (Figure 1e, 1f, and 1g) clustered almost exclusively outside of Toronto's downtown core. Haitians were found in two main clusters on the Scarborough-Pickering border in the East as well as on the Etobicoke-Brampton-Mississauga boundary in the West. The two North African immigrant groups clustered together in North and East York just north of the old city of Toronto, as well as in Oakville on the western extremity of the CMA. The spatial distribution of these North African communities is reminiscent of the Petit Maghreb community in Montreal, where the same immigrant groups clustered (Manaï, 2015). While this study does not seek to understand why these groups cluster, this demographic group may possibly stay together based on their common language, religion or geographical region. Based on the spatial assimilation model, there may also be a link between the immigrants' socio-economic status and where they live. Visible minority immigrants have historically had fewer resources than their non-minority European counterparts, leading them to being pushed to the outskirts of the city to find affordable housing (Logan, Zhang, & Alba, 2002).

The three European groups, in comparison, found themselves clustered within the city boundaries as well as in the outer suburbs of the city, with very few residents in the inner suburbs. French immigrants find themselves in a large cluster spanning across the entire core. Another sizable cluster can be seen on the Brampton-Caledon border in the West, while a smaller one was in Oakville in the Southwest. Belgians

clustered in a slightly smaller area to the east of Yonge Street downtown and along the lakeshore as well as in Vaughan to the North of the city of Toronto. The Swiss were the least clustered of the three, with several small clusters across the CMA. While a Swiss cluster exists in the old city of Toronto, similarly-sized clusters are also seen in Brampton, Newmarket, Vaughan and Mississauga.

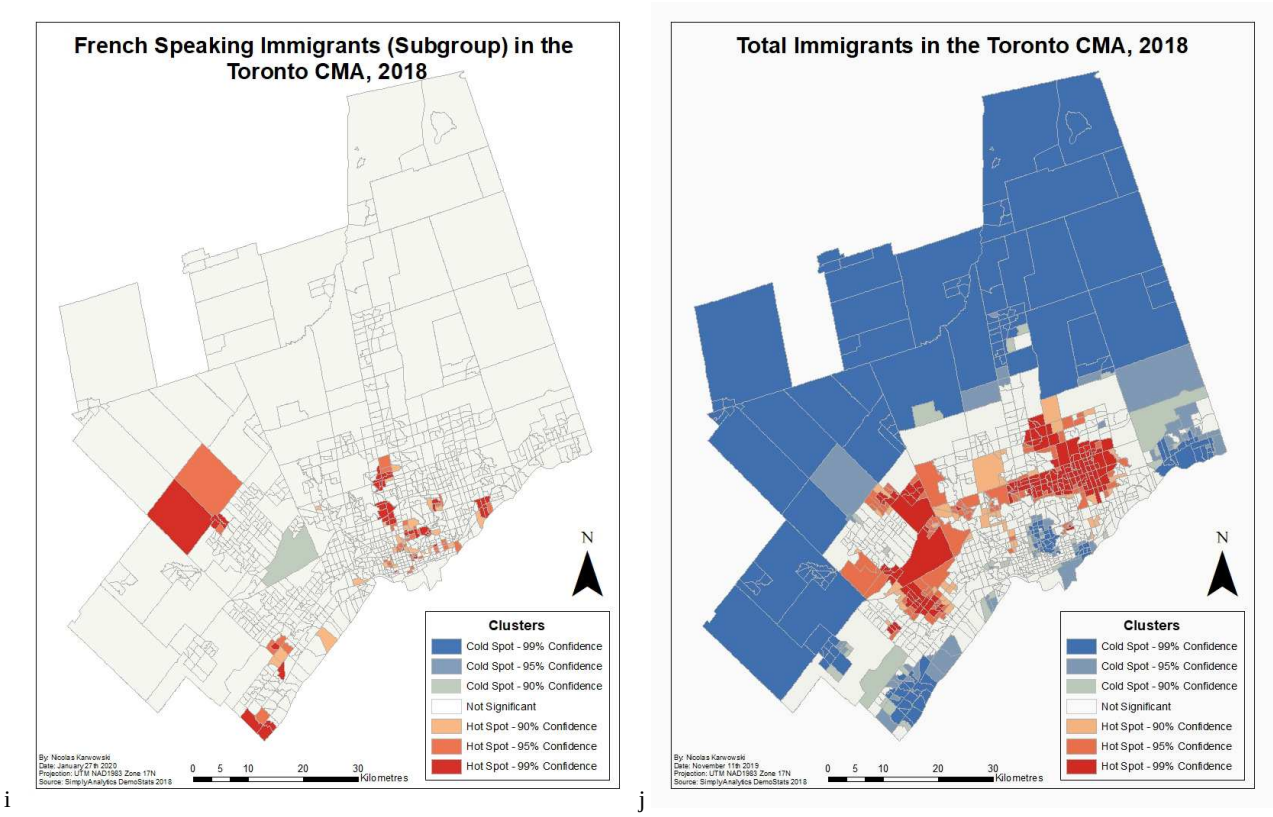

Figure 1. Local clustering of different immigrant and language groups: a) all speakers of French as their mother tongue; b) French immigrants; c) Swiss immigrants; d) Belgian immigrants; e) Algerian immigrants; f) Morrocan immigrants; g) Haitian immigrants; h) Chinese immigrants (control variable); i) combination of French-speaking immigrant groups; j) total immigrants (control variable).

When compared to the Chinese immigrant control variable, the difference in the type of clustering is apparent. The Chinese cluster both in Chinatown within the city of Toronto but also in the suburb of Markham. This cluster is almost entirely significant at the 99% level and is geographically approximately twice as large as the French immigrant cluster, which ranks second in size.

When all the Francophone immigrants were aggregated, clustering did occur, but it consisted of smaller groups of CTs scattered across the CMA. On the other hand, the French mother tongue variable, which adds native-born Canadians and other Francophone immigrants to the previous variable, revealed completely different results (Figure 1a). Three distinct clusters appeared across the CMA, with the most populous one being in the heart of Toronto, whereas the other two are found in Halton Hills and Oakville. A ring-shaped cold spot surrounds the Toronto cluster, stretching from northern Scarborough across Vaughan to Eastern Brampton. Interestingly, while the French mother tongue hot spots do correspond with some of the immigrant group clusters, the cold spot does as well. It may be that the individual groups have a significant presence, but as a communal Francophone group, their presence is no longer significant. The results for the total immigrant group (Figure 1j) show different settlement hot spots as compared to those of Francophone immigrants, indicating that immigration in itself was not the only factor contributing to the aforementioned patterns.

5 CONCLUSION AND OUTLOOK

This study proposes a statistical and visual analysis of the clustering of French-speaking people within the Toronto CMA. Global Moran's I was used for statistical testing of global clustering and Getis-Ord Gi* visually identified smaller-scale clustering. Ten variables were passed through these two tests. Six of them represented immigrants from Francophone countries on three continents to test whether clustering occurred based on country of origin. One was the aggregation of these six countries to test whether their immigrant status contributed to their clustering. Another was a French mother tongue variable to test whether language was the unifying factor. The last two variables were different immigrant populations, used as control variables to ensure a viable methodology and compare patterns with the Francophone variables. Both tests confirmed clustering at various scales and locations.

The limitations of the study stem primarily from the types of data and methods used but also from the lack of prior research on this topic. Cluster analysis could be done in several ways. While Getis-Ord Gi* was appropriate to identify local hot spots rather than outliers, outlier analysis using Local Moran's I may result in different findings. Different spatial relationship conceptualizations may also result in different outcomes. The use of the control variables was to ensure that the methodology delivered results consistent with past research on these test groups.

In terms of the input data, the six countries of origin do not fully represent the French-speaking immigrant populations of Toronto. It is also possible that small segments of some groups (Swiss, Belgian) do not speak French but another official language of their place of birth. Additionally, the variables do not account for second- (and later) generation immigrants and their spatial dispersion in the study area. Unfortunately, at the current time, French-speaking immigrant data by country of origin and generation is unavailable. Finally, it must be reiterated that the visual comparisons of clusters can be affected by the size of the spatial units of analysis, here CTs. A future study could compare results across different Census geographies.

While this study did not seek to verify connections between the clustering of the groups and specific explanatory factors, hopefully it lays down the groundwork for follow-up research. We can conclude that clustering does occur at global and local scales. However, this study has shown that the clustering of French-speaking people is not cut and dry, and that further analysis of individual subgroups will be needed to understand the factors and processes that lead to these spatial distributions. Such future results could have implications on the planning of service locations and programs for population groups based on French language and/or regional culture of their birth place.

1 ABSTRACT

Rapid urbanisation and the ever-growing world population have put a heavy toll on world climatic conditions especially in the way existing and new urban developments emit carbon. As per an estimation[1], 28% of all energy related carbon emission worldwide accounts for energy used to heat, cool and light the buildings. In this context along with new approaches in urban designs, it requires continuous new technological developments, smart tools, and processes that can audit these urban designs particularly based on its energy efficiency. This calls for the development of a common process which supports urban designers, sustainable technology experts, and geospatial technology experts alike in producing results which help a) to reach sustainable city targets and b) to create climate change mitigation and adaptation strategies. A major technical challenge in developing such a process is the heterogeneity of tools, methods and data formats that architects, urban designers, sustainability experts, and geospatial pundits traditionally work with. This paper tries to counter this challenge and derive an exemplary data exchange process between commonly used urban design tools Rhinoceros3D, AutoCAD, Esri CityEngine and the Open Geospatial Consortium (OGC) standardised open data model of CityGML version 2.0 aiming to assess new urban designs regarding cities' energy demands using 3D City Models.

Keywords: Data Interoperability, Geometric Modelling, Urban Design, Energy Simulation, CityGML

2 INTRODUCTION

Urban design, on the one hand, as a process of shaping and characterising new neighbourhoods are becoming more complicated due to the rapid expansion of cities. On the other hand, urban design is getting more scrutinised than ever before, particularly regarding carbon emission reduction, as well as climate-responsive building designs. Conventional urban design methods focused more on designing and characterising the physical arrangement of urban elements in the neighbourhood but lacked performance assessments such as building stock energy audits for the proposed urban design. However, with the rapid evolution of computer science and geospatial technologies, modern urban design methods involve continuous use of 3D city modelling for better understanding, planning, and visualisations of the urban design (Chundeli, 2017). In present times, applications of 3D city models have gone far beyond visualisation (Biljecki et al., 2015). One such domain, where these virtual 3D city models find themselves increasingly used is in City Energy Modelling (CEM). CEM relies on a bottom-up approach to know the total energy demand of cities and districts by analysing its building stock's energy demand. One way to analyse building stock energy demand is by using individual building geometries and their characteristics. To store and share such semantically rich 3D city models, City Information Models (CIM) has been developed. One such standardized open data model to store and share 3D semantic city models is CityGML.[2] With the continuous development and implementation of CityGML, as of today, buildings of more than 100 megacities (under open data initiatives from different governments) are freely available for public use on different Level of Details (LoD):[3] LoD1 represents buildings in block models while LoD2 includes additional roof geometries. LoD3 in addition to LoD2 also includes building openings e.g. doors and windows. LoD4, in addition to LoD3 also includes building interiors (Biljecki, 2013) (LOD4 data are normally not distributed as open data due to privacy issues). CEM software, such as SimStadt[4], make use of these CityGML models to calculate building stock

energy demands. Additionally, SimStadt also helps in simulating energy demands based on different refurbishment scenarios (Nouvel et al., 2014).

The application of SimStadt, an energy demand simulation for existing buildings has been successfully demonstrated by Nouvel et al. (2015), but it remains interesting to see how new urban designs can be converted into CityGML based open data model e.g. for use in SimStadt. A challenge in such a study is to produce error-free CityGML building geometries which can be used for analysis and simulations tasks within the tools which were initially used to sketch new urban designs (Biljecki et al., 2016). To address this challenge, the three case study regions, namely Gowanus (Brooklyn – New York, USA), Nordwestbahnhof (Vienna, Austria) and Wienerplatz (Stuttgart, Germany) were probed. The case studies regions of New York and Vienna were modelled using Rhinoceros3D. In the case of Vienna, the project also utilised the Rhinoceros3D'S parametric plugin of Grasshopper before converting it to CityGML LoD1. For the CityGML conversion, the Feature Manipulation Engine (FME) has been used to create the buildings' and building parts' geometry. The case study region of Stuttgart was modelled in LoD2 using Esri's CityEngine before converting it to CityGML, also using FME. The resulting CityGML geometries were then simulated with SimStadt to compute their heating demand. Additionally, in the Stuttgart case, the photovoltaic potential of roof surfaces was also calculated using the converted LoD2 models.

The aim of this paper is, to describe the data conversion process leading to above-mentioned datasets and shall serve as a guideline to generate simulation ready semantic CityGML building models. Such a well-defined data exchange process, between commonly used 3D modelling urban design software and energy simulators, supports initiating a workflow especially between urban designers and sustainability experts to produce enhanced outcomes of both the domains.

The work presented by the authors in this paper is carried out during an ongoing project "Integrated analysis and modelling for the management of sustainable urban food water energy ReSOURCEs (IN-SOURCE)".[5]

3 TOOLS, TECHNIQUES AND DATA FORMATS USED FOR 3D CITY MODELLING

3D city models are georeferenced, digital semantic models representing real-world physical elements such as buildings, vegetations, street furniture, terrain surfaces and landscapes in three dimensions. Past decades have witnessed the evolution of many different tools, techniques and data formats that are used for developing, managing and visualising 3D city models. A typical city model can be constructed automatically or semi-automatically from various acquisition methods such as aerial images and maps (Buyukdemircioglu et al., 2018), stereo satellite images (Kocaman et al., 2006), synthetic aperture radar (SAR) (Sharafzadeh et al., 2018) and LiDAR point clouds (Buyuksalih et al., 2019). Along with these photogrammetric and remote sensing tools and techniques, processes for constructing 3D city models using vector datasets from computer-aided design (CAD) and geographic information systems (GIS) have also been in practice for a long time. Last but not least, using shape grammar for 3D city models (Dobraja, 2015), implementing urban planning with procedural modelling using Rhinoceros3D (Fink, 2018), utilising OpenStreetMap to generate 3D models (Over et al., 2010) and, modelling 3D buildings using CAD-based software such as Autodesk InfraWorks or SketchUp (Wang et al., 2012) have all been widely used techniques to create a digital twin of cities.

Elements of 3D city models are encoded in data formats. Each tool used to generate the 3D city models will produce outputs in its own readable data format. Exemplary data formats, used by architects, urban designers, geoinformatics experts, and municipalities worldwide, range from CAD software such as AutoCAD (.dwg) or (.dxf) over 3D multipatch shapefiles from Esri ArcGIS and CityEngine (.shp) to COLLADA (.dae) and the native data format of Rhinoceros3D (.3dm). Moreover, during the last decade, the XML based open data model of CityGML has gained a lot of user attraction because of its capability to not only store georeferenced 3D city models but also the ability to store semantics and topological information of these 3D city models (Kolbe, 2009). OGC approved CityGML encoding standards[6] form the basis on how real-world physical elements must be stored and represented as virtual 3D city models in CityGML. Storage and representation of these 3D city models should follow a certain set of rules and regulation defined as conformance requirements in the encoding standards. These conformance requirements are particularly

[5] https://www.hft-stuttgart.de/Forschung/Projekte/Projekt208.html/en
[6] https://portal.opengeospatial.org/files/?artifact_id=47842

important when 3D city models in CityGML are to be used beyond visualisation such as in analysis and simulation (Coors et al., 2020). The 3D City Database (a.k.a 3DCityDB), an open-source 3D geo-database is used to store, represent and manage CityGML datasets in a relational database which is providing the additional capability to perform complex analytical tasks beyond visualisation. Additionally, to store 3D objects and their semantics which are not a part of core CityGML schema, CityGML application domain extensions (ADE) can be developed. As of 2018, 44 CityGML ADEs supporting various applications have already been developed and used (Biljecki et al, 2018). However, it is worth mentioning that new geometrical objects and related properties, introduced as a part of any CityGML ADE, by default inherit characteristics of the CityGML encoding standard and do not relate with data interoperability between CityGML and any other data formats. In a simple term, CityGML ADEs are placed on top of CityGML to enrich its core schema to accommodate application-specific new objects and their features.

As there are so many different tools and data formats available and used by various domain experts, one of the current issues and challenges in 3D city modelling is the definition and development of a data exchange interface to produce joint outputs when combining different domains (Billen et al., 2014). This is, in particular, true for architects and urban designers, who, along with their building stock designs, are also interested in the assessment of these building stocks based on their energy demands. Typically, architects and urban designers use tools like Rhinoceros3D (with its parametric plugin Grasshopper), AutoCAD and Esri CityEngine for proposing new urban designs, while geospatial and urban energy simulation experts use CityGML as an input for their CEM software such as SimStadt. Neither Rhinoceros3D nor AutoCAD or Esri CityEngine can produce CityGML datasets out of the box. In a related paper, Jesus et al. (2018) demonstrated a data conversion process from Rhinoceros3D to CityGML. As an input, a shapefile was first imported into Rhinoceros3D with its Heron plugin and then extruded to produce a 3D geometry. This 3D geometry was later exported to COLLADA file using Rhinoceros3D built-in file export functionality before converting it into CityGML LoD1 using FME. However, since the focus of this work was on visualisation, conformance requirements for CityGML buildings were not considered during the conversion process. Such a translation process justifies visualisation output but is not recommended for analysis and simulation exercises such as calculating energy demands of buildings using 3D city models. Furthermore, the building footprint shapefile, when extruded, produced a uniformly extruded block model, which, in reality, is not always a relevant geometry for all building types as most buildings have building parts, too, which can have different building geometries and attributes than the main building. In particular for architects and urban designers who are not always GIS users, unanswered questions still remain, like (i) how to translate building geometries to CityGML buildings which are originally modelled in a non-georeferenced local coordinate system using Rhinoceros3D without importing georeferenced shapefiles of building footprints? (ii) How to translate Rhinoceros3D buildings having building parts and related attributes to CityGML adhering to the conformance requirements of the encoding standard for CityGML?

In another study, Billen et al. (2014) mention that Esri CityEngine shows LoD1 modelling for CityGML well, but there is still a problem in using it to model buildings with roofs and building openings for translating it to valid CityGML LoD2 and LoD3 geometries respectively. This issue was once again highlighted by Janečka (2019) in their Esri shapefile to CityGML conversion. Output CityGML dataset only contained property of gml:building having multisurface geometry to justify their results for visualisation purpose. However, as per CityGML conformance requirement 10.3.9.4, required semantic information of ground, wall and roof surfaces for LoD2 buildings were missing. Considering both the studies ones again the same question stands, how to translate 3D geometries particularly of LoD2 from CityEngine to CityGML with semantics which is following the CityGML conformance requirements?

4 GEOMETRY VALIDATION IN CITYGML FOR ANALYSIS AND SIMULATION

The quality of results produced by any analytical or simulation software directly relies on the quality of the input data. The same is true for 3D city models and CityGML. With an increasing number of users using CityGML models for various analysis and simulation (Biljecki et al., 2015) use cases, such as solar radiation analysis, visibility analysis, noise propagation in traffic planning, wind flow analysis, flood damage analysis, data quality and consistency approaches of CityGML datasets are now being thoroughly investigated. OGC itself launched the CityGML Quality Interoperability Experiment to study and investigate aspects of schema conformance, geometry and, semantics validation and validation of conformance requirements for CityGML

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

datasets (OGC, 2016).[7] As an outcome of the experiment, different software packages were developed, and several recommendations were given to improve the quality and consistency of CityGML models. In his article, Biljecki et al. (2016) have synthesised most regularly occurring geometric and semantic errors in CityGML datasets. Based on his findings and other similar investigations (Coors et al., 2020), several tools such as val3dity (Ledoux, 2018), FME geometry validator and CityDoctor[8] are in continuous development. Furthermore, based on the validation report, FME geometry validator and CityDoctor can also automatically heal building geometries of CityGML to a certain extent. (Alam et al., 2013).

Since this paper is also dealing with an energy demand simulation test case, in particular, validation of building solid geometries and face orientation of building surfaces is critical as those directly affect the building volume calculation and therefore energy demand calculations. In their article, Coors et al. (2020) proved this by comparing the building volume of a correct building solid geometry with an error-prone building solid geometry. Hence, to compute a correct building volume, it becomes very important that building solid geometries in CityGML are created correctly following the conformance requirement 10.3.9.4 of the CityGML encoding standard. As an example, based on this CityGML conformance requirement, Padsala and Coors (2018)[9] explained how to insert building solid geometry in CityGML building and building part datasets using FME.

Considering the above-mentioned validation parameters and adhering to the CityGML encoding standard, this paper tries to overcome some data interoperability limitations mentioned in chapter 2 and explains how to translate valid CityGML geometries from Rhinoceros3D and Esri CityEngine that can be used for analysis and simulation such as of energy demand calculation using SimStadt.

5 DATA CONVERSION FROM URBAN DESIGN TO ENERGY SIMULATION

5.1 Case Study 1: Gowanus (Brooklyn, New York, USA)

The case study region of Gowanus (previously known as South Brooklyn) represents a neighbourhood in the New York City (NYC) borough of Brooklyn. Formerly, a dominant industrial zone, it is now under rezoning led by NYC's planning department, the American Institute of Architects New York Chapter (AIANY), New York Institute of Technology (NYIT) and community stakeholders.

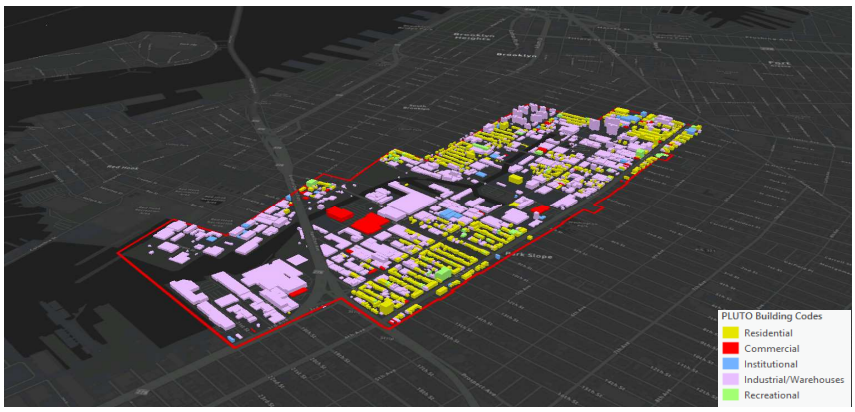

Fig. 1: Gowanus existing land use 3D map

Based on population projections and following NYC landuse mapping guidelines, a full build-out redeveloped 3D scenario was modelled in LoD1 using Rhinoceros 3D. i.e all the building footprints were applied with the highest and best use of available zoning laws. The redeveloped 3D scenario was modelled in a non-georeferenced local coordinate system.

[9] https://gitlab.com/volkercoors/CiD4Sim/-/wikis/usefulTools/FME-Workbenches

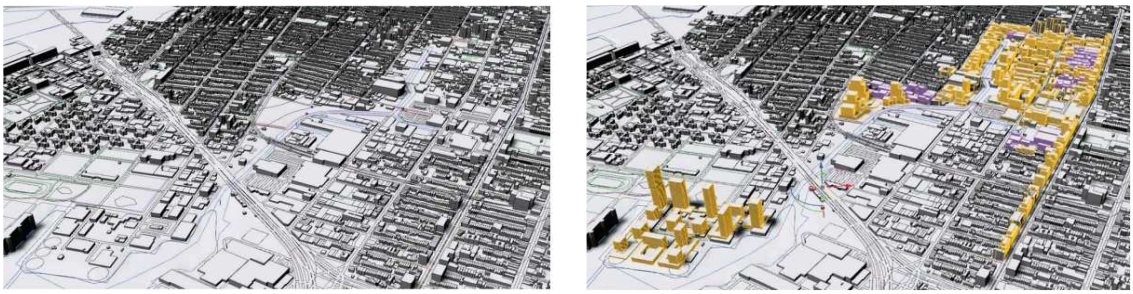

Fig. 2: Left figure shows existing building stocks, the right figure shows new building stocks modelled in Rhinoceros3D

Each building geometry was given a unique ID to be later used during the conversion to CityGML. In a separate spreadsheet, related building attributes of the year of construction and building functions were maintained, for each building ID, which represents the minimum set of attributes to calculate an energy demand using SimStadt. In this particular use case, overlapping, intersecting or adjacent building parts, belonging to the same building but having different building heights, were modelled as single building geometries, instead of an individual building part of the building. Since Rhinoceros3D cannot export semantics for geometries, a comment column with the value “Building” was specified against each building ID in the above-mentioned spreadsheet.

	B	C	D	E
1	ID	Year	Land Use	Comment
2	GBU__0	1970	E1	Building
3	GBU__1	1930	E1	Building
4	GBU__2	1917	C1	Building
5	GBU__3	2050	RC	Building
6	GBU__4	2010	RM	Building
7	GBU__5	2035	RC	Building
8	GBU__6	2045	RC	Building
9	GBU__7	2045	RI	Building
10	GBU__8	2035	RW	Building
11	GBU__9	2045	O5	Building
12	GBU__10	2050	F5	Building
13	GBU__11	2050	F4	Building

Fig. 3: Left figure shows building geometry with ID in Rhinoceros3D, the right figure shows its related information

For this use case, the end to end workflow from urban design to the energy simulation can be represented as below (Fig. 4). The FME workbench used for Rhinoceros3D to CityGML conversion will be discussed in chapter 6 section 6.1.

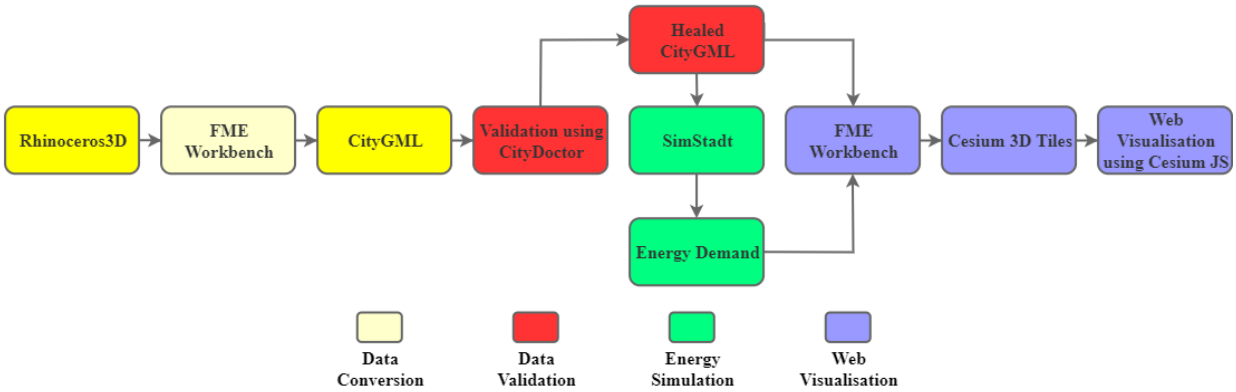

Fig. 4: Workflow Diagram

5.2 Case Study 2: Nordwestbahnhof (Vienna, Austria)

The Nordwestbahnhof case study focuses on the application of the parametric urban design strategy on a central site in Vienna. The use of parametric modelling techniques allows generating a broad set of urban design variants that meet the criteria of sustainable development targets. The goal is, to create and simulate different designs to achieve a decision basis and to draw a possible outline for further steps. As a first step, the described urban development model of the Nordwestbahnhof was modelled in LoD1 using Rhinoceros3D and its parametric plugin of Grasshoper3D based on a georeferenced building footprint shapefile.

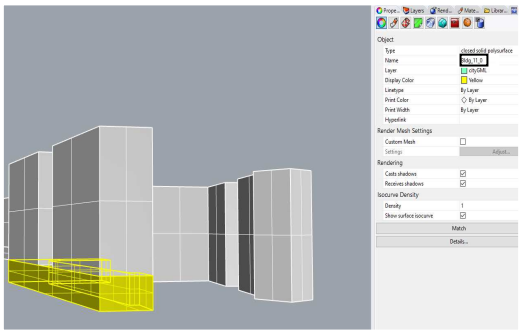
Fig. 5: A 3D Map of Nordwestbahnhof

This use case differs from the previous use case of Gowanus in the way the building models are designed. As, in the case of Gowanus, overlapping, intersecting or adjacent building parts, belonging to the same building but having different building heights were modelled as single building geometries, for Nordwestbahnhof, algorithms were applied in Grasshopper to correctly classify the volumes into single buildings and buildings coupled with their building parts. Each building geometry was given a unique ID to be later used during the conversion to CityGML. In a separate spreadsheet, for each building ID related building attributes of the year of construction and building functions were maintained. Furthermore, to preserve the hierarchical structure of CityGML (i.e building consists of building parts) for each unique ID, a parent ID was introduced. “Building” and “BuildingPart” were used as semantic parameters within the comment column to identify buildings with or without building parts.



Bldg_Parent_ID	Bldg_ID	Comment	block	use	m2	floors	height[m]

Fig. 6: Left figure shows building geometry with ID in Rhinoceros3D, the right figure shows its related information

For this use case, the end to end workflow remained the same as in the use case of Gowanus (See chapter 5, section 5.1, Fig.4). However, the FME workbench used to convert Rhinoceros3D to CityGML was updated to write both gml:Building and gml:BuildingPart, this is further discussed in chapter 6, section 6.2.

5.3 Case Study 3: Wienerplatz (Stuttgart, Germany)

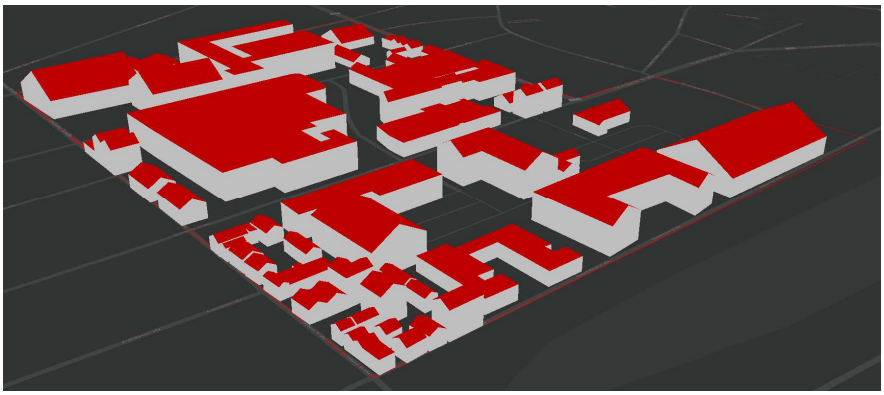

Fig. 7: A 3D Map of Wienerplatz

The case study region of Wienerplatz was modelled using Esri’s CityEngine. Initially, building footprints from AutoCAD were converted to a georeferenced 2D shapefile before importing it into CityEngine. Unlike the above two use cases, instead of a spreadsheet, attributes related to each building footprint such as

building height, roof type, year of construction and building function were stored in a shapefile. Inside CityEngine, a certain rule-based algorithm known as computer generated architecture (CGA) shape grammar[10] was applied on the shapefile dataset, which generated LoD2 building models based on its geometry and attributes.

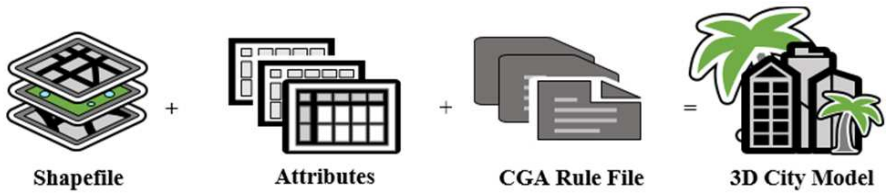

Fig. 8: 3D city modelling workflow in Esri CityEngine

An end to end workflow for the use case of Wienerplatz can be represented as below (Fig. 9). The FME workbench used for CityEngine to CityGML conversion is discussed in chapter 6 section 6.3.

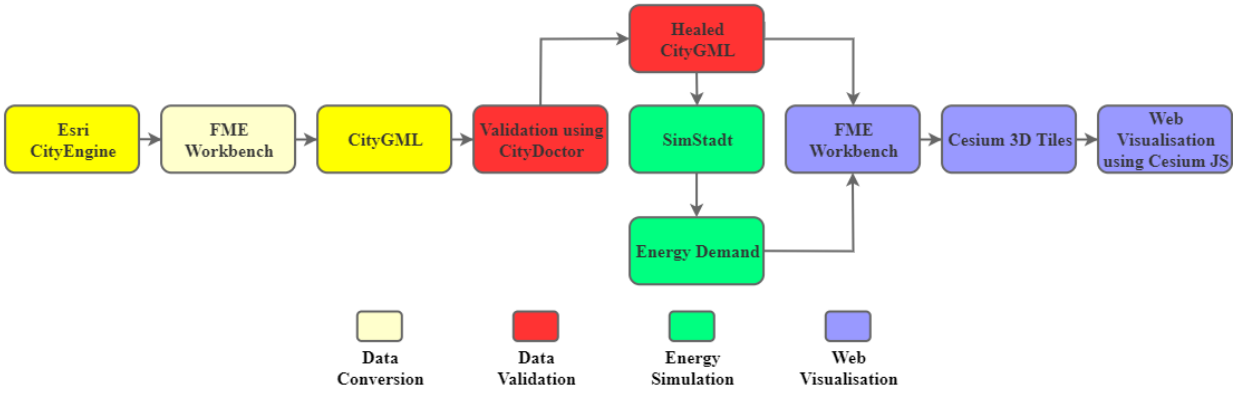

Fig. 9: Workflow Diagram

6 RESULT AND DISCUSSION

6.1 Case Study 1: Gowanus (Brooklyn, New York, USA)

The workflow represented for the use case of Gowanus resulted in the following output

Fig.10: Left figure shows 3D models in Rhinoceros3D, the right figure shows its heating demand visualised on cesium globe

The FME workbench, used to generate the CityGML LoD1 building dataset from Rhinoceros3D data, can be represented as shown below (Fig. 11). Since FME doesn't support the native data format of Rhinoceros3D (.3dm), 3D building models from Rhinoceros3D were exported to COLLADA using inbuilt COLLADA exporter as a first step and were then imported into FME alongside its relevant attribute spreadsheet.

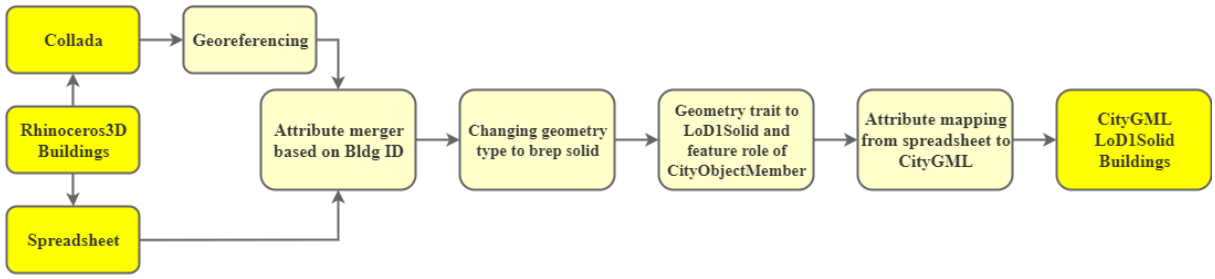

Fig. 11: FME Workbench Diagram

Since the redeveloped 3D scenario of the use case of Gowanus was modelled in a local coordinate system of Rhinoceros3D, georeferencing was done in FME using "3DAffiner" transform. An openly available CityGML dataset of NYC was used as a reference. Alternatively, if no such georeferenced datasets are available for reference, the "EarthAnchorPoint" command in Rhinoceros3D can also be used to georeference the data in the WGS84 spatial reference system. The data can then be projected to the required projected coordinate system using FME. In the case of the Gowanus data, misoriented surface normals of the 3D models were encountered which lead to wrong orientation in Rhinoceros3D and in return, to an incorrect translation into CityGML during the conversion process. In the end, CityDoctor was used to validate the resulting CityGML geometry and to heal wong surface normals. Alternatively, the geometry validator of FME could also be used to perform validation and repair tasks. The healed CityGML dataset was then used for the simulation within SimStadt to compute the heating energy demand of the buildings. Afterwards, the results were again combined with CityGML to visualise them on the web framework CesiumJS[11] by using 3D Tiles.

6.2 Case Study 2: Nordwestbahnhof (Vienna, Austria)

Workflow represented for the use case of Nordwestbahnhof resulted in the following output

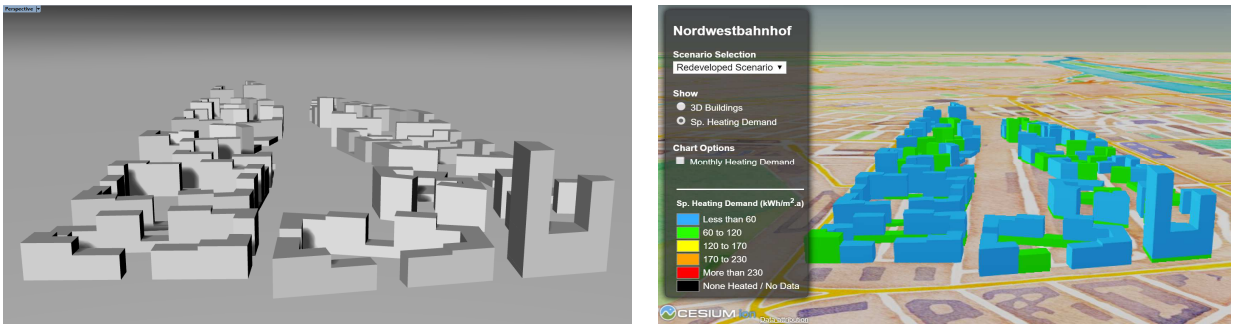

Fig.12: Left figure shows 3D models in Rhinoceros3D, the right figure shows its heating demand visualised on cesium globe

The FME workbench used to generate CityGML LoD1 building with its building part dataset from Rhinoceros3D can be represented as below (Fig. 13).

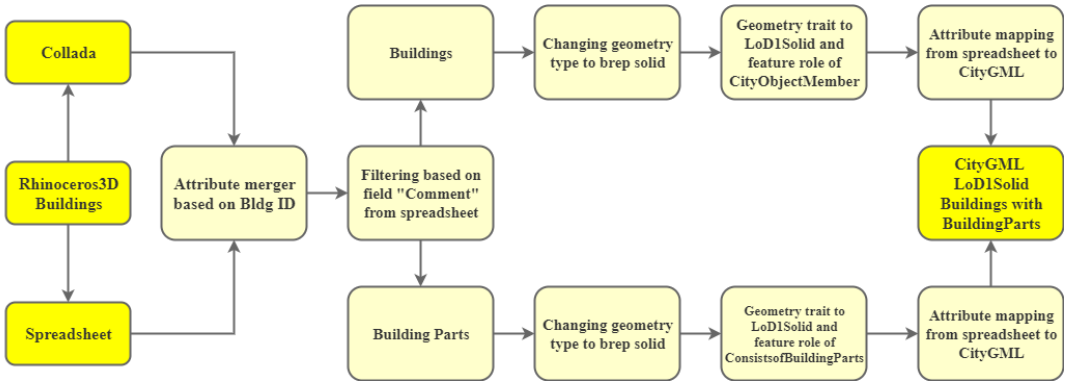

Fig. 13: FME Workbench Diagram

[11] CesiumJS is an open source javascript library used to develop interactive 3D geospatial applications for web.

For the case of Nordwestbahnhof, 3D building geometries in Rhinoceros3D were modelled on top of an imported georeferenced building footprint shapefile. Hence, "3DAffiner", as used in the use case of Gowanus, was not needed. Furthermore, separate geometries with relevant semantics for building parts and integrating them with its related attributes', proved to be an added benefit, particularly during the energy calculations in SimStadt. In this way, heating energy demand for individual building parts within the same building, taking into account different building uses and geometrical appearance, could be calculated.

6.3 Case Study 3: Wienerplatz (Stuttgart, Germany)

Workflow represented for the use case of Wienerplatz resulted in the following output

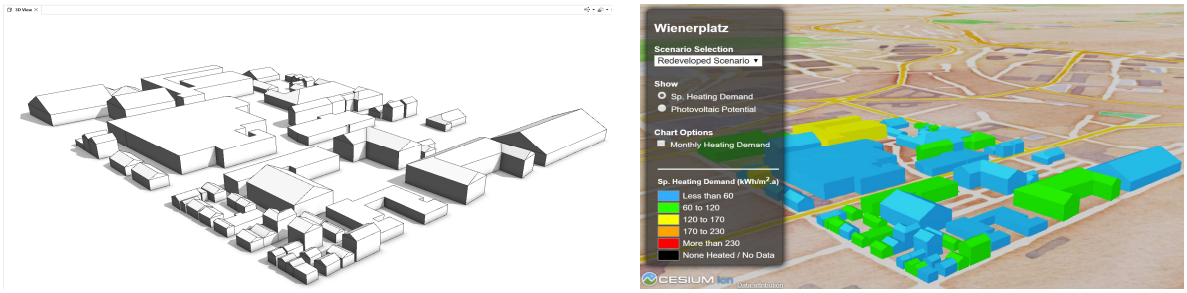

Fig. 14: Left figure shows CityEngine 3D model, the right figure shows its heating demand visualised on cesium globe

The FME workbench used to generate CityGML LoD2 building from Esri CityEngine can be represented as shown below (Fig. 15). As an input to FME, 3D building models from CityEngine were first exported as a 3D multipatch shapefile using its inbuilt shapefile exporter and then imported into FME for further conversion to CityGML.

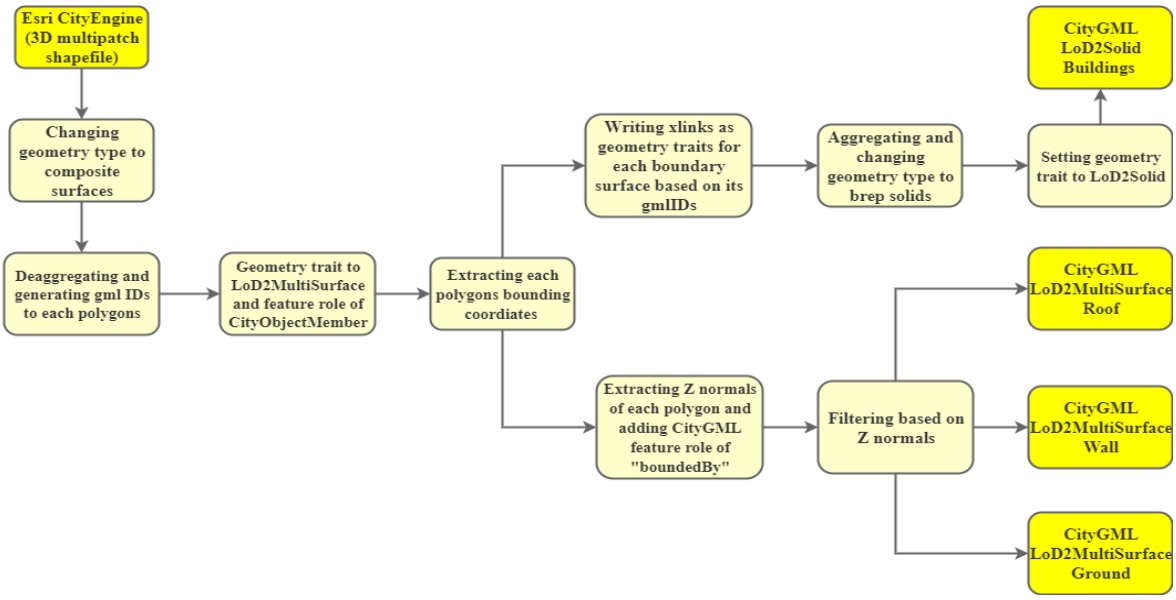

Fig. 15: FME Workbench Diagram

Since LoD2 CityGML building datasets were produced for Wienerplatz, a photovoltaic potential analysis of roof surfaces for individual buildings was also made possible within SimStadt.

As an alternative to the workflow described for Wienerplatz, Esri's data interoperability extension for ArcGIS Pro was also tested. However, the produced CityGML building geometry was defined as a generic city object having a LoD4 multi-surface geometry which was not following the encoding standards of CityGML for LoD2 building datasets. As a result, even though the produced CityGML dataset could have been used for visualisation purposes, it could not be used for heat demand and photovoltaic potential analysis within SimStadt.

A reverse workflow from CityGML to 3D multipatch shapefiles, with integrated heating demand and photovoltaic potential results from SimStadt, is explained by Padsala and Coors (2015) in their article.

7 CONCLUSION

Since 3D city models encoded in the open data format of CityGML are increasingly used for analysis and simulation, it becomes critical that the geometries and semantics are modelled correctly following the encoding standards set by the OGC. Thus, this article sought to identify and explain some of the difficulties and obstacles encountered when implementing data interoperability between commonly used 3D city modelling tools like Rhinoceros3D, Esri CityEngine and CityGML using three use cases as examples. The differences among the use cases lay in the way building geometries were modelled in Rhinoceros 3D for the use case of USA (LoD1 buildings) and Austria (LoD1 buildings with their building parts), while for the use case of Germany, 3D building models were created using Esri's CityEngine. These 3D building models, once converted to CityGML, were then used as an input to the urban energy simulator SimStadt. They were based on the geometry, semantics and other attributes such as building function and year of construction. Buildings were analysed and heating demands, along with photovoltaic potentials of roof surfaces (only in the case study of Germany), were calculated and visualised on the web using CesiumJS. Thus, the method presented in this paper successfully demonstrates one approach were different tools, techniques and data formats used by urban designers, sustainability experts and geospatial pundits can be integrated to deliver joined outcomes that fulfil the targets of a sustainable city and the climate change mitigation and adaptation goals. This forms a starting point in developing an intelligent digital environment that supports informative decisions and facilitates the exchange of information between stakeholders. This investigation also opens further research in data exchange methods for LoD3, LoD4, and BIM-CityGML scenarios which can be further used for analysis and simulations.

8 ACKNOWLEDGEMENTS

We would like to give our acknowledgements to the JPI Urban Europe, the Belmont Forum, the Federal Ministry of Education and Research – BMBF Germany and the Federal Ministry Republic of Austria Transport, Innovation and Technology for their financial support to the project IN-SOURCE. We would also like to thank our IN-SOURCE project partners from the west, New York Institute of Technology (NYIT) and the Central University of New York (CUNY) for their continued help and support. We would also like to extend our sincere thanks to the project "SimStadt" for giving us the necessary data required for the case study of Wienerplatz.

Geographies of Ageing in Flanders (Belgium)

Wesley Gruijthuijsen, Dominique Vanneste

(MSc. Wesley Gruijthuijsen, KU Leuven, Division of Geography and Tourism, Celestijnenlaan 200E, 3001 Heverlee, Belgium, wesley.gruijthuijsen@kuleuven.be)
(Prof. Dr. Dominique Vanneste, KU Leuven, Division of Geography and Tourism, Celestijnenlaan 200E, 3001 Heverlee, Belgium, dominique.vanneste@kuleuven.be)

1 ABSTRACT

In line with other regions and countries in Europe, Flanders (Belgium) is characterized by an ageing population. The share of population older than 65 will increase from approximately 20 percent in 2018 towards 25 percent in 2030. Of course, this goes together with several challenges, not only related to the sustainability of the healthcare and retirement system, but also in terms of housing, mobility and planning. Although ageing-in-place is stimulated from a policy perspective, there is very limited insight into which neighbourhood characteristics stimulate or limit the possibility to get older at home and if family networks are capable of taking up a bigger role in informal care. Although several indicators point to less potential informal caregivers in the future, a geographical perspective on informal care and the importance of distance in informal care provision are largely lacking. For tackling this a clear view on patterns of ageing can be seen as a precondition. Therefore this paper sheds more light on the relation between ageing-in-place and informal care, both from a theoretical as from a policy perspective. Furthermore it tries to set the scene in terms of geographies of ageing in Flanders on which future research can build. In this way more insight can be gathered in the tensions mentioned above and in factors that can potentially contribute to age-friendly care environments, as well as more insight in neighbourhoods that are suitable for ageing-in-place. In other words, this paper tries to disentangle geographies of aging by following a multiple-scale approach making use of national population databases (2002 – 2017). It looks into patterns of ageing on different spatial scales (ranging from NUTS 2 to statistical districts). The results clearly indicate that there is not a single 'wave' of ageing characterising every locality in the same way. Although regional differences are relatively easy to interpret and straightforward, on a lower level patterns become more complex and less clear. A cluster analysis re-arranges the data in an attempt to get better insight in different ageing profiles on the level of municipalities and statistical districts.

Keywords: Distance, Informal care, Ageing, Flanders, Belgium

2 INTRODUCTION

Although ageing is slowly gaining attention in the fields of geography and urban planning, it is still an under researched and underdeveloped theme. In general there is a lack of insight in the conditions of neighbourhoods or homes that support or limit the possibility to get older at home. The negligence of elderly is not limited to geography and urban planning. There is a need for more trans- or multidisciplinary research when it comes to ageing-in-place (Woolrych & Sixsmith, 2017). Our research is part of a four-year research project in which we try to disentangle the concept of ageing in place and try to enhance our knowledge about this concept from a perspective of geography, architecture and social sciences. The emphasis in the geographical part of the research is focusing on "environment", "distance" and "sustainability". Environment relates in this study to age-friendly neighbourhoods and the presence or lack of facilities and care networks. Sustainability is not only considered from an urban planning perspective, but also from a more social perspective, namely in terms of inclusive space, whereby for example gender relations in care are considered as well. Distance is thereby seen as a relative concept with both a physical and a social component. More specifically, from a geographical perspective, this research project wants to develop a better understanding of the geographical setting when it comes to aging and care relations. In terms of physical distance it aims at getting more insight in distances between older people and adult children as well as patterns of co-residence and how these shift over time (including moving patterns). When it comes to the emotional or social distance, family solidarity and informal networks, as well as characteristics of the living-environment are at stake. In all of the abovementioned aims and goals there will be a specific focus on informal care, due to an increasing importance appointed to this from a policy perspective.

This specific paper aims at presenting a framework for other research(ers) to build upon, by providing more insight in geographies of aging based on general population statistics. Although this sounds like a

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

straightforward proces, untill now there is very limited insight and the ageing of the population is often assumed to be more or less evenly spread (with the exception of differences between rural and urban areas). Section 3 focuses on ageing-in-place from a theoretical and general viewpoint, while section 4 looks into ageing-in-place from a policy perspective in Flanders. In section 4 the methodology will be explained in more detail as well as the data used. Section 5 will present the results followed by some reflection as well as desirable next steps in the last section.

3 AGEING-IN-PLACE

3.1 Ageing-in-place: preference or imposed from above?

Ageing-in-place or getting older at home is not something new, although it gets more attention in policy making since the 1990s (Skinner et al., 2015; Wiles et al., 2012; Andrews et al., 2007). Severel reasons can be distinguished. Although it is often seen as a way for the government to stabilize or even decrease the expenses towards the health sector, it is in line with the wish of most elderly people (Wiles et al., 2012; Milligan, 2009; Ahn & Goss, 2006). Although motivated by cost savings the results are at least ambiguous (Huduser, 2013; Graybill et al., 2014). In the American context the so-called 'woodwork effect' is often mentioned (Doty, 2000). This means that people who are not eligible for institutional care will make use of community-based home care, offsetting initial planned cost savings (Weissert & Frederick, 2012), although others do not find such an effect (Berish et al., 2018). Furthermore ageing-in-place can lead to higher costs when needs are not detected in time and certain treatments would have been preventable in an earlier stage (e.g. Horner & Boldy, 2008).

In the European context, the Netherlands provides an example where the long-term (elderly) care system was reformed and became more decentralized and thus largely a responsibility of local municipalities. Institutional care homes saw their roles being changed and were largely closed (Verbeek-Oudijk & Campen, 2017). This is partly a consequence of a decline in the amount of people staying in care homes due to the preference of ageing-in-place (Alders & Schut, 2019), and partly as a consequence of the reforms focused on increasing the financial sustainability of the care system (Maarse & Jeurissen, 2016). However, Alders & Schut (2019b) point to a probable mismatch between supply and demand for institutional care, in the Netherlands as well as in other OECD countries. They stress that although ageing-in-place initially lowers the demand in institutional (residential) care, there will be a bounce back in the demand, especially when it comes to higher-need institutional care. In other words, while there is (currently) an oversupply in low-need institutional care, there will be a (further) lack of supply when it comes to more higher-need care (ibid.).

In practice, this is confirmed by several recent statements of the Association of Dutch Municipalities who are worried about increasing costs for elderly care not only due to a need for expensive facilities for home care (VNG, 2019; 2019b), but also due to a large gap between ageing-in-place and institutional care (VNG, 2020). The commission "Future Care- Independent living at home" published a report 'Old and Independent in 2030' in which this gap is also mentioned combined with an advise to re-consider and revalue collective and semi-collective living arrangement for older people (Dutch Government, 2020). It stresses that independent living should not (always) be understood as 'living longer at home'. This is in line with several researchers who point towards a too narrow or ambiguous definition of ageing-in-place (Martens, 2018). Fret et al. (2018) stress that ageing-in-place in Belgium is not necessarily affordable for everyone and that especially older women, older tenants on the private market and bigger households are at risk. This is confirmed by other researchers (Ewen et al., 2017; Kendig et al., 2010), who also stress that both, in general and for specific groups, care needs are not always easily detectable combined with ageing-in-place (De Witte et al., 2010; Pijpers, 2019).

Even as there are some (very small) recent shifts and developments ageing-in-place is still the main policy mantra in most OECD countries. The foregoing indicates that ageing-in-place is not always the best option – either due to financial troubles or due to a specific care need- but that other options or choices are not always available. Nevertheless, it should be prevented that people are forced to age-in-place and that it becomes too much of a normative framework in which moving to institutional residential care is seen as a failure of both the person itself and policy (e.g. Vasara, 2015). As active ageing is not possible or desirable for everyone (e.g. Golant, 2011; Holstein & Minkler, 2003) the same can be said regarding ageing in place. We should not forget that a home that is not adjusted to older age, can limit the competence and autonomy of elderly people

(Golant, 2011) while an unsafe and non-supporting neighbourhood limits the quality of ageing-in-place (Lee et al., 2017). From this perspective we should ask ourselves if we should stimulate a moving in time framework instead of ageing-in-place (Golant, 2015; De Decker et al., 2018). Therefore, there is a need to look in more detail into the consequences of ageing-in-place and changes in geographies of care and ageing as well as the impact of the neighbourhood and home.

3.2 Ageing-in-place: shifting geographies of (informal) care

It is already stressed implicitly that ageing-in-place is related to changes in care relations, but also with shifts in the localities in which care is provided. Milligan (2009) points to the impact of extramuralisation and the institutionalisation of the home. Ageing-in-place is often combined with more attention and pressure on informal care whereby care is often seen as a shared responsibility. Fret et al. (2018) speak in this respect about the 'socialisation of care', which fits into the broader trend of rolling back or reconfiguring the welfare state. In Flanders this is presented as the so-called 're-communitizing' of care (e.g. Flemish Government, 2016;2016b). Furthermore, the emphasis on informal care is often combined with a decentralisation or re-scaling of governmental care responsibilities (with or without transfer of financial responsibilities) towards regional or local governments. The example of the Netherlands was already mentioned, but also in Japan there is a trend towards community-based integrated care and a decentralisation of responsibilities to make ageing well in place possible (Morikawa, 2014; UNESCAP, 2015). In this 'Community-based Integrated Care system' informal care (of the family and broader society) has an important role to play which is reflected in the core components of the system: self-help (Ji-Jo), mutual aid (Go-Jo), social solidarity care (Kyo-jo) and governmental care (Ko-Jo) (Sudo et al., 2018). Of course one can imagine several consequences, some of them being regional (spatial) differences in care provision and resilience or the care capacity of an community. It is clear that a more decentralised implementation of care leaves room to take the local context better into account and consequently deliver better (integrated) care. The Japanse system can be traced back to a specific rural village, which was characterised by a higher share of older population compared to adjacent regions. It was able to develop and implement a new community-based integrated system which led to less bedridden elderly and lower costs and which was later seen as an example throughout reforms in Japan as a whole (Hatano et al., 2017). On the other hand, it can lead to (even stronger) regional and spatial differences in terms of care provision and supply and discrepancies in (un)met care needs of several groups. Traditionally, several researchers point to differences in acces to health care between urban and rural areas. Dewulf et al. (2013) found through a spatial analysis that mainly rural and suburban areas (in Belgium) are characterized by a shortage of physicians, while the same can be true when it comes to home care provisions (e.g.Mitchell et al., 2006; Allan & Cloutier-Fisher, 2006; Van Noort et al., 2018). At the same time it should be noticed that most research on formal care does not take into account informal care (e.g. Allan & Cloutier-Fisher, 2006). Although some researchers point to the more close-knit network in rural areas, others indicate the higher availability of services in urban areas (e.g. Vanhoof et al., 2018). Therefore, it is difficult to decide which neighbourhood might be the best to age-in-place (Chaudbury et al., 2012). Insights in geographies of aging and movement patterns between parents and children can help to gain more insight in these complexities.

3.2.1 (In)formal care and distance

Although the emphasis on informal care is not completely new – around 58% of care in Europe is informal (Verbeek-Oudijk et al., 2014)- the context changed considerably. We can refer to globalization and related aspects such as increased mobilities, different perceptions of distance, changes in neighborhood compositions, changing family arrangements and individualisation. This can have impact on the identification with a specific place and thus challenge the concept of ageing-in-place, but also on the social network and the possibility to receive informal care (Thómese et al., 2018; Buffel et al.,2018). Some insights can be gained from a broader European perspective, although results are often ambiguous and loaded with uncertainties. Hank (2007) emphasize that 85 percent of all people aged 50+ in Europe have at least one child living within 25 kilometres. Nevertheless, Knijn and Liefbroer (2006) mention that distances below or above 5 kilometres can make a big difference when it comes to exchange of care and support (in the Netherlands). Although there are some indications that a need for care and/or support leads to smaller distances, this is often not in function of the older generation (Michielin & Mulder, 2007). Van Diepen & Mulder (2009) and Mulder & Kalmijn (2016) confirm this, pointing out that distance between parents and

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

children is mainly influenced by the presence of grandchildren. Van der Pers & Mulder (2013) show regional differences (in the Netherlands) when it comes to intergenerational proximity, which can be explained by the level of urbanisation and the regional culture. Nevertheless, they stress that, in general, the distance between adult children and parents increases with age. Furthermore an effect is found related to urbanisation: while parents have a bigger change to live close to their children when they live in an urban area, for adult children the chance to live closer to parents is bigger while living in a more rural areas (ibid.).

When discussing the relation between distance and informal care, we should not forget the gender dimension. Blaauboer et al. (2011) found that married couples live closer to the parents of the man, due to a greater importance of the socio-economic position of the man when it comes to locational decisions, which is in line with the male dominance in migration in general. However, when there are young children the distance to the woman's parents is decreasing while the distance to the man's parents remains stable (ibid.). Van der Pers & Mulder (2013) also stress that sons live closer to parents than daughters, although this is less explicit when parents are older. Considering that women in general fulfill more care tasks than men, the results are at least partly surprising and ask for more insight in the relation between informal care and distance. At the same time we should not forget that distances, gender roles and informal care are concepts that can be interpreted in different ways. In some families specific tasks are appointed to women while, in other families, the same tasks are considered as typical for men (e.g. Potting, 2001). The same is true for distance, for some 5 kilometers is already considered a hindrance to provide care, while others are happy to travel 50 kilometres multiple times a week (ibid.). For example, in Flanders there are indications that people with a migration background have a higher tendency for multigenerational living and another interpretation of distance (Draulans & De Tavernier, 2016). In addition it can be mentioned that there is often a too big focus on the primary informal carer, while informal care is often a shared responsibility. This can not only result in an overestimation of the care load of the primary carer, but also in an underestimation of the tasks of others, and men in particular (Potting, 2001), without denying the potential for conflict when care tasks are shared (e.g. Luyten & Emmery, 2016). A lot of people do simply not consider themselves as informal carers, while they actually are (Vandeurzen, 2016b).

Except for the importance of distance, it can be mentioned that the link between formal and informal care (in combination with distance) is not always clear. Verbeek-Oudijk et al. (2014) stress for example that while there are indications that in the Netherlands formal and informal care seems to be complementary, in Germany it seems more justified to consider them as substitutes. Bremer et al. (2017) also found a substitution effect (across Europe), whereby more informal care is connected to a lower demand for formal care services at home among people with dementia. Brandt et al. (2009) find not such an effect and speak about a specialization whereby the state takes care of physical care and children help parents with other less intensive tasks. Although Hank (2007) finds differences across European countries when it comes to familial solidarity, there are no indications that solidarity is declining throughout generations. However, the Dutch case warns us that even though informal care and solidarity may not decline, it does not mean it will automatically fill the gap left behind by a policy that emphasize informal care (Kromhout et al., 2018).

3.3 Ageing-in-place from a health policy perspective in Flanders

Although the focus in this section is on the specific health care policy targeted at the elderly, it should be stressed that the social policy in Flanders, in general, is putting more emphasis on informal care (e.g. Dermaut et al., 2019 – related to care for disabled people) and thereby following the earlier mentioned international trend of reconfiguration of the welfare state. From this perspective, the policy in Flanders can therefore not be seen in isolation from the World Health Organization (WHO) policy and initiatives on the level of the European union. It should be stressed that (elderly) care in Belgium is to a large extent a responsibility of the regions (Walloon region, Flemish region, Brussels Capital region) and that therefore the focus in this section is on Flanders (northern Dutch speaking part). In the Flemish governmental policy agreement it is explicitly mentioned that one tries to stimulate to 'live as long at home or in the neighbourhood'. This is also reflected in the other policy papers, in which it is furthermore stressed that one tries to strengthen the social tissue and cooperation between citizens and (in)formal caregivers (Vandeurzen, 2014). At the same time it is acknowledged that the demand for care will increase due to shrinkages in the social network, which seems to be in contrast with the foregoing. Except for the general health and care policy we can point to a policy paper which specifically focuses on the welfare and care policy for elderly,

and which can be seen as the framework for (future) policy. According to this document the main goal is: "To realize a demand-driven and person-centred care for elderly. Thereby, they are supported by an individual care budget […]" (Flemish Government 2016b:4, translated from Dutch). Furthermore, the vision consists of several core concepts or principles which are considered as starting points for further (local) policy making. Most of them have a strong link with ageing-in-place. It emphasizes the own competences and capabilities of elderly, while it acknowledges a role for the family, community and the government. This comes together in the principle of "vermaatschappelijking" (re-communitizing) in which it is stressed that when someone needs care, this must be provided in the own environment (neighbourhood) and by the 'own environment', being the family, friends and the broader local community.

As a conceptual framework the Flemish policy uses the framework as proposed by the WHO (2015) (figure 1). This framework consist of several concentric circles in which the previously mentioned principles are used. It illustrates that the person with a care need can be seen as a focus, whereby care needs are a shared responsibility between the family, the community and the government, which cannot be separated from each other and are embedded in a specific context. This context has to provide a universally accessible, person-centred and integrated care and support system. Of course this implies a holistic view on ageing, whereby it is also necessary to take into account the living environment and stress interdisciplinary cooperation. It is therefore not surprising that these aspects are reflected by the 15 objectives (or so-called) perspectives which are described in the Flemish policy paper.

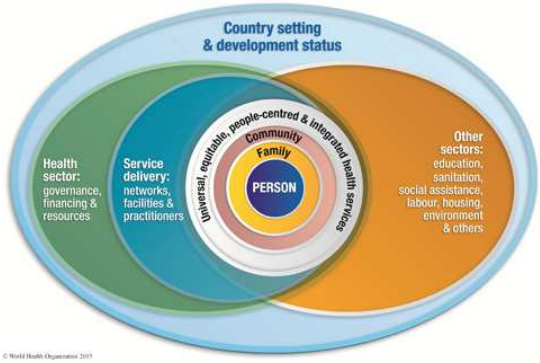

Figure 1 Conceptual framemework person-centred and integrated care and support (WHO, 2015: 13)

Besides the fact that the objectives remain very abstract, most of them relate to the activation or stimulation of social participation, self-development and ageing in the own environment. Although it is mentioned that both, the house as the neighbourhood, need to be suitable and adjusted, very little attention is paid to this. Nevertheless, several other policy documents look into this in (slightly) more detail. First of all it is useful to consider the policy on residential elderly care, even when focusing on ageing-in-place. It should be stressed that only elderly with the highest care needs are admitted to residential care settings, which means that on average more care and expertise is needed to fulfill the needs of the inhabitants, compared to a situation in which also elderly with a lower care profile are admitted to these facilities. Nevertheless, the residential care facilities are evolving into a kind of local care hub in which expertise is also related to for example day care or respite care and functioning as an important link within the primary health care (Flemish Government, 2017). It is stressed that a residential care facility is and should be part of the society and is not to be considered as something closed. In line with this, residential care facilities are an important link between the different kind of housing and care options. The activation and strengthening of the social network(s) is consequently seen as an important role for these facilities as well. They should contribute towards the liveability and social cohesion in the neighbourhood and thus contribute to a neighbourhood-centred approach on housing and care with the end goal of creating "lively and careful neighbourhoods" (ibid.).

The Flemish Government (2017b) listed some transition priorities in their 'vision 2050' one of them being 'care and living together'. In this, the two concepts of 'social cohesion' and 'vermaatschappelijking' are at the core. The latter is defined as: "the shift in the care sector which aims to give people with disabilities, the chronically ill, and frail elderly their own position in the society, and support them and deliver the care as integrated as much in the society" (Flemish Government, 2017b:3). Thereby it is mentioned that (specialized) institutional care should be the exception and that self-care, family care and informal care will receive priority. Although it is mentioned that this priority should be considered as interdisciplinary and thus

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

beyond the departments of welfare, health, culture and sport, the link or referencing towards other disciplines and departments seems to be rather limited. The importance of 'health in all policies' is stressed but no explicit link with urban planning or housing and attention to age-friendly environments is lacking. Even the policy paper which is explicitly focused on neighbourhoods: "Caring Neighbourhoods" (Vandeurzen, 2018) remains abstract and vague and does not mention explicit measures or goals. It rather tries to spark a discussion on the role of the neighbourhood and which factors can contribute to the so-called caring neighbourhoods.

As became clear from the foregoing, the focus on informal and family care is increasing. 'Shared responsibility' and 're-communitizing' can be seen as the keywords. But as mentioned before, this cannot simply be an assumption and thus requires an extensive and well-balanced policy towards informal care. At the same time and as mentioned before, there is often a lack of information related to informal care, especially when it comes to distance. The most important policy document in this respect is the so-called 'Flemish Family Care plan' (Vlaams Mantelzorgplan – Vandeurzen, 2016b) in which the focus is explicitly on family care. Several broader demographic and social changes are mentioned influencing the demand and supply for informal family care. Thereby it is mentioned that distances are getting bigger, although this is a mere assumption not supported by data. Most data about family carers is based on the so-called 'social-cultural shifting' surveys (2014, in Vandeurzen, 2016b) and on numbers of officially registered family carers, as well as the 'health survey'(2013, in Vandeurzen, 2016b). The latter for example concludes that 8 percent of people (15+) provide informal care at least once a week. Based on the SCV-surveys and registered family carers it becomes clear that most informal family carers are between 45 and 64 years old, although the share of older people providing care should not be underestimated. In general, there are more female informal carers, which is especially true when it comes to persons with heavy care needs. Regarding the socio-economic position it is mentioned that informal family carers, in general, have a lower labour participation and educational level. Although most informal family carers fulfill care tasks in the own household or family, slightly less than one fifth of the care is provided to neighbours or friends. More than half of the informal family carers living in the same household are over 65, which implies providing care to a spouse. This is often done to prevent a move to a residential care facility, which is reflected in a stronger intensity in the informal care provided (Vermeulen & Declerq, 2011 in Vandeurzen 2016b). That there is a need for additional attention for informal carers is also illustrated by Bronselaer et al. (2016) who stress that the quality of life of informal family carers is lower than average. It is therefore not surprisingly that "supporting informal family carers to limit the burden and increase the capacity" is one of the main policy goals, as well as "acknowledging and recognizing informal family carers" and "improving the cooperation between formal and informal carers". It is acknowledged that better information provision for informal carers is needed, as well as a pro-active stance to reach them. The stimulation of social cohesion and adjustments to home are mentioned as well, as is the focus on digital health and care. Furthermore it stresses that the informal carer should be seen as a fully acknowledged actor in the care system, which means that there is need for a better integration.

3.4 Ageing-in-place from a housing and spatial policy perspective in Flanders

Although, from a health perspective, it is acknowledged that there should be a more interdisciplinary approach towards aging, and the importance of housing is often briefly mentioned, we cannot speak about a real integrated policy perspective. The same can be said when we look in more detail into the housing and planning policy in Flanders. In general it can be mentioned that there is very little attention being paid to the elderly when it comes to housing. Although there is a strategic goal related to quality, sustainability and a tailor made housing offer, whereby there is a reference towards the extramuralisation of care and demographic change, no specific or tangible measures are mentioned (Homans, 2014). Not much is mentioned about adjustments of the housing stocks for older people or policy related to this. Also when it comes to communal living or other housing alternatives there is barely attention for the elderly. This is especially surprising since it is acknowledged that there is a discrepancy between supply and demand on the housing market. Most properties which are available on the market are larger suburban houses which are not suitable for most elderly. The aim is to come to a better balance on the housing market and at the same time stimulate housing mobility. Thereby, it is stressed that living in the same home during the complete life course is often not the best solution (Agentschap Wonen, 2018). Stimulating housing mobility is also something which is stressed in the policy paper "intelligent housing and living". In this document 4 pillars

are distinguished: sustainable homes and environments, the right location, fulfilment of the needs and wishes, influencing and trying to shift the ideal picture of living (from a detached house with a garden towards more compact living arrangements). It is for example stressed that there is a need for more flexible, compact, and multi-functional arrangements, specifically at well-connected locations, whereby the link with spatial planning is mentioned. There are high expectations with regard to technological developments which are seen as a transversal innovation. Nevertheless, also when it comes to this policy paper there are no concrete measures or objectives. It aims at creating a platform where several policy domains can discuss future challenges and start some experiments (Agentschap Wonen, 2017).

When it comes to the spatial planning policy there is barely attention for the needs of the elderly. Belgium is characterised by a high level of urban sprawl and spatial fragmentation (ribbon development). This is especially true in Flanders with a population density of more than 450 inhabitants per square kilometre (Verbeek & Tempels, 2016). Flanders and Belgium in general are considered to have one of the highest levels of urban sprawl in Europe (EEA, 2016). Furthermore, the level of sprawl is still increasing, partly due to path dependency (EEA, 2016; De Decker, 2011). Verbeek et al. (2014) stress for example that the length of ribbon development increased considerably between 1989 and 2012. Poelmans & Engelen (2014) stress that the additional net land take per day is around 6 hectare. Nevertheless, and as mentioned in an earlier paper (Gruijthuijsen et al., 2018) the Flemish policy is focused on limiting additional land take by focusing on concentration, increasing the spatial yield, increasing densities and stimulate multifunctional and mixed land-use and interweaving of activities. In other words, it is aiming at a more sustainable management of land, whereby the aim is to avoid additional land take altogether in 2040 (Departement Ruimte Vlaanderen, 2018). Thereby it should be stressed that it is still only limited to a strategic vision, and no decrees were yet agreed on or adopted, which means no changes are visible at the moment.

And although the potential shift in spatial planning means there are possibilities to limit the sprawl and sustain or create more open space and benefit for example from shrinkage in certain localities (Segers et al., 2020), there are also potential conflicts between the spatial policy on the one hand and the health policy on the other hand, especially when one takes into account the needs and capabilities of elderly. A strong concentration of facilities in well-connected localities can result in a limited acces to facilities for the elderly which not seldom live in suburban areas characterised by a strong sprawl. Cant (2019) for example shows that there are so-called 'food-desert' detectable in Flanders, in particular in suburban localities with an increasing share of older inhabitants. The same is probably true when it comes to formal care facilities, which makes it even more important to get insight in the relation between informal care and distance and if informal care can bridge spatial developments and compensate for a lack of facilities. Furthermore, it is conceivable that a lack of facilities not only limit the possibilities for formal care, but also complicates informal care provision and is therefore not always stimulating or facilitating ageing-in-place. There is need for strategic cooperation between different policy domains, and this requires more insight into geographies of ageing and care. This not only true when it comes to planning on the national, regional or provincial level, but also when it comes to the neighbourhood.

There is in general a lack of insight into the factors that can contribute to an age-friendly environment (e.g. Scharlach, 2017; Hwang, 2017). There are some initiatives in the right direction such as the WHO Age-Friendly Cities – which also list up several indicators, but no Belgian municipality is part of this initiative which also indicates a lack of attention at the local level. According to Scharlach (2017) these initiatives often neglect the more dynamic relation between the person and the environment. Furthermore, there is limited (academic) evidence for the effectiveness of these initiatives. Sun et al (2018) stress that even when it goes about the person-environment fit, this is often limited to housing and thus neglecting the neighbourhood. Greenfield et al. (2019) therefore bring the term 'community gerontology' to the forefront. They argue that much of the research is either focused on the macro-level (housing policy) or on the micro-level (house), while the meso-level is largely neglected. And this is true for the case of Flanders. There is very limited information about for example the relationship between neighbourhood or environmental characteristics and formal and informal care. Vandenboer et al. (2010) and Demaerschalck et al. (2012) can be mentioned as exceptions. They conclude that municipal characteristics have no influence on informal care. Contrary to the expectation, the offer of formal care is not influencing the use of informal care, although a higher use of formal care can be noticed. Besides, they conclude that the higher the ratio of the population older than 80 compared to the population of 50 – 59 years, the higher the chance to use formal

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

care. In other words, the less potential caregivers, the higher the usage of formal carers (Vandenboer et al., 2010; Demaerschalck et al., 2012). As will be illustrated later, this ratio is increasing, which means that it is likely that there will be an even bigger pressure on informal caregiving in conjunction with the current health policy. This also makes it more relevant to look into geographies of ageing.

4 METHODOLOGY AND APPROACH

As mentioned in the introduction we used general population statistics to get more insight in geographies of aging (and care) and demographic developments. The focus is on ageing, both the share of elderly in the general population as well as ratios between older people and for example the working population or the population that traditionally provides most care. In total around a dozen of ratios were used, based on common definitions (e.g. Statistics Belgium, 2019) of which the following can be considered the most important:

1) Ageing: Population aged 65 or above in % of total population

2) Silvering: Population aged 80 or above in % of total population

3) Old age dependency ratio: Population aged 65 or above compared to the population between 20 and 64

4) Family care ratio: The ratio between the population with the biggest care needs and the population that provide most informal care: population aged 80 or above compared to the population aged between 50 and 59.

The data we used is received from Statistics Belgium and relates to the period between 2002 and 2017 (Algemene Directie Statistiek – Statistics Belgium, 2019). Calculations are made by making use of Excel and SPSS and visualized by making use of ArcGis. With regard to the visualization we used the authentic source of the Belgian administrative borders (FOD Financien, 2019). It concerns the version of 2018 due to merging of some municipalities in 2019.

As a first step we visualized several of these shares and ratios for both Flanders, Walloon and Brussels Capital Region and looked into general patterns. At first instance we did this on both the spatial level of the provinces (NUTS 2) and the administrative regions (NUTS 3). Afterwards, we tried to discover more fine-grained and detailed ageing patterns at the level of the municipalities and statistical districts (being the level of the neighbourhood). In this paper we will show a very limited selection of this, focused on Flanders. Thereby, we interpreted the results mainly based on visual aspects combined with some descriptive statistics.

As a second step we used cluster analysis to get more insight in different ageing profiles across both administrative regions, municipalities and statistical districts. In this paper we will mainly focus on the latter. For identifying the clusters we used both ArcMap (Spatial Statistics Toolbox) and SPSS. We mainly used K-means clustering and the two-step cluster method. K-means clustering divides a data set in several clusters and attempts to minimize the difference within a cluster, while the difference between clusters is maximized (Heremans, 2001). This method comes with several drawbacks, the most important being that the results depend on the chosen parameters and pre-defined number of clusters. Therefore, we used other clustering methods to get better insight in the optimized amount of clusters through this method. Furthermore, we worked with standardised scores (Z-score) to circumvent the sensibility of the method for measurements on different measurement levels. An advantage of this method is that it can handle large datasets, although only on ratio or interval level. The two-step cluster method can also handle categorical variables and is thus mainly used when it comes to enrichment with for example urbanization typologies or other datasets. This method pre-clusters data in a first step before carrying out a conventional hierarchical cluster analysis (e.g. Norusis, 2011). Another advantage is that it automatically select the optimal number of clusters. Although the method assumes that variables are not strongly correlated and are normally distributed, a lack of this does not seem to influence the robustness of the method, whereby an interpretation can give the decisive answer (ibid.). It is mainly in the third step that we make use of this method. After the identification of the initial cluster based on only demographic data, the third step tries to enrich the results. In this paper we will only focus on the level of urbanization, but several other enrichments will be possible as well, depending on the research goal. To name an example, we compared some results from the first step with the availability of facilities, in which there are indications that the municipalities with the highest level of ageing do not necessarily have the best facilities for the elderly, something which will also be possible to relate the different clusters.

5 INSIGHTS IN GEOGRAPHIES OF AGING

The first step and visualization of different demographic ratios informs us already that there are several differences visible across Belgium, both on the regional level (Flanders, Walloon, Brussels Capital Region) (see figure 2), but also on the level of provinces and municipalities (figures 3 and 4). Figure 2 shows that the ageing of the population increased, although not uniform across the country. Although the differeces between the regions were relative small in 2001, we can notice that there was not an uniform path towards ageing across the country. While in Belgium the share of population older than 65 increased from 16,9% in 2002 towards 18,7% in 2018, in Brussels Capital region it decreased from 16,5% towards 13,2%. In Flanders the increase (from 16,9% to 20,0%) was larger than in the other regions. In Flanders differences between provinces can be detected. Figure 2 shows that even though in all provinces the level of ageing is stronger than in Belgium as a whole, there is one province where the level is considerable higher than the others and is characterised by a stronger growth. In West-Flanders, the share of population aged 65 or above evolved from 18,3% in 2002 towards 23,0% in 2017. When looking into a lower spatial level and by visualizing the data per municipality (figure 3 & 4), we see again considerable differences. It becomes clear that especially at the seaside there is high level of ageing (already in 2002) as well as a relatively large growth in the period 2002 – 2017, while in other municipalities in the same province the share of people aged 65 or above even decreased during that period. This is not surprisingly since the seaside is traditionally an area which is characterised by retirement migration (e.g. Provincie West-Vlaanderen, 2017). The pattern becomes even more complex when looking into the more detailed and lower level of the statistical districts (not shown), where for example at the seaside it is noticeable that ageing is mainly located at the direct seaside and already more limited in the direct hinterland.

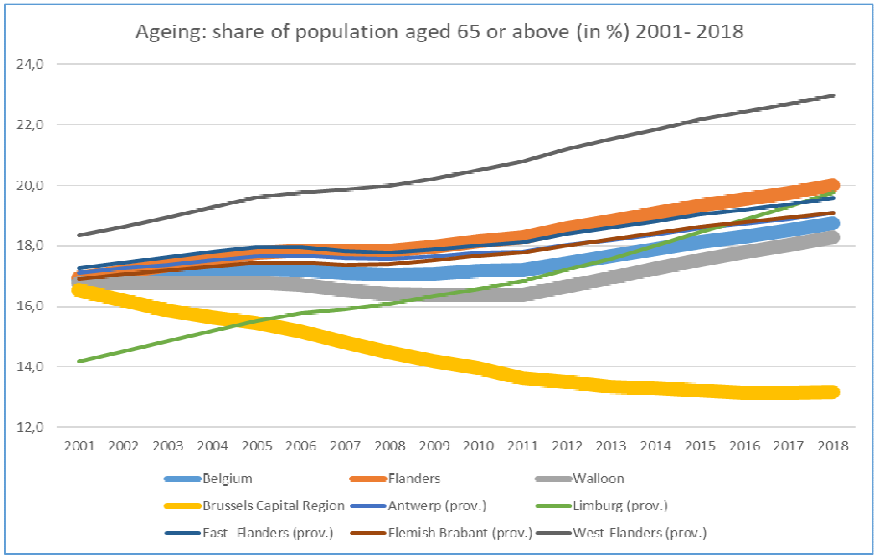

Figure 2: Ageing per region and province in Belgium, 2001 - 2018

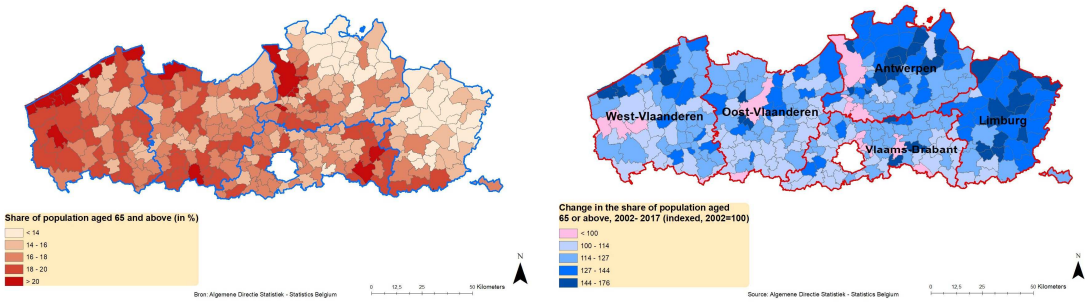

Figure 3: Ageing in Flanders, 2002, Figure 4: Indexed numbers ageing, 2017 compared to 2002, per municipality, Flanders

Figure 4 shows furthermore that especially the eastern parts of Flanders (especially in Limburg and some parts of Antwerp) are characterized by a relatively strong growth during the period 2002- 2017. This is partly the consequence of a catch-up since figure 3 shows that exactly these areas were characterized by a lower level of aging in 2002. Moreover, most of the municipalities in these regions are still being characterized by a lower level of ageing compared to average (not shown). This lower starting position in

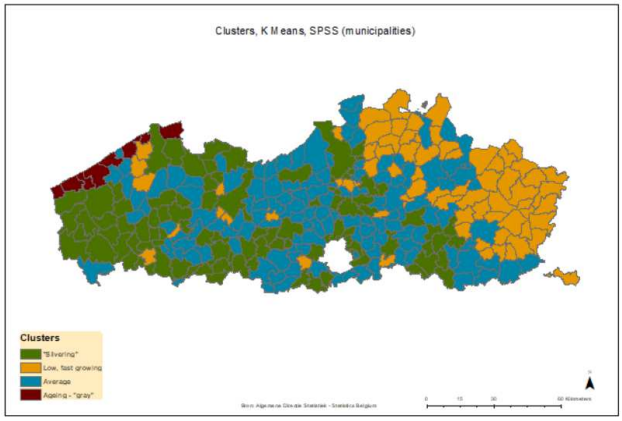
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

2002 can mainly be explained by labour migration in the period after World War II resulting in a younger population. The contrast between on the one hand the western part of Flanders and on the other hand the eastern part of Flanders, is something that is also reflected when we look into other ratios. In general, it can be mentioned that based on these visual interpretation of patterns some dynamics become visible as well as some indications of the existence of spatial clusters (e.g. based on a high level or a fast(er) growth). Although the figures above do only relate to ageing, it is interesting to reflect as well on for example the so-called family care ratio (population aged 80 or above compared to the population between 50- 59). Thereby it can be stated that also this ratio is higher in the western part of Flanders, while the eastern part is characterised by a strong(er) growth. However, also in this case patterns become more complex on a lower spatial level. We should furthermore not forget that the consequences of this ratio can differ between both urban and rural regions, but also between regions which already adjusted to this reality compared to regions who are characterised by a more recent growth (and decline in potential informal carers). This points to the need to get for example more insight in distances between parents and children and residential movements.



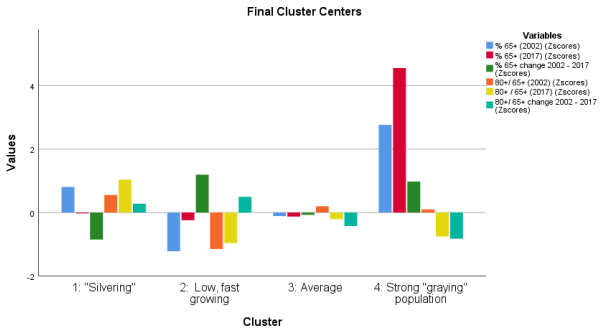


Figure 5: K-Means clustering (demographic ratios), municipalities, Flanders . Figure 6: Clusters (municipalities)

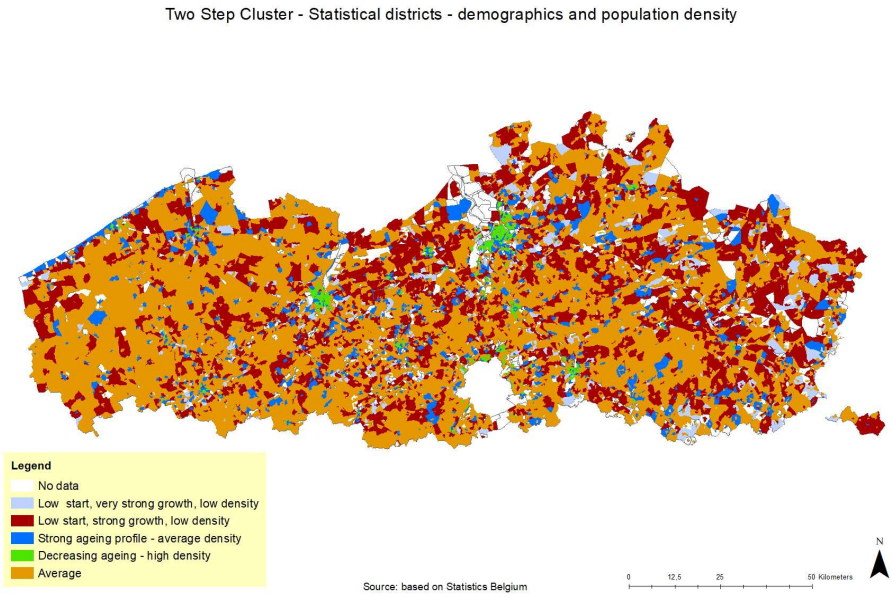

Figure 7: Two-step cluster approach relating to statistical districts and making use of demographics and population density

As a second step a K-means cluster approach was used to divide the municipalities (n=308) based on their ageing profile. Thereby we made use of the share of population older than 65 (in 2002, 2017 and the growth between 2002- 2017) and the share of the oldest old compared to the older population (in 2002, 2017 and the growth between 2002 – 2017). Thereby we identified four clusters, which partly relate to the results and insights described in the foregoing. First of all, a small cluster of municipalities at the seaside are identified as localities with a high level of ageing (n=8), while mainly in the eastern part of Flanders we see a concentration of municipalities who can be considered as being characterized by a relatively low level in 2002 but a fast growth level (n=71). However, most municipalities (n=131) can be characterized as having

an average ageing profile. The remaining ones (n=98) are characterized especially by a high level of inhabitants older than 80 years, while the level of ageing (65+) is decreasing. This is for example the case in large cities, which were traditionally characterised by an older population but have seen an influx of younger population and migrants. But also several rural municipalities show the same development. In other words, more insights are needed in for example the impact of population densities and levels of urbanization.

As an example of the third step, figure 7 shows a cluster approach whereby we took into account the population density, this time on the level of the neighbourhood (statistical district). Although figure 8 shows us that further refinements in terms of clusters are desirable, the results are nevertheless interesting. Except for a further subdivision, the demographic characteristics of the clusters itself are not that much different from the ones identified in figure 5. However, it is clearly visible that the pattern on a lower spatial level is much more complex. Furthermore, the (larger) urban areas (e.g. Antwerp, Ghent, Mechelen, Leuven) are clearly defined as a specific cluster characterized by a high population density and a level of ageing which decreased between 2002 and 2017.

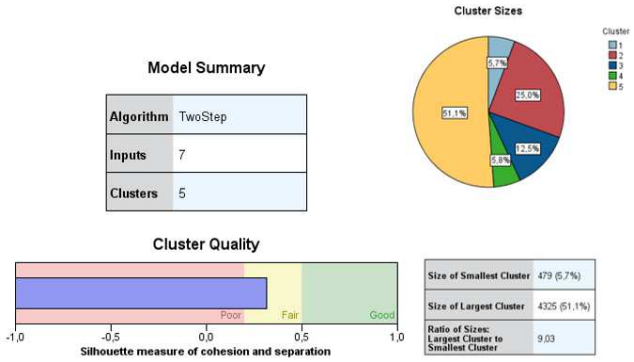

Figure 8: Model summary related to figure 7

6 DISCUSSION AND CONCLUSION: TOWARDS NEXT STEPS

This paper started with pointing towards the need to get more insight in geographies of ageing and care which are too often neglected or downplayed. More insight is needed to support ageing-in-place and better define the environmental characteristics that stimulate this. Although ageing-in-place is stimulated from a policy perspective it is often not clear if for example (potential) informal care is available in every region. The aim of the paper was to present a framework or starting point for research into these aspects and stimulate better integrated policy making, as well as research into informal care related to ageing-in-place. To realize this we used macrodata obtained from the statistical office to visualize several demographic ratios throughout the period 2002 – 2017. Based on these visualizations we could already confirm the existence of 'geographies of ageing' and differences across spatial scales. On a higher spatial scale differences in ageing are relatively easy to explain by migration patterns and residential movements, while on the level of the neighbourhood patterns are more complex and less straightforward. Therefore, we carried out several cluster analysis to emphasize more fine-grained and detailed ageing patterns at several spatial levels, in which we also took into account the population density.

Further research can for example compare and/or enrich the results with aspects such as formal care facilities, retail activities and mobilities and transport. Although macrodata (aggregated) can already give improved insight into geographies of ageing and care, there is need for making use of microdata to get more detailed patterns and insights in residential movements and distances. This is especially true in a context in which informal care is more and more emphasized. In Flanders there is a lack of information about for example distances between parents and children and if informal care can compensate for the (potential) decline in formal care. Microdata can be useful here, also to see regional differences in this respect, as well as how distances between family members evolve over time. It will also enable to us to look into gender differences when it comes to distances, as well as potential biases in clusters for which macrodata is not suitable. Furthermore, as informal care and distances are relative concepts, qualitative research can shed light on the negotiating of distances and informal care, and enhance our knowledge about ageing-in-place, also by complementing quantitative approaches to interpret patterns.

1 ABSTRACT

Lastenräder, die insbesondere in urbanen Räumen eine umweltfreundliche Transportalternative zum motorisierten Individualverkehr gelten, sind bisher jedoch ein Nischenprodukt. Das Teilen (Sharing) von Transporträdern bietet die Chance, einige der Nutzungshürden zu überwinden. Neben der damit möglichen Umgehung der relativ hohen Anschaffungskosten wird damit auch eine Möglichkeit zum Ausprobieren von Transporträdern geschaffen. Die dadurch gesammelten Erfahrungen zu den Einsatzmöglichkeiten bilden eine wichtige Grundlage für die Intention zur künftigen Nutzung von Lastenrädern.

In host-basierten Systemen übernehmen in der Regel lokale Kleinbetriebe (z. B. Gastronomie, Einzelhandel) Wartung und Verleih der Räder. Beim Projekt Grätzlrad in Wien erhielten zehn Unternehmen bzw. Organisationen eine hohe Förderung für die Anschaffung eines Transportrades unter der Bedingung, dieses für mindestens zwei Jahre kostenfrei interessierten Nutzerinnen und Nutzern zur Verfügung zu stellen. Gegen Ende dieser zwei Jahre fand eine Evaluierung des Projekts statt, die unter anderem eine Auswertung von Reservierungsdaten und eine Befragung der Nutzerinnen und Nutzer umfasste.

Im Betrachtungszeitraum der ersten 18 Monate des Bestehens des Grätzlrad-Angebots fanden rund 1600 Ausleihen statt. Umweltfreundlichkeit, Fahrspaß und das Ausprobieren neuer Transportmittel stellen wesentliche Gründe für die Nutzung von Transporträdern dar. Die Struktur der Nutzerinnen und Nutzer weicht von der Gesamtbevölkerung deutlich ab, was sich insbesondere in einem sehr hohen Bildungsgrad und einer großen Bedeutung von Fahrrädern für die persönliche Mobilität äußert. Dennoch nutzte der überwiegende Teil zum ersten Mal ein Lastenrad, was den Stellenwert derartiger Programme zum Kennenlernen dieser Transportoption unterstreicht. Im Beitrag werden Erkenntnisse zu (1) räumlicher und zeitlicher Verteilung der Ausleihen, (2) Einsatzzwecken der Lastenräder und (3) verkehrliche Wirkungen des Angebots vorgestellt sowie Implikationen für die Förderung von deren weiteren Verbreitung diskutiert.

Keywords: Evaluierung, Sharing, Lastenrad, host-basiert, Verkehr

2 LASTENRÄDER

Lastenräder (auch Transporträder) sind Fahrräder, deren Bauform für den Transport größerer Lasten und Volumina optimiert ist. Viele Modelle sind auch für Personentransporte (insbesondere Kinder) geeignet. Die Nutzlast beträgt bist zu 500 Kilogramm, wobei Transporträder für die Privatnutzung üblicherweise Transporte von bis zu 100 Kilogramm aufnehmen können (Becker & Rudolf, 2018a; Hagen, Lobo & Mendonça, 2013; IRALA, 2017; Masterson, 2017; Riehle, 2012; Riggs & Schwartz, 2018; Weirich, 2012) Der Übergang zwischen herkömmlichen Fahrrädern und Lastenrädern ist fließend. Für eine klare Abgrenzung werden in der Regel nur Fahrräder mit mindestens 50 Kilogramm Nutzlast zu den Lastenrädern gezählt (Riehle, 2012).

Lastenräder gibt es in einer Vielzahl verschiedener Bauformen, die noch durch ein Zahl von Sonderanfertigungen sowie Rädern mit experimentellem Charakter ergänzt werden. Wesentliche Unterscheidungsmerkmale sind die Anzahl der Räder und die Position der Ladefläche im Verhältnis zu dem/der Fahrerin oder Fahrer. Obwohl es grundsätzlich eine große Zahl an Bauweisen gibt, kommen für die nicht-gewerbliche Nutzung im Wesentlichen nur vier Typen zum Einsatz: (1) Bäckerrad, (2) Longtail, (3) Long John und (4) Bakfiets (nicht zu Verwechseln mit dem gleichnamigen Hersteller) (Ghebrezgiabiher & Poscher-Mika, 2018). Die einzelnen Modelltypen sind schematisch in Abbildung 1 dargestellt. Die einzelnen Bauformen sind mit Stärken und Schwächen in Bezug auf Nutzungseigenschaften wie Fahrverhalten, Nutzlast, Leergewicht, Höhe des Schwerpunktes oder Stehenbleiben und Abstellen verbunden. Die Eignung der einzelnen Typen ist deshalb insbesondere im Kontext des Einsatzbereiches zu sehen (Becker & Rudolf, 2018b; Ghebrezgiabiher & Poscher-Mika, 2018; Gruber & Rudolph, 2016; Rüdiger, Kopka Jan-Philip & Hohaus, 2016).

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Zu den typischen Ausstattungsmerkmalen von Transporträdern zählt die elektrische Antriebsunterstützung, die bei den meisten Modellen optional angeboten wird. Zudem kann man insbesondere bei Long John- und Bakfiets-Modellen zwischen verschiedenen Transportaufbauten wählen, zu denen in der Regel eine für den Kindertransport optimierte Kiste und eine verschließbare Box für Gütertransporte zählen (Ghebrezgiabiher & Poscher-Mika, 2018; Riehle, 2012).

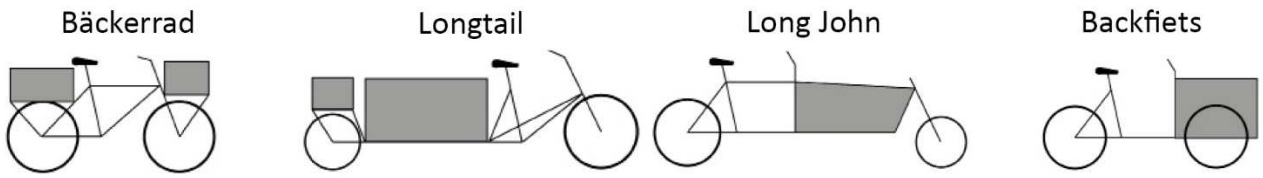

Abbildung 1: Überblick über weit verbreitete Bauweisen von Lastenrädern anhand gängiger Klassifizierungsmerkmale

3 LASTENRAD-SHARING

Durch die Möglichkeit größere Gegenstände bzw. Mengen sowie Kinder zu transportieren, bieten sich Lastenräder als Alternative zum motorisierten Individualverkehr an. Damit können sie einen erheblichen Beitrag zur Reduktion von Luftschadstoff- und Treibhausgasemissionen leisten. Dennoch stellen Transporträder bisher ein Nischenprodukt dar. Zu den wesentlichen Nutzungsbarrieren zählen die geringe Bekanntheit und die hohen Anschaffungskosten.

Lastenrad-Sharing ermöglicht die Verwendung von Transporträdern ohne dass eine Eigentumsübertragung stattfindet. Daraus ergeben sich auf drei Weisen verkehrliche und damit auch ökologische Wirkungen: (1) durch die niederschwellige Verfügbarkeit werden Fahrten mit anderen Verkehrsmitteln ersetzt und (2) Interessierte erhalten die Möglichkeit sich damit vertraut zu machen, was Basis für wiederholte Nutzungen oder eine Anschaffung sein kann. (3) Letztlich sind Transporträder dadurch vermehrt im Öffentlichen Raum sichtbar (entweder an den Verleihorten oder wenn diese genutzt werden), was zur Verankerung dieses Verkehrsmittels im Bewusstsein beiträgt.

3.1 Angebotsformen

Das Angebot im Bereich Lastenrad-Sharing ist derzeit durch eine große Zahl relativ kleiner Initiativen geprägt. Neben Angeboten, die nur einem geschlossenen Nutzendenkreis zur Verfügung stehen (z. B. geschlossenes Lastenrad-Sharing in Wohnausanlagen, Testnutzungsprogramme für Unternehmen, Leih-Lastenräder von Handelsketten), gibt es auch verschiedene Varianten von Lastenrad-Sharing, die der Allgemeinheit offen stehen.

Bei Öffentlichen Lastenradverleihsystemen erfolgt die Ausleihe an fixen Stationen im Selbstbedienungsbetrieb, die Rückgabe ist in der Regel an jeder anderen Station im System möglich. Obwohl dieses Modell bei Bikesharing in Städten weit verbreitet ist, spielt es beim Teilen von Lastenrädern nur eine untergeordnete Rolle (Becker & Rudolf, 2018b). Beispiele für öffentliche Lastenradverleihsysteme sind das Pilotprojekt TINK das zu Forschungszwecken in den deutschen Städten Konstanz und Norderstedt etabliert wurde und die SeestadtFLOTTE im Wiener Stadtentwicklungsgebiet Seestadt aspern, bei der auch herkömmliche Fahrräder angeboten werden (TINK; Wien 3420 aspern Development AG, 2019). Vereinzelt ist der Verleih von Transporträdern Teil des Angebots an Mobilitätsstationen.

Bei Peer-to-Peer Lastenrad-Sharing treten Privatpersonen als Verleihende auf, die ihr privates Lastenrad anderen Personen zur Verfügung stellen. Die Vermittlung erfolgt meist über internetbasierte Sharing-Plattformen (Becker & Rudolf, 2018b; Scholl, 2019). Im deutschsprachigen Raum gibt es mit das-lastenrad.at nur eine derartige Plattform, die auf Lastenräder spezialisiert ist. Dort können registrierte Nutzerinnen und Nutzer alle verfügbaren Transporträder ausleihen und selbst welche anbieten.

Host-basiertes Lastenrad-Sharing greift auf Kleinbetriebe und andere lokale Organisationen als Verwalterinnen und Verwalter der geteilten Lastenräder zurück. Diese übernehmen die Abwicklung von Ausleihen und meist auch kleinere Wartungsarbeiten. Zudem fungieren die Hosts als Mulitplikatorinnen und Multiplikatoren im Stadtviertel, die das Sharing-Angebot an Ihre Kundinnen und Kunden weitertragen. Im Gegenzug erhalten sie Vorteile wie die kostenfreie Nutzung der Räder oder eine erhöhte Förderung für deren

Anschaffung (Becker & Rudolf, 2018b). Auch ergeben sich häufig zusätzliche Vorteile wie eine erhöhte Kundenfrequenz und die Möglichkeit den eigenen Betrieb auf dem Lastenrad zu bewerben. Ein Beispiel für ein derartiges System ist Carvelo2Go in der Schweiz, das mit rund 300 Transporträdern gegenwärtig auch das größte derartige Angebot darstellt (Becker & Rudolf, 2018b; Suter, Stawicki & Schmid, 2017).

Freie Lastenräder sind Transporträder, die von zivilgesellschaftlichen Initiativen angeboten werden und in der Regel gegen freie Spende genutzt werden können. Die Abwicklung des Verleihs variiert stark mit den einzelnen Initiativen. In einigen Städten werden beispielsweise lokale Betriebe als Verwalterinnen und Verwalter der Lastenräder eingebunden (Becker & Rudolf, 2018a), wodurch es Überschneidungen mit host-basierten Systemen gibt.

3.2 Nutzung

Befragungen unter Nutzenden von Freien Lastenrädern sowie der Initiativen TINK und Carvelo2Go zeigen, dass deren Merkmalsausprägungen erheblich von den Werten der Gesamtbevölkerung abweichen. So sind 63% der befragten Nutzerinnen und Nutzer freier Lastenräder männlich, während der Anteil männlicher Nutzer bei Carvelo2Go bei 67% und bei TINK bei 68% (Konstanz) bzw. 70% (Norderstedt) liegt. Mit 77% Akademikeranteil und einer durchschnittlichen Haushaltsgröße von 2,68 weisen zudem befragte Carvelo2Go-Nutzende in Basel auch in Bezug auf diese Merkmale überdurchschnittliche Werte auf. Beim Alter der Befragten liegt der Mittelwert bei 38 (freie Lastenräder und TINK Konstanz) bzw. 42 Jahren (TINK Norderstedt). Eine schweizweite Analyse der Carvelo2Go-Nutzenden zeigt, dass 50% davon in der Altersgruppe zwischen 25 und 44 sind (Suter et al., 2017). In Bezug auf die Mobilität zeichnet sich diese Gruppe durch eine häufige Nutzung des Fahrrads für die Alltagsmobilität aus (Becker & Rudolf, 2018a; Hess & Schubert, 2019; Scheffler & Bleh, 2018).

Geteilte Lastenräder werden überwiegend für private Erledigungen wie dem Transport von Einkäufen bzw. Lebensmitteln oder Möbeln genutzt. Auch der Kindertransport spielt bei den betrachteten Lastenrad-Sharing Angeboten eine wesentliche Rolle, häufig im Zusammenhang mit Ausflügen. Bei rund 58% der Ausleihen von freien Lastenrädern wurden weniger als zehn Kilometer zurückgelegt. Die durchschnittliche Distanz liegt bei 14,5 Kilometern, wobei einige Ausreißer nach oben das Ergebnis verzerren (Becker & Rudolf, 2018a).

3.3 Projekt Grätzlrad

Im Frühjahr 2017 schüttete die Stadt Wien eine Förderung für die Anschaffung von Lastenrädern aus. Ein Teil des Förderbudgets war für zehn Betriebe oder ähnliche Organisationen mit fixem Standort und Öffnungszeiten vorgesehen, die eine volle Kostenübernahme von bis zu 3000 Euro erhalten konnten. Bedingung für die Inanspruchnahme der Förderung war, dass das damit angeschaffte Lastenrad zumindest für 24 Monate kostenfrei zum Verleih angeboten wird (Mobilitätsagentur Wien). Dieses Angebot wird unter dem Namen Grätzlrad beworben (Grätzl ist Wienerisch für Stadtviertel oder Quartier). Die mit der Abwicklung der Förderung beauftragte Mobilitätsagentur Wien stellte dafür eine eigene Website mit Reservierungsfunktion[1] zur Verfügung. Die Reservierungsseite stand auch anderen Lastenrad-Sharing-Initiativen offen, wodurch fünf weitere Transporträder an vier Standorten über die Seite reserviert werden können. Diese Lastenräder wurden von Bezirken, Gebietsbetreuungen und Stadtteilmanagements finanziert. Die bereitstellenden Organisationen werden als „Grätzlrad-Partner“ bezeichnet (Mobilitätsagentur Wien). Nach 18 Monaten wurde das Projekt evaluiert um eine Wissensbasis für die weitere Vorgehensweise zu schaffen. In diesem Beitrag werden Erkenntnisse aus der Evaluierung in Bezug auf die Zusammensetzung der Nutzerinnen und Nutzer, deren Nutzungsverhalten sowie die Zufriedenheit mit dem Angebot zusammengefasst.

4 METHODIK

4.1 Auswertung Reservierungsdaten

Aus den Reservierungsvorgängen der Lastenräder über die von der Mobilitätsagentur Wien bereitgestellte Buchungsplattform wurde ein Datensatz generiert, der Informationen zu Alter und Geschlecht der Ausleihenden, dem Verleihzeitraum sowie dem Standort enthält, an dem die Ausleihe stattfand. Insgesamt

[1] aufrufbar unter www.graetzlrad.wien

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

besteht der Datensatz auch 1348 Fällen, was zugleich auch der Zahl der Reservierungsanfragen über die Online-Reservierungsseite im Zeitraum März 2017 bis November 2018 entspricht. Da angenommen werden musste, dass ein Teil der Befragungen abseits des Reservierungssystems (also telefonisch oder persönlich) stattfanden, wurden die Verleihenden nach einer Einschätzung nach der Anzahl solcher Anfragen gebeten. Damit war einerseits eine Abschätzung der Gesamtzahl der Ausleihen möglich und andererseits konnte damit auch die Aussagekraft der Reservierungsdaten beurteilt werden. Die Reservierungsdaten bilden die Grundlage für die Analyse zeitlicher und räumlicher Verleihmuster.

4.2 Befragung von Nutzerinnen und Nutzern

Um vertiefende Einblicke in die Zusammensetzung der Ausleiherinnen und Ausleiher und verschiedene Aspekte der Ausleihe zu erhalten, wurde ergänzend zur Auswertung der Reservierungsdaten eine quantitative Befragung durchgeführt. Dazu wurde ein über das Internet abrufbarer Fragebogen erstellt und der Zugangslink allen Personen, die über die Grätzlrad-Website eine Reservierung tätigten, per E-Mail zugeschickt. Insgesamt erhielten damit rund 700 Personen die Einladung zur Teilnahme an der Befragung. Der Rücklauf umfasste 284 vollständig ausgefüllte Fragebogen, die für die weitere Analyse verwendet werden konnten.

Neben Fragen zu personen- und haushaltsbezogenen Merkmalen, waren Verwendungszwecke der Lastenräder und der damit einhergehenden im Zuge der Ausleihen gefahrenen Distanzen, Gründe und Motive für die Lastenrad-Nutzung sowie zur Zufriedenheit mit dem Angebot wesentliche Inhalte des Fragebogens.

5 ERGEBNISSE

5.1 Nutzerinnen- und Nutzerstruktur

Unter den Nutzenden, welche die Reservierungsfunktion auf der Grätzlrad-Seite nutzten, waren 62% männlich. Unter den Befragten gaben 59% als Geschlecht männlich an, 27% weiblich und weitere 4% anderes. Die Verteilung nach Altersgruppen ist in Tabelle 1 dargestellt. Der überwiegende Teil der Personen, die ein Transportrad ausliehen, sind zwischen 25 und 45 Jahren alt, auf sie entfallen rund 75% der Ausleihen. Der Vergleich mit der Verteilung der Altersgruppen in der Wiener Gesamtbevölkerung zeigt deutliche Abweichungen. Weibliche Nutzende sind mit einem Durchschnittsalter von 38,2 Jahren etwas jünger als Männer mit 38,9 Jahren, die Unterschiede sind jedoch nicht signifikant, wie ein Kruskal-Wallis Test zeigt (Chi-Quadrat (2) =1,903, p = 0,386).

	Weiblich			Männlich			Gesamt		
Altersgruppen	Anzahl	Anteil	Verteilung Bevölkerung Wien	Anzahl	Anteil	Verteilung Bevölkerung Wien	Anzahl	Anteil	Verteilung Bevölkerung Wien
unter 20	0	0,0%	16,3%	4	0,5%	18,3%	4	0,3%	19,3%
20 bis unter 25	40	7,8%	2,0%	51	6,2%	2,2%	91	6,8%	7,1%
25 bis unter 30	95	18,5%	6,9%	126	15,4%	7,3%	221	16,6%	8,6%
30 bis unter 35	95	18,5%	8,3%	151	18,4%	8,8%	246	18,5%	8,2%
35 bis unter 40	146	28,5%	7,9%	169	20,6%	8,5%	315	23,6%	7,5%
40 bis unter 45	71	13,8%	7,2%	151	18,4%	7,7%	222	16,7%	6,8%
45 bis unter 50	37	7,2%	6,7%	86	10,5%	6,9%	123	9,2%	7,2%
50 bis unter 55	11	2,1%	7,2%	44	5,4%	7,3%	55	4,1%	7,4%
55 bis unter 60	11	2,1%	7,2%	24	2,9%	7,6%	35	2,6%	6,4%
60 bis unter 65	3	0,6%	6,3%	6	0,7%	6,5%	9	0,7%	5,1%
über 65	4	0,8%	5,2%	7	0,9%	4,9%	11	0,8%	16,5%

Tabelle 1: Nutzerinnen und Nutzer des Grätzlrads nach Geschlecht und Altersgruppen

Der Bildungsgrad der Teilnehmenden an der Befragung liegt deutlich über dem Durchschnitt der Wiener Bevölkerung: während in Wien 26% über einen akademischen Abschluss verfügen, sind es unter den Befragten 74%. Weitere 17% der Befragten verfügen über eine Matura. Diese Erkenntnis deckt sich im

Wesentlichen mit Untersuchungen zu den Nutzenden anderer Lastenrad-Sharing-Angebote (Becker & Rudolf, 2018a; Hess & Schubert, 2019; Scheffler & Bleh, 2018).

Die Mittelwerte zur Gesamtanzahl der Personen als auch zur Anzahl der Kinder und Jugendlichen im Haushalt sind deutlich höher als die entsprechenden Werte für die Gesamtbevölkerung Wiens. Dies ist ein Hinweis darauf, dass überproportional viele Familien das Angebot in Anspruch nehmen. In Bezug auf die Mobilitätsausstattung liegt die Zahl der Fahrräder im Haushalt deutlich über dem Durchschnitt, während die Zahl der Pkw wesentlich geringer ist.

	Mittelwert Befragte	Mittelwert Bevölkerung Wien
Haushaltsgröße	2,70	2,07[1]
Haushaltsmitglieder unter 18 Jahren	0,72	0,36[1]
Anzahl Fahrräder im Haushalt	3,81	1,62[2]
Anzahl Pkw im Haushalt	0,31	0,97[2]

[1] Daten: Statistik Austria 2018

[2] Daten: österreichweite Mobilitätsbefragung Österreich unterwegs 2013/2014

Tabelle 2: Mittelwerte Haushaltsgröße und Mobilitätsausstattung der Haushalte im Vergleich zur Wiener Gesamtbevölkerung

Die überdurchschnittliche Fahrradverfügbarkeit in den Haushalten der Befragten äußert sich auch in einer starken Nutzung dieses Verkehrsmittels in der Alltagsmobilität. Wie Tabelle 3 zeigt, nutzen 93% der Befragten das Fahrrad in der warmen Jahreszeit zumindest wöchentlich, davon rund drei Viertel täglich. Im Winter nimmt dieser Wert etwas ab, 79% der Befragten fahren zu dieser Zeit zumindest wöchentlich mit dem Fahrrad. Damit heben sich die Nutzerinnen und Nutzer des Grätzlrads auch in Bezug auf die Verkehrsmittelwahl deutlich von der Wiener Gesamtbevölkerung ab, wo nur 7% der Wege mit dem Fahrrad zurückgelegt werden.

	Warme Jahreszeit		Kalte Jahreszeit	
Antwortmöglichkeiten	Anzahl	Anteil	Anzahl	Anteil
(fast) täglich	204	72%	124	44%
mehrmals wöchentlich	54	19%	71	25%
ca. einmal wöchentlich	8	3%	26	9%
ein- bis mehrmals monatlich	8	3%	21	7%
seltener	10	4%	41	14%
weiß nicht	0	0%	1	0%

Tabelle 3: Häufigkeit der Fahrradnutzung der Befragten in Abhängigkeit von der Jahreszeit

5.2 Ausleihen

Über die Grätzlrad-Reservierungsplattform wurden im Zeitraum von 20 Monaten 1348 Reservierungen getätigt. Angaben der Verleihenden von Grätzlrädern zufolge wurden zusätzlich 260 Ausleihen telefonisch, per E-Mail oder persönlich angefragt. Dadurch kamen insgesamt 1608 Ausleihvorgänge von Transporträdern zustande. Der durchschnittliche Reservierungszeitraum betrug 4,25 Stunden. Mit 41% fallen die meisten Ausleihen in die Kategorie 2,5 bis 5 Stunden. Jeweils 10% der Ausleihen waren kürzer als 2,5 Stunden bzw. länger als 10 Stunden. Bei diesen Daten ist zu berücksichtigen, dass es sich um Reservierungszeiträume handelt. Die tatsächliche Nutzungsdauer dürfte aufgrund der von Nutzerinnen und Nutzern eingeplanter Zeitpuffer kürzer sein.

Auf die Wochentage bezogen ist zum Ende der Arbeitswoche hin eine Zunahme von 149 Ausleihen an Montagen auf 349 Nutzungen an Freitagen hin zu beobachten. Auf Samstage entfielen 210 Ausleihen, auf Sonntage 31. Die geringe Zahl an Verleihvorgängen an Sonntagen erklärt sich dadurch, dass die Verleihbetriebe an Sonntagen in der Regel geschlossen sind. Für die Betrachtung des saisonalen Nachfrageverlaufs wurde der Beobachtungszeitraum auf 12 Monate reduziert (Juli 2017 bis Juni 2018) um Verzerrungen durch doppelt gezählte Monate zu vermeiden. Auf die Sommermonate Juli und August entfielen jeweils etwas mehr als 200 Ausleihen, während im Jänner nur 20-mal ein Grätzlrad ausgeliehen wurde. Die saisonalen Nachfrageschwankungen sind also deutlich.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Aus räumlicher Perspektive lag der Schwerpunkt der Ausleihen auf den innenstadtnahen Bezirken, die einen Ring um den zentralen Bezirk Innere Stadt bilden. Auf die flächenmäßig großen Außenbezirke entfielen hingegen, trotz deutlich höherer Zahl an dort lebenden Menschen, weniger Ausleihen. Deutlich erkennbar ist dabei, dass jene Bezirke, die über ein oder mehrere Grätzlrad-Standorte verfügen, eine höhere Zahl an Ausleihen verzeichnen (s. Abbildung 2). Durchschnittlich liegt der Ausleihstandort 2,32 Kilometer vom Wohnort der Nutzerinnen und Nutzer entfernt. Dies liegt unter anderem daran, dass nicht immer der Grätzlrad-Betrieb für die Ausleihe gewählt wurde, der am nächsten zum Wohnort liegt, sondern auch andere Gründe in die Entscheidung einflossen, wie beispielsweise die Nähe zum Arbeitsort, die Bauweise des verfügbaren Lastenrads oder die Öffnungszeiten des verleihenden Betriebs. Zudem verzerren einige Ausreißer nach oben, das Gesamtbild. Der Median der Distanz zwischen Wohn- und Ausleihort liegt dementsprechend auch deutlich niedriger bei 1,25 Kilometern.

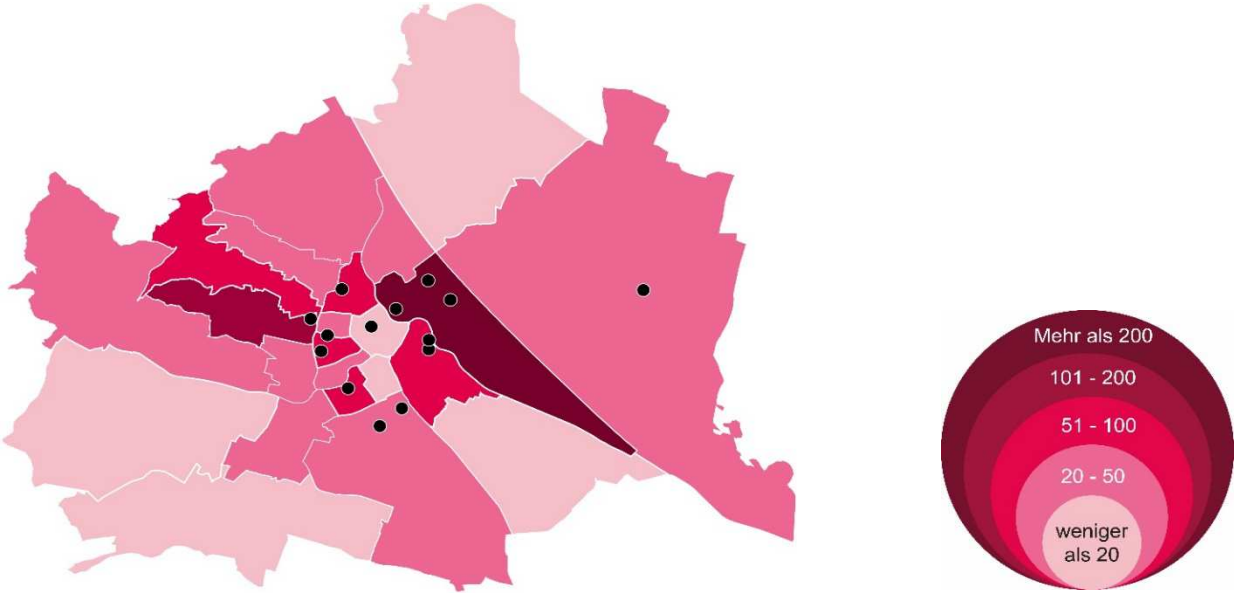

Abbildung 2: Räumliche Verteilung der Ausleihen von Grätzlrad-Lastenrädern

5.3 Einsatzzwecke

82% der Befragten gaben an, dass Transportrad für private Zwecke genutzt zu haben, 9% nutzten aus beruflichen Gründen. Weitere 9% verwendeten es sowohl privat als auch beruflich. Tabelle 4 zeigt, dass die Beförderung von Personen der wichtigste Transportzweck ist. Darüber hinaus werden die Lastenräder für den Transport schwerer Haushaltsgegenstände, Lebensmitteln und Arbeitsmaterialien genutzt. Ausflugs- bzw. Entsorgungsfahrten sind weitere relevante Gründe für die Ausleihe eines Transportrads.

Was wurde transportiert?	Anzahl Nennungen	Anteil an den Nutzenden gesamt
Kinder und Erwachsene	121	42,6%
schwere Gegenstände (z. B. Möbel, Haushaltsgeräte)	91	32,0%
Lebensmittel	76	26,8%
Arbeitsmaterialien	58	20,4%
Sachen für Ausflug	54	19,0%
Dinge zum Entsorgen	52	18,3%
Einkäufe mittelfristigen Bedarfs (z. B. Elektronik, Kleidung)	35	12,3%
Sportausrüstung	18	6,3%
Musikinstrument	10	3,5%
Haustier	6	2,1%
Sonstiges	37	13,0%
weiß nicht	0	0,0%

Tabelle 4: Von den Befragten mit dem Lastenrad durchgeführte Transporte (Mehrfachantworten möglich)

5.4 Zufriedenheit

Die Zufriedenheit der Nutzenden wurde mit der Frage gemessen, ob sie das Angebot ihren Bekannten weiterempfehlen würden, wobei für die Antwort eine zehnstufige Skala zur Verfügung stand. Der Wert von 1 bedeutet dabei, dass man das Angebot keinesfalls weiterempfehlen würde, während 10 stellvertretend dafür steht, dass das Angebot jedenfalls weiterempfohlen wird. Der Mittelwert von 9,51 deutet somit auf eine sehr hohe Zufriedenheit hin. 78,0% der Befragten wählten auf der Skala den Wert für die höchste Zufriedenheit. Tabelle 5 zeigt die Zufriedenheit mit den einzelnen Aspekten des Angebots im Detail. Vergleichsweise die höchste Zufriedenheit konnten dabei die Betriebe und Hosts verzeichnen, die als Hosts fungieren. Der Mittelwert der Beurteilung liegt bei 5,36, theoretisch maximal möglich wäre ein Wert von 6,0. Insbesondere jene Schritte in der Nutzung, Herausgabe und Rücknahme des Lastenrads, die mit persönlichem Kontakt verbunden sind, wurden von den Nutzerinnen und Nutzern positiv wahrgenommen. Auch die Zufriedenheit mit den Transporträdern ist mit einem Mittelwert von 5,27 gut. Die vergleichsweise schlechteste Bewertung erhielt die Reservierungsplattform, hier wird insbesondere der Reservierungsprozess als wenig nutzerfreundlich empfunden. Eine Auswertung der Kommentare zur Bewertung der Reservierungsplattform zeigt einige wesentliche Kritikpunkte der Befragten. Kritisiert wurde vor allem, dass die Reservierungen für maximal einen Tag getätigt werden können, die Bestätigung der Reservierung mit (teils großer) Zeitverzögerung erfolgt und dass es keine Übersicht der verfügbaren Räder zu einem bestimmten Wunschdatum gibt.

Beurteilungskriterien Zufriedenheit		N	Mittelwert	Std.-Abweichung	Mittelwert übergeordnet	Korrelation (Spearman)	Signifikanz
Bewertung Reservierungs-plattform	Übersichtlichkeit	270	1,181	4,66	4,65	0,122	0,049
	Informationen zu den verfügbaren Transporträdern und Verleihstandorten	268	1,156	4,89		0,167	0,007
	Reservierungs-prozess	272	1,531	4,40		0,137	0,026
Bewertung Grätzlrad-Verleih-standorte	Reaktion auf Reservierungs-anfrage und weitere Fragen	275	1,433	4,98	5,36	0,176	0,004
	Herausgabe des Transportrades und Erläuterung Funktionsweise	270	,990	5,50		0,355	0,000
	Abwicklung Rückgabe des Transportrades	271	,921	5,60		0,293	0,000
Bewertung der Transporträder	Zustand	272	,942	5,42	5,27	0,276	0,000
	Eignung für den durchgeführten Transport	272	,921	5,37		0,301	0,000
	Fahrverhalten	272	1,079	5,05		0,341	0,000
	Abstellen und Abschließen	273	,928	5,23		0,304	0,000

Tabelle 5: Zufriedenheit mit dem Grätzlrad-Angebot in Bezug auf verschiedene Aspekte

Von den erwähnten Bewertungskriterien lässt sich ein Zusammenhang mit der globalen Zufriedenheit mit Angebot (Bereitschaft das Angebot an Bekannte weiterzuempfehlen) erkennen. Die Effektstärke der Korrelationen liegt im Bereich zwischen 0,122 und 0,355 was einem schwachen bis mittleren Effekt entspricht.

Aspekte im Zusammenhang mit der Betreuung durch die Hosts sowie Zustand und Eigenschaften der Transporträder weisen dabei stärkere Zusammenhänge mit der Gesamtzufriedenheit auf. Einen schwächeren Zusammenhang gibt es mit der Beurteilung der Reservierungsplattform. Eine geringe Zufriedenheit mit der

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Buchungsfunktion schlägt sich also weniger stark in einer schlechteren Gesamtbewertung nieder. Bei den Transporträdern sind insbesondere die Aspekte Fahrverhalten, die Praktikabilität des Abstellens und Abschließens sowie deren Eignung für die durchgeführten Transporte in höherem Zusammenhang mit der hohen Gesamtzufriedenheit. Bei den Verleihstandorten scheint insbesondere der positiv wahrgenommene persönliche Kontakt mit den Hosts einen wesentlichen Beitrag zur guten Beurteilung des Gesamtsystems beizutragen.

5.5 Wirkung

Im Rahmen der Befragung wurden Wirkungen in Bezug auf die direkte Substitution anderer Verkehrsmittel durch die Verwendung eines Lastenrades sowie indirekte Effekte in Bezug auf die zukünftige Nutzung bzw. Anschaffung eines Transportrads adressiert. Der Beitrag des Projekts zur Verankerung von Lastenrädern im Bewusstsein der Bevölkerung konnte mit der gegebenen Methodik nicht abgebildet werden. 33,9% der Fahrten mit dem Transportrad ersetzten eine Pkw-Fahrt: entweder mit dem eigenen Auto, einem geliehenen Auto von Bekannten oder mittels Carsharing. Im Vergleich zu den freien Lastenrädern ist damit der Anteil der substituierten Pkw-Fahrten gering (Becker & Rudolf, 2018a). Auf der anderen Seite wurden auch zusätzliche Wege induziert, 16,1% der Befragten gaben an, dass der Transport sonst nicht durchgeführt worden wäre. 29,2% der Nutzerinnen und Nutzer hätten stattdessen ein herkömmliches Fahrrad oder ein anderes Transportrad verwendet.

Zur Abschätzung der indirekten Effekte sind einerseits der Anteil der Personen, die im Zuge der Grätzlrad-Ausleihe erstmals ein Lastenrad verwenden, von Interesse sowie die Absichten in Bezug auf die zukünftige Nutzung. 70% der Befragten waren Erstnutzerinnen und Erstnutzer, weitere 16% hatten zuvor erst ein- oder zweimal ein Lastenrad verwendet. Das zeigt, dass mittels Transportrad-Sharing Menschen zum Ausprobieren von Lastenrädern animiert werden können. Tabelle 6 stellt die Häufigkeit der Transportrad-Nutzung vor der ersten Ausleihe eines Grätzlrades in Beziehung zur geplanten künftigen Verwendung. 99,3% der Befragten möchten in Zukunft zumindest gelegentlich ein Transportrad nutzen. Personen, die schon häufiger ein Transportrad genutzt haben, tendieren dazu, sich das auch für die Zukunft öfter vorzunehmen (Spearman-Rangkorrelation: rs = 0,275, p = 0,000, n = 269). Insgesamt ist der Anteil der Personen, die eine wiederholte Nutzung beabsichtigen auch unter bisherigen Nicht-Nutzerinnen und Nicht-Nutzer sehr hoch, weshalb eine starke, verkehrlichen Wirkung des Angebots erwartet werden kann.

Häufigkeit Lastenrad-Verwendung vor erster Ausleihe	geplante zukünftige Häufigkeit Lastenrad-Nutzung										
	nie		ja, aber weniger als einmal pro Jahr		ja, mehrmals pro Jahr		ja, mehrmals pro Monat		ja, wöchentlich oder häufiger		Gesamt
	Anzahl	Anteil	Anzahl	Anteil	Anzahl	Anteil	Anzahl	Anteil	Anzahl	Anteil	Anzahl
nie	2	1,1%	24	12,8%	140	74,9%	12	6,4%	9	4,8%	187
1-2 mal	0	0,0%	2	4,7%	31	72,1%	4	9,3%	6	14,0%	43
3-5 mal	0	0,0%	1	4,8%	17	81,0%	2	9,5%	1	4,8%	21
6-10 mal	0	0,0%	0	0,0%	2	50,0%	1	25,0%	1	25,0%	4
> 10 mal	0	0,0%	0	0,0%	5	35,7%	4	28,6%	5	35,7%	14
Gesamt	2	0,7%	27	10,0%	195	72,5%	23	8,6%	22	8,2%	269

Tabelle 6: Kreuztabelle Häufigkeit Lastenrad-Nutzung vor erster Ausleihe und geplante künftige Nutzung

8,2% der Grätzlrad-Nutzerinnen und Grätzlrad-Nutzer planen die Anschaffung eines Transportrads, weitere 37,5% ziehen es zumindest in Betracht und 5,4% haben sich schon eines gekauft. Auch hier besteht eine signifikante Korrelation zur vorhergehenden Häufigkeit der Transportrad-Nutzung (Spearman-Rangkorrelation rs = 0,281, p = 0,000, n = 280). Im Vergleich zu den Nutzerinnen und Nutzer freier Lastenräder, bei denen 20,2% angeben, in Zukunft ein Transportrad anschaffen zu wollen (Becker & Rudolf, 2018a), ist dieser Wert sehr niedrig. Andererseits zeigt das Ergebnis auch, dass knapp 10% der Erstnutzerinnen und Erstnutzer ein Transportrad angeschafft haben oder eine Anschaffung planen. Da der Erstkontakt mit Transporträdern über das Sharing-Angebot zustande kam, ist davon auszugehen, dass dieses einen entscheidenden Impuls dargestellt hat. Je geringer die Zahl der vorhergehenden Nutzungen von Transporträdern, desto stärker dürfte der Einfluss des Grätzlrad-Nutzung auf die Entscheidung, ein Lastenrad anzuschaffen, sein.

Häufigkeit Lastenrad-Verwendung vor erster Ausleihe	geplante Anschaffung eigenes Transportrad

6 DISKUSSION

Die Nutzerinnen- und Nutzerstruktur von Lastenrad-Sharing besteht derzeit im Wesentlichen aus Personen, die für ihre Alltagswege Fahrräder nutzen und über eine hohen Bildung verfügen. Eine Diversifizierung dieser Gruppe ist, nicht nur wegen der Vergrößerung des Nutzerinnen- und Nutzerkreis, sinnvoll. Insbesondere wenn Personen mit einem hohen Anteil an Wegen, die mit dem Auto zurückgelegt werden, als Nutzerinnen und Nutzer gewonnen werden können, führt zu einer größeren Einsparung an umweltschädlichen Emissionen. Zudem könnte das Lastenrad im Bewusstsein einer breiteren Masse verankert und die Auslastung der Räder durch eine größere Zahl potenzieller Nachfragenden verbessert werden. Neben entsprechender Bewerbungsstrategien, bietet auch die Wahl der Verleihstandorte in Bezug auf Lage und Zusammensetzung der Kundinnen und Kunden einen Ansatzpunkt zur Erweiterung der Zielgruppe.

Die räumliche und zeitliche Verteilung von Ausleihen ist noch sehr ungleich. Aus zeitlicher Perspektive könnten Maßnahmen zur Steigerung der Nachfrage in der kalten Jahreszeit sowie zu Wochenbeginn angedacht werden. Um die Nachfrage auch in weniger zentral gelegenen Bezirken zu steigern, müsste dort das Angebot erweitert werden. Aufgrund der längeren Wege als im Stadtzentrum (z. B. für Einkäufe) könnten Transporträder gerade dort einen Beitrag zur Reduktion des Pkw-Verkehrs leisten.

Der persönliche Kontakt mit den Grätzlrad-Hosts wird aus Perspektive der Befragten positiv wahrgenommen und hat zugleich auch Relevanz für die positive Gesamtbewertung des Angebots. Insbesondere für Erstnutzerinnen und Erstnutzer dürfte wichtig sein, eine Ansprechpartnerin oder einen Ansprechpartner für Fragen in Bezug auf das Lastenrad zu haben. Das dürfte auch den bisherigen Erfolg host-basierter Systeme im Bereich des Transportrad-Sharing erklären, da hier, im Gegensatz zu bspw. Bikesharing, der Anteil unerfahrerenen Nutzenden sehr hoch ist. Bei der Auswahl der Hosts ist jedoch zu berücksichtigen, dass diese für die Abwicklung der Ausleihen und Erklärung der Funktionsweise die notwendigen Zeit- bzw. Personalressourcen zur Verfügung stellen können. Vorteilhaft ist zudem, wenn diese auch kleine Wartungs- und Reparaturarbeiten an den Transporträdern durchführen können.

Die Ergebnisse zeigen deutlich, dass Lastenrad-Sharing zu einem direkten Ersatz von Fahrten im motorisierten Individualverkehr führt. Als wesentlich bedeutender werden jedoch die indirekten Effekte eingeschätzt. Knapp 99% der Erstnutzerinnen und Erstnutzer wollen in Zukunft wieder ein Transportrad verwenden, was die Bedeutung von der Ausleihmöglichkeit für die Erprobbarkeit unterstreicht. Diese Erkenntnis unterstreicht, dass die Etablierung von Sharing-Angeboten eine geeignete Maßnahme ist, um eine noch wenig bekannte Mobilitätsoptionen einem breiten Publikum zugänglich zu machen, deren Anwendbarkeit im Alltag erfahrbar zu machen und stärker im Bewusstsein zu verankern.

Die präsentierten Ergebnisse bieten einen ersten Einblick zur Zusammensetzung der Nutzerinnen und Nutzer von Lastenrad-Sharing sowie darüber wie die Transporträder verwendet werden. Auch zur Wirkung des Angebots konnte auf Basis der Ergebnisse eine erste Einschätzung getroffen werden. Insgesamt bleiben die Erkenntnisse an der Oberfläche und sind daher als Ausgangspunkt für weitere Forschungsarbeiten, die sich vertiefend mit den angesprochenen Aspekten auseinandersetzen, zu sehen. Im Zusammenhang mit (potenziellen) Nutzerinnen- und Nutzergruppen könnten durch bevölkerungsrepräsentative Befragungen weitere Gruppen identifiziert werden, die mit solchen Angeboten angesprochen werden können. Um die

direkten verkehrlichen Wirkungen genauer abzubilden, bedarf es weiterer Untersuchungen, die sich vertiefend mit Mobilitätsverhalten der Nutzerinnen und Nutzer und dessen Veränderung durch die Verfügbarkeit von Lastenrädern befassen. Mittels Längsschnittuntersuchungen könnten auch die langfristigen Änderungen des Mobilitätsverhaltens, die sich beispielsweise durch eine Anschaffung und/oder regelmäßige Nutzung von Lastenrädern ergeben, beleuchtet werden.

Größere Discounter, kleinere Verbrauchermärkte und Onlineshops: Welche Rolle spielen die aktuellen Trends im Lebensmitteleinzelhandel für die Nahversorgung im ländlichen Raum?

Thomas Wieland

(Dr. Thomas Wieland, Karlsruher Institut für Technologie, Institut für Geographie und Geoökologie – Humangeographie, Kaiserstr. 12, 76131 Karlsruhe, thomas.wieland@kit.edu)

1 ABSTRACT

In den letzten Jahren sind im deutschen Lebensmitteleinzelhandel mehrere Entwicklungen hinsichtlich der Betriebsformen- und Standortstruktur festzustellen: Bestehende Discounterfilialen werden erweitert und neue Filialen werden mit Verkaufsflächengrößen weit oberhalb der in Deutschland geltenden planerischen Grenze des großflächigen Einzelhandels eröffnet; Discounter werden daher auch immer häufiger Gegenstand von Verträglichkeitsbeurteilungen in Planungsverfahren. Gleichzeitig sinkt die Marktbedeutung von großen Verbrauchermärkten bzw. SB-Warenhäusern und mehrere Supermarktketten bzw. -kooperativen treiben ein kleinflächiges Citymarkt-Konzept voran. Während Amazon und Rewe in ausgewählten Großstadtregionen einen Online-Lieferdienst für Lebensmittel aufgebaut haben, erweitern etablierte Supermarktketten ihr stationäres Angebot um einen online-gestützten Abholservice (Click and collect). Anhand eines regionalen Fallbeispiels aus dem ländlichen Raum (Südniedersachsen) untersucht dieser Beitrag, inwiefern diese Entwicklungen – konvergierende Marktgrößen und Cross-Channel-Einbindung im LEH – mit dem tatsächlichen Einkaufsverhalten der Bevölkerung in Einklang zu bringen sind. Denn die planerischen Ideale zielen auf eine intakte Nahversorgung ab, die in erster Linie als gute Erreichbarkeit übersetzt wird. Sprechen also „große“ Discounter oder Supermärkte mit einem Onlineshop überhaupt die Verbraucher an? Und: Relativieren diese Entwicklungen die hohe Relevanz, die der Erreichbarkeit in Nahversorgungsfragen zugesprochen wird? Konkret wird daher untersucht, welche Rolle die (betriebsformenspezifische) Verkaufsflächengröße und die Click-and-collect-Option – unter Berücksichtigung der Erreichbarkeit – für die Einkaufsstättenwahl im LEH spielen. Hierzu wird ein quantitatives Modell der Einkaufsstättenwahl aufgestellt und die Einflüsse anhand von empirischen Echtdaten zum Einkaufsverhalten überprüft. Interessanterweise zeigt sich, dass das Angebot eines online-gestützten Abholservices (bisher) keinerlei Effekt auf die Einkaufsentscheidungen der Kunden hat. Es lässt sich allerdings belegen, dass Verkaufsflächenerweiterungen bei Discountern die Kundenzuflüsse erhöhen, wobei dieser Effekt stärker ist als bei allen anderen Betriebsformen. Als wichtigste Determinante des Einkaufsverhaltens im LEH zeigt sich jedoch wieder einmal die Erreichbarkeit der Anbieter. Die Ergebnisse leisten einen Beitrag zu der Frage, wie Neuansiedlungen und Erweiterungen von LM-Märkten in Planungsverfahren ggf. differenzierter beurteilt werden können.

Keywords: Modell der Einkaufsstättenwahl, Einkaufsverhalten, Lebensmitteleinzelhandel, Nahversorgung, Click and collect

2 EINFÜHRUNG

Von rd. 513,3 Mrd. EUR an gesamtem Einzelhandelsumsatz in Deutschland (2017) entfallen rd. 187 Mrd. EUR auf den Lebensmitteleinzelhandel (LEH) (IfH, 2018). Abseits dieses hohen Umsatzanteils hat der LEH aber auch eine wichtige gesellschaftliche Funktion, nämlich die Bereitstellung von Grundbedarfsgütern bzw. Gütern des täglichen Bedarfs für die gesamte Bevölkerung. Die Verfügbarkeit bzw. Erreichbarkeit von LEH-Einkaufsmöglichkeiten ist ein wesentlicher Faktor der Lebensqualität, weshalb die Nahversorgung – deren zentraler Baustein der LEH ist – auch eine normative Zielvorstellung in der räumlichen Planung der Bundesrepublik Deutschland darstellt (Einig, 2015; siehe z.B. Raumordnungsgesetz: §2 Abs. 2 Satz 3 ROG). Regelmäßig wissenschaftlich begleitet wird diese Entwicklung durch Untersuchungen zu den Strukturen von Versorgung bzw. Erreichbarkeit im LEH sowie der Definition ausreichender oder „qualifizierter“ Nahversorgung, alles vor dem Hintergrund stetiger Strukturveränderungen auf der Betriebsseite. Grundsätzlich wird Nahversorgung i.d.R. mit der kleinräumigen Verfügbarkeit bzw. Erreichbarkeit der relevanten Betriebe übersetzt (Überblick z.B. Krüger et al., 2013; Kokorsch/Küpper, 2019; Wieland, 2018).

Seit etwa 2010 sind im deutschen LEH (mindestens) vier Entwicklungen hinsichtlich der Betriebsformen- und Standortstruktur festzustellen, die sich notwendigerweise auch auf die Nahversorgung auswirken müssen: Erstens findet im Bereich der Lebensmitteldiscounter eine deutliche Maßstabsvergrößerung statt. Die landesweit präsenten Discount-Filialunternehmen – insbesondere Aldi und Lidl – erweitern bestehende

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Filialen und eröffnen neue Verkaufsstellen mit Verkaufsflächengrößen weit oberhalb der in Deutschland geltenden planerischen Grenze des großflächigen Einzelhandels (800 qm). Viele moderne Filialstandorte von LM-Discountern erreichen Größen von deutlich über 1.000 qm Verkaufsfläche und werden daher auch immer häufiger Gegenstand von Verträglichkeitsbeurteilungen in Planungsverfahren (siehe z.B. LebensmittelZeitung online, 2014). Zweitens sinkt gleichzeitig die Marktbedeutung von großen Verbrauchermärkten bzw. SB-Warenhäusern. Den Standortschließungen stehen nur wenige Neueröffnungen gegenüber. Bestehende Märkte dieser Betriebsform werden z.T. sogar verkleinert (siehe z.B. Handelsblatt, 2019). Drittens treiben einige Supermarktketten bzw. -kooperativen ein kleinflächiges Konzept insbesondere für hochfrequentierte Innenstadtstandorte voran (z.B. Rewe City, Edeka xpress). Diese Entwicklungen – Discounter werden „größer“, Vollsortimenter wieder „kleiner“ – spiegeln sich auch in den Marktdaten zur betriebsformenspezifischen Entwicklung des LEH in Deutschland wider (z.B. bulwiengesa AG, 2017).

Die vierte Entwicklung betrifft die Etablierung des Onlinehandels im deutschen LEH: Beispielsweise ist Amazon in den Lebensmitteleinzelhandel eingestiegen, wobei ein Online-Vollsortiment (AmazonFresh) bisher nur in ausgewählten Großstädten mit einer hohen Kundendichte (Berlin/Potsdam, Hamburg, München) verfügbar ist (Amazon, 2020). Parallel haben etablierte Supermarktfilialisten bzw. -kooperativen ihr Angebot um einen online-gestützten Liefer- und/oder Abholservice erweitert: Während der Online-Lieferdienst von Rewe nur in einigen Großstadtregionen verfügbar ist, wird ein online-gestützter Abholservice (d.h. „Click and collect“ für Lebensmittelkäufe) auch von einzelnen Anbietern im ländlichen Raum angeboten, die als eigenständige Kaufleute der jeweiligen Kooperative angeschlossen sind. Beispielsweise ist bei den teilnehmenden Rewe-Märkten ein vollständiges Supermarkt-Sortiment von 10.640 Artikeln (inkl. Non-Food-Artikel; Abfragedatum: 17.01.2020) über den Onlineshop verfügbar. Aus diesem Angebot stellt der Kunde seinen individuellen Warenkorb zusammen und gibt im Anschluss ein Abholzeitfenster an; die Abholung erfolgt im Markt und ist dementsprechend an dessen Öffnungszeiten gekoppelt. Es existiert aktuell (Abfragedatum: 08.01.2020) kein Mindestbestellwert, allerdings wird eine Servicepauschale von 2,00 EUR erhoben (Rewe, 2020). Ein weiteres Beispiel sind mehrere eigenständige Märkte unter dem Dach der Edeka Südwest, die „Click and collect“ für Lebensmittel und teilweise auch einen (regional begrenzten) online-gestützten Lieferservice anbieten (Edeka Südwest, 2020).

Diese skizzierten Entwicklungen betreffen im Kern die Marktgrößen sowie die Cross-Channel-Einbindung von Lebensmittelmärkten. Sprechen aber „große“ Discounter oder Supermärkte mit Onlineshop die Verbraucher überhaupt an? Und: Relativiert sich dadurch die Rolle der räumlichen Nähe, der im Kontext der Nahversorgung die höchste Relevanz zugesprochen wird? Der vorliegende Beitrag behandelt die Frage, welche Rolle die (betriebsformenspezifische) Verkaufsflächengröße und die Click-and-collect-Option – unter Berücksichtigung der Erreichbarkeit und anderer Erklärungsgrößen – für die Einkaufsstättenwahl im LEH spielen. Hierzu wird ein quantitatives Modell der Einkaufsstättenwahl aufgestellt, wobei anhand empirischer Daten zu realem Einkaufsverhalten im ländlichen Raum (Südniedersachsen) die Einflüsse der genannten Erklärungsgrößen identifiziert werden. Im folgenden Kapitel werden zunächst die (standort-) theoretischen Grundlagen zur Einordnung dieser Aspekte dargestellt und im Anschluss Hypothesen formuliert sowie die Analysemethodik und das Untersuchungsgebiet vorgestellt. Daraufhin werden zunächst deskriptive Teilergebnisse zur erfassten Angebots- und Nachfragesituation dargestellt und im Anschluss die Modellergebnisse besprochen. Der Beitrag schließt mit den Schlussfolgerungen aus den Ergebnissen für den Planungskontext.

3 THEORETISCHE VORÜBERLEGUNGEN UND METHODISCHER ANSATZ

3.1 Das Huff-Modell

Ein etabliertes Modell zur Darstellung und Erklärung des räumlichen Wettbewerbs im Einzelhandel ist das Marktgebietsmodell von Huff (1962, 1964). Ungeachtet vieler Kritikpunkte ist dieses quantitative Modell zugleich auch häufig die Grundlage von Auswirkungsanalysen bzw. Verträglichkeitsgutachten in Planungsverfahren bei Einzelhandelsgroßprojekten (Khawaldah et al., 2012; Wolf, 2012). Das Huff-Modell ist aber vor allem ein theoretisches Modell, das Aussagen zur Wirkung von Marktgrößen und der Erreichbarkeit von Standorten trifft, und daher eine sinnvolle Grundlage für die o.g. Fragestellungen.

Huff (1962) definiert den Nutzen eines Angebotsstandortes *j* für die Nachfrager in Wohnort *i*, U_{ij}, durch zwei Erklärungsgrößen (Teilnutzen): Die Größe des Angebotsstandortes, A_j, wirkt als Attraktivitätsmerkmal,

wobei als Größenindikator typischerweise die Verkaufsfläche herangezogen wird. Die hinterliegende ökonomische Begründung dieser Modellformulierung bezieht sich auf das Informationsniveau der Nachfrager: Den (potenziellen oder tatsächlichen) Einzelhandelskunden wird – realistischerweise – unterstellt, dass sie ihre Einkaufsentscheidungen unter Unsicherheit treffen und daher nicht genau wissen, ob sie die von ihnen nachgefragten Güter auch tatsächlich am jeweiligen Angebotsstandort bekommen. Je größer jedoch der Angebotsstandort ist, desto höher ist aber die Wahrscheinlichkeit eines „erfolgreichen" Einkaufs; die Verkaufsfläche ist also – sofern Angebotsstandorte derselben Branche mit vergleichbarer Sortimentsbreite betrachtet werden – lediglich eine Proxyvariable für die Sortimentstiefe (Auswahl) bzw. Sortimentshöhe (Vorrätige Artikelzahlen). Da mit steigendem Sortimentsumfang auch die Such- und Entscheidungskosten der Nachfrager steigen (Stichworte: „tyranny of freedom of choice", „choice overload", „customer confusion"), wirkt dessen Anstieg nicht proportional auf den Konsumentennutzen, sondern es wird von abnehmendem Grenznutzen ausgegangen.

Die zweite Erklärungsgröße ist die Erreichbarkeit der Angebotsstandorte, d_{ij}, die ausdrücklich keine physische Raumüberwindung i.e.S. darstellt, sondern eine Wegezeit. Um die Opportunitätskosten der Raumüberwindung (Einkaufsfahrt mit dem Auto, Fahrrad, ÖPNV etc.) auszudrücken, wird davon ausgegangen, dass die „investierte" Zeit überproportional wahrgenommen wird.

Die konsumentenseitige Einkaufsentscheidung wird als probabilistisch angesehen, d.h. die „Zuordnung" des Nachfrageortes *i* zu einem Angebotsstandort *j* ist eine Wahrscheinlichkeit (p_{ij}, wobei: $0 < p_{ij} < 1$), die von der Ausprägung des Nutzens aller zur Verfügung stehenden Alternativen abhängt:

$$p_{ij} = \frac{U_{ij}}{\sum_{j=1}^{n} U_{ij}} = \frac{A_j^{\gamma} {d_{ij}}^{-\lambda}}{\sum_{j=1}^{n} A_j^{\gamma} {d_{ij}}^{-\lambda}}$$

Die Gewichtungsparameter (γ, λ) spiegeln die Wirkung der beiden Einflussfaktoren wider ($0 < \gamma < 1$, $|\lambda| > 1$).

Mit Hilfe ökonometrischer Abwandlungen des Huff-Modells oder anderer Modellvarianten wurden die beiden Kernaussagen des Huff-Modells im Kontext des Lebensmitteleinkaufs bereits häufig bestätigt: Die Verkaufsfläche (die ja eigentlich das Sortiment symbolisiert) wirkt sich unterlinear positiv auf die Kundenzuflüsse aus, während eine steigende Fahrtzeit die Kundenzuflüsse überproportional senkt (siehe z.B. Lademann, 2007; Orpana/Lampinen, 2003; Tihi/Oruc 2012; Suárez-Vega et al., 2015; Wieland 2015, 2018, 2019a). In einigen Fällen konnte auch über Sensitivitätsanalysen (Lademann, 2007; Wieland, 2019a) oder standardisierte Parameter (Wieland, 2015) gezeigt werden, dass bei Lebensmitteleinkäufen die Erreichbarkeit den wichtigsten Einflussfaktor bei der Einkaufsentscheidung darstellt.

3.2 Forschungshypothesen

Da die im Huff-Modell angenommene positiv-degressive Wirkung der Verkaufsfläche (als Proxy für das Sortiment) unzählige Male bestätigt wurde, wird auch hier vom selben Effekt *über alle Betriebsformen hinweg* ausgegangen. Allerdings steht hier die betriebsformenspezifische Wirkung im Vordergrund: Da LM-Discounter erweitert bzw. mit größeren Verkaufsflächen (VKF) neu eröffnet werden, große LM-Vollsortimenter (insb. Große Verbrauchermärkte bzw. SB-Warenhäuser) hingegen an Marktrelevanz verlieren, werden diesbezüglich folgende Hypothesen zum Effekt der VKF-Größe formuliert:

$H1_a$: Bei LM-Discountern ist der positive Effekt der VKF auf die Einkaufsentscheidung von allen LEH-Betriebsformen am größten

$H1_b$: Bei großen Verbrauchermärkten ist der positive Effekt der VKF auf die Einkaufsentscheidung von allen LEH-Betriebsformen am geringsten

Da die Erreichbarkeit von Lebensmittelmärkten regelmäßig als signifikanter (und wichtigster) Einfluss auf deren Marktgebiete identifiziert wurde (siehe Kap. 3.1), ist dieser Indikator natürlich in einer modellgestützten Analyse des Einkaufsverhaltens zu berücksichtigen (auch wenn sich die Forschungsfragen hier nicht auf diesen Aspekt beziehen). Es sind für die vorliegende Untersuchung daher zwei Hypothesen zu formulieren, die sich aus dem Huff-Modell und den genannten empirischen Untersuchungen ableiten:

$H2_a$: Die Wegezeit zum Lebensmittelmarkt hat einen negativen Einfluss auf die Einkaufsentscheidung

$H2_b$: Der Einfluss der Wegezeit auf die Einkaufsentscheidung ist überproportional

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Etwas schwieriger gestaltet sich allerdings die Verknüpfung des Click-and-collect-Angebotes mit den bisherigen Überlegungen, die aus der Standorttheorie des (stationären) Einzelhandels stammen, die – aufgrund ihrer Datierung und ihres raumwissenschaftlichen Charakters – keinen Bezug zum Onlinehandel nimmt. Zunächst ist festzustellen, dass im Hinblick auf die Erreichbarkeit von Lebensmittelmärkten kein Unterschied besteht, ob der eigentliche Einkauf im Markt oder mit Hilfe eines online-gestützten Abholservices vollzogen wird; in beiden Fällen muss der Kunde den Anbieter selbst aufsuchen, da ein Lieferservice (in dem Sinne wie in Kap. 2 beschrieben) im hiesigen Untersuchungsgebiet nicht verfügbar ist.

Allerdings steht ein online-gestützter Abholservice in Bezug zu einem anderen Aspekt des hier zu Grunde gelegten Einkaufsstättenwahlmodells, selbst wenn die physischen Eigenschaften der Einkaufsstätte bzw. ihres Standortes durch die virtuelle Anbindung nicht verändert werden: Für die Einkaufsentscheidungen wird angenommen, dass die Kunden keinen vollständigen Überblick über das Angebot von Handelsstandorten haben und ggf. nicht alle gewünschten Produkte beim ausgewählten Anbieter beziehen können; aus dieser Annahme heraus wird erst die Attraktivitätswirkung der „Größe“ hergeleitet. Mit steigender „Größe“ steigt aber auch der Suchaufwand *innerhalb* der Einkaufsstätte, womit u.a. der degressiv-positive Effekt begründet wird (siehe Kap. 3.1). Ein integrierter Onlineshop, über den der Warenkorb am Bildschirm zusammengestellt werden kann, hebt dieses Prinzip nahezu vollständig auf bzw. entkräftet den im Modell angenommenen „Größen“effekt, und zwar in zweierlei Hinsicht: Über den Onlineshop besteht erstens die Möglichkeit, sich eine vollständige Information über das Sortiment des Marktes und die Verfügbarkeit der Produkte (sowie Preise, weitere Produktinformationen etc.) zu verschaffen, ohne den Markt selbst zu besuchen. Zweitens: Es entfällt der Suchaufwand im Markt (und mit ihm weitere Einzelbausteine des Einkaufs, z.B. Wartezeit an der Kasse). Ein (Lebensmittel-)Markt mit Click-and-collect-Option senkt also insbesondere die Unsicherheit der Einkaufsentscheidung sowie die Suchkosten, was bei Erfahrungsgütern wie Lebensmitteln ausgehend von den o.g. standorttheoretischen Überlegungen ein Wettbewerbsvorteil sein *muss*. In Bezug auf die Cross-Channel-Integration von LM-Märkten wird also die folgende zu prüfende Hypothese formuliert:

H3: Das Angebot eines online-gestützten Abholservices („click and collect“) durch einen Lebensmittelmarkt hat einen positiven Einfluss auf die Einkaufsentscheidung

3.3 Modellierung des Einkaufsverhaltens

3.3.1 Das Modell

Zur Überprüfung der Hypothesen wird ein Modell für beschränkte abhängige Variablen verwendet, das auf Mullahy (1986) zurückgehende Hürdenmodell. Eine spezielle Abstimmung dieses allgemein formulierten mikroökonometrischen Modells auf die Erklärung der Einkaufsstättenwahl bzw. auf Kundenzuflüsse im Einzelhandel wurde bereits vorgenommen (Wieland, 2019a). Sinn des Modelleinsatzes ist, wie auch bei anderen ökonometrischen Modellen der Einkaufstättenwahl (z.B. Multiplicative Competitive Interaction Model [MCI], Discrete Choice Model) auf der Grundlage empirisch erfasster Einkäufe bzw. Einkaufssummen von befragten Individuen auf die Wirkung einzelner Teilnutzen zu schließen.

Ein besonderer Vorteil dieses Modells ist die Möglichkeit der Zerlegung des räumlichen Einkaufsverhaltens in zwei Aspekte, und zwar die Entscheidung *ob* bei einem bestimmten Anbieter eingekauft wird (oder eben nicht), und, *wenn ja*, wie „intensiv“ diese Einkaufsinteraktion ist, d.h. wieviele Einkäufe vollzogen werden oder wie hoch die Einkaufssummen sind. Dahinter steht die implizite Annahme eines zweistufigen Entscheidungsprozesses: Im ersten Schritt erfolgt die Entscheidung, *ob* etwas getan wird; danach wird in einem zweiten Schritt entschieden, *wie* etwas gemacht wird, wobei diese Entscheidung durchaus von ganz anderen Faktoren – oder von denselben Faktoren mit umgekehrter Kausalität – abhängig sein kann als die erste. Anders als das Huff-Modell und dessen Erweiterungen ist das Hürdenmodell für Individualdaten konzipiert und akzeptiert – nicht wie z.B. das MCI-Modell – (viele) empirische Ausprägungen der abhängigen Variable gleich null (was die mathematische Motivation der Modellkonstruktion ist).

Das Konzept lässt sich wie folgt zusammenfassen (die Darstellung orientiert sich an der in Wieland, 2019a):

Der Nutzen der Einkaufsstätte j für den Kunden i, U_{ij}, lässt sich in einer Nutzenfunktion mit einem „erklärten“ Teil V_{ij} (repräsentativer Nutzen) und einem nicht erklärten Teil ε_{ij} (Fehlerterm) ausdrücken:

$$U_{ij} = V_{ij} + \varepsilon_{ij}$$

Der repräsentative Nutzen besteht aus einer bestimmten Menge erklärender Variablen (Teilnutzen) in einer linearen Funktion:

$$V_{ij} = \boldsymbol{x_{ij}}'\boldsymbol{\beta}$$

Das Hürdenmodell besteht aus zwei Gleichungen, wobei die erste ein binäres Logit-Modell darstellt, dass die Wahlentscheidung modelliert (Kunde *i* kauft bei Anbieter *j* oder nicht). Die Zielgröße dieses Modells ist die Wahrscheinlichkeit, dass Kunde *i* Anbieter *j* aufsucht (p_{ij}), d.h. dass die Zahl der empirisch erfassten Einkaufsinteraktionen (Einkäufe oder Einkaufssummen), S_{ij}, größer als null ist. Diese Wahrscheinlichkeit wird durch den repräsentativen Nutzen erklärt:

$$p_{ij} = Pr\left[S_{ij} > 0 | V_{ij}\right] = \frac{e^{V_{ij}}}{1 + e^{V_{ij}}}$$

Eine lineare Interpretation des repräsentativen Nutzens ergibt sich durch die Betrachtung der Logits (Logarithmiertes Verhältnis der Wahrscheinlichkeiten des Eintretens und des Nichteintretens):

$$\ln \frac{p_{ij}}{1 - p_{ij}} = V_{ij}$$

Der zweite Teil des Modells behandelt die Intenstität der tatsächlich stattfindenden Einkaufsinteraktionen, d.h. alle Werte von S_{ij}, die größer null sind. Hierfür wird ein linkstrunkiertes Poisson-Modell verwendet, wobei der Poisson-Parameter λ_{ij} dem Mittelwert von S_{ij} entspricht:

$$E\left(S_{ij}, S_{ij} > 0 \middle| V_{ij}\right) = \frac{\lambda_{ij}}{1 - e^{-\lambda_{ij}}}$$

Die Linkfunktion des Poisson-Parameters λ_{ij} stellt durch eine loglineare Form einen linearen Zusammenhang mit dem repräsentativen Nutzen her:

$$\ln \lambda_{ij} = V_{ij}$$

Der Erwartungswert des Hürdenmodells ist das Produkt aus der Auswahlwahrscheinlichkeit und dem Erwartungswert aus der Intensitätsgleichung:

$$E\left(S_{ij} \middle| V_{ij}\right) = \left(Pr\left[S_{ij} > 0 | V_{ij}\right]\right)\left(E\left[S_{ij}, S_{ij} > 0 | V_{ij}\right]\right)$$

Beide Modellteile werden zunächst separat betrachtet, da sowohl die Effektstärke als auch die Richtung des Zusammenhangs keinesfalls gleichartig sein müssen (was i.d.R. plausibel durch die hinterliegenden Kausalzusammenhänge erklärt werden kann). Für Simulationen bzw. Prognosen wird dann das integrierte Modell verwendet. Die Berechnung des Hürdenmodells im vorliegenden Fall erfolgte in R (R Core Team, 2019) mit dem Paket pscl (Zeileis et al., 2008).

3.3.2 Erklärende Variablen und Nutzenfunktion

Im repräsentativen Nutzen sind diejenigen Variablen aufgeführt, auf die sich die Hypothesen beziehen, sowie etwaige Kontrollvariablen. Die Hypothesen $H1_a$ und $H1_b$ beziehen sich auf die Verkaufsfläche der Anbieter, weshalb dieser Indikator (A_j: Verkaufsfläche des LM-Marktes *j*) natürlich Teil der Nutzenfunktion ist. Um allerdings die betriebsformenspezifischen Effekte analysieren zu können, ist eine Differenzierung innerhalb des Modells notwendig, die über Dummy-Variablen (1/0) und Interaktionsterme hergestellt wird. Die LM-Märkte werden über Dummies als zugehörig zu den Betriebsformen (DG_j: Großer Verbrauchermarkt bzw. DD_j: LM-Discounter) gekennzeichnet. Für beide Dummies wird noch eine Interaktion mit der Verkaufsfläche integriert; die Koeffizienten der Interaktionsterme zeigen dann die Abweichung des VKF-Effektes der großen Verbrauchermärkte bzw. Discounter vom Effekt bei allen anderen Betriebsformen.

Die Wegezeit, auf die sich die Hypothesen $H2_a$ und $H2_b$ beziehen, findet sich ebenso als kontinuierliche Variable im Modell (d_{ij}). Da im Huff-Modell für beide Fälle (Verkaufsfläche und Wegezeit) ein nichtlinearer Einfluss angenommen wird (der sich auch immer wieder bestätigt hat, siehe Kap. 3.3.1), gehen die Verkaufsfläche und die Wegezeit in logarithmierter Form (ln) in die Gleichung ein. Die Koeffizienten der kontinuierlichen Variablen in beiden Teilmodellen können dann als Elastizitäten interpretiert werden, d.h. die prozentuale Veränderung der abhängigen Variable *Y* (odds ratio bzw. Erwartungswert der Intensität) unter der Bedingung, dass sich die betrachtete abhängige Variable *X* um 1% verändert.

Die Hypothese H3 (Positive Wirkung der Click-and-collect-Option) wird mit Hilfe einer weiteren Dummy-Variable (DC_j) in der Nutzenfunktion überprüft, die anzeigt, ob der jeweilige LM-Markt einen online-gestützten Abholservice anbietet (1) oder nicht (0). Um einen etwaigen verzerrenden Effekt durch große Unterschiede im Preisniveau abzubilden, wird eine zusätzliche Kontrollvariable integriert, die ebenso in Dummy-Form anzeigt, ob der betreffende Markt ein Bio-Supermarkt ist (DB_j). In die Intensitätsgleichungen wird weiterhin noch der Gesamtwert der Einkäufe bzw. Einkaufssummen je Kunde aufgenommen, um den zu erwartenden Unterschieden zwischen den einzelnen Käufern gerecht zu werden (z.B. einmalige große Ausgaben, Unterschiede in der Zahl der angegebenen Käufe).

Die Funktion des repräsentativen Nutzens (unter Aussparung der letztgenannten Kontrollvariablen, die nur im zweiten Teil der Modelle auftauchen) lässt sich dann wie folgt formulieren:

$$V_{ij} = \beta_0 + \beta_1 \ln d_{ij} + \beta_2 \ln A_j + \beta_3 DC_j + \beta_4 DB_j + \beta_5 DG_j + \beta_6 DD_j + \beta_7 \left(\ln A_j * DG_j\right) + \beta_8 \left(\ln A_j * DD_j\right)$$

3.3.3 Untersuchungsraum und Datenerhebung/-nachbearbeitung

Das Untersuchungsgebiet der vorliegenden Studie ist das südliche Niedersachsen, hier abgegrenzt durch die Landkreise Göttingen (inkl. Altkreis Osterode am Harz), Northeim und Holzminden. Das Gebiet wird in der BBSR-Gebietstypisierung weit überwiegend dem ländlichen Raum zugeordnet (Landkreise Northeim und Holzminden sowie der Altkreis Osterode entsprechen in der Klassifikation von 2015 dem siedlungsstrukturellen Kreistyp „Dünn besiedelte ländliche Kreise“; BBSR, 2017). Die drei Kreise haben gemeinsam 531.814 Einwohner (Stand: 31.12.2018; Statistische Ämter des Bundes und der Länder, 2020).

Die notwendige Datenerhebung gliederte sich in zwei Teile: Zunächst wurden im 1. Quartal 2019 sämtliche Lebensmittelmärkte des Untersuchungsraumes nach der Defintion von AC Nielsen (The Nielsen Company, 2017) erfasst, d.h. Supermärkte, Verbrauchermärkte und LM-Discounter. Die Standorte wurden für die späteren Modellschritte georeferenziert. Die aktuellen Verkaufsflächengrößen der Betriebe wurden i.d.R. bei den jeweiligen LEH-Unternehmen erfragt; in den übrigen Fällen wurden diese Daten öffentlich verfügbaren Quellen (z.B. Medienberichte, Bebauungspläne, Einzelhandelsgutachten) entnommen oder manuell abgeschätzt. Zudem wurde protokolliert, ob im Fall von rechtlich eigenständigen Märkten innerhalb einer Kooperative ein online-gestützter Abholservice angeboten wird.

Die Erfassung des Konsumentenverhaltens erfolgte im Zeitraum von März bis Juni 2019 mit Hilfe einer schriftlich-postalischen Befragung. Hierbei wurde eine Zufallsstichprobe aus dem amtlichen Melderegister per Brief kontaktiert und um Teilnahme gebeten, wobei eine einmalige Nachfassung stattfand. Die kontaktierten Personen konnten den ausgefüllten Fragebogen mit einem portofreien Umschlag zurücksenden oder ihre Antworten stattdessen in ein Online-Formular beim Dienst q-set (www.q-set.de) eingeben. Als Erhebungsinstrument fungierte ein standardisierter Fragebogen, bei dem das Einkaufsverhalten in mehreren Sortimentsbereichen sowie Einstellungsmerkmale und sozio-demographische Daten abgefragt wurden. Die Erfassung der Einkäufe erfolgte analog zu Vorgängerstudien (Wieland, 2015; 2019a) über die Abfrage der drei zuletzt getätigten Einkäufe und der zugehörigen ungefähren Einkaufssummen. Für die vorliegende Untersuchung wurden nur die erfassten Lebensmitteleinkäufe verwendet. Im Untersuchungsgebiet wurde eine Stichprobe von n = 297 Befragten realisiert, hiervon 265 auf dem schriftlichen Weg und 32 über das Online-Formular. Die Dateneingabe sowie Nachbearbeitung erfolgte mittels SPSS (IBM Corp, 2016). Die angegebenen LM-Märkte wurden entsprechend der vorherigen Angebotserfassung codiert.

Aus den Rohdaten wurden Interaktionsmatrizen (i befragte Personen * j erfasste Lebensmittelmärkte) erstellt und für alle möglichen Kombinationen Wegezeiten durch die Abfrage von PKW-Fahrtzeiten aus dem OSRM-Dienst (Open Source Routing Machine) ermittelt. Diese beiden letzten Schritte, die unmittelbare Vorarbeiten für die Berechnung der Hürdenmodelle darstellen, erfolgten in R (R Core Team, 2019) mit dem Paket MCI2 (Wieland, 2019b).

4 ERGEBNISSE

4.1 Deskriptive Statistiken

4.1.1 Angebotssituation im Untersuchungsgebiet

Tabelle 1 zeigt das Angebot an Lebensmittelmärkten im Untersuchungsgebiet zum Zeitpunkt der Datenerfassung, aufgeschlüsselt nach LEH-Betriebsformen nach der Nielsen-Definition. Ingesamt wurden 195 Lebensmittelmärkte mit einer Gesamtverkaufsfläche von 254.646 qm erfasst. Es zeigt sich hierbei z.B. auch, dass die durchschnittliche Verkaufsflächengröße der LM-Discounter mit rd. 857 qm oberhalb der Grenze des großflächigen Einzelhandels (800 qm) liegt. Ein online-gestützter Abholdienst (Click and collect) wurde zum Erfassungszeitpunkt von fünf Lebensmittelmärkten – allesamt selbständige Verbrauchermärkte unter dem Dach der Rewe Group – angeboten.

Betriebsform (Nielsen-Typologie)	Anzahl (davon mit Click & Collect)	VKF [qm], Summe	VKF [qm], Mittelwert
Supermärkte, klein (bis 399 qm) [+]	11 (0)	2.180	198,18
Supermärkte, groß (400-999 qm) [++]	19 (0)	11.404	600,21
Verbrauchermärkte, klein (1.000-2.499 qm)	58 (5)	88.269	1.521,88
Verbrauchermärkte, groß (ab 2.500 qm)	18 (0)	76.558	4.253,22
LM-Discounter	89 (0)	76.235	856,57
Gesamt [+++]	195 (5)	254.646	1.305,88

[+] darunter 4 subventionierte Betriebsformen (Dorfläden) mit einer durchschnittlichen VKF von 94 qm
[++] darunter 4 Bio-Supermärkte mit einer durchschnittlichen VKF von 519 qm
[+++] In der Tabelle nicht inkludiert: 2 Märkte außerhalb des Untersuchungsgebietes (1x kleiner VM, 1x großer VM; Summe VKF: 6.560 qm)

Tabelle 1: Lebensmittelmärkte im Untersuchungsgebiet nach Betriebsformen (Quelle: Eigene Erhebungen und Berechnungen).

Diese Aufstellung entspricht nicht exakt der Angebotssituation, die in der weiteren Modellanalyse berücksichtigt wurde: Es wurden noch zwei Verbrauchermärkte außerhalb des Untersuchungsgebietes (Stadt Höxter, Nordrhein-Westfalen) mit einer Gesamtverkaufsfläche von 6.560 qm ins Modell aufgenommen, da diese in der Haushaltsbefragung aus mindestens zwei Gemeinden als Einkaufsquelle angegeben wurden.

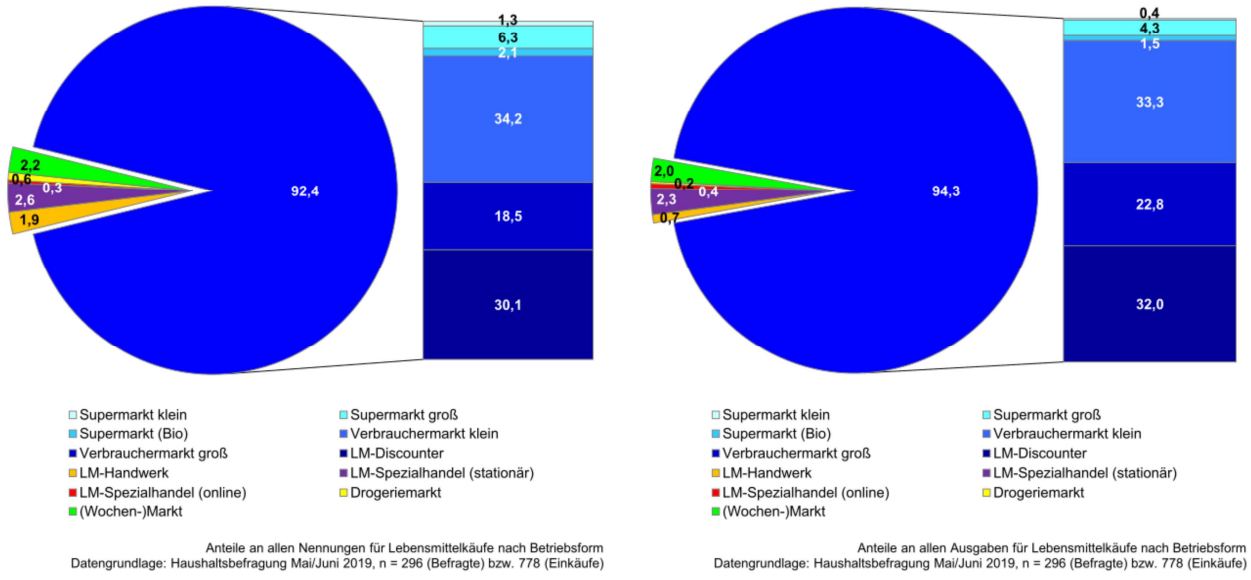

Abbildung 1: Anteile der Nennungen bzw. Einkaufssummen (Quelle: Eigene Erhebungen und Berechnungen).

4.1.2 Erfasste Marktanteile nach Betriebsformen bzw. Vertriebskanälen

Die in der repräsentativen Haushaltsbefragung erfassten Lebensmitteleinkäufe wurden für eine deskriptive Übersichtsdarstellung nach Betriebsformen klassifiziert (siehe Abb. 1), wobei hier auch Angebotsformen berücksichtigt sind, die für die Modellanalyse extrahiert wurden (z.B. Einkäufe im Lebensmittelhandwerk). Separat ausgewiesen werden hier auch die Bio-Supermärkte, die in der Nielsen-Kategorisierung zu den

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

„großen Supermärkten“ gezählt werden. Es zeigt sich hier, dass 92,4 % aller Einkäufe bzw. 94,3 % aller Ausgaben im Lebensmittelbereich auch in Lebensmittelmärkten getätigt werden. Die Marktanteile von kleinen Verbrauchermärkten (1.000-2.499 qm VKF) und LM-Discountern sind nahezu gleich (34,2 % aller Einkäufe bzw. 33,3 % aller Ausgaben vs. 30,1 % und 32,0 %). Einige wenige Online-Lebensmittelkäufe bei Spezialanbietern spielen keine nennenswerte Rolle (0,3 % der Käufe bzw. 0,4 % der Ausgaben).

Am Vergleich der Einkaufs- und Ausgabenanteile zeigen sich auch die funktionalen Unterschiede zwischen den LEH-Betriebsformen: Bei den kleinsten Betriebsformen (kleine und große Supermärkte) liegen die Anteile der Einkäufe deutlich höher als die Anteile der Ausgaben; im Fall von großen Verbrauchermärkten oder Discountern ist dieses Verhältnis umgekehrt. Dies weist auf deutlich geringere Durchschnittsausgaben bei den kleinen Betriebsformen hin, die eher für häufig durchgeführte Ergänzungskäufe genutzt werden. Discounter und insbesondere große Verbrauchermärkte sind dagegen überwiegend die Einkaufsquelle für Großeinkäufe, die zwar regelmäßig, jedoch insgesamt seltener stattfinden (Reutterer/Teller, 2009).

4.2 Modellergebnisse

Tabelle 2 zeigt die Ergebnisse der Berechnung der Hürdenmodelle für die Einkäufe und die Ausgaben bei den Lebensmittelmärkten. Das erste Teilmodell, dessen Zielgröße die Auswahlwahrscheinlichkeit der zur Verfügung stehenden Alternativen ist (binäres Logit-Modell), ist für beide Modellvarianten identisch, da hier nur die Information zu Grunde gelegt wird, *ob* bei einem bestimmten Anbieter eingekauft bzw. Geld ausgegeben wird. Die dritte und vierte Spalte der Tabelle zeigen jeweils den zweiten Teil des Hürdenmodells für die Einkäufe bzw. die Ausgaben. Die Koeffizienten (β) der kontinuierlichen Variablen sind aufgrund der Logarithmierung als Elastizitäten (prozentuale Veränderung von Y bei einer 1-%-Änderung von X) zu interpretieren, die Koeffizienten der Dummy-Variablen als Semi-Elastizitäten (β*100 gibt an, um wieviel Prozent sich Y erhöht oder senkt, wenn sich der Wert der Dummy-Variable X von 0 auf 1 ändert).

Erklärende Variablen	Null-Hürden-Modell (binäres Logit-Modell) $Einkäufe_{ij}$ / $Ausgaben_{ij}$	Zähldatenmodell (zens. Poisson-Modell, Logit-Verknüpfung)

Tabelle 2: Ergebnisse der Hürdenmodelle für die LM-Einkäufe und -Ausgaben (Quelle: Eigene Erhebungen und Berechnungen).

Der Verkaufsflächeneffekt für die Referenzgruppe (Alle Supermärkte und kleine Verbrauchermärkte) ist entgegen der a-priori-Annahme überproportional positiv: Eine Erweiterung der Verkaufsfläche um 1% erhöht die Chance, für einen Einkauf ausgewählt zu werden, um rd. 1,11 %. Ist der Lebensmittelmarkt bereits ausgewählt, steigert eine 1-%-Erhöhung der VKF die dort getätigten Ausgaben um rd. 0,18 %. Allerdings liegt der Fokus an dieser Stelle auf den Abweichungen von diesem Wert, die durch die Koeffizienten der Interaktionsterme angezeigt werden: Bei großen Verbrauchermärkten hat eine Erweiterung der Verkaufsfläche um 1% einen um 0,78 Prozentpunkte geringeren Effekt als bei der Referenzgruppe: Eine solche Erhöhung steigert demnach die Auswahlwahrscheinlichkeit um nur rd. 0,33% (1,113 - 0,784 = 0,329). Wird der jeweilige Markt allerdings besucht, steigert die Verkaufsfläche die Kunden- und Ausgabenzuflüsse

dieser Anbieter. Bei LM-Discountern ist der positive Effekt der VKF-Größe um rd. 0,20 Prozentpunkte höher als bei der Referenzgruppe; tatsächlich steigert also die VKF-Erhöhung eines Discounters um 1 % die Auswahlchance um rd. 1,32 % (1,113 + 0,204 = 1,317). Auch die Bonsummen bei bereits ausgewählten Märkten steigen mit der Verkaufsfläche. Offensichtlich zeigt sich also eine wie in den Hypothesen $H1_a$ und $H1_b$ formulierte Wirkung: Lebensmitteldiscounter profitieren von Verkaufsflächenerweiterungen am stärksten, während große Verbrauchermärkte hierdurch nur unterproportionale Kundenzuflüsse erwarten können. Dass bei Besuchen von Discountern im Mittel geringere Summen ausgegeben werden, wie der Koeffizient der Dummy-Variable DD_j anzeigt, verwundert aufgrund des geringeren Preisniveaus dieser Betriebsform (DISQ, 2017) nicht.

Auffällig ist das Ergebnis zur Prüfung der Hypothese H3: Die Click-and-collect-Option hat keinen signifikanten Einfluss auf die Auswahlwahrscheinlichkeit und erhöht auch nicht die Intensität der Einkaufsbeziehungen. Die insgesamt fünf Verbrauchermärkte können *im Mittel* also keine zusätzlichen Kunden- oder Kaufkraftzuflüsse durch das Angebot eines online-gestützten Abholservices generieren. Die Hypothese einer Attraktivitätssteigerung durch die Cross-Channel-Integration der LM-Märkte muss damit zumindest im vorliegenden Fall verworfen werden.

Zudem zeigt sich ein signifikant negativer Effekt der Wegezeit sowohl auf die Auswahlwahrscheinlichkeit als auch auf die Zahl der Einkäufe und die zugehörigen Ausgaben. Ein Anstieg der Fahrtzeit um 1% resultiert in einer Reduzierung der Besuchschance um rd. 2,6 %, was einen stark überproportionalen Effekt bedeutet und vollkommen konsistent mit früheren Ergebnissen zum Einkaufsverhalten im LEH ist (siehe Kap. 3.1). Dies führt zur Bestätigung der formulierten Hypothesen $H2_a$ und $H2_b$. Weiterhin sind die Effekte der Wegezeit sowohl im Entscheidungsmodell als auch beim Zählmodell für die Einkäufe deutlich höher als die der Verkaufsfläche und des – ohnehin niemals signifikanten – Cross-Channel-Angebotes. Es bestätigt sich also auch hier, dass die Erreichbarkeit von Lebensmittelmärkten die wichtigste Einflussgröße beim LEH-Einkauf darstellt und Betriebsformen- und Verkaufsflächeneffekte sowie ergänzende Online-Angebote in ihrer Relevanz deutlich überschattet.

5 SCHLUSSFOLGERUNGEN

Die Entwicklungen im LEH der letzten Jahre zeigen einerseits eine Tendenz konvergierender Marktgrößen – Discounter werden „größer“, Vollsortimenter „kleiner“ – und andererseits eine wachsende Online-Anbindung auch traditioneller LEH-Ketten und -Kooperativen. Tatsächlich zeigt sich der erstgenannte Effekt im Kundenverhalten: Discounter profitieren aufgrund ihres spezifischen Betriebsformenkonzeptes wesentlich stärker von größeren Verkaufsflächen als Vollsortimenter (was sich auch in den weitgehend höheren durchschnittlichen Flächenproduktivitäten der Discounterfilialen bemerkbar macht; siehe z.B. Hahn Gruppe, 2019); bei großen Vollsortimentern ist der Effekt gegenteilig. Dies führt unweigerlich zu der Frage, ob die Beurteilung der Zulässigkeit bzw. Schädlichkeit von betrieblichen Neuansiedlungen oder Erweiterungen, die planungsrechtlich zunächst nur an der Verkaufsfläche festgemacht wird, möglicherweise ausdifferenziert werden müsste. Ab einer Verkaufsfläche von 800 qm (bzw. 1.200 qm Geschossfläche) gilt nach § 11 BauNVO die Vermutungsregel, dass negative Auswirkungen von Einzelhandelsprojekten nicht ausgeschlossen sind; in Bayern gelten in der Landesraumordnung Ausnahmen dieser Regelungen für Lebensmittelmärkte bis 1.200 qm (LEP Bayern, Ziel 5.3.1). Unabhängig davon, welche Grenze in welchem Fall angewendet wird, zeigt sich aber, dass etwaige Auswirkungen in jedem Fall betriebsformenspezifisch sein *müssen*, denn die Effekte der VKF-Größen auf die Kundenzuflüsse sind es auch. Dieses Argument wurde bereits in der deutschlandweiten Studie „Qualifizierte Nahversorgung“ (u.a. Anders, 2015; Krüger et al., 2013) diskutiert, da sich hier zeigte, dass zwischen Discountern und (durchschnittlich größeren) Verbrauchermärkten (800-1.500 qm) keine Unterschiede im Hinblick auf deren Einzugsgebiete sowie induzierte Verkehrseffekte bestehen.

Ein weiterer Untersuchungsgegenstand lag im Effekt der Cross-Channel-Einbindung von LM-Märkten. Es war hier zu erwarten, dass diese einen Wettbewerbsvorteil darstellt und möglicherweise den Attraktivitätseffekt der Marktgröße abschwächt. Allerdings konnte diese Hypothese hier ausdrücklich nicht bestätigt werden. Dies ist allerdings möglicherweise auf eine noch zu geringe Bekanntheit bzw. Etablierung online-gestützter Abholdienste zurückzuführen. Im vorliegenden Fallbeispiel haben die – insgesamt nur fünf – Verbrauchermärkte im Untersuchungsgebiet dieses Angebot erst vergleichsweise kurz eingeführt (der erste

dieser Märkte war ein Rewe-Markt in Göttingen, dessen online-gestützter Abholservice seit Februar 2017 besteht). Es ist hier jedenfalls dringend geboten, diese Hypothese in späterer Zeit nochmals zu prüfen.

Tatsächlich zeigen die Ergebnisse aber auch, dass die hier diskutierten Veränderungen im LEH-Markt nichts am eigentlichen Nahversorgungscharakter des Lebensmitteleinzelhandels geändert haben: Nichts spielt in der konsumentenseitigen gedanklichen Abwägung bei der Auswahl der Einkaufsstätte eine größere Rolle als die Erreichbarkeit der Lebensmittelmärkte. Das wissenschaftliche Monitoring der Nahversorgungsstrukturen sollte, ebenso wie die planerische Steuerung der räumlichen Einzelhandelsentwicklung, auch weiterhin eben diesen Aspekt fokussieren.

6 FÖRDERUNGSHINWEIS UND DANKSAGUNG

Das Forschungsprojekt „Zur Raumwirksamkeit des Onlinehandels“ (Antragsteller: Dr. Thomas Wieland) wird durch die Deutsche Forschungsgemeinschaft (DFG) gefördert (Projektnummer 402130768). Der DFG sei für die finanzielle Förderung des Projekts gedankt. Der Autor dankt außerdem den beiden studentischen Hilfskräften (B.A.) Anne Auinger und Anjulie Kappler für ihre Mitarbeit in diesem Projekt. Dank gebührt zudem den Ansprechpartner/-innen mehrerer Handelsunternehmen für die Bereitstellung von Standortdaten.

1 ABSTRACT

During the past few years, our research has examined and described the spatial patterns and organisation of economic activities. In order to link these findings to policy, we introduced the concepts of demand and supply segments, and applied them on the scale of an area or a certain spatial environment.

Considering the business needs of companies on a certain location, we identified 16 demand parameters of companies, that are spatially relevant on the scale of an area: the size of good flows, the alternative freight transport, the nearness to the market,… Literature, interviews and observations offer supporting evidence for the parameters. We linked them to 24 other parameters that reflect the characteristics of the area where a company is located. These include amongst others mobility, level of foot fall, the presence of green infrastructure, other companies (or mix of companies), density, parking possibilities,… The combination of this information with our typology of economic area's (Giaretta, Pennincx, De Mulder, Zaman, 2019) resulted into 24 main segments, that show the relation between demand of companies and supply of spatial characteristics on the scale of an area. The segments are ideally grouped according to the characteristics, and in this sense they differ from typology of economic areas, that is based on the observed location preferences of companies.

This way of grouping into segments generates new questions, that enable us to spatially differentiate economic environments, and to make decisions regarding the location of economic activities. We aim at getting concrete answers to three main questions:

(1) Is my company located in the right place? Does this area spatially deliver what my company needs?

(2) Does the area deliver the right services, that the companies in this area need?

(3) If we want to transform an area, which area characteristics do we need to change in order to attract the wanted companies?

We subdivide these three main questions into sub questions.

The first question considers the demand side and uses the micro-economic considerations, made by a company, in order to choice a certain segment. Several questions succeed each other and deal with the demand of companies regarding the effects of agglomeration, economic and environmental spatial use, freight transport, price per square meter,…

The second question can lead to the segment that is the closest to the actual situation, based on the typology of economic areas. Indeed, there is usually a gap between the actual situation and the best fitting segment. Using the typology and the segments on an actual situation uncovers information about visibility, land price value, good flows, land use plan.

The third and last question deals with areas that are in a process of transformation. After finding out the desirable segment, it is possible to evaluate which companies belong to this segment, which need to adapt or to disappear. In addition, the transition in terms of services that the area delivers (which is implied when transforming from one segment to another), can be determined.

Keywords: upgrading areas, future of mixed use areas, urban economy, economic space, segmentation

2 INTRODUCTION

During the first decade of the 21st century, spatial planning for economic space was focussing on two questions: (1) What are the characteristics of a preferred location of companies that are looking for a place to start or that are in the process of leaving their current location? and (2) How much space (new developped businessparks) is needed to accommodate the growth of the economy in Flanders? The first question was adressed in the 'strategic plan for regional economy' (SPRE) (Cabus et al, 2004) and was based on a

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

questionnaire filled out by more than 5.500 companies in Flanders. In the context of desindustrialisation and suburbanisation, with an oversupply of cheap available green field development for offices and light industry, company owners where asked to stated their preferences for a future location. These are 'stated preferences'. However, when combined with a dominant view of modernist planning, the way the questions were asked implied a social set of values that can be best described as a 'constructed preference'. The second question was answered by making forecasts based on macroeconomic data such as the current number of employees per hectare per sector, trend analysis of workforce growth in these sectors, investment,… In order to decide whether these parameters were good for these forecast purposes, a sensitivity analysis was done (Jacobs et al, 2003). Without much surprise, the results had a big variance, and the Flemish Government decided that, in order to be on the safe side (and not limiting economic growth), they would go for the moderate scenario, while providing extension possibilities towards the high demand scenario.

By 2012 first signs appeared that the public was no longer happy with the ever expanding businessparks that popped up everywhere in the countryside (Pisman et al. 2018, p 73)

In 2014, the government agency Flanders Innovation and Entrepreneurship (VLAIO) presented a research (Idea consult, 2014) where they tried to recalculate the need for additional industrial land and the net land take. In this project they had to find a way to measure whether a company really needed to occupy industrial land, or if it could also thrive in a mixed urban context.

Soon after this project, we started the research project called 'segmentation of economic locations', (van Dinteren, 2015) where we aimed to reframe the questions, both from the perspective of a business owner and of a local spatial/economic policy maker. The central position is that economy is everywhere, and that we (as spatial planners) do not fully understand how this functions. We asked ourselves how this understanding can be improved, for audiences such as the businesses, workers, and the public in general. In order to graps how economy functions, we have to know where specific activities take place, in what circumstances, and also try to understand what were implicit business related decisions that a company made in different phases of its history.

We complemented the stated preference from SPRE, with an observed choice of companies by mapping all activities present in different areas in Flanders and Brussels. From 2016 until 2019, we mapped almost 45.000 individual economic units in a 375 km² territory. We interpret the observed choice as a 'revealed preference' (Varian (2005), Samuelson (1938, 1948)) for micro economic site location choices of individual companies. As discussed in Huybrechts et al (2019), companies not only make a location choice when they first settle in a specific space: the law of minimizing costs obliges them to make a recurring evaluation of the location cost. The cost of moving a company is high and doing so has many uncertainties, which result in the statement that companies do not change location unless absolutely necessary.

We therefore assume that the best way of understanding location choice is to look at existing complex environments or economic ecotopes. This concept means that we focus on economic activities that are located on one or more parcels, taking into account their business models, and that we look into the area surrounding the economic activities. These economic area's have certain (spatial) characteristics that can be seen as economic ecotopes.

As discussed by Giaretta et al (2018, 2019), the revealed preference from the comprehensive mapping of economic activities had to be transformed into 'types' or economic ecotopes? An iterative inductive method was used to define the 16 economic types. For some small areas we produced a first proposal. This proposal was used by a group of people involved in spatial planning, urbanism, economics and real estate development. All of them have a good understanding of the field and have an in depth knowledge of that specific territory. The users discussed the nature of the types, the specific subdivision and how to use it in spatial and economic transformation of the territory. From these discussions, a new set of rules was derived for a new version of the types. This was done in different areas in and around Brussels and in Flemish cities, Kortrijk, Roeselare and Herentals.

3 FROM ECONOMIC ECOTOPES TO MARKET SEGMENTS

In 2018, we proposed a first version of the economic types (Giaretta et al, 2018), that we later used in discussions about transformation of areas, area specific development en regional economic planning. By november 2019 we applied an improved version of the method for the complete mapped area of 37.558ha in

Flanders and Brussels (Fig), allowing a more in depth study of the implicit parameters of each ecotope. The extend of the mapping (almost 45.000 economic units) resulted in the definition of 3.300 areas in 16 types (update of the 2018 version), ordered into 'continous', 'close', 'discontinous' and 'solitary' categories, and into several mixes of activities. From this mapping of units we were able to deduce a 'fingerprint' of each type (Fig 1).

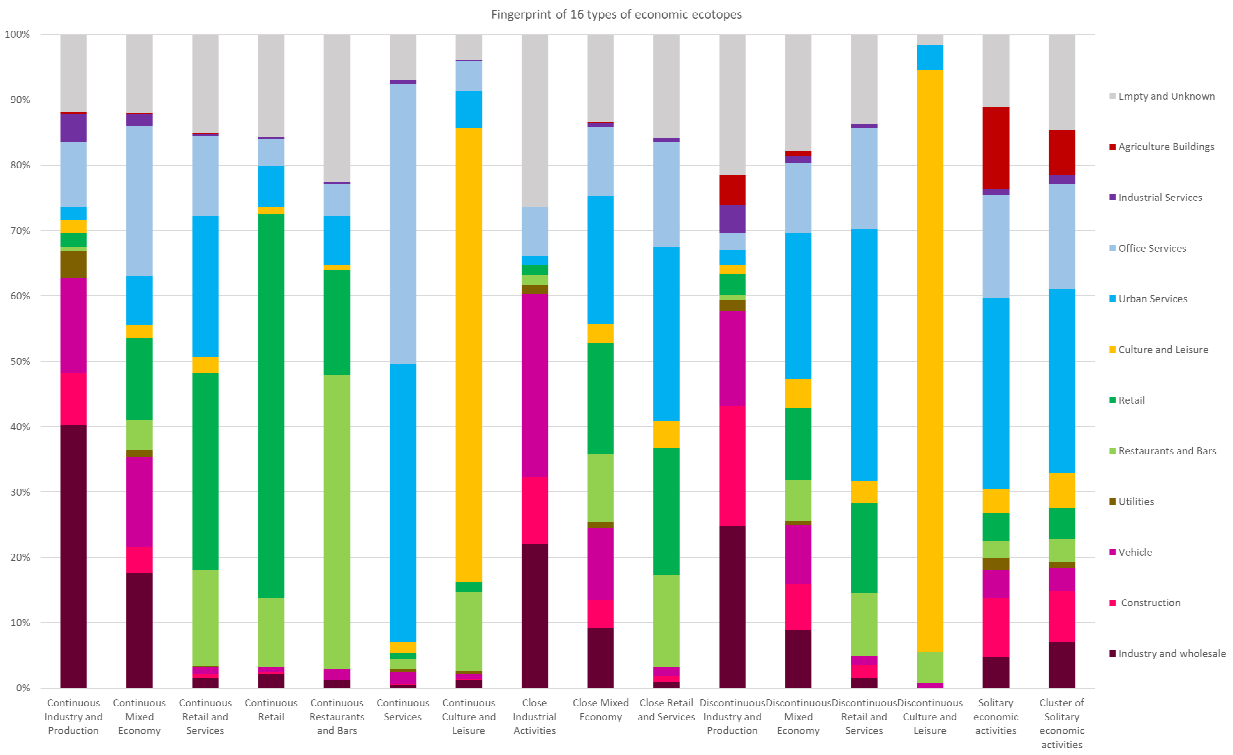

Fig. 1: Characteristic presence of different economic activities in each type or economic ecotope, based on the amount of units of the different economic activities.

As discussed in previous papers, it is expected that some types have a very similar composition because the main difference is not the type of activities but the distance between the economic activities in that type of ecotope. This is most striking between 'Continuous Culture and Leisure' and 'Discontinuous Culture and Leisure', and off course both types with solitary economic activities. In general, one can say that every economic activity can be present in every economic ecotope. So we can also use the data to calculate the probability that a company active in a specific sector will locate itself in any of the 16 types. Figure 2 shows this for a manufacturing company. As you would expect, a manufacturing company will most likely locate itself in a 'Continuous Industry and Production' type. However, the huge variety of manufacture and the different scales of these companies, make that the second observed choice is 'Discontinuous Mixed Economy'. Not all producing companies need the infrastructure provided in an industrial zone, nor do they have the necessary size and scale to be eligible for such sites. These graphs give a first glimpse of how individual companies might behave.

While site location choice is a discrete choice, the constant proces whether to stay in the same location or move to a new one, has more in common with a spatial planning 'Wicked Problem' (Rittel, 1972) than with a rationalisation of consumer choice. For wicked problems, no explicit basis exists for the termination of a problem solving activity; any time a solution is proposed, it can be developed still further (Rowe, 1987). This means that location choice is a recurrent problem. The interviews conducted by Huybrechts et al. (2019) with companies that remained in their original site, clearly show this proces. Every new event, acquisitions, hostile take over, new investment, environmental disputes with neighbours,… can suddenly revive the wicked problem of questioning the location of the firm. Changes in the value chain, e.g. outsourcing of material stock and logistics, can also influence the optimal location of a company.

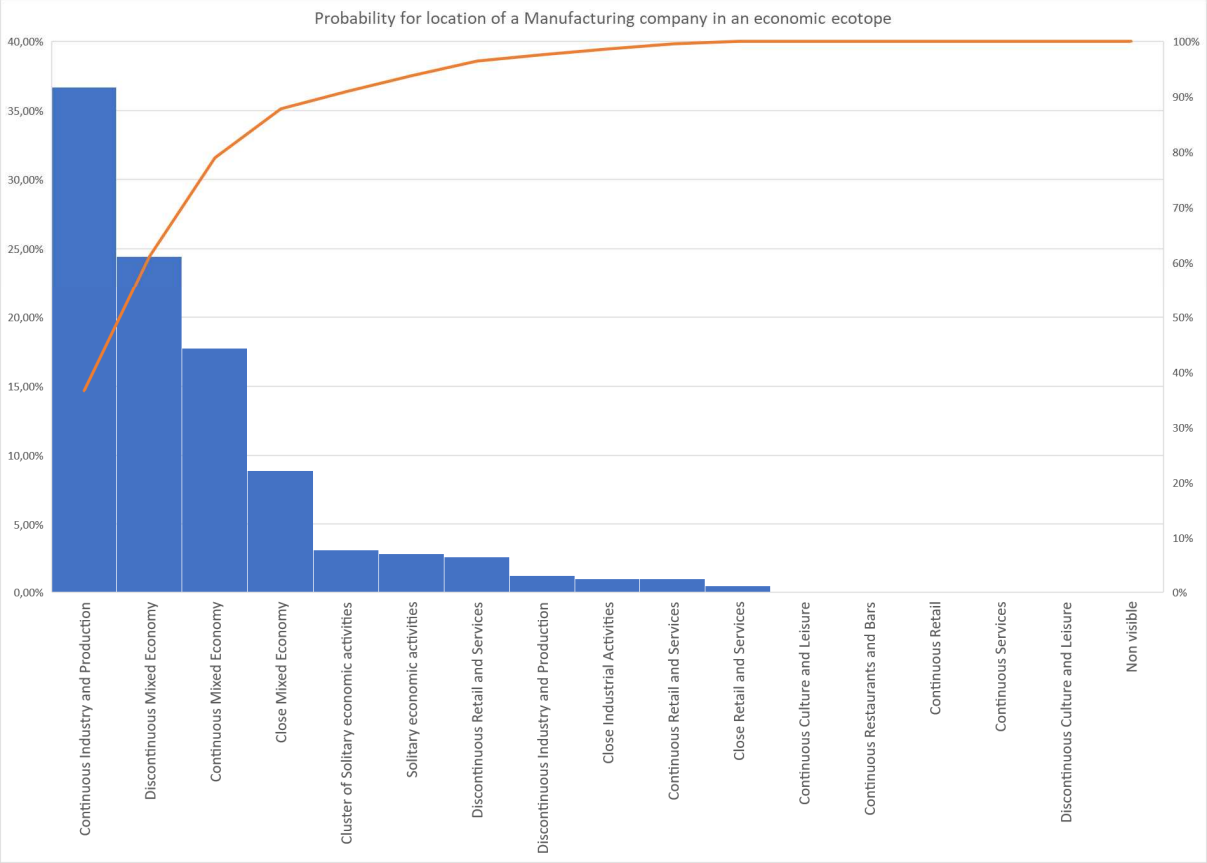

Fig. 2: probability of location of a manufacturing company in a Type of economic ecotope.

Different interdependent parameters play a role in the location decision making proces. In order to understand which parameters are relevant in making this discrete choice (demand side) we listed the parameters in site location that are differentiated territorially and are relevant on the scale of the economic ecotopes.

Starting with Alfred Weber's 'Theory on the location of Industries' (Weber, 1929), combined with industry and retail sales annual reports (JLL, 2019), and discussions with local stakeholders in the area of Buda in Brussels, we selected 16 relevant parameters for the demand side, and 26 for the product stratification (DeLisle, 2019).[1] The first stable version was tested for the Buda area in a workshop (29 August 2019), and later with the Province of Flemish Brabant (15 October 2019). Based on the comments and reviews, an adjustment was made to the proposed market segmentation. To keep a direct link with the economic ecotopes, we decided to slightly adjust the method, so types of ecotopes are either grouped or subdivided, but not spread around in different market segments.

A confrontation between the ecotope types and the territorial demand and product stratification parameters brings forward these findings:

[1] Territorial relevant parameters for the demand side and for the product stratification:
Demand: (D01) mix of activities in the area, (D02) size of units, (D03) cost of space, (D04) operational cost (environmental restrictions), (D05) population density in the area, (D06) population in the wider region, (D07) proximity to public services, (D08) image of the area, (D09) footfall, (D10) visibility from cars, (D11) number of cars passing, (D12) accessibility by public transport, (D13) accessibility by alternative goods transport, (D14) number of deliveries per week, (D15) type of goods vehicles, (D16) parking needs;
Product stratification: (P01) type of economic ecotope, (P02) proximity to economic activities, (P03) size of units, (P04) land use plan, (P05) combination with housing, (P06) environmental restrictions, (P07) external risk and hazard allowance, (P08) Floor Area Ratio, (P09) population density, (P10) average rent, (P11) land price, (P12) safe walking and cycling, (P13) large sidewalk, (P14) public transport service level, (P15) altenative goods transport infrastructure, (P16) direct access from the road, (P17) accessibility restrictions, (P18) parking availability, (P19) organization of loading and unloading, (P20) busy walking route between attraction points, (P21) footfall, (P22) visibility from a car, (P23) number of cars passing, (P24) availability of green spaces, (P25) public accessible green areas in the wider surroundings, (P26) collective water management.

(A) When the distance between economic activities increases, the potential relationship (Tobler, 1970) deminishes. Slight differences in distance between economic units are not distinctive when seen from the demand side. Three categories of proximity remain relevant: Continuous, Close (combining Close and Discontinuous), and Solitary.

(B) Where the mix of economic activities provides positive agglomeration effects and shared infrastructure in the Continuous economic ecotopes, this is no longer the case when economic activities are dispersed. The dominant presence of other activities (housing, farmland, forest,…) is more important for site location choice than the observed differences in mix of economic activities. The analytical subdivision of 'Close' and 'Discontinuous' types based on economic activity mix is not distinctive.

(C) The demand side parameters that are most relevant on this territorial scale are (1) footfall, (2) visibility from a main road, (3) potential clients in the area (= density), (4) shared infrastructure, and (5) organisation of loading and unloading. These parameters also explain the price of the accomodation. Areas will be subdivided in different segments where these parameters are considered important.

(D) The product stratification approach adds the (1) built form, (2) floor area ratio, (3) indoor/outdoor activities, (4) environmental restrictions and the (5) combination with housing as important parameters. As for the demand side, market segments will be subdivided accordingly.

Table 1 shows the resulting relation between the types and market segments. Not all parameters are equally relevant, and most are linked to one another. This is also reflected in the description of the market segments. The Type 'Continuous Industry and Production' exists both with and without a strong presence of housing. For the market segments, we propose a clear split between 'Urban Industry and Production', which includes substantial amounts of housing, and has a high Floor Area Ratio, and the other market segments, where there is no or very limited housing included in the area. When analyzing existing areas, an economic ecotope 'Continuous Industry and Production', that also contains a large proportion of housing, is associated with the 'Urban Industry and Production' market segment. Similarly, the 'Modern Industry and Production' segment refers to the absence of outdoor activities and storage, and 'Logistics and Wholesale' implies a very good freight transport accessibility and a dominance of Wholesale, Transport and Storage activities.

Type of economic ecotope	**Market Segment**
Continuous Industry and Production	Urban Industry and Production
	Industry and Production along a Main Road
	Modern Industry and Production
	Standard Industry and Production
	Logistics and Wholesale
Continuous Mixed Economy	Mixed Economic Activities along a Main Road
	Standard Mixed Economic Activities
Continuous Retail and Services	Retail and Services High Street
	Retail and Services Area
Continuous Retail	Shopping Street
	Shopping Mall
	Car Based Retail
Continuous Restaurants and Bars	Restaurants and Bars
Continuous Services	Office Services
	Urban and Public Services
Continuous Culture and Leisure	Culture
	Sports and Leisure
Close Industrial Activities; Close Mixed Economy; Close Retail and Services; Discontinuous Industry and Production; Discontinuous Mixed Economy; Discontinuous Retail and Services; Discontinuous Culture and Leisure	Close Economic Activities along a Main Road
	Close Economic Activities in Urban Areas
	Close Economic Activities in Low Density Areas
Solitary economic activities; Cluster of Solitary economic activities	Solitary Economic Activities in Built Areas
	Solitary Economic Activities in Agricultural Areas
	Solitary Economic Activities in Green Areas
	Areas without visible economic activities

Table 1: relationship between 16 types of economic ecotopes and 24 market segments

As in every attempt to propose market segments, this does not erase the differences between the individual locations or products within a segment. Within a an economic ecotope, different plot sizes, building properties,… will be available while other characteristics will be common for the entire ecotope. For specific economic activities (e.g. huge environmental impact, need for very large space,…) more in depth market research will be necessary to find a suitable location.

4 CASE: MARKET SEGMENTS IN BUDA (FLANDERS, NORTH OF BRUSSELS)

Buda (central in Figure 3) is a historic industrial cluster south of Vilvoorde. This area is located in Flanders, but strides the border between the Brussels Capital Region and Flanders. This administrative divide however is invisible on the field. The development of the area started from the 1920s and resulted into different economic ecotopes of industrial type, around major transportation axes that link Brussels to Antwerp. In the Types map (Figure 3) we see how the industrial and mixed activities developed around the Canal Brussels-Scheldt and the railway Brussels-Antwerp. This patchwork of continuous industrial ecotopes highlights the perception problems this old industrial zone faces. Due to the historic soil pollution and strategic location close to Brussels and the Orbital Motorway (left to right in the middle of the orthophoto), there is real estate speculation in Buda, as many ambitious transformation proposals are currently discussed.

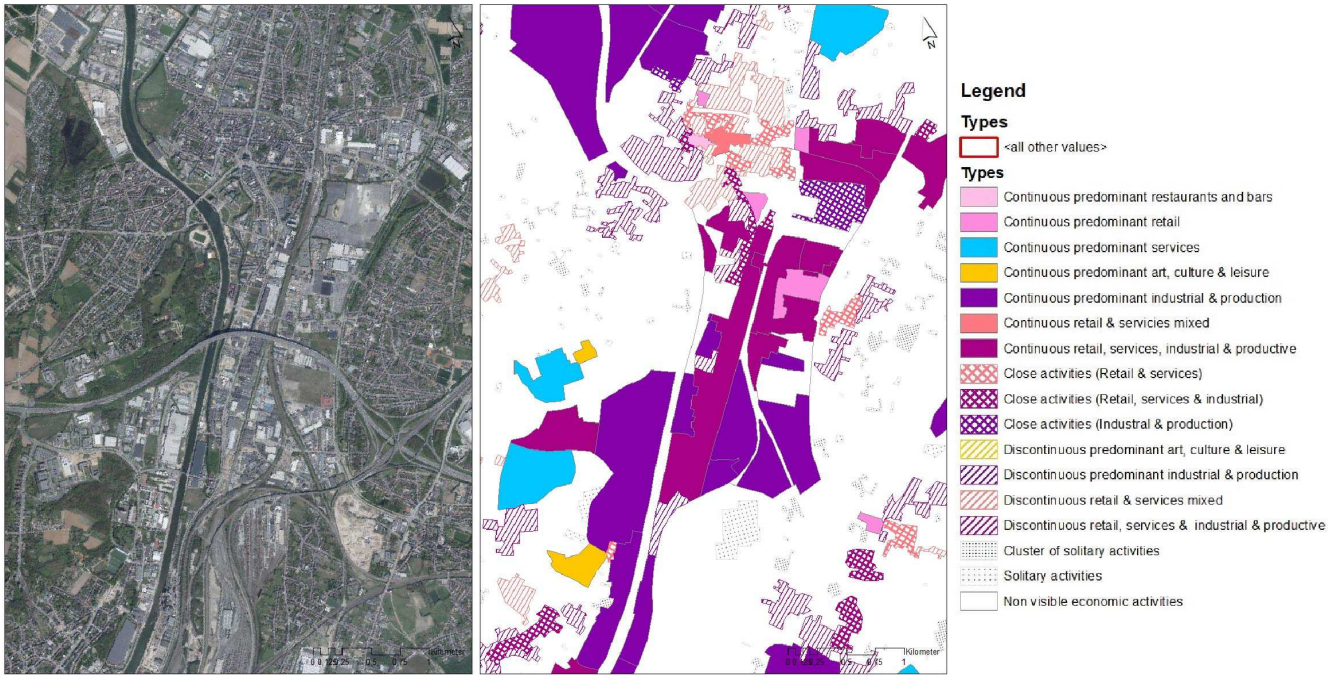

Fig. 3: Buda situation: orthophoto (left), Types of economic ecotopes in Buda (Central) and Type Legend (right)

Taking the step from types to segments in the Buda case, we attribute the most likely market segment to the existing areas. As both the set of demand parameters and of the product stratification are for a large part based on stated preferences of companies and policy makers, this does not necessarily correspond to a reality on the field. Everyone wants safe walking and cycling, but in real life this is not provided everywhere, especially not in industrial estates. As shown above in Table 1, the Segments map (Fig. 4) gives less detailed information for the non-continuous economic fabric, but highlights relevant site location factors such as visibility and accessibility. The Segments located along a main road or a high street are defined using local knowledge, additional data (such as population density) and network analysis. The morphological characteristics of areas surrounding solitary activities were used to create three different segments that focus on the interaction with either housing, agriculture or green areas.

In the following part of the paper we will show how this map of market segments can guide companies and policy makers to fully understand their decision making power. First, we will look through the eyes of a company that wants to move. Second, we will show how the segments can only be used to their full potential if all required services are provided, and last, we will demonstrate how market segments can contribute to the transformation of existing areas.

5 MINIMIZING COSTS BY CHOOSING THE RIGHT SEGMENT… AND A GOOD LOCATION

As shown in Figures 1 and 2, companies active in a specific type of activity could find a good location in almost any marked segment. Minimizing the cost of location depends on other factors than the trade or industry of a company. The 9 variables that describe the demand side of each market segment, can be used to help site location choice. As mentioned earlier, these variables are highly interdependent, meaning you only need to make a clear choice on three or four parameters to get a suggested type of ecotope. Furthermore, a

company may attach more importance to certain parameters than to others. We constructed several decision trees from the demand side.

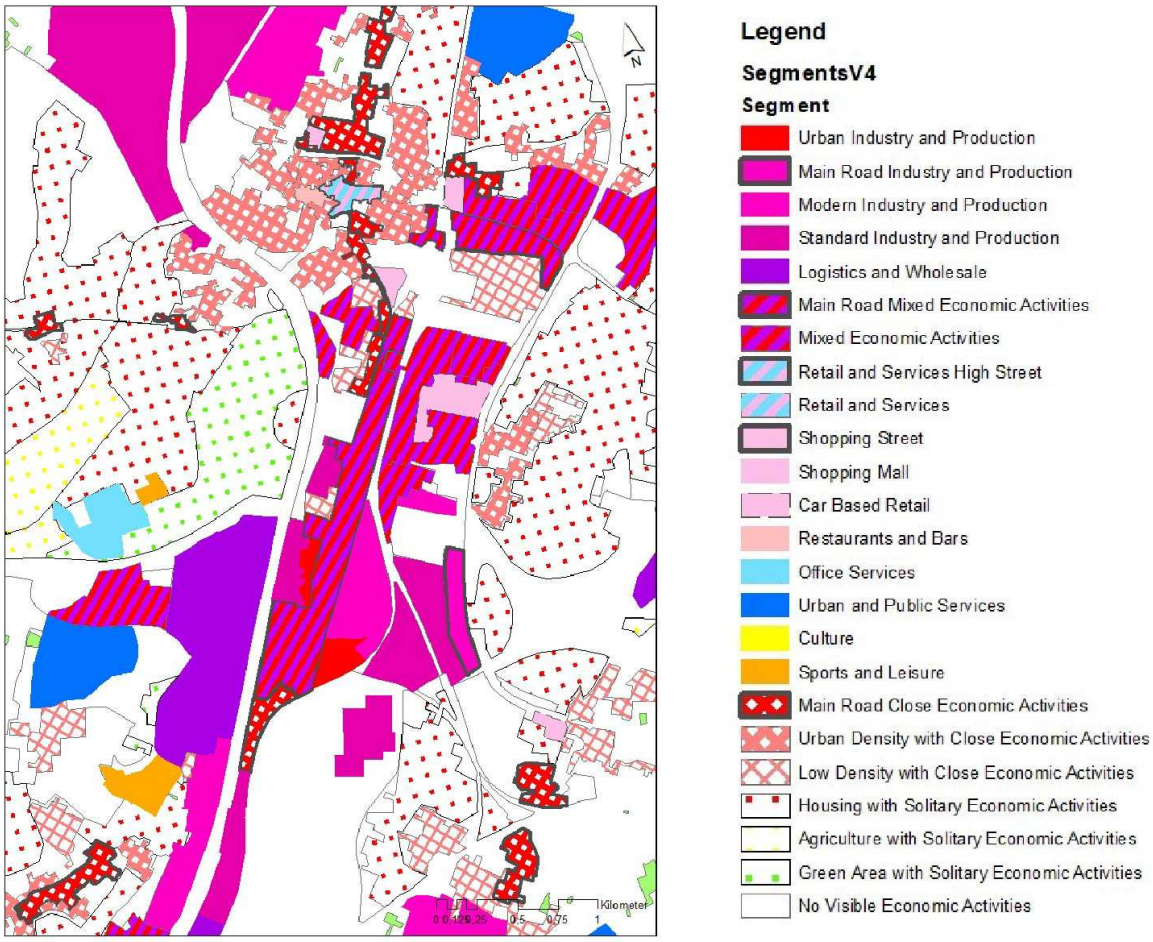

Fig. 4: Market Segments in Buda (Cross Border Brussels-Flanders)

In Fig. 5 you find a decision tree where the first question relates to rent price. This can easily be changed in a land purchase value (€/m² land) or building purchase value (€/m² floor). When we consider a furniture manufacturing company, it can use the decision tree depending on its specific activity characteristics. If it produces furniture on an industrial scale, the rent price, frequency of deliveries (1-5/day) and the indoor character would lead it to the 'Modern Industry and Production' segment. If is a highly specialised company that produces bespoke furniture and sells mainly through people seeing their products in their shop window, they may find it important to be visible on a high street and end up in the 'Retail and Services High Street' segment.

As the different parameters have a high interdependance, the scheme in Figure 5 is not the only way of getting to a suggestion for a market segment.

As mentioned above, the importance of certain parameters can vary according to the type of activity. That means that other decision trees will be developed, e.g. starting with the environmental impact of the activity, or with the characteristics of the area. An individual company can choose which cascade of questions seems more appropriate for its specific situation, or even use different decision trees in parallel in order to understand the nature of their 'Wicked Problem'.

6 OPTIMIZING THE COLLECTIVE BENEFITS /WELFARE MAXIMIZATION (VARIAN) BY PROVIDING THE RIGHT SERVICES

In the Buda case, we mentioned that the attribution of the 'most likely' Market Segment to an existing economic ecotope does not imply that all the requirements from the demand side are necessarily met. Most areas only approximate the 9 demand parameters and 26 product stratification characteristics.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The market segments (Fig. 4) suggest that you could have similar loading and unloading conditions in the same segments (e.g. Modern Industry and Production). However, the current situation (Fig. 6) shows that there is no clear relationship between the most likely market segments and the actual organisation on the field. For policy makers this is a good opportunity to improve these areas according to market segment. This can lead to communicate to existing and new companies what behaviour is expected from them and what services (e.g. space for loading and unloading, public space, other activities in the neighbourhood,…) the local government will deliver to accommodate the economic activities. In this way, governments are taking steps to welfare maximization by providing the right services.

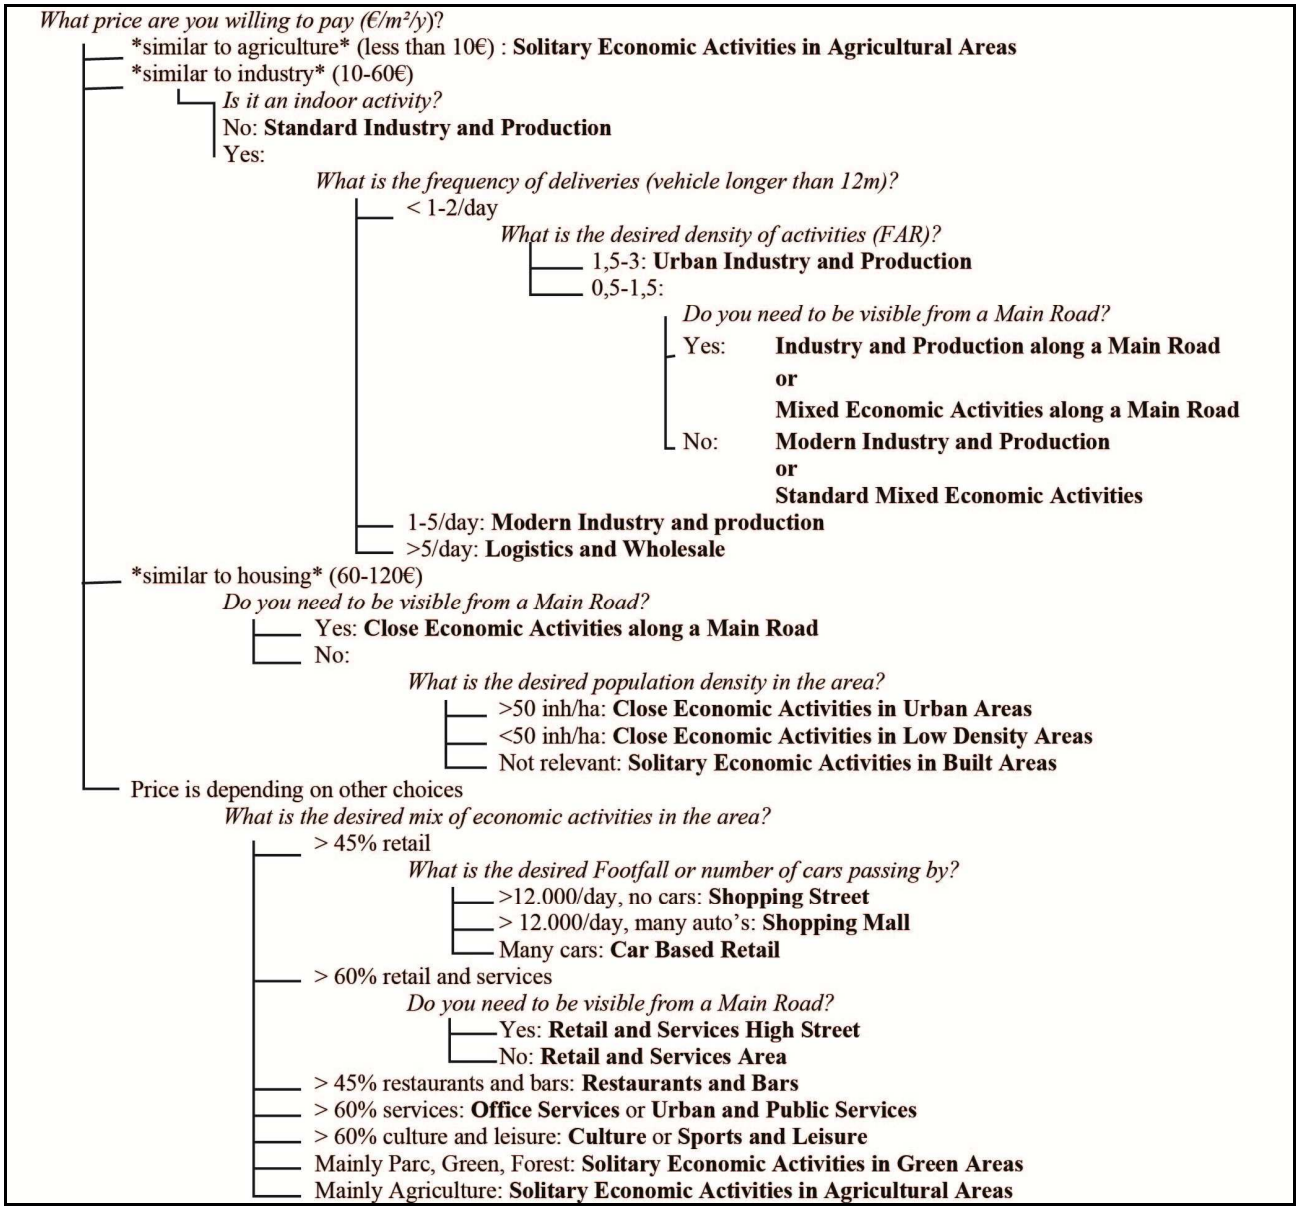

Fig. 5: Example of decision tree for site location choice between market segments

7 TRANSITIONS AND TRANSFORMATIONS

For policy makers, the creation of market segments based on an analysis of the current situation, is not sufficient. Especially in areas that are in a process of transformation at a high rate, such as Buda, the main objective is to redevelop large parts and therefore to change the existing segment into another segment. This will result in attracting new investments that are in line with the redevelopment goals, while existing companies will have to adapt to the new context or move to another location. For this purpose we will develop a different set of decision trees, with the 26 product stratifications parameters as a starting point. These trees guide policy makers through different main questions in order to get to a specific market segment. As a result, policy makers will get a clear idea about the most likely behouviour of companies in

this segment. Next to this, the trees will help them to get a clear understanding of what public services they have to provide.

Fig. 6: Current organisation of Loading and Unloading in Buda.

8 CONCLUSION

In this paper, we gave a brief overview of the spatial economic research we carried out and commisioned over the last 5 years. We started from the assumption that a new approach was needed to give economic planning an appropriate position within a spatial planning policy framework, in order to restrain green field development. The change from an urban expansion paradigm to a transformation of built up space paradigm necessitates a good understanding of the current economic functioning. By mapping economic activities on the field, and conducting many interviews and site visits, we got a good idea of territorial and spatial important parameters. The view point of micro economics and site location choice models gave crucial information. Thanks to this, we were able to move from an analytical tool to a decision support scheme for individual companies. In a final step we aim to transform the findings and maps into a policy making support tool, both for maximizing welfare and for the transformation of existing areas.

To get to a stable and fully developed spatial planning tool, more experiments and tests on the field are needed. We aim at combiing this with the elaboration of a separate set of decision trees.

Identifying Locations Suitable for Innovative Urban Public Transport Integration in Gauteng Province

Siphiwe Mbatha, Trynos Gumbo

(Siphiwe Given Mbatha, University of Johannesburg, Department of Urban and Regional Planning, Office 3rd floor, Buxton Building, Doornfontein Campus, Johannesburg, South Africa, gmbatha@uj.ac.za)

1 ABSTRACT

Globally, integrated urban public transport systems have been used as a solution to improve public transport services and reduce reliance on private cars which assists in reducing traffic congestion on the roads. In South Africa, Gauteng province is challenged daily with traffic congestion on the roads during certain peak hours. Therefore, the government of Gauteng province has developed innovative urban public transport systems - the BRT system and the Gautrain system - to improve the state of reliability and movement frequency of urban public transport. However, there is still a lack of reliability and of seamless travelling. This paper aims to explore locations where innovative urban public transport systems (BRT system and Gautrain system) can be further integrated in the province. The study adopted a qualitative research design that facilitated the gathering and analysis of spatial data and qualitative data from the innovative urban public transport officials, commuters and GIS data (BRT and Gautrain shapefiles). Results reveal that there are numerous locations that can be integrated where commuters can switch from one urban public transport system to another to improve travelling by public transport. The study concludes that this level of integration can create seamless travelling in the province and easy access to different modes of public transport. The study recommends that the identified locations need to receive attention as most commuters of these innovative UPT systems are located around these areas and to use the created model of the study to this effect.

Keywords: Urban Public Transport; Spatial Integration; GIS data; Reliability; Seamless travelling.

2 INTRODUCTION

Urban Public Transport (UPT) has become an increasing need to transport people from origin to destination. UPT is designed to reduce the various negative impacts on the roads. In developed countries UPT functions well with periodic improvements. In developing countries such as South Africa, UPT is not functioning at its best potential as planned, thus it struggles with attracting most of the private vehicle owners on the roads. Although Gauteng province has developed innovative UPT systems it still lacks public transport network connectivity within these systems. The objective of the study is to identify a way to attract more UPT users. Therefore, it aims to explore locations where more innovative urban public transport systems (BRT system and Gautrain system) can be integrated in the province. This is expected to improve the Gauteng province UPT network and hopefully attract many new UPT users.

3 LITERATURE REVIEW

Burt (2014), defines transportation planning as a cooperative process designed to foster involvement by all users of the system, such as the business community, community groups, environmental organisations, the traveling public, freight operators, and the general public, through a proactive public participation process conducted by the Metropolitan Planning Organisation (MPO), state Department of Transportation (state DOT), and transit operators. Transportation planning and design choices have a direct influence on development patterns, travel mode choices, infrastructure costs, redevelopment potential, the health of natural resources, and other community concerns. Transport planning/evolution and demand usually respond to how communities' function spatially (Redman et al., 2013) and, in some cases, transport planning can be used to force spatial change (Browning 2013). Further, transportation helps shape an area's economic health and quality of life. Not only does the transportation system provide for the mobility of people and goods, it also influences patterns of growth and economic activity by opening access to land. Transportation planning is more than listing highway and transit projects. It requires developing strategies for operating, managing, maintaining, and financing the area's transportation system to achieve the community's long-term transportation goals (Burt 2014).

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

According to Hidalgo (2009), the public transport planning phase is critical as part of an overall planning system, while the design element is tied to a management plan as it will involve planning of routes and stops integrated with location and frequency of use. What needs to be considered at the strategic level of planning the public transport system is long-term stability of a high service quality for the public transport system to influence urban development and create more sustainable transport patterns (Moyo et al., 2018). Consequently, Mbatha and Gumbo (2019), state that planning a public transportation system is a multi-objective problem that includes among others line planning, timetabling, and vehicle scheduling. For each of these planning stages, there are known models and advanced solution techniques. Some of the models focus on spatial integration, others on commuter convenience. Devising a transportation system is usually done by optimising each of these stages sequentially.

In some instances, the challenge is physical connectivity, as some transport modes are not entering certain locations and, in some cases, the problem lies in the planning phases. For urban public transport to function well, there are certain elements that need to be considered. In the planning process, there is a need to find the current demand and the relationship of movement between different public transport modes and environmental demands. There is a need to formulate a plan which predicts future travel demand and makes recommendations on how to deal with challenges that might occur. The plan needs to assess whether the proposal will meet demand and provide maximum benefit to the community. This includes monitoring existing conditions, such as future population forecast and employment growth; assessing projected land uses in the region and identifying major growth corridors; identifying current and projected future transportation problems and needs; together with detailed planning studies to analyse various transportation improvement strategies to address those needs. Urban public transportation planning in South Africa has been improving over the years as more strategies from around the world are adopted by the Republic. Several transport modes have been implemented in order to improve the state of public transport in the country. Bus Rapid Transit & Speed train are implemented in order to boost quality, efficiency, effectiveness and reliability of the public transport network. Existence of these modes can be found in Gauteng province.

3.1 Integrated Transportation Approach

Transport systems are complex and multi-dimensional with many parts that compose the whole. The objective of integrated transport planning is to find a balance among these dimensions so that planning and investment decisions contribute optimally to the economic, social, cultural and physical potential of the transport system and society in general. Integration is a concern with the whole, with common objectives and agreed desired outcomes. The different options, goals and points of view must be integrated to identify realistic solutions to community problems. Integrated transport planning is more than coordinated transport planning. It integrates multiple and sometimes-conflicting objectives to reach more sustainable transport outcomes that contribute to community, industry and government priorities. Further, it is significant that the transportation network is well established from the beginning of the development, thus designs need to incorporate links between roads to link and foresee enough space for future vehicle movement and potential smart transportation development. In South Africa, Gauteng implemented smart UPT, such as the BRT system in the City of Tshwane (A Re Yeng bus), Ekurhuleni (Harambee bus) and City of Johannesburg (Rea Vaya bus). The development of these concepts played a positive role as it brought more alternatives to UPT; however, it reduced the width of the road used by other vehicles - both public and private transport- leading to traffic congestion at certain peak hours. Hence, environmental challenges and high human health risk are arising due to time spent on the roads where cars release noxious gases (Mbatha and Gumbo 2019).

3.2 Physical and Network Integration

Proximity to, and ease of access at mode interchanges are greatly enhancing public transport services. Hence, walkways must be carefully designed for passengers to change mode. Passengers must be within a short walking distance from their residences to a transit stop. Cities like Hong Kong and Singapore have been able to build mass transit stops in the heart of neighbourhoods, thereby providing proximity to residences, offices and retail outlets. Bus and rail systems should be an integrated network whereby these separate networks are complementing one another. Feeder services using buses, trams or light rail should be designed to maximise the patronage of the trunk routes (Liu and Ceder 2017). Network integration is closely linked to physical integration and both contribute towards the integration of infrastructure. For instance, it is relatively easy to change between different lines on the London Underground (tube) network as tube stations have been

designed with several interchange points between tube lines (Moyo and Musakwa 2016). Cities such as Hong Kong, Singapore and Kuala Lumpur have been able to redesign bus routes so that they feed into and support the mass transit/metro lines (Luk and Olszewski 2003). Similarly, London's underground and buses connect with the overground heavy rail network to take passengers to their final destinations. An essential part of network integration involves timetabling services so that intra-modal and inter-modal services connect efficiently and effectively.

3. STUDY AREA

The study area is Gauteng province which provides many economic opportunities in the Republic with a land cover area of 18 176 m2/ The province is the heart of economic activity.

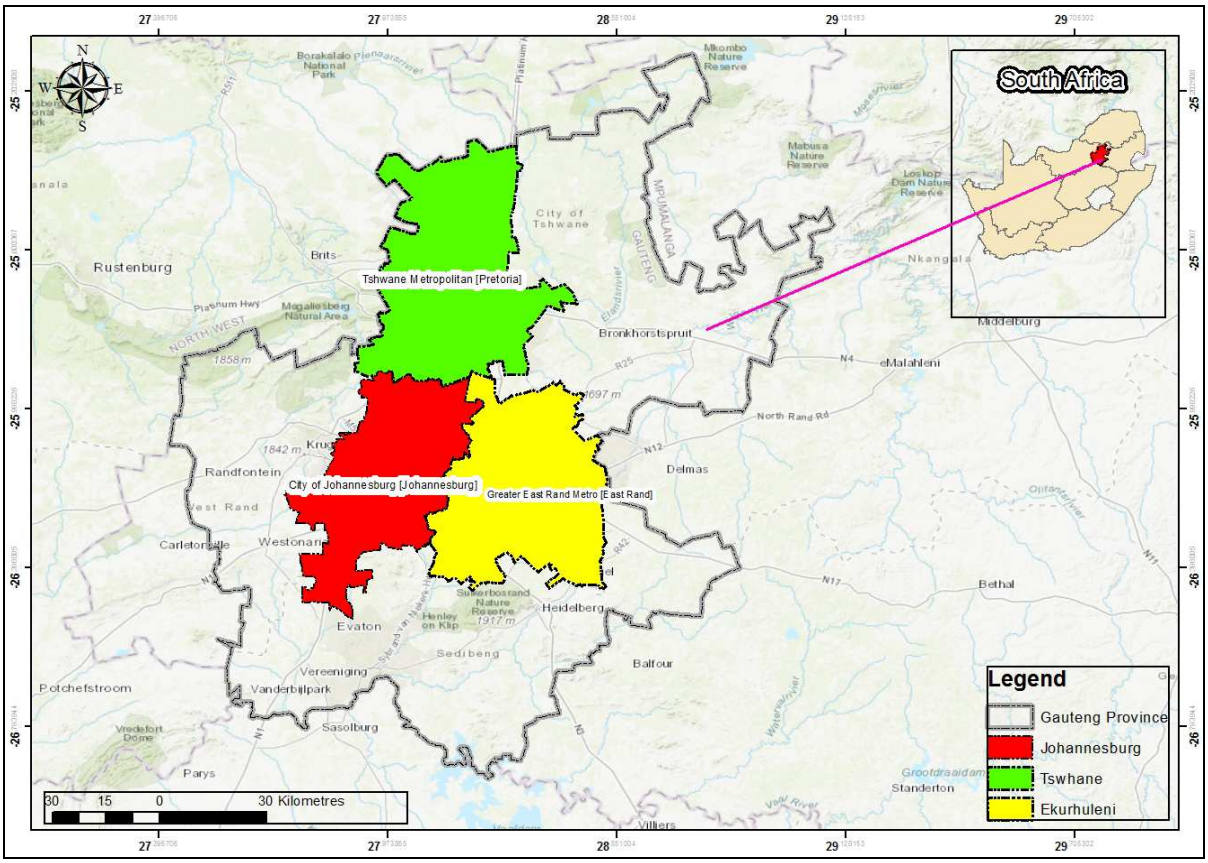

Figure1: Gauteng Province [Source: Author, 2020]

The depicted map (Fig 1) indicates the study area. According to Stats SA (2011), the population of Gauteng Province is 12,27 million. The study focuses on the formal urban public transportation system in the province, specifically Bus Rapid Transit (BRT) system and Gautrain system. The Gautrain system operates in selected locations in the province; however, it services all three metropolitan cities in the province which include the City of Johannesburg indicated in red, the City of Tshwane indicated in green and Ekurhuleni indicated in yellow. The BRT systems established in the province differ in names and work in the designated cities, and designated locations. In the City of Tshwane there is A Re Yeng bus, in the City of Johannesburg there is Rea Vaya bus and in Ekurhuleni there is the Harambee bus.

4 METHODOLOGY

A mixed method research design was adopted where qualitative data and spatial data analysis was used. Various research instruments were employed in the study. Ten interviews were carried out with officials from different departments, including the Johannesburg Road Agency, Department of Transport, Gautrain and BRT officials and Metropolitan Municipalities transport planners/ They assisted in providing insights for the study about the possibility of integrating the different public transport modes (bus and train) in general, and how to integrate the different entities of UPTs in the province. Accordingly, commuters were also interviewed to understand the commuter patterns and if there are any commuters who commute to and from one metropolitan city to another. 20 different daily commuters were interviewed who may have

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

different experiences taking place daily. Purposive sampling was adopted as it was necessary to conduct interviews with informed officials and commuters. ArcGIS assisted with creating Gautrain rail tracks; BRT route maps were showing locations serviced, together with physical integration of the FUPT modes. BRT data (shapefiles), Gautrain data (shapefiles), interviews and documented studies relating to this study were the sources of data. Experimental analysis was conducted in order to develop a model through kriging interpolation that explains strategies of identifying suitable locations for integrating innovative Urban Public Transport in the province. Further, content analysis was employed to review previous documented studies. Secondary data used was obtained from larger data base such as Scopus, Science direct, Sage and Google scholar.

5 FINDINGS

The results obtained for this study were from both interviews and kriging interpolation. Interviews is one of the most important technique to collect data as researchers can gather views of some of the important role players involved. Interviews conducted with the officials in Gauteng province, indicated that there are various alternatives of urban public transport modes which include both informal and formal urban public transport. The use of taxis, bus and train services are in operation. Commuters using the City/Municipality bus services are currently subsidised, based on multi-journey ticket sales, by Gautrans in terms of an interim contracts. The subsidy funds originate from the budget of the National Department of Transport (NDoT) (Department of Transport 2007). The City of Johannesburg and the City of Tshwane have implemented the BRT system to improve the state of formal urban public transportation in the province for some time while Ekurhuleni BRT is still new. Further, there are also trains which include types such as Metrorail and Gautrain. Metrorail has schedules which are slow but very cheap. On the other hand, Gautrain is very quick in terms of operating schedules but expensive to use. Implementation of the Gautrain system was both to improve the state of urban public transport and to connect the three metropolitan municipalities in the province.

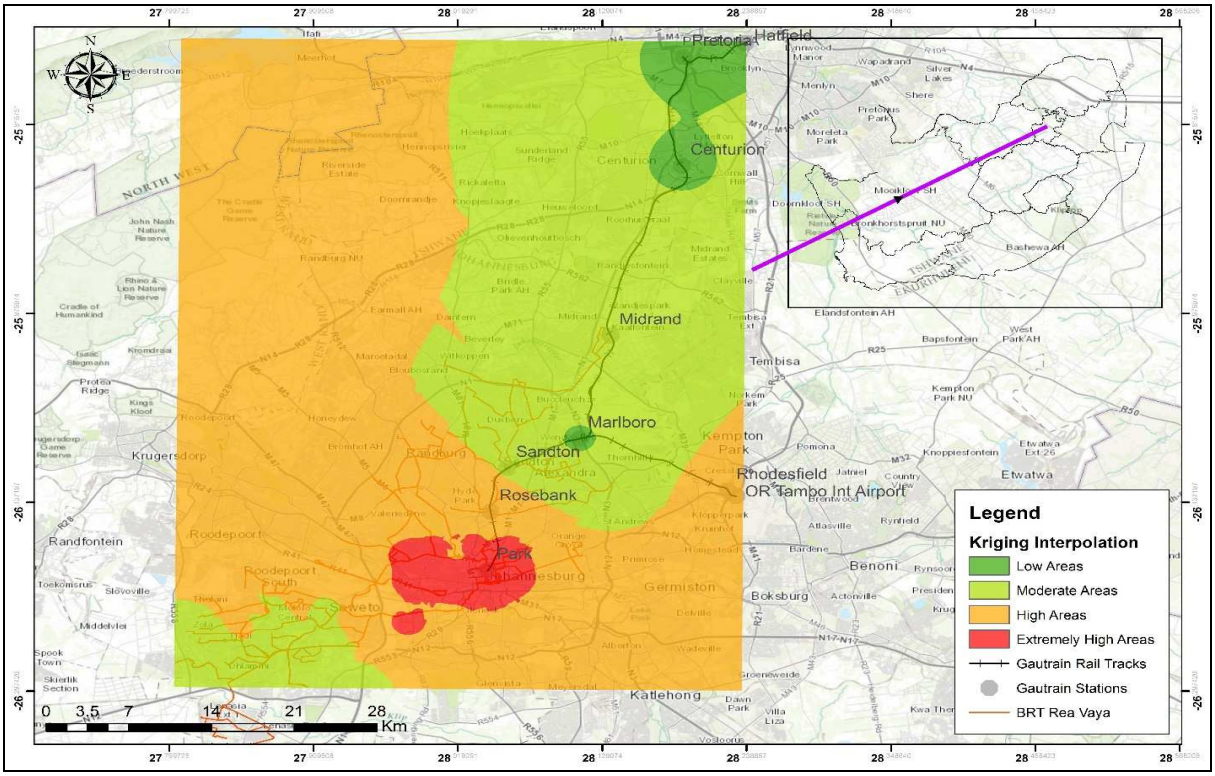

Figure 2: Gautrain and Rea Vaya Kriging Interpolation [Source: Author, 2020]

Officials highlighted that when these systems were developed plans put in place located these innovative UPT systems not far from one another. Gautrain was operating through all three metropolitan cities to act as a spine and connect with BRT systems in the three cities. It was found that the routes serviced by the BRT busses were mostly the busier routes. They were chosen for that purpose and could become potential route extensions planned to increase the BRT services to other locations in the province. Accordingly, this strategy

could lead to the physical integration of numerous routes in the province. Commuters indicated that there was also a need of spatial integration between the two systems as some of them travel between and within these three metropolitan cities and therefore an integrated system would be a positive asset for the overall UPT network of the province. Such integration would lead to seamless travelling which would less stressful for individuals who are travelling within the province.

5.1 Kriging Interpolation

When performing the analysis of UPT integration, this technique assists with creating a model that identifies the locations suitable for BRT and Gautrain integration in Gauteng province. This tool is important to identify hot spots and cold spots of locations concentration.

The map (Fig 2) indicates the suitable locations for physical integration in the City of Johannesburg between BRT Rea Vaya and Gautrain toward innovative UPT. In the index different colours are used to show different concentrations. All the areas overlaid by the location concentration indicate where there is a possibility for physical integration and/or a possibility for future expansions of these innovative UPT modes to develop an integrated UTP for Gauteng province.

Physically suitable integration locations	Percentage of suitable locations for integration%	Location Concentration
Red	15	Extremely high Concentration
Orange	40	High Concentration
Lime Green	30	Moderate Concentration
Green	15	Low Concentration

Table 1: Suitable locations for integration in COJ [Source: Author, 2020]

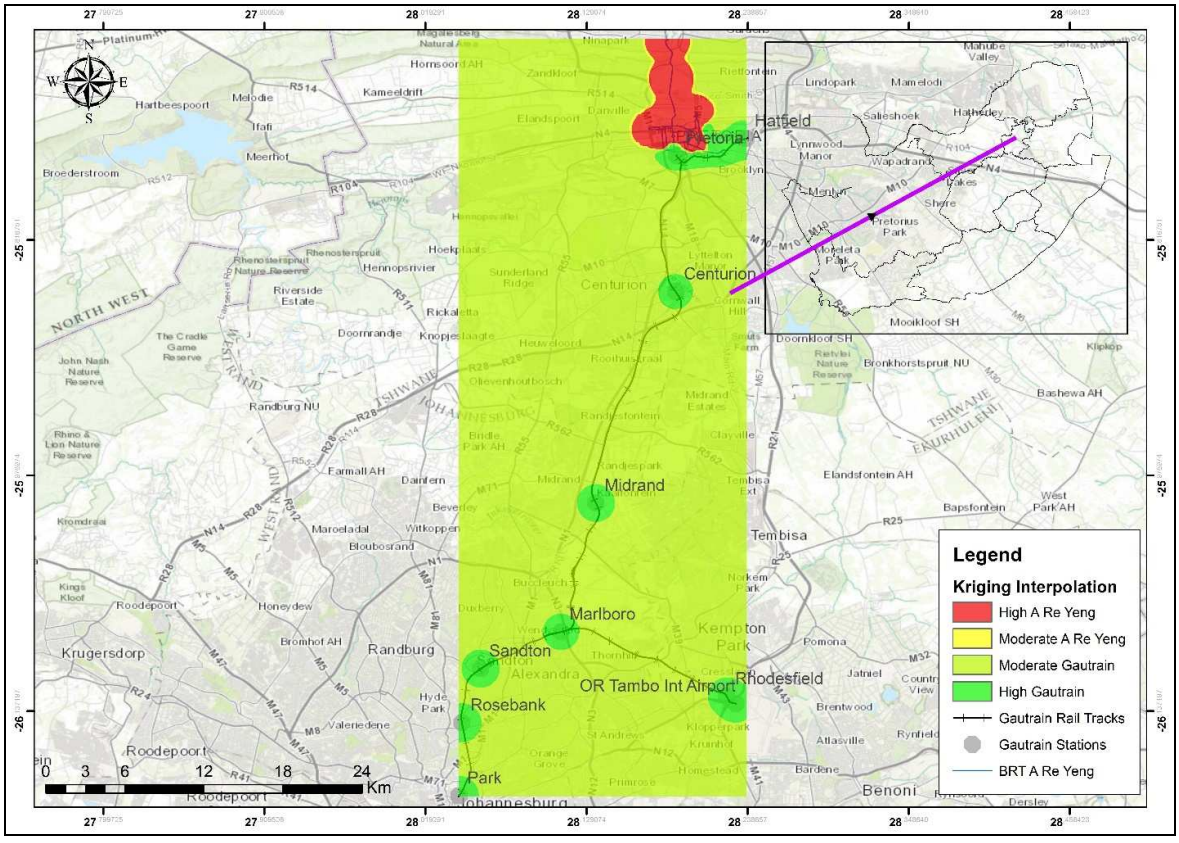

Figure 3: Gautrain and A Re Yeng Kriging Interpolation [Source: Author, 2020]

In the City of Johannesburg, Park station and its surrounding areas show extremely high concentration which is indicated in red. These locations indicated in red shows that it is suitable for physical integration in the city between Rea Vaya and Gautrain so that commuters can switch smoothly from bus to train. However, areas of 'extremely high concentration' in the city are very low in percentages and only identified in Park station and surrounding areas. 'High concentration areas' have a higher concentration percentage which is identified in

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

many locations in Gauteng province, moving towards Roodepoort where future Gautrain stations are proposed. Moving towards Ekurhuleni close to Boksburg there are also opportunities for future expansion of the Gautrain station. Rea Vaya services occupy some other locations in Roodepoort. This indicates that when the Gautrain station is being developed in Roodepoort, this presents the possibility of future physical integration between Gautrain and Rea Vaya. Consequently, 'moderate concentrated areas' show a slightly possibility of integration as there is transport network of either Gautrain or Rea Vaya. This indicate that there is a possibility of whereby future stations of these innovate UPT systems could be developed. Further, low concentrated locations indicate that possibilities for physical integration of Rea Vaya and Gautrain are unlikely to happen. Below it is the map indicating suitable locations for physical locations in the City of Tshwane.

The map (Fig 3) shows Gautrain and A Re Yeng kriging interpolation. This analysis was conducted to identify locations that are suitable for physical integration in the City of Tshwane between A Re Yeng and Gautrain. Gautrain rail track, Gautrain stations and BRT A Re Yeng routes were all added to make sense of the suitable location areas for physical integration.

Physically suitable integration locations	**Percentage of suitable locationsfor integration%**	**Location Concentration**
Green	20	High Gautrain Concentration
Yellow	5	Moderate A Re Yeng Concentration
Red	20	High A Re Yeng Concentration
Lime green	55	Moderate Gautrain Concentration

Table 2: Suitable locations for integration in COT [Source: Author, 2020]

The above index of location concentration highlights that most of the areas that are concentrated are close to the Gautrain rail track, Gautrain stations, A Re Yeng bus routes and A Re Yeng bus stations. All the areas far from this have 0% of concentration where there could be a possibility of innovative UPT integration. However, if in the locations where there is concentration expansion of rail track, roads and stations could take place, there could be more concentration throughout Gauteng province and more areas could be identified for suitable physical integration. In the City of Tshwane, both a high A Re Yeng concentration area and high Gautrain concentration area are identified. Where these two-high innovative UPT concentrations connect indicates the suitable areas for physical integration in the City of Tshwane. Most of the locations with high concentration which include Gautrain stations and A Re Yeng station refer to the possibility of integration, as there are existing stations around those locations. Moderate Gautrain concentration also indicate a possibility of where more stations can be developed in the province and a possibility of physical integration could take place. The map (Figure 5) shows the integrated network for innovative UPT in the Gauteng province.

The map (Fig 4) indicates the integrated innovative UPT network of A Re Yeng bus in the City of Tshwane, Rea Vaya bus in the City of Johannesburg and Gautrain moving around all three metropolitan municipalities. As mentioned earlier, there is a possibility of integrating innovative UPT in Gauteng province as there is spatial integration on some locations in the province. This would lead to seamless travelling in Gauteng province. Rea Vaya bus in the City of Johannesburg connects physically with numerous Gautrain stations, A Re Yeng bus in the City of Tshwane physically connects with two Gautrain stations while the Harambee bus is still new and only connects physically with one station in Ekurhuleni. Integrating the BRT system with the Gautrain system will create reliability in UPT and easy access to different locations in the province. There are people travelling daily around the three metropolitan cities for different reasons, mostly work and school. Commuters travelling from the City of Tshwane to the City of Johannesburg can use the A Re Yeng bus from origin (home) and switch modes at a Gautrain station (Hatfield or Pretoria central) to a Gautrain to travel to the City of Johannesburg. Consequently, when commuters get to the City of Johannesburg, they can use Rea Vaya from the integrated areas between BRT and Gautrain to travel to their destination (work, school or place of interest). Further, Rea Vaya services a larger area in the City of Johannesburg including South Western Township (SOWETO), Tembisa, Rosebank etc. Therefore, there are commuters from other locations in SOWETO who travel to Ekurhuleni and the City of Tshwane. Commuters from Soweto, Tembisa can use Reya Vaya to travel to the City of Tshwane and Ekurhuleni by switching in between at Park station to a Gautrain and travel to Ekurhuleni and the City of Tshwane. When commuters reach the City of

Tswane they can switch to an A Re Yeng bus to their destination (work, school, home or place of interest) and on the other hand when commuters reach Ekurhuleni, they can switch to a Harambee bus to their destination.

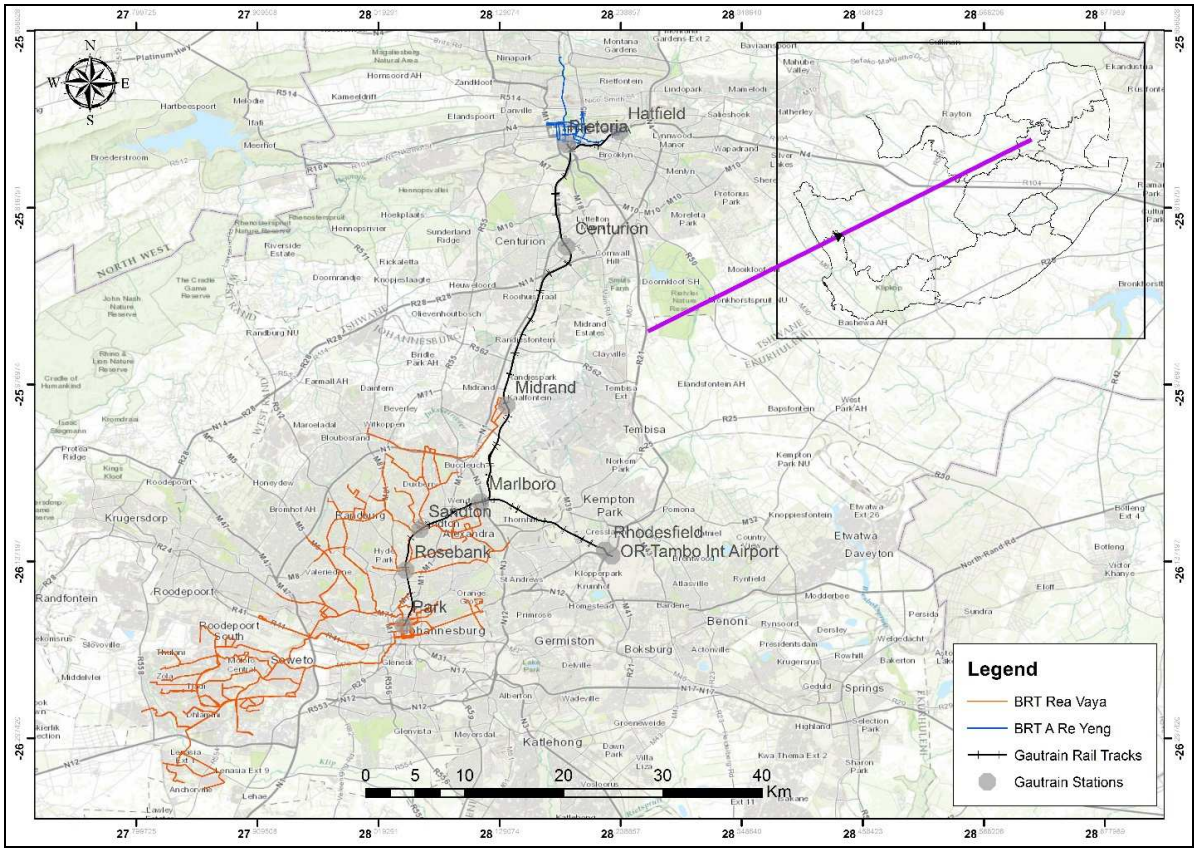

Figure 4: Integrated BRT and Gautrain Network [Source: Author, 2020]

6 CONCLUSION

South Africa is a developing country with good functioning UPT modes. Gauteng province has developed two of the world class UPT systems which are the BRT system and the Gauteng System. However, the study has indicated that these systems are currently not integrated which leaves a huge gap to commuters who use both UPT systems to reach desired destination. Therefore, an experimental analysis using kriging interpolation was performed to identify locations that can be suitable for physical integration in the Gauteng province. In the City of Tshwane, the results have shown a possibility for physical integration between A Re Yeng and Gautrain in Pretoria Central and Hatfield station. In Johannesburg the results have also shown a possibility for physical integration in Park station and other areas close by, and in Ekurhuleni Harambee is still small but over time it will increase and it will assist to connect Ekurhuleni metropolitan with the two metropolitan cities (COT and COJ). This shows that there is a possibility of bringing these services together and create one integrated transport network that will function across the province. Furthermore, the analysis also indicated areas which are possible for future expansion for implementation of stations to expand the transport network.

7 URBAN PUBLIC TRANSPORT INTEGRATION MODEL

Figure 5 explains the model regarding how to identify suitable locations for integration between the BRT system and the Gautrain system. Kriging interpolation was performed to designate suitable locations and help to identify current cold and hot spots of locations that need formal urban public transport services. When kriging interpolation was performed, first, Gautrain shapefiles and Rea Vaya shapefiles were combined to produce desired locations for integration in the City of Johannesburg. Second, Gautrain shapefiles and A Re Yeng shapefiles were combined also to produce desired locations for integration in the City of Tshwane. Kriging interpolation analysis was performed with an ARCGIS software. Lastly, the analysis also revealed locations that need services for the expansion of this UPT network. Accordingly, an

integrated network map was designed to show the integration of BRT with Gautrain from the City of Johannesburg to the City of Tshwane in Figure 4.

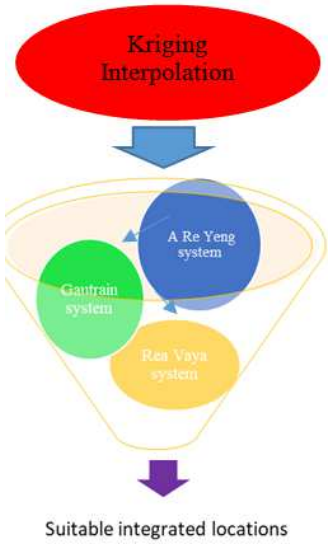

Figure 5: Spatial integration UPT model [Source: Author, 2020]

8 RECOMMENDATIONS

Adoption of integrated UPT network across the province is significant to attract more ridership of UPT and reduce private vehicle ownership and use on the roads resulting in less car accidents, less GHG emissions and producing smooth travelling from one city to the next. This is important, as in South Africa private car ownership increases regularly every year. The model used for the study can be adopted in order to identify suitable locations for UPT integration.

9 FUTURE STUDIES

Integrated UPT system allow for reliable, effective, convenient, safe, efficient and smart public transport in a certain place. The study focused on integrating spatially innovative UPT services in Gauteng province with the primary focus on both the BRT system and the Gautrain system. If there is a possibility of integrating these systems, the above-mentioned factors will take place. Therefore, there will be a need for such innovative UPT networks to connect all nine provinces in the country to create seamless travelling with well-functioning spatial integration. Future work will look at integrating UPT networks throughout South Africa.

1 ABSTRACT

Urban Public Transport (UPT) plays an imperative role in a society, it allows people to access different locations easily. Good urban public transport services attract more users reducing private vehicle on the roads and creating an environment with less gas emission produced. Key instruments used globally for good public transport service are policies and legislative frameworks. In South Africa, all three spheres of government National, Provincial and Local have implemented good urban public transport systems. However, in all the three spheres of government, there seems to be lack of connectivity of different systems of innovative urban public transport (Bus Rapid Transit (BRT) system and Gautrain system). Therefore, this paper aims to identify policies and legislative frameworks put in place to integrate innovative urban public transport in Gauteng province and what strategies can be implemented from these documents. The study adopted qualitative research approach were literature of previous documented studies, urban public transport drafted policies and legislative framework documents in South Africa, and interviews conducted with urban public transport officials. The results revealed that there are policies and legislative frameworks implemented, however, it is difficult to practice the strategies and ideas documented as these systems are owned by different entities. The study concluded that the provincial government need to identify ways of strengthening the available policies and legislative frameworks to integrate the different innovative public transport systems, by doing so, a common ground could be identified for integration leading to convenient public transport creating seamless travelling in the province. The study recommends that policies and legislative frameworks used in developed countries with good integrated urban public transport should be adopted and practiced in Gauteng province.

Keywords: Urban Public Transport; Integration; Policies and Legislative Frameworks; seamless travelling

2 INTRODUCTION

Globally, developed countries with good public transport system have good policies and legislative framework supporting sustainability, and integration to allow commuters easy access to UPT services. Urban public transport plays a significant role in the social and economic development of any country, and the National Government of the Republic of South Africa has recognised transport as one of its priority areas for socio-economic development. The effectiveness of the role played by urban public transport is to a large extent dictated by the soundness of the transport policy and the strategies utilised in implementing the policy (Chowdhury et al., 2018). Gauteng has developed innovative UPT in the past 10 years BRT system and Gautrain system. However, there is lack of integration in these systems. Therefore, the paper aims to identify policies and legislative frameworks put in place to integrate innovative urban public transport in Gauteng province and what strategies can be implemented from these documents for the province to have a world class functioning UPT.

3 LITERATURE REVIEW

Recently, integration of Pubic Transport (PT) systems has received attention from policy makers. Government authorities are investing in new infrastructure to improve the quality of PT services (Vassallo et al., 2012). Globally, regional plans are typically established to indicate amendments in the current system to alter it into a connected system. As most cities have an existing PT network, it can be difficult to create the changes that are required for integration. Implementation occurs in steps. For this reason, it is important to determine the key attractive features for the users (Chowdhury et al., 2018). The main purpose of an integrated transport system is to provide PT users with a “wide spectrum” of destination choices and with a convenient, accessible, comfortable, safe, speedy and affordable system (Ibrahim, 2003; Luk and Olszewski, 2003; Ulengin et al., 2007). Studies have shown that integrated systems can attract a greater number of users.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Ibrahim (2003) discussed that in Singapore, where PT use is considerably high at 60% of mode share, the government aimed to increase the mode share to 75% through integration. Matas (2004) investigated the significant increase of PT use (>40%) in Madrid, Spain from 1986 to 2004 and found the reason to be the changes made for integration. The study discussed that integrated fare system and network integration had the most impact on ridership. Buehler (2011) conducted a comparison study between USA and Germany and showed the ridership of sustainable transport in Germany to be greater; 40% of German travelers used sustainable modes (8% for PT) while only 11% of American travelers used sustainable modes (2% for PT). One of the reasons given was better integration of PT services in Germany. Abrate et al. (2009) assessed the impact of fare integration on the ridership of services from 69 Italian operators. The effects of integrated fare systems on patronage were 2% in the short-run and 12% in the long–run (Chowdhury et al. 2018). These, countries managing to improve to higher ridership have well design policies and legislative frameworks focusing on supporting integration.

The provision and management of well-integrated, affordable and reliable modern public transportation systems in South African cities is critical in ensuring both smart cities and mobility within them. Notwithstanding the evident benefits of modern urban public transport systems, governments of the developing world at all levels, have been struggling to plan for, develop and manage public transport systems of acceptable standards (Musakwa & Gumbo, 2017). African governments have been struggling to provide well-coordinated, efficient, reliable and affordable public transport systems in their ever-growing cities spatially and demographically (Risimati & Gumbo, 2018). Consequently, there have been spirited efforts in South Africa to not only enact relevant urban transport legislative frameworks and policies but also their implementation to facilitate the development of efficient modern public transport systems. Notably, South Africa has adopted several enabling policies and legislative instruments to promote innovative urban public transport systems since the realisation of the democratic dispensation in 1994 (Risimati and Gumbo 2019).

4 METHODOLOGY

A qualitative study research design was adopted with most of the data drawn from the policies and legislative framework. Some of the data was drawn from the key informant interviews to understand why policies and legislative frameworks can't be implemented or used practically with 3 officials from the Department of Transport, 2 officials from City of Johannesburg Metropolitan Municipality and Larger database. Larger database used are Scopus, Science direct, Sage and Google scholar. Secondary data sources were used such as journal articles, Newspaper articles and documents from municipalities. The publication of authors featured on many journal articles in search results were studied for any relevant information to assist the study. For preparation of this study, 50 publications were reviewed, and only relevant publications were used. Further, Up-to-date conference proceedings were reviewed to assist with the current awareness, improvement from industry practitioners and researchers. Secondary data is important in supporting the study based on what other studies revealed. Purposive sampling was selected to assist this study with relevant data, only UPT journals articles and other materials were used. Journals as well as other materials selected only focused on integrated innovative UPT, Policies and Legislative frameworks. Journal articles focusing on UPT not relating to this study were excluded. Distillation of existing literature and documented analysis was used for the data analysis. Documented analysis highlighting ways of supporting integration of innovative UPT through drafted and approved policies and legislative frameworks was conducted.

5 FINDINGS

Interviews from different personnel have indicated that there are different modes of innovative UPT in Gauteng province which are owned by different entities with different visions. With these different innovative UPT modes developed in Gauteng, it has been agreed that there is lack of integration and it is not easy to connect all these modes due to different objectives. However, the study has identified numerous policies and legislative frameworks supporting integration of different modes of UPT. These policies and legislative frameworks are implemented to support the modal shift from private vehicles to UPT. This will minimize several challenges on the roads such as traffic congestion, GHG emission and drive less by reducing private vehicles and drive smart by using innovative UPT. Below are the policies and legislative frameworks identified;

5.1 National Development Plan (NDP) 2030

The National Development Plan offers a long-term perspective for the entire country. It aims to eliminate poverty and reduce inequality by 2030. The plan identifies the improvement of the quality of public services as critical to achieving transformation. This requires provinces to focus on identifying and overcoming the obstacles to achieving improved outcomes, including the need to strengthen the ability of local government to fulfil its developmental role. Transportation planning aims of the NDP 2030 are focused on the need to address inherited spatial divisions and call for a strategy that focuses on the space economy to address the legacy of the apartheid geography and create conditions for more humane and environmentally sustainable living and working environments by defining a spatially targeted approach.

The need for modal shift from private transport in the long term is highlighted. Behavioural change is critical in reducing environmental, social and economic cost, by shifting user and supplier decisions about movement, travel and sources of energy. While some forms of private transport, such as the car, will still be used in 2030, a marked change to PT will emerge through concerted effort, strong leadership, consistent messages and actions, and public system alternatives that work. By 2030, PT will be user-friendly, less environmentally damaging, cheaper and integrated or seamless.

5.2 Draft Revised White Paper on National Transport Policy 2017

Integrated transport planning has experienced limited success and difficulties in implementation, in that integrated transport planning is subservient to prioritised public transport and associated planning, and land use and transport integration is missing from current practices. An integrated transport planning framework should be established that integrates planning for infrastructure and operations across different modes, integrates the transport system with other sectors, and fosters integrated transport planning between the DoT and other departments, across and within the three spheres of government using shared data and information.

The part of the policy's mission in to provide integrated, well-managed, viable and sustainable transport planning and infrastructure meeting national and regional goals in the 21st century, in order to establish a coherent base to promote accessibility and the provision of safe, reliable, effective and efficient transport services. Accordingly, the strategic objectives for ITP are as follow:

- To establish sound integrated intermodal coordinating structures and promote the provision of seamless intermodal services;
- To promote seamless integration and harmonisation of standards with neighbouring member states; and to develop a comprehensive transport data and information system to inform integrated transport planning decisions;
- To find a practical and reasonable solution that leads to an equitable distribution of infrastructure capital, management, operating and maintenance costs across transport modes;
- To encourage more urban land use densification, correcting spatial imbalances and reducing travel distances and times for commuting to a limit of about 40 km or one hour in each direction;
- To promote a strong, diverse, efficient and competitive transport industry within the limits of sustainable transport infrastructure;
- To enhance the competitiveness of South African industry and the quality of life of its citizens by providing protection of consumers, safety and security, and meeting accessibility, reliability and mobility needs by providing transport infrastructure to serve the purpose;
- To ensure that the transport needs of persons with disabilities are considered when new infrastructure and operations are planned and designed;
- To advance human resource development in the provision of transportation infrastructure and management of operations (Department of Transport 2017).

5.3 Green Transport Strategy for South Africa: (2018- 2050)

South Africa has launched a Green Transport Strategy in June 2019 (GTS). Green Transport Strategy promote a transport system that is environmentally friendly and help boost economic growth and create jobs. This aims to minimize the adverse impact of transport on the environment, while addressing current and

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

future transport demands, and encourages electric vehicle use and public transport enhancement. Fundamental to the greening of the transport sector is the seamlessly integrated functioning of the transport system. These integration policies and strategies have been defined in all transport sector planning, policy and strategy documents. Integration is the key principle on which all transport strategy rests for successful execution and functioning. In terms of the GTS, the modal shifts to rail and away from private vehicle use are premised on integrated transit and feeder systems that make far greater use of public transport and non-motorised transport.

GTS acknowledges the importance of advance technology in integrated transit systems as it notes that Intelligent Transport Systems have the potential to reduce GHG emissions and can be used through transport planning processes to provide advanced data via digital connectivity such as signal timing, real-time traveller information, incident management, etc. Transport planning and investment decisions can improve the operational efficiency of multi-modal transport networks and integrated transport and land use planning to reduce travel time. The DoT in consultation with National Treasury will provide a national team of experts to consult to all spheres of Government as infrastructure expands. The team of green transport integration experts will also consult to the Strategic Integrated Projects throughout their planning and execution.

5.4 National Land transport act of 2009

The national land transport act 5 of 2009 (“NLTA”) provides for the development and implementation of the Integrated Rapid Public Transport Network (“IRPTN”) plans by the metropolitan cities in order to provide uninterrupted public transport services to commuters. The Gauteng province consequently initiated the implementation of the IRPTN plan to improve the quality of lives of its commuters through facilitating an affordable and safe public transport services that will reduce the daily travel time between home and work. Bus travel time is naturally unstable since a small disturbance, such as a delay in boarding or alighting, can start a vicious cycle that results in bus unpunctuality. Further, buying a ticket for every public transport mode cost and take time. This reduce the attractiveness and the competitiveness of public transportation (Letaifa, 2015).

5.5 Gauteng 25-Year Integrated Transport Master Plan (2013)

The 25-year Integrated Transport Master Plan (ITMP25) contains a full Implementation Strategy for the transformation of the transport system in Gauteng over the next 25 years. However, given the current state of transport in the Gauteng City Region and the associated pressing problems and challenges, some urgent interventions are required. A number of various initiatives have been identified in order to integrate urban public transport in the Gauteng province. Regarding the study, integrated public transport ticketing and information are identified as one of the key importance initiatives.

5.5.1 Integrated Public transport tickets

In April 2011, Gauteng Department of Roads and Transport undertook the completion of Public Transport Systems Planning and Development of an Integrated and Interoperable Fare Management Framework. The objective of Integrated Fare Management (IFM) is to make it possible for seamless travel and transfer across an entire journey using a single fare media (and possibly a single fare) for different operators and modes of transportation. Furthermore, it is to promote an integrated fare collection system that will improve the transit experience and convenience for commuters. The IFM approach is to make public transportation systems more efficient by reducing the need for cash and cash management, and improving boarding times, which in turn reduces delays leading to better schedule adherence.

IFM relates to multiple operators (and multiple modes such as bus, rail, taxi) who deploy and accept the same fare collection mechanism for public transport services within a defined region. This type of system allows customers to travel throughout the region in a seamless manner. At a minimum, the use of a common fare media permits commuters to load individual Transit Products (e-Tickets or passes) from multiple operators as well as e- Money (electronic cash for fare payment) onto a single card. The purpose of the IFM Framework is to establish a common basis and vision from which to promote and execute Integrated Fare Management, towards establishing an integrated public transport system in Gauteng. The framework is being developed on a provincial level (to ensure consistency for strategic components), although operational components of the framework will be carried out primarily at a municipal level.

5.5.2 Integrated Public transport Information

The potential for collecting and integrating passenger travel information has always existed, but never realised because complex surveys were necessary to record this data. However, this problem has been resolved with the advent of Integrated Fare Management and the requirement for fare collection systems to comply with National AFC Regulations through the of use bank issued fare media. Many such electronic fare collection systems calculate and deduct a passenger's public transport fare through a "tap on tap-off" process. With the aid of vehicle satellite tracking systems this data translates into information on passenger travel patterns and volumes. A central data warehouse is required to be established in order to collect and collate this passenger travel data from different operators. The data can then be analysed to produce passenger travel information and real-time data for schedule information systems at stations and on-board busses. The advent of fast, reliable and affordable wireless/Internet communication has made it possible for travel information to be disseminated timeously and reliably via mobile phone (sms or social media), web sites and electronic signs. The use of an integrated, bank issued fare media must be established, through compliance with National AFC Regulations, followed by a Provincial Public Transport Data Warehouse. This will ensure the centralised collection of passenger data, to be disseminated as required once analysed. A Passenger Information Call Centre would be one means of co-ordinating the dissemination of such travel information.

5.6 Comprehensive Integrated Transport Plan 2015 - 2020

CITP 2015 to 2020 addresses all the chapters specified by the Department of Transport (DoT) CITP Minimum Requirements. The CITP is a statutory plan required by the National Land Transport Act No. 5 of 2009 (NLTA) and the Gauteng Transport Framework Revision Act. The CITP forms an integral component of the Integrated Development Plan (IDP). The CITP formulates City of Johannesburg, City of Tshwane and Ekurhuleni's vision, mission, policy and objectives for transport, consistent with the NLTA. The scope of the CITP has gone beyond what is required by the DoT in its minimum requirements, including aspects such as sustainable transport, aviation, road and public transport safety and security, intelligent transport systems, and micro-simulation of traffic in congested areas (Department of Transport 2007). The Gauteng province goals and objective are develop a transport system that improves accessibility and mobility whilst enhancing social inclusion, and provide a fully integrated public transport system. Consequently, develop a transport system that drives economic development, improve the safety and security of the transport system, and develop an efficient, effective, development orientated public transport system and integrates land use and public transport plans.

6 CONCLUSION

Improving the reliability of UPT services is a key priority and primary focus for the Gauteng Province Roads & Transport as stated in the Gauteng 25 - year Integrated Transport Master Plan. Consequently, National transport act 5 of 2009 ("NLTA") supports integrated UPT which provides for the development and implementation of the Integrated Rapid Public Transport Network ("IRPTN") plans. The City of Tshwane (A Re Yeng BRT), City of Johannesburg (Rea Vaya BRT) and Ekurhuleni (Harambee BRT) innovative FUPT services are the focus and Gauteng province is the primary unit of study. The aim of the study was to identify policies and legislative frameworks that supports the integration of innovative UPT. Therefore, policies and legislative frameworks have been identified. Accordingly, the province needs to initiate the implementation of the Integrated Rapid Public Transport Network policies in its Metropolitan cities to improve the quality of lives of its commuters through facilitating an affordable and safe public transport services that will reduce the daily travel time between home and work. Consequently, other policies and frameworks used in the province indicate strategies that could be used to strengthen and integrate different modes of UPT services, and this include integrated information dissemination, integrated payment system and spatial integration. With this, a common ground could be discussed, a working relationship for collaboration amongst public transport service providers with various entities to assist produce quality UPT services could be designed to benefit everyone. Non-integrated transport planning across various modes result in modes that are not sufficiently customer-focused and that are inefficient and have poor levels of reliability, predictability, comfort and safety. Such planning does not reflect the world-class aspiration of the NDP 2030. The fragmented nature of institutional governance over public transport is also not helpful. Therefore, there is a need for emergency solution to adopt and implement right policies and frameworks in the province.

7 RECOMMENDATIONS

Policies and legislative frameworks in Gauteng province supports the integration of urban public transportation as their strategies of improving the public transport are focusing on integration. Therefore, the study recommends the adoption of the available policies and legislative frameworks in the province. Policies are available, however, the challenge they are not implemented practically. This is due to that, some entities are private and the others are public. Cooperation of public and private entities will strengthen the province's public transport. Therefore, policies and legislative frameworks need to support the relationship between the two (private and public) as they bring different perspective in UPT services. Further, countries with developed UPT make private and public entities relationship workable this include fare collection, information dissemination that is inline with one mode to the next and spatial integration with good transport networks. If such can be implemented at a global level, Gauteng province is capable as there is availability of innovative UPT. South Africa, Gauteng province, could adopt strategies used by these countries providing good UPT services.

Improving Urban Regulations to Raise the City's Green Area Rates to Achieve Quality of Life Standards

Youssef Abdelhakeem Elsayed, Said Hassanien Al-Sayed

(Dr Youssef Abdelhakeem Elsayed, High Institute of Engineering-Thebes Academy for Sciences-Cairo-Egypt, johakeem@hotmail.com)
(Dr Said Hassanien Al-Sayed High Institute of Engineering-Thebes Academy for Sciences-Cairo-Egypt, siag_gis@yahoo.com)

1 ABSTRACT

Open and green spaces are comfort elements and the necessary essential landscapes to improve the urban tissue and promote the urban environment of the city. This increases the level of welfare and contributes to the economic and aesthetic value of the city to achieve the quality of life standards. The Urban Regulations represent the cornerstone which help in reformation of a distinguished urban environment. The urban environment is planned through two important elements: buildings (residential –services) and spaces (public –streets –green). The Urban Regulations of the city are the mail element of planning buildings and system of public spaces, which determined the green spaces of the city, whether horizontal represented in (gardens and parks, green spaces, and green spaces in roads, routes and spaces) or vertical represented in (green spaces on building roofs, and vertical spaces on building façades). Therefore, it is necessary to evaluate the current Urban Regulations of construction in some Arab countries to plan a green urban as one of the regulations of the regulations of quality of life standards. This is the research objective.

Keywords: Quality of Life Standards, Green Area Rates, Urban regulations, Green Urban Formation, Arab countries

2 QUALITY OF LIFE AND GREEN SPACE

2.1 Quality of life

The green urban design in cities is one of the tools that helps in recognizing the quality of life standards among people, as the quality of life standards represent the full satisfaction of urban. There is a strong relationship between one of the tools, which is considered as the most important one, of green urban planning represented in (buildings and green services, horizontal and vertical green spaces, and green roads) and quality of life standards represented in (satisfaction of urban planning of a city, satisfaction of natural environment, social satisfaction, satisfaction of city economics). Therefore, we get acquainted of the quality of life standards and definition of green urban planning.

2.1.1 Definition of quality of life

Definition of Quality of Life is a wide and complicated definition, which includes various definitions. In brief, the definition of quality of life measures the level of satisfaction in relation with the most important aspects of individual life. In order to reach a specific definition of quality of life, an integrated research program was conducted to determine the most common definition. The initial research defined number of global indicators that define and measure the quality of life from various aspects. Each indicator was tackled in details for determination of the common elements. [1]

We depended on six indicators of the most important comprehensive indicators, which are globally known as main references: [2]

- Global Liveability Ranking: It is an annual indicator issued by the Unit Intelligence Economist, which categorizes cities in 140 countries in accordance with the urban quality of life, settlement evaluation, healthcare, culture, environment, education, sports, infrastructure, public spaces, and green spaces.
- Mercer Quality of Life Survey: It categorizes 231 countries based on the following aspects: transport, political, social and cultural environment, public service, health, economic environment, schools, education, natural environment, housing, and provision of media, theaters, cinemas, sports, commodities, restaurants, recreation, entertainment, and picnicking.
- Monocle Magazine List for Quality of Life: It is an annual list including 25 cities of the best cities for living around the world. The evaluation is based on the following aspects: global

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

telecommunication, environmental issues, accessibility of nature and green places, urban quality, quality of urban designing, healthcare, and infrastructure.

- Happy Planet Index 2017: It categorizes 155 countries in accordance with the levels of happiness based on the following aspects: corruption, free choice, average life expectancy, gross domestic product for individual, social support, and granting.
- Organization for Economic Co-operation and Development Quality of Life Index: It is an index, which compares quality of life among countries based on 11 main aspect in accordance with the Organization: security, health, income, jobs, urban balance, life, work, education, level of satisfaction, housing, environment, society, and civil participation.
- ARRP Quality of Life Index: It is a distinguished initiative by the Policy Public Institute (for Measurement of quality of life of American communities based on the following aspects: transport, health, economy, education, housing, urban quality, residential districts, environment, community participation, and equal opportunities. [2]

2.1.2 Urban aspects of quality of life

Urban quality of life is a multidisciplinary and cross-cutting definition between a network of different aspects. The urban quality resulting from the relationship between these combined and compounded aspects consisting of seven aspects –contributes to the achievement of urban quality of life (environmental, urban, mobility and transport, social, psychological, and political). [3]

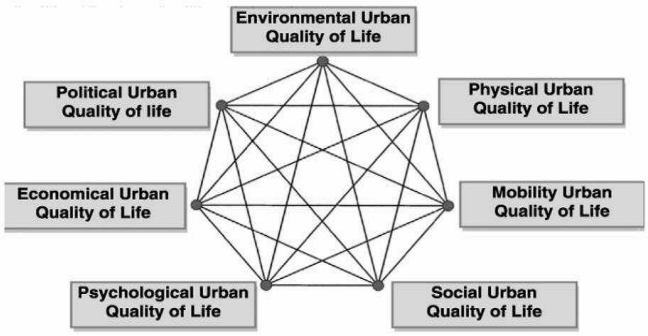

Fig. 1: Urban Quality of Life Aspects.

2.1.3 Quality of life standerds

A group of standards and principles, which achieve the quality of life, were derived by the European Union through a survey about (quality of life in European countries) in 2013. This group included all capital cities in the European countries, which reached to 79 cities. It was approved by the EU General Directorate of Regional and Urban Policy. It concluded to the following urban results, which achieve the quality of life as follows: [4]

Satisfaction of Urban Planning through:	
Sustainable Public Transport	Healthcare Services
Sport Facilities	Cultural Facilities
Educational Facilities	Availability of Shopping and entertainment stores
Administrative Services	Streets and Green Roads
Pedestrian Sidewalks	Public Parks
Public Green Spaces	Complementary Green Spaces
Security and Safety	
Satisfaction of Nature Environment through:	
Quality of Air	Quality of Hygiene
Quality of Water	Combating Climate Changes
Social Satisfaction:	
Feel of Happiness	Participation and Influence
Community Bonding	Living Place
Satisfaction of City Economics:	
Prices of Lands	Job Opportunities
Family Income	Housing Capabilities

Table 1: quality of life standerds

2.2 Green spaces

2.2.1 Benefits of green spaces. [5]

- Improvement of Environmental Conditions in Cities
    - Some of the problems which face cities are air pollution, urban heat island, and severe temperature in summer and winter. The foundation of urban biodiversity is the solution for these problems, as it largely contributes to improvement of environmental conditions in cities in several methods:
    - Green spaces work as CO2 absorbents. It is the gas, which is responsible for climate change. For each 100 m2 of green roofs, the gas, which is responsible for global warming, reduces to be 1.8 ton annually. In addition, installation of 100 m2 of green roofs above buildings results in producing oxygen for 100 persons annually.
    - Pollution resulting from 15 cars annually can be removed by 100 m2 of green roofs, as the leaves of the green space can keep these harmful particles on their surface.
    - Green spaces can reduce the surrounding temperature of cities of 1° C, which reduces the phenomenon of urban heat island and harmful smog in the city. In the same manner, it prevents the urban environments, which are more cold of 1° C, the harmful ozone layer, which happens during the emergence of severe temperature cycles.
    - One of the other features of green spaces that it keeps 40% of rain water too, and can delay disposal of water for 18 minutes in cycles of heavy rains. In addition, it prevents the collapse of sewage network in urban areas.
    - Green spaces work as filters for many harmful air pollutions; for example, 1 meter of green space can keep up to 200g of small health-harmful polluting particles annually.

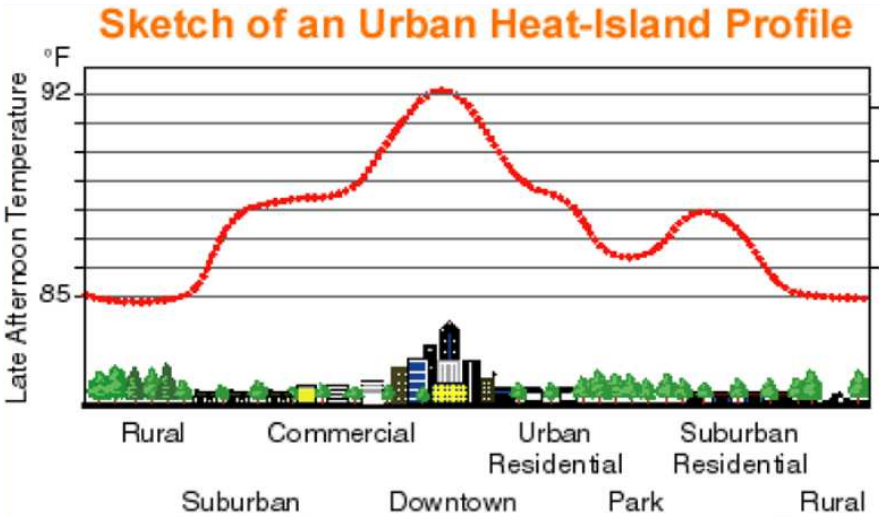

Fig. 2: Urban Heat Island Profile

- Green Space Ratios are one of the Most Important Urban Regulations in Cities

Recently, cities management witnessed the need for ensuring the availability of green spaces in cities to improve the environmental conditions and citizens' health and welfare. In addition, the green infrastructure, promotion of the nature capital of Europe (2013), is one of the EU initiatives to promote designing and establishing of more nature areas for sustainable development. Since 2013, Member States work on implementation of these guidelines through development of new policies aiming at achievement of environmental, economic and social benefits through natural solutions. Thereupon, the urban green spaces indicator allows the measurement of green space for each person in the urban areas, in addition to the green space in the city. In accordance with the World Health Organization, there is a need for 10 to 15 m2 of green space for each person to ensure healthy urban environmental system through various methods to merge green spaces and plan green architecture; for example, vertical gardens on building façades, green roofs, green roads, and urban parks.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

- Improvement of Cities Attractiveness

Beauty can change our view of life in the city. Decoration of building with green spaces does not enrich its architecture only, but also provides an attractive area for people who spend most of their time at the building. This promotes creativity and encourages innovation. Therefore, green cities have many psychological benefits; for example, vertical garden, green roofs and gardens increase city attractiveness, as people believe that it has better quality of life and more healthy and sustainable spaces. In addition, direct communication of green spaces promotes using of renewable energy and greener quality of life. In addition, modern studies show that more travelers choose sustainable destinations and visit cities that are committing to environment and nature, which is characterized by its environmental attractiveness, as it includes many green spaces, high quality of air and huge biodiversity.

- Improvement of Thermal Isolation of Buildings

Installation of green roofs on buildings and private houses provides more isolation resulting in cooler temperature in summer and warmer weather in months that are supposed to be the coldest. In addition, this reduces consumption of energy by 25% in summer and 10% in winter.

- Social Cohesion

In accordance with recent studies, cities with green spaces promote social cohesion and relationships. Who do not like to walk in a green park, or ride a bike or read a book under a tree? It provides points for sharing and establishing bonds between city people. In addition, green spaces positively affect people behavior, as urban garden build and develop relationship between neighbors and promote community bonds and feeling of identity.

- Improvement of People Welfare

In accordance with the World Health Organization, urban green spaces are necessary for people welfare, physically and emotionally. This means that people who live in cities with more gardens and parks have better quality of life that those who live in a high volume of pollution. The allocation of a part of the day for walking or relaxation in green space can make us feel comfort and think well. It reduces life pressures in the city. London is one of the most crowded and fastest growing cities around the world. Few years ago, London has changed some of its urban areas into green spaces to improve life of citizens and their relationship with nature.

Fig. 3: improvement of people welfare through green spaces

2.2.2 Considerations of green spaces desining[6]

- Distribution of green spaces near people.
- Diversity in green spaces.
- Simple design of components of green space.
- Maintenance of green spaces.
- Application of plan principles and ratios.

2.2.3 Green spaces impacts[6]

Green Space Criteria			
accessibility	Aesthetic	Amenities	Management
Location-distance -size - quantity-quality - security	Landscape - quality - perception	Infrastructure - service	Frequency- pesticides- watering

Table 2: Green Space Criteria

Green Space Impacts		
Use and function	Setting features	Environmental regulation service
Active mobility - Food production – Gardening - Physical - activity and sports - Relaxation and leisure - Social exchange	Impact on land price and rent levels - Medications of living environment and residential quality	Biodiversity support - Carbon storage - Pollution regulation - Soil protection - Temperature regulation - Water regulation

Table 3: Green Space Impacts

Pathways to Health		
Individual status	Physical environment	Social environment
Healthy lifestyle - Immune system function - Mental state - Physical fitness	Air quality - Climate change adaption - Neighborhood quality -traffic emissions - Water quality	Living expenses - Safety issues Social cohesion interaction and participation

Table 4: Pathways to Health through Green Space

3 URBAN REGULATIONS AND GREEN SPACES RATIOS

3.1 Definition of urban regulations

The urban regulations is a group of legislations, general regulations, decisions, and practices that control the urban environment in order to improve the Livelihoods and living conditions. However, the urban legislations failed in many developing countries in guiding and supporting sustainable urban development and modern urban orientations in addition to implementation of urban regulations and legislations efficiently. There is a gap between the urban legislations and regulations and objectives and tools of sustainable development, which must be improved and developed to get the urban quality ratios to the highest levels

3.2 Green spaces in Egypt

Green spaces is one of an important and essential element in modern cities planning, as it contributes to development of cities and districts development from the environmental aspect. Lack of green spaces or its low availability results in environmental imbalance of this area, which lacks of trees and gardens. In accordance with the global ratios, which is different from one country to another in accordance with the site and geographical nature of the country, each 5000 people “who are living for example in one district or neighborhood” shall have 3000 m2 of green spaces. These are the average ratios, which apply to the geographical nature in Egypt. By applying the mentioned ratio to the number of people in Egypt, which is 96 million people currently inside the Country, we need to provide 85 million square meters of gardens and parks. However, the existing spaces as mentioned by the Central Agency for Public Mobilization and Statistics are shocking and totally far from the space that should be available across the Country.

The existing green spaces in Egypt are less than 10% of the spaces that should be available to the current population of Egypt, as it is supposed to be “75 million square meters, while the Country, in accordance with the official statistics issued by the Central Agency for Public Mobilization and Statistics, has only 5,370 million square meters only”.[7]

3.2.1 Problems

- Change of cities into cement forests destructing its nature and green spaces: the sole lung and breath for the people.
- Poor distribution of green areas.
- Controlling the mechanics on the urban planning in unfair infringement of pedestrians rights and needs.
- Non-availability of human dimension and scale in designing the existing open spaces.
- Domination of constructed elements on natural landscapes on open spaces.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

- Poor utilization of the existing open spaces

3.2.2 Reasons

- Lack of thinking including planning strategies of green spaces at national, regional and local levels.
- Lack of comprehensive definition for open spaces network, which results in poor distribution of choosing sites and lack of linking to each other.
- Lack of financial resources that allow provision and maintenance of open spaces.
- Increase of population and construction density and increase of construction value of lands, which result in poor utilization of open spaces.
- Neglect and deterioration of the little existing open spaces, and non-maintenance of them periodically.
- Lack of environmental awareness of visitors and users of open spaces and non-application of urban regulations for standards.

3.3 Current Urban Regulations and requirements to the Ratios of Green Spaces

The green spaces are in all planning levels (neighborhood –district –city) and include different spaces for children playing in accordance with different ages, which is necessary for health aspects. However, they are used in cultural and social aspects, as they are used for festivals and public events in different occasions. [8]

3.3.1 City Park (Planning Ratios of Green Spaces)

- Serviced population: (40) thousand population and more.
- Green space around (0.3 -0.4) m2 per capita.
- Total proposed space (20000) m2 and more.
- Provision of car parking; one parking for (2) garden workers, one parking lot for (4) visitors.
- Provision of more waiting areas in the park to serve a specific part. Such parking shall be linked to entrances and exits of the park and internal roads to distribute the motion well

3.3.2 Residential District Park (Planning Ratios of Green Spaces)

- To be available at residential districts in big cities and at small capitals.
- Serviced population: between (15-25) thousand population.
- Green space around (0.4 -0.5) m2 per capita.
- Total proposed space (0.6-1.2) Hectare.
- Provision of car parking; one parking for (4) visitors.

3.3.3 Residential Neighborhood Park (Planning Ratios of Green Spaces)

- To be available at residential neighborhoods.
- Serviced population: between (3-5) thousand population.
- Green space around (0.9 -1.2) m2 per capita.
- Total proposed space (2700-6000) m2.
- Provision of car parking; one parking for (4) visitors.

3.3.4 Children Play Yards (Planning Ratios of Green Spaces)

- To be available at residential neighborhoods or residential groups in all cities.
- Serviced population: between (1500-4000) population.
- Play yards around (0.22-0.33) m2 per capita.
- Space of play yards: (500-900) m2.
- Provision of car parking; one parking for (4) visitors.

3.3.5 Big Gardens and Specialized Quality Gardens (Planning Ratios of Green Spaces)

- To be available at national and big regional centers, in addition to big cities and capitals.
- Serviced population: (100) thousand population and more.
- Big gardens around (0.6-0.8) m2 per capita.
- Space of play yards: (60000) m2 and more.
- Provision of car parking; one parking for (2) park workers and one parking for (4) visitors.

Green Spaces	Population (Thousand)	Per Capita (m^2)	Total Space (m^2)
City Park	40 and more	0.30 -0.40	20000
District Park	15-25	0.40 -0.50	6000 -12000
Neighborhood Park	3-5	0.90 -1.20	2700 -6000
Children Play Yards	1.5 -4	0.22 -0.33	500 -900
Big Gardens	100 and more	0.60 -0.80	60000

Table 5: All Proposed Levels of Green Space Standards

3.3.6 The current per capita green area according to the current urban regulations in some Arab countries

Indicator	Damascus Syria	Manama Bahrain	Dubai Emirates
Area (km)	105	30	4.12
Per Capita Green Space (m^2 per inh.)	0.70	2.5	13.18

Table 6: the current per capita green area in some Arab countries

3.4 Global Ratios of Green Space Distribution

3.4.1 percentage of Green Space Distribution in the City .[9]

It is a simple and clear indicator, but its negatives can be distracting in case of high densities of residents, high building ratios, and high ratios of heights, but the minimum level usually between 10% to 20% of the space of the city. For example, in Germany, the percentage is 40% to 50% for most of the German cities.

3.4.2 Ratios of Green Space Distribution in the City. [10]

Indicator in Europe	Western	Southern	Eastern	Northern
Area (ha)	29625.04	25595.24	18958.96	48816.15
Residential Area	4936.69	2489.48	2665.92	5661.93
Green urban areas	853.24	399.2	462.06	1288.32

3.5 Leading Models of Green Urban Planning to achieve Quality of Life Standards: Malmö [11] and Nantes Metropole [12]

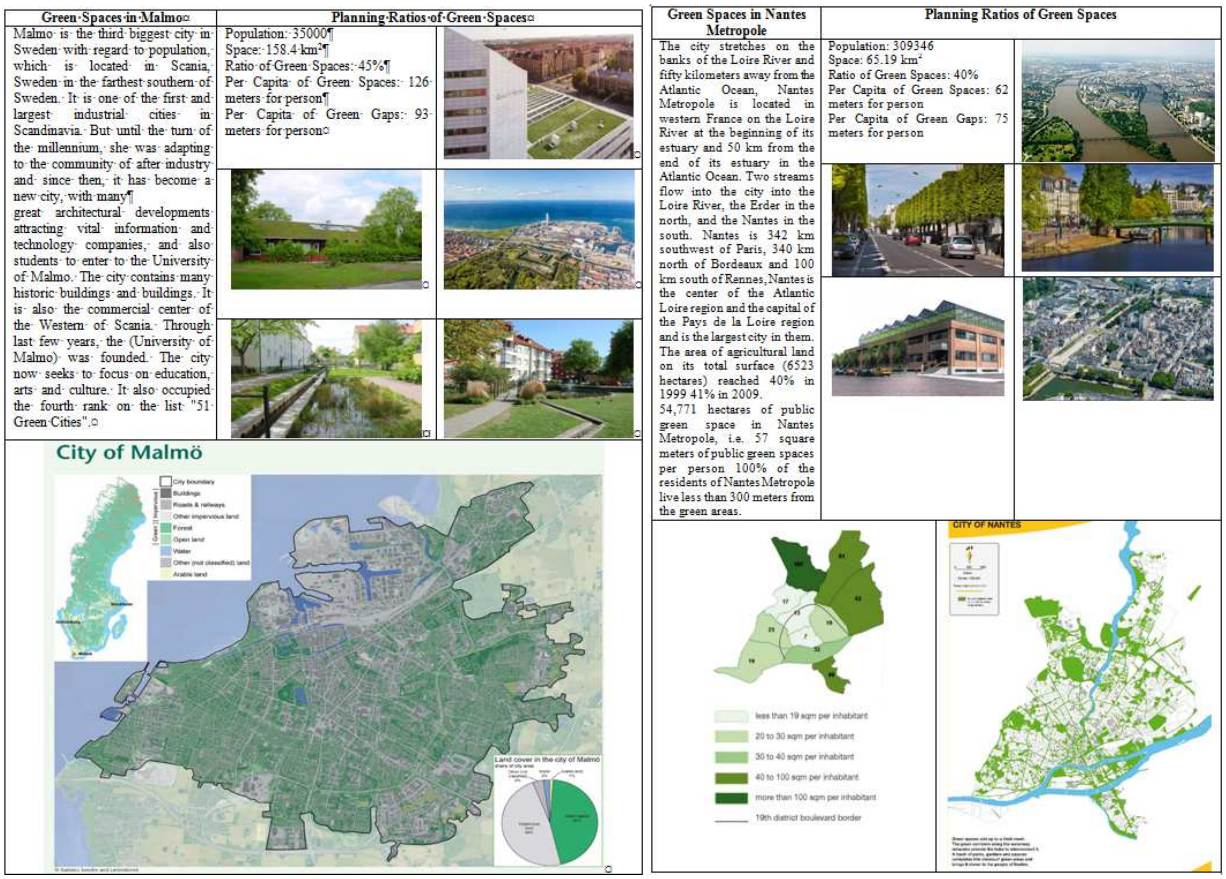

Table 10 (left): shows the Regulations and requirements of Green Spaces in Malmo, Sweden. Table 11 (right): shows the Regulations and requirements of Green Spaces in Nantes Metropole, France

4 EVALUATION AND DEVELOPMENT OF URBAN REGULATIONS OF GREEN SPACES IN ARAB COUNTRIES

4.1 Evaluation of Current Urban Regulations

By comparing the global ratios of green spaces to ratios in our Arab and Egyptian cities, we can find that there is a huge difference between the urban ratios and regulations, which results in an urban construction unqualified to achieve quality of life standards. Therefore, it is necessary to amend regulations and requirements regulating the green spaces system planning and using of new and different approaches and suggestions to raise the ratios of green spaces to achieve quality of life standards. The following table shows the gap between ratios of green spaces:

City	Cairo, Egypt	Nantes Metropole, France	Malmo, Sweden
Per capita (m^2/ person)	1.5	75	93

Table 12:shows comparison between global and local ratios

4.2 Urban Regulation Suggestions to raise Green Space Ratios

4.2.1 Residential Buildings

- Modification of urban construction ratio to the residential volume applicable in the Arab countries from 60% to 45% of the total lands. It is necessary to allocate 50% of the remaining space as a green space.

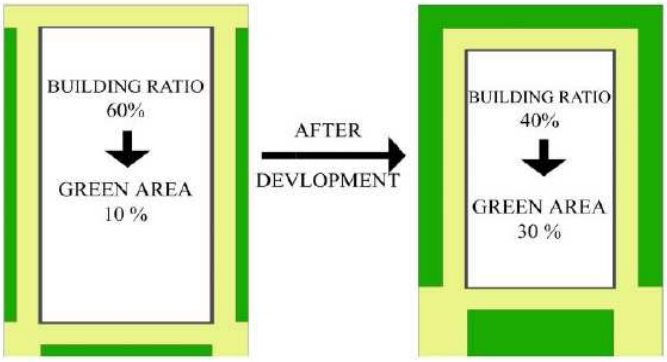

Fig. 4: Modification of Residential Requirements to raise Ratios of Green Space

- Modification and development of urban regulations of residential buildings and change them from nature-destructing cement buildings to green buildings through the reformation of buildings and using the building factor, Floor Area Ratio (F.A.R). The Floor Area Ratio is total space of the building (total land space) to volume of the land on which buildings were built. This factor is usually used as one of the regulations of cities planning in addition to the ratio of building to land) in order to change the residential building from a residential block into a form and height changing block.

Fig. 5: Modification of Residential Requirements through the Building Factor (Floor Area Ratio)

- Using green roof systems, which is represented in live plants fixed on roofs that positively contribute to mitigate urban area impacts and promote thermal and environmental performance. There are three main types of green roofs; each of them has its own characteristics in accordance with table (10),(11) which shows the types of green roofs system. [13]

Characteristics	Extensive	Semi-intensive	Intensive
Depth of material	150 mm or less	Above and below 150 mm	More than 150 mm
Accessibility	Often inaccessible	May be partially accessible	Usually accessible
Fully saturated weight	Low (70-170 kg/m2)	Varies (170-290 kg/m2)	High (290-970 kg/m2)
Cost	Low	Varies	Highest
Maintenance	Minimal	Varies	Highest

Table 13:shows types of green roofs system

Green Roof Components.[13]	Benefits
	**Ecology** Wildlife habitat Air Quality Biodiversity
	Social less stressed Increased productivity Reduced sick days
	Noise Reduction
	Energy and Heat energy consumption Moderate roof temperature Improve solar efficiency
	Economy Reduce size of HVAC equipment Higher productivity Extend roof membrane life
	Rain water Utilization of rain water

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

4.2.2 Services

- Modification of building ratio of residential block applicable in the Arab countries from 50% to 30% of the total space of the land, and it is necessary to allocate 50% of the space as a green space, and the remaining spaces as parking and service facilities.
- It is necessary to treat service facilities with the F.A.R system.
- Using green roofs

Fig. 5: University of Miami Lakeside Village Student Community Housing

- Using of green façades in the service facilities, which is a type of green wall systems, as plants climbs and form a plants cover. The green façades can be installed on the existing walls or built as stand-alone. [14]

Fig. 6: Green wall, Semiahmoo Library in South Surrey (http://www.vancouversun.com 2013)

4.2.3 Green Spaces

Modification of urban regulations of green space ratios inside the city reaching between 10 50 15 square meters of green spaces for each person to ensure the existing of healthy urban environmental system in accordance with the World Health Organization. In addition, modification of green space ratios (children play yards –district parks –district parks –city parks –big parks) in accordance with the following table.

Green Spaces	Population (Thousand)	Per Capita (m^2)
City Park	40 and more	1.5 -2.0
District Park	15-25	1.5 -2.5
Neighborhood Park		3.5 -5.0
Children Play Yards	1.5 -4	1.0 -1.5
Big Parks	100 and more	2.5 -4.0
Total		10.0 -15.0

Table 15: Modified Green Space Ratios to reach 10-15 meters for person

4.2.4 Roads

Development and improvement of ratios relating to green spaces on roads and streets, and increase the ratio of trees and green spaces on both sides of roads and traffic islands to raise ratios of green spaces in the city. Figures (8) and (9) show the way of distribution of trees on both sides of roads and traffic islands:

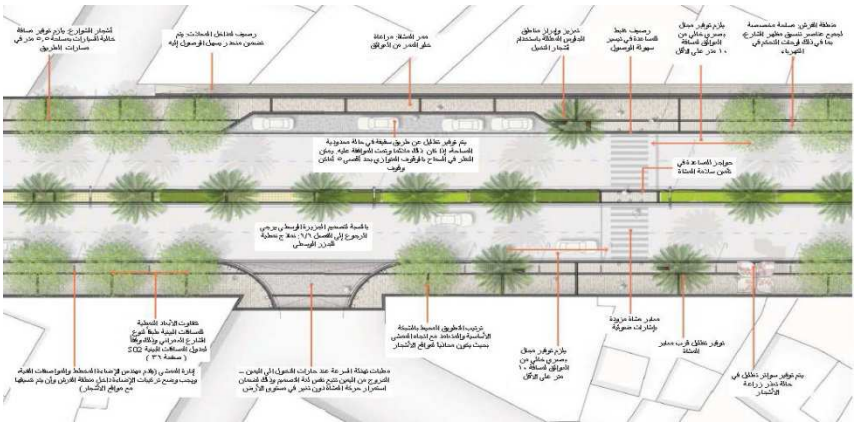

Fig.7: Distribution of Tree Ratios on Both Sides of Roads and Traffic Island

Fig.8: Sector shows distribution of Tree Ratios on Both Sides of Roads and Traffic Island

5 RESULTS

- Definition of quality of life is a wide and complicated definition including several definition. In brief, the quality of life measures the level of satisfaction relating to the most important aspects in person's life. It can be said that judging quality of life standards is represented in one important element, which is green spaces.
- Green spaces are an important and essential element in planning modern cities, as it contributes to development of cities and districts from the environmental aspect. The non-availability or lack of green spaces may result in environmental imbalance in areas that lacks the availability of trees and gardens.
- Green spaces has many benefits to human-beings in improvement of environmental conditions of cities and cities attractiveness in addition to the thermal isolation of cities, social cohesion and human welfare.
- It is necessary to consider many consideration in designing green spaces (distribution of green spaces near people –diversity of types of green spaces –simple design for green spaces –maintenance of green spaces –application of planning principles and ratios).
- Urban regulations are group of legislations, general regulations, decisions, and practices that control the urban environment development to improve livelihoods and living conditions. However, the urban legislations failed in many developing countries to guide and support sustainable urban development and modern construction orientations, and implement urban regulations and legislations efficiently.
- In accordance with the World Health Organization, there is a need for 10 to 15 m2 of green space for each person to ensure healthy urban environmental system.
- Green space ratios in the European countries are between 10 meters to 35 meters, and it increases in some cities to be 93 square meters as in Malmo, Sweden.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

- The existing green spaces in Egypt are less than 10% of the spaces that should be available to the current population of Egypt, as it is supposed to be "75 million square meters, while the Country, in accordance with the official statistics issued by the Central Agency for Public Mobilization and Statistics, has only 5,370 million square meters only". The per capita of green spaces in Cairo is 1.5 square meters.
- By comparing the global ratios of green spaces to ratios in our Arab and Egyptian cities, we can find that there is a huge difference between the urban ratios and regulations, which results in an urban construction unqualified to achieve quality of life standards.
- It is necessary to amend regulations and requirements regulating the green spaces system planning and using of new and different approaches and suggestions to raise the ratios of green spaces to achieve quality of life standards.
- Modification of urban construction ratio of the residential volume to the total space of land, and it is necessary to allocate 50% of the remaining land to be green spaces and allocate the remaining spaces as parking and service facilities.
- It is necessary to treat service facilities using F.A.R system.
- Using green roofs.
- Using green facades.

1 ABSTRACT

In Italy, industrialization had a remarkable development in the 1950s and 1960s, and aimed with priority of ensuring economic growth and development. The location of the industrial complexes was determined by the dynamics of the production that required a territory equipped to supply specific infrastructures such as water connections, sewers, gas pipelines and the electricity grid, and above all areas where to build transport terminals capable of mitigating the costs of handling the product. This led Italy to locate industrial activities in many coastal sites, close to pre-existing urban contexts, resulting in a well-defined coastal industrial landscape especially in the areas of Southern Italy that were chosen as centers of development. Today, the determining factor for location choices is the cost of the workforce and this has made more and more frequent the processes of delocalization of the companies with worrying repercussions both for the direct and induced occupation and for the degradation of the landscape. This process, linked to the safety regulations, to the updating of the systems and to an increasingly more rigorous landscape legislation, makes critical the framework of the existing and not yet abandoned disused industrial realities. For these reasons, the main objective of this article is to evaluate the compatibility between existing industrial areas at risk of delocalization and new interpretations of the environment and the landscape to be reconstituted, in order to allow the realization of goods that maintain the levels of industrial production within a framework of ecological protection rules and recently adopted landscape constraints. In this regard, in this paper the authors use the Eurallumina industry in Sulcis in Sardinia (Italy) as a case study, in order to analyze the problem that concerns the uses in the territories with an industrial vocation and the landscape components, that deserve particular attention to safeguard not only for the economic and social context but also for the quality of the coastal environment. The case study is particularly significant because the Euralluminia industry for some years was at risk of delocalization because it needs of a conversion of some parts of the plants, blocked due to the landscape regulation imposed by the Superintendence of Cultural Heritage of Southern Sardinia for the expected changes in the coastal environment. Therefore, keeping in mind the theories of localization and the pushes for the delocalization of the industrial contexts, the study discusses the importance of the interconnection between economic and landscape factors paying particular attention to the coastal areas.

Keywords: Eurallumina, Environmental Sustainability, Landscape Constraints, Industrial Landscapes , Smart Region

2 INTRODUCTION

For production activities (industries, large commercial chains, agricultural and livestock production) the territory is no longer the keypoint for the location choices, because the theory of the lowest transport cost (Camagni, 1980), from the product and from the correlated production processes to the origin is not decisive as it was before, when the production system at international level was not yet "governed" by multinationals interested only in the financial market (stock market quotations and more).

A factor that has instead assumed a relevant dimension for the location choices is the labor cost, especially when it comes to "heavy" productions that employ hundreds of people with work contracts that are not competitive with respect to those applied in emerging and developing countries (for instance India). For this reason, relocation processes are increasingly frequent for companies that "employ a lot of manpower" and that must remain competitive with respect to competitive markets even when the size of demand changes at local, national and international level.

In Italy, this problem is having worrying dimensions and is not currently easy to find solutions because without radical interventions, which unfortunately mainly affect the workforce, companies decide to move production processes in other countries, leaving the previously used territory, without remediation and restoration for pollution and for degradation.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

In addition, the investment models for the socio-economic development of the various Italian contexts (for example the theories on the industrial development poles of the South are outdated) changed, such as the problem of the land consumption is in constant evolution to allocate businesses, which produce technologically advanced tools for the digital society. This type of low-polluting activities (noise, processing waste etc.) does not require dedicated areas "outside the city" but lends itself to revitalizing urban centers.

In Sardinia, the framework of existing industries and of the ones that are not yet disused (in sectors such as mining, petrochemical and energy) is very critical and lends itself to operations of relocation with worrying repercussions for the direct and induced job.

Unfortunately, in Sardinia - but also in other regions in Italy and in Europe - the decision-making process is uncertain and too slow for taking structural initiatives, capable of reconverting already vocationally industrial areas, such as the Sulcis-Iglesiente in the Province of South Sardinia.

Even for the energy sources (that replaced coal in that area) is a lot of uncertainty and this does not favor negotiations with non-Sardinian companies that require preventive guarantees. The territorial offer is also lacking in administrative and bureaucratic facilities. Considering these assumptions, Figure 1 shows two important industrial areas (Machiareddu and Portovesme), in the southern of Sardinia, that are in crisis for many years with great difficulty in finding reliable policy-makers interested in intervening.

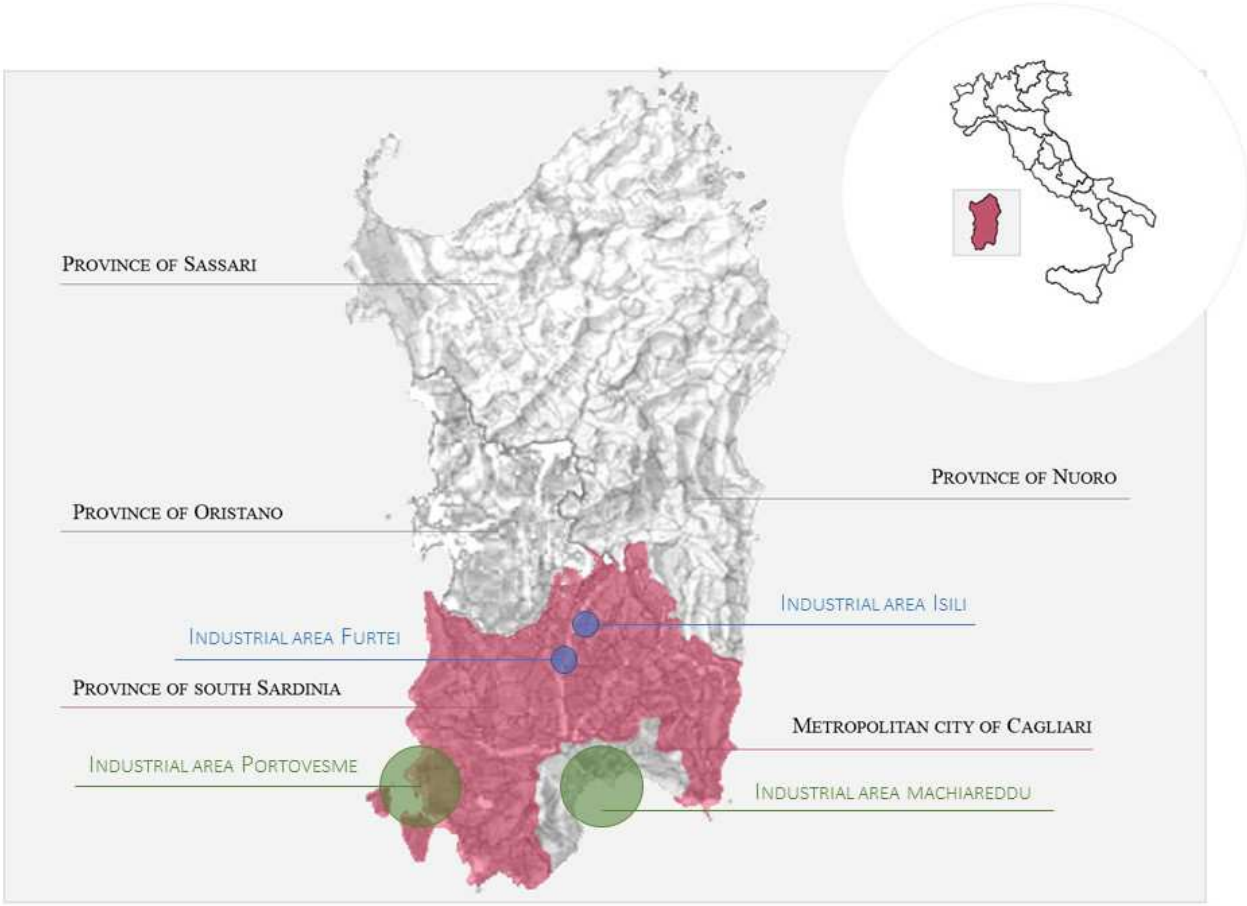

Fig.1: The Province of South Sardinia with the industrial areas of Portovesme and Machiareddu

The analyzed case studies want to focus on the problem that concerns the intended use in the territories with an industrial vocation. In addition, the components of the landscape deserve particular attention for the protection not only of the geographical context but also for the quality of the environment in presence of "polluting" activities.

3 ENVIRONMENTAL SUSTAINABILITY AND LANDSCAPE CONSTRAINTS IN SARDINIA

In this discussion, the historical process to evaluate the decision-making behavior of the policy on the territory with the succession of legal rules (of planning and of bargaining) is really important because in the past 50 years also the economic interests of the companies changed and, with them, the formulas for

establishments managing, for realigning the use of new technologies and digital tools and finally for increasing the competitive and unstable market frontier.

In addition, the historical process allows to understand the substantial changes in the way of life and the relationships of the inhabitants with the new dimension of the relationship space. It is hard to believe it, but different philosophies of thought with as many behavioral codes are still evident. The historical conflict between two cultures, the agro-pastoral one and the urban-industrial one, consolidated in this area of Sardinia, arose because the former was a simpler culture measured by the sites and the environment, while the latter was considered a certainly more advanced culture, but complex to evaluate the balance between the built and the environment (Mistretta, Garau; 2011).

It is also necessary to take into account how much the territory identifies itself as an expression of people's well-being or people's suffering, so much that in some cases it creates habituation phenomena and little interest in changes, in other cases it can produce the appreciation or refusal of projects aimed at having large industrial complexes which, through steel and reinforced concrete structures, verticalized by fireplaces with a continuous flame, the productive culture and work of thousands of workers are a diversified expression of industrial culture.

Therefore, the reasoning cannot be reduced to the tension between safeguarding the landscape “tout court” and the production process of industrial activities. In fact, in continuity with the plans launched in the context under study since the 1960s, the territory is equipped with specialized ports, road infrastructures and with technological energy and hydraulic networks. In addition, the classical rules of homogenizing the building typologies cannot be applied on the urban planning for industrial use, because the evolutionary scenarios of the production system of each company (from the first phase of the establishment to the subsequent phases that guarantee the competitiveness of the industrial product in the markets by innovating the establishments for production) require volumetric flexibility for the working spaces and for the use of the areas.This presupposes an Urban Master Plan (UMP) with non-detailed intervention proposals in order to use the territory in a way that incentivize the location of new companies and the relaunch of existing ones.

Unfortunately, the tendency to plan the territory in a sectoral way, both dimensional and typological one, does not allow to evaluate the processes and the proposals (even if they are excellent from a technical planning point of view) in a more composite framework of theories, experiences and professionalism that represent as many ways of operating, but with different goals.

This cultural and planning "conflict" occurs when green economy proposals call into question the persistence of economic realities that are still financially and occupationally efficient. This does not mean that all the industrial settlements that played an important role in the development of the areas and in the regions in which they operated are to be safeguarded without taking into account the necessary environmental and hygienic-sanitary remediation and those concerning the typology of buildings with new technologies. In other words, the compatibility between green expectations and the related guarantee rules must be guaranteed with a smart collaboration between public administrations and private operators in order not to cause irremediable crises that could induce delocalization processes that are in any case harmful to the general economy of the territory. This is to establish the relationships between the different social and economic functions for estimating the central level that are able to express the settlements.

Sardinia is an emblematic case because the legislation on landscape safeguarding (through the Regional Town Planning, RTP of 2006 [Garau Pavan; 2010; Pintus et al., 2019]) of not building within 300 meters from the sea in the coastal areas struggles with existing and economically active situations that concern two specific typologies: 1) the hotel accommodation; 2) the industries activated on lots that are part of specific industrial development plans, of which Sardinia, like the other regions of Southern Italy, was able to benefit from the industrial development poles (1965) to be located in the areas with the highest settlement vocation such as Cagliari with its port called “porto Canale”.

The authors are well aware that the "remote past" in urban planning can only have an experiential value for changes in the rural environment and in particular on the organization and remuneration of work, but it cannot be underestimated because the effects of the medium and long term are still evident in the territory with the urbanization works of scale and with the redistribution of the inhabitants urged by the central functions of the cities with directional activities (Cagliari, Sassari). This presupposes the precise identification and planning of the functional areas at urban level and of the infrastructures, directly related to

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

the traffic flows, which have a particular meaning when they integrate the commercial and service functions with the other more important ones than the residential ones.

The habit of people, in general and without being socially and economically involved, is to look only at the geographical and environmental composition of the landscape, expressing a cold or emotional judgment based only on the aesthetic components, although behind the eye of the beholder of the landscapes, they are the different components of its DNA. Behind the eye of the viewer, the different components of its DNA coexist: environment and social context, affection for places, quality of life and level of well-being, education, culture, sensitivity, experience, age and gender.

General data of the Eurallumina company	Eurallumina is a company, today 100% owned by U.C. Rusal, through its subsidiaries, which built in the early 70s and operates in Portoscuso in Sardinia, in the Sulcis Iglesiente industrial area, an establishment for the transformation of bauxite into alumina (aluminum oxide) according to the Bayer process. The company operates on a transformation account for its shareholder or for U.C. group companies. Rusal which supply the establishment with bauxite and collect the alumina and aluminum hydrate produced. Eurallumina, therefore, does not directly sell its products on the market but delivers them entirely to the shareholders who, in turn, market them through the United Company Rusal.
Production Establishment	The Portovesme production establishment entered in production in May 1973 and has a potential production of approximately 1,100,000 tons/year. On 30 November 1990 the Council of Ministers adopted the resolution with which the Sulcis-Iglesiente area was declared an area at high risk of environmental crisis pursuant to and for the effects of art. 7 of the law of 8 July 1986, no. 349, as amended by art. 6 of the law of 28 August 1989, n. 305. In 1993 the Ministry of the Environment highlighted the main environmental problems in the Sulcis-Iglesiente area and the examinations and discussions with the bodies involved and with the appropriate coordination committee State-Region-Local authorities, on April 23, 1993 with Decree of President of the Council of Ministers n. 72, the decontamination plan for the restoration of the Sulcis -Iglesiente area was approved. In the conclusions of this document (point 2.4) of Chapter 2.0 "Summary of environmental problems", the main problems were hierarchized into 6 points, including Point 4: "the aspects of landscape and urban degradation and marine pollution related to the presence of the industrial center of Portovesme, although not insignificant, appear to be second-rate, especially in view of their limited extension (essentially limited to the areas closest to the pole, in the Municipality of Portoscuso), verified on the basis of available data". The production of the Eurallumina establishment was temporarily suspended in March 2009 after about 36 years of uninterrupted operation, due to the changed cost situation, mainly energy as mentioned in the 2009 Memorandum of Understanding and in the subsequent addendum of 2012, which they undermined economic competitiveness, and because of the global economic crisis that brought down the demand and price of alumina. Economic competitiveness, on the other hand, is critical for the high production costs, largely due to structural factors such as: the high cost of energy and the distance from the source of supply of the raw material (bauxite from Australia). The technological competitiveness of the Eurallumina establishment is good, although it can be further improved by using tri-hydrate type bauxites.
The Industrial Establishment	The Eurallumina establishment was built by EFIM (through ALSAR), in the 60s and 70s, like the other main establishment in the aluminum chain which form part of the Portoscuso Industrial Core with the aim to create a strategic hub of worldwide importance for the production of aluminum. The industrial area was built near the sea where an existing port was also expanded to make it suitable for unloading raw materials and shipping products.
Employees	Eurallumina currently has about 300 employees, many of whom have long experience in the refinery. Today, despite the suspension of the production process, the company guarantees the maintenance of the establishments using 70 daily work units in the company.
Regulation for this area (Scope Datasheet n° 6 Carbonia and Sulcitane Islands pp. 11 - 12 of the RTP)	"1. Redevelop the coastal landscape of the inland sea between the archipelago and the mainland, rebalancing the relationship between industrial activities, traditional fishing activities and tourist use, in a perspective of integrated conservation and management of the Area, also in reference to the "Marine area to find the island of San Pietro". 2. Progressively rebalance the relationship between the industrial presence of the Portovesme pole, the urban settlement, the tourist use, the agricultural activities and the marine and lagoon fishing of the Area, reducing the problems of interference of industrial activities with the environmental system. 3. Redevelop the areas of industrial degradation, selecting priority areas of intervention, on which to activate a progressive process of clean-up and environmental regeneration, which requires unitary coordination for the municipalities concerned in relation to problems of high environmental risk, for the programs of pollution control and environmental monitoring." 4. Part of the red sludge basin, the coal loading area (CHP site), the area on which the conveyor belt insists (site 2), the area of the Eurallumina port quay fall within the coastal territories included in a strip of depth of 300 meters from the shoreline, even for high ground on the sea.

Table 1: identity scheme of the case study of Eurallumina

With these premises, the main objective of this article is to evaluate the compatibility between existing industrial areas at risk of delocalization and new interpretations of the environment and landscape to be

reconstituted, in order to allow the realization of works that maintain the levels of industrial production within a framework of ecological safeguard rules and recently adopted landscape constraints.

In this regard, in this article the authors use the Eurallumina industry in Sulcis in Sardinia (Italy) as a case study, in order to analyze the problem that concerns the intended use in the territories with an industrial vocation and the components of the landscape, which deserve particular attention to safeguarding not only the economic and social context but also the quality of the coastal environment. The case in question is particularly significant because it encompasses the fundamental points of the discussion. In fact, the industry is at risk of delocalization for some years because it is asking for reconversion of some parts of the establishments, blocked due to the landscape relationship which provides for changes in the coastal environment which are excessive for the Superintendency of Cultural Heritage of Southern Sardinia. So keeping in mind the theories of location and the pushes for the delocalization of industrial contexts, the study discusses the importance of the interconnection between economic and landscape factors, paying particular attention to coastal areas.

4 THE EURALLUMINA OF SULCIS IN SARDINIA

The topic is particularly felt in Sardinia because, of all the industrial interventions realised in the past decades, the only one still in activity is that of the Sulcis Iglesiente which, heir to the mining culture, demonstrates competitiveness in the national and international market. Therefore, the case study that describes the events suffered by Eurallumina, constitutes an opportunity for political reflection and scientific evaluation that can be compared with other realities in Italy but also in Europe in corporate suffering due to localization factors.

The U.C. Rusal (global aluminum producer) as an example of resistance in Sardinia

Before tackling the discussion on the compatibility between industrial settlements and the protection of the environment and the landscape, it is necessary to analyse the most significant data through the table 1, in order to know the context and to understand the attitude taken by the various public decision-makers and environmental associations.

After Table 1 which describes the Eurallumina establishment, it is necessary to underline the points on which the technical discussion that empowered the political decision maker of the Sardinia Region and activated the binding opinion of the regional Mibact on the compatibility landscaping required for changes to the systems of the production system.

Environmental remediation (4.1.1): 1. Hydrogeological with reference to aquifers to eliminate causes and effects of pollution; 2. sanitary hygiene to make the area affected by the fumes of the production cycle healthy

Landscape compatibility (4.1.2): 1. the intended use of the area of land included in the Sulcis Iglesiente Industrial District with the destinations of the 2006 RTP; 2. the impact of the company's structural changes on the coastal landscape

4.1.1 Environmental remediation

After five years of discussion, not without tensions with the workers of the factory under the cassaintegration regime, the Board of the Sardinia Region adopted the plan presented by the RUSAL company regarding the interventions on the aquifers, on the red mud accumulation basins, on the emission of fumes and finally on public health not only referred to workers but also to the populations of the Municipality of Portovesme and the impact areas, concluding the procedure with the approval of the Environmental Impact Assessment (EIA) DELIBERATION N . 49/17 OF 5.12.2019). A complex document that analyzes all the most delicate points of the conversion of the industrial plant which in fact authorizes the resumption of the production process until January 2020. A historical result that rewards the tenacity of the workers who fought for this goal.

In fact, the restarting of EurAllumina is crucial for the recovery of the Alumino supply chain, which is valid as an official statistical multiplier of 1450 total jobs.

4.1.2 Landscape compatibility

Unfortunately, this is still an open problem because the Superintendency of Cultural Heritage of Southern Sardinia, which had not pronounced at the conference of services promoted by the Region, expressed its

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

contrary opinion in its own seat for some of the proposed changes as they do not respect the environmental and landscape value requirements referring to the territory concerned. Another chapter of the infinite dispute that once again highlights the conflict of competences between a State body and the Sardinia Region, which according to the Statute has primary competence in urban and landscape matters.

To better explain the size and content of the respective interpretations, authors believe it useful to make some reflections on the interpretation of the natural environment and the landscape with reference to some points:

a) The first one marked by the physicality of the places and their interpretative relevance. However, although geodiversity is the most characteristic and stable landscape factor over time, it is not sufficient to excavate and study the anthropological components of the past and the current ones that emphasize the mountains, valleys, villages and cultivated fields.

b) The second one takes into account the anthropization in the history of the island through the types of settlement in the form of scattered villages and houses (Gallura and Sulcis) and which contribute to humanising the coastal landscapes, the flat hinterland, the areas of mountain.

c) The third one identifies itself as an expression of people's well-being or suffering, so as to create in some cases, habituation phenomena and of little interest in changes, in other cases the appreciation or rejection of the projects aimed as in the realities where they coexist large industrial complexes which, through steel and reinforced concrete structures, verticalized by the chimneys with a continuous flame, are a diversified expression of the productive culture and work of thousands of workers.

Attention to the historical process is fundamental to understand the substantial changes in the way of life and the relationships of the inhabitants with the new dimension of the relationship space where different philosophies of thought are still evident with the historical conflict between the agro-pastoral and urban culture -industrial. Great attention must therefore be paid to the ability of the communicative language that makes the relations between politics, economy, land use and environment manifest (Mistretta, Garau; 2011).

Furthermore, it should be considered that the European Landscape Convention (Council of Europe, Florence, October, 2000) has brought substantial innovations to the interpretation of the landscape and to the method for safeguarding and designing. Particularly significant is the description of the landscape, seen as "a certain part of the territory, as perceived by populations, whose character derives from the action of natural and / or human factors and their interrelationships". (Art. 1 letter. A). Equally important is the subtitle which on the "safeguard of landscapes" «indicates the conservation and maintenance actions of the significant or characteristic aspects of a landscape, justified by its heritage value deriving from its natural configuration and / or the type of human intervention» (Art. 1 lett. D).

This description of the industrial landscape of which Eurallumina was not considered sufficient to allow the regional superintendency of MIBACT to express a positive opinion on the changes described in the redevelopment and relaunch projects of the industrial process. In fact, to justify the negative opinion, the regional superintendency of MIBACT notes that the context is characterized by: a) natural and landscape features of exceptional relevance, characterized by the presence of numerous assets - protected by the law pursuant to Art. 142 of the Code; b) characterized by the succession of lagoons and dune complexes; c) directly overlooking the coast; and therefore; d) inserted in an aqueous space of relationship in which the various coastal contexts (Calasetta, Carloforte and S. Antioco) constitute mutually perspective and landscape scenes.

In this regard, the authors indicate the most significant observations (Biolchini, 2011) made for the discussion on the landscape in industrial areas already built and subject to innovation:

1. The project presented does not show the implementation process of the mitigation works, on the contrary it would seem that "the proposed mitigation works are feasible only at the end of the cultivation of the relative deposit and that the intermediate landscape impacts generated in the long term are not taken into consideration period for using the landfill"

2. "The final evaluation of the VIncA regarding the "wetlands" (SIC) immediately concerning the deposit of the" red mud "has not yet been acquired and, therefore, it is not possible to evaluate the impact of the project in question on the conservation of the 'natural area, recognized as a landscape asset by the RTP and, therefore, a subject of direct interest of this Superintendency for its conservation".

3. "The intervention is likely to adversely alter the skyline that characterizes the context of the numerous areas declared of considerable public interest pursuant to art. 136 of Legislative Decree 42/2004" as "The works envisaged by the project are in clear visual relationship with a vast air of the coastal territory" with "significant and negative morphological changes observable from numerous lookout points - including the water mirror included between the coast and the sulcitano archipelago - also subject to protection".

4. In this regard, it has yet to be highlighted that "the expansion of the Red Mud Basin determines the occupation of soils currently also free and it doubles the height of the landfill, generating a huge artificial hill of toxic waste, about 40 meters high".

5. The works envisaged by the project further contribute to altering the systems of relationships, introducing new elements of strong impact, absolutely dissonant and not compatible with the quality elements that the measures protect and that find in the water in front of the privileged area of relationship natural and environmental emergencies that define a context whose panoramic value is recalled by all the protection measures that are part of the coastal marine space which represents the identity and relationship element of the complex system of historical center, settlement and environmental resources with the centers urban with a historical layout (Carloforte, Calasetta, Portoscuso, Sant'Antioco).

The Superintendency concludes with this negative opinion: “definetely, the intervention conflicts with the protection purposes defined for the area concerned since it increases the landscape impact of the existing industrial complex and therefore is not consistent with the rules of the RTP explained for the areas of environmental recovery and in the reference area"

5 DISCUSSION: REASONS AND DEDUCTIONS ON THE INTERPRETATIONS OF THE LANDSCAPE OF PORTOVESME

It is important to consider the validity and legal competence, translated on the territory, of the RTP (approved with regional law 25 November 2004, No. 89) and those of the Provincial Industrial Consortium Sulcis - Iglesias (established with LR No. 10 of 27 / 07/2008) on the areas included in the Portovesme area (Fig. 2). In fact, it is necessary to assess whether the purposes of the 2008 law (SICIP) are conditioned by the previous provisions of the RTP (2004) which would subordinate the objectives of the same law described in article 1 letter a) and b) with the obligation to ensure coordination of the interventions.

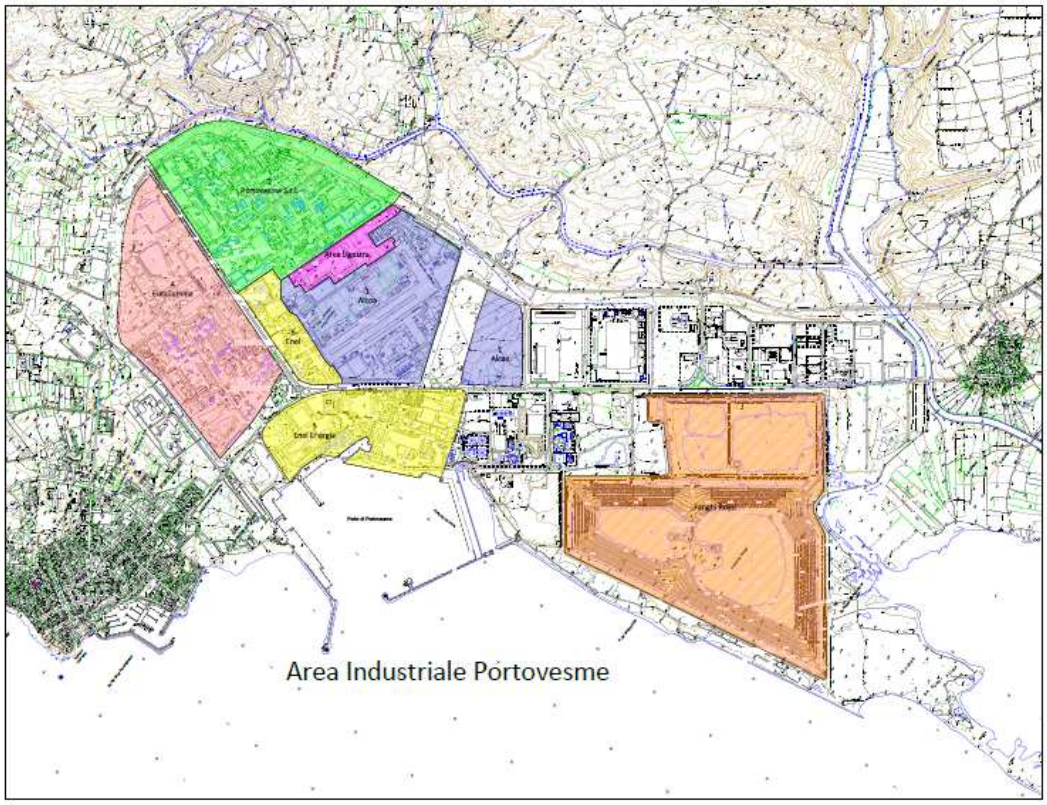

Fig. 2: Portovesme Industrial Area

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

The reasoning is not only based on legal quibbles inherent in the consequentiality of dates and intentions of the Regional Legislator - "fought" between the industrialization and the landscape protection of a territory with an industrial vocation since the 1960s, which has equipped itself with a port specialized, with road infrastructures and with technological energy and hydraulic networks paying particular attention to the compatible treatment of waste water with the natural river basin - but on the planning of the territory for industrial use which requires not only the installation of industrial activities in the lots to be assigned to the individual companies, but above all the evolutionary scenario of the different production systems of each company, from the first phase of the establishment to the subsequent phases to guarantee the competitiveness of the company product in the markets by innovating the production systems, reducing the energy cost and keeping the specialization of the workforce high.

Therefore, the analysis of the document of the Superintendency resumed below to make the deductions based on the interpretations of the landscape, already formulated in this paper.

In point 2 at letter a) reference is made to the "natural and landscape features of exceptional importance". It is important to emphasize that in the on-site and remote inspections it has been difficult to find cultural and substantial reasons to justify "landscapes of exceptional importance". In fact, the territory included in the S.I.C.I.P. consortium, even if all the existing industries were eliminated, would have a flat morphology, barely moved by the artificial hills produced by the landfills of the mines, today covered by spontaneous Mediterranean vegetation. In other words, although there are significant landscapes that Sardinia also shows in the Iglesiente area, this area of Eurallumina does not deserve any attention and therefore no invitation to visit it by virtue of the natural landscapes (Fig. 3).

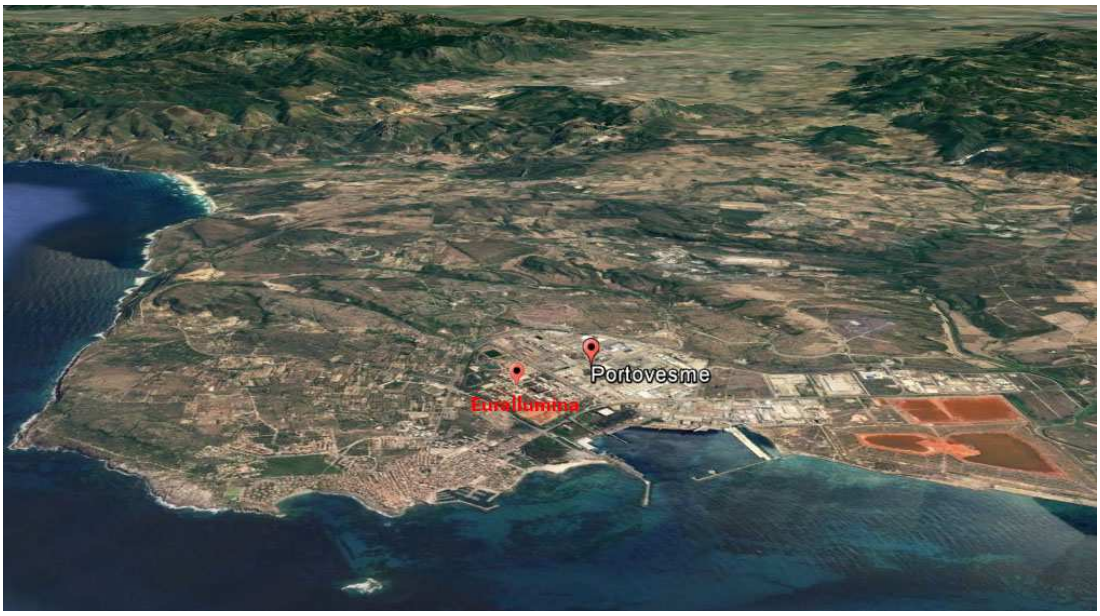

Fig. 3: Panoramic view of the territory without emerging factors of importance (Google earth)

This judgment is not intended to be malicious towards Portoscuso and its inhabitants, but can also be confirmed by the remote visions which are considered important in the Superintendency document with reference also to the horizons observed by Carloforte and Calasetta.

In point 2 at letter c) it is possible to evaluate how much the industrial establishment and the sludge basin are "directly facing the coast". It is quite obvious that we are dealing with a company that was born and develops its production in front of the sea as the supply of raw materials is guaranteed by ship carriers placed alongside the docks of the specialized port. So all the equipment for transporting materials to the storage area, which are part of the production process, must be viewed with the emotional attention that the conveyor belts at height with their structures.

As for the prospecting on the coast of the mud basin, the problem is less significant because with the natural vegetation that already guarantees the total mimicry of the retaining walls, the elevation of the main basin will be seen from below as a green hill facing the sea. A sea front of very little value composed of breakwater boulders and one that extends for a few kilometers and which does not offer bathing spots. With regard to the mitigation that according to the Superintendency would not be guaranteed with continuity over

time, it is noted that they are instead guaranteed by the spontaneous vegetation that grows along the stone walls, in steps, camouflaging them with the continuity of the seasonal rhythms.

6 CONCLUSIONS

To conclude this discussion on the interpretation of the landscape that reinforces the emblematic nature of the Eurallumina question in Sulcis Sardinia, the authors consider some food for thought (on which they have already had the opportunity to express theirselves) which are useful because they open up to a Sardinia to be "known and to love" not only through the slides and posters posted at the airports or entrusted to splendid videos, as well as to the many books on landscapes, beaches and culturally effective cultural heritage, but which do not reveal the true characters of the island society.

In any case, the relationship and the difference that exist between the impact of "things" on the landscape and the visual impact is important, as the former affects character, quality and cultural factors; the second is limited to seeing the changes through the available "views" and the effects they have on people. There is not necessarily coincidence between the two, in fact the impact on the landscape can also occur in the absence of a visual impact where the development is, for example, completely shielded from the available views; and similarly, when in already characterized areas very high works for mainly technological use emerge (electric pylons, wind turbines, industrial chimneys, antennas). And this is why the authors defend the thesis of the interpretative flexibility of the landscape; because it is necessary to take into account and foresee the possible changes in the territory that you would like to "fix" which in Sardinia are due to the extraction quarries, the mining landfills to be reclaimed, the forestation with the probability of fires, viaducts and road tunnels, productive settlements and the intensification of the agricultural use of soils which can influence geometry and also changes in natural factors.

1 ABSTRACT

The accelerated pace of climate change in today's global world has intensified the frequency and intensity of extreme weather events. Structural engineering measures are the common ways to cope with disasters. However, with the increasing frequency and intensity of extreme disaster events, the general engineering design standards could not stand with severe disasters. Non-structural engineering measures are the alternative including zoning and insurance. In fact, resettlement or relocation is the possible approach to relocate people from high risk areas to relative safer places. Nevertheless, such relocation might destroy the original living context and livelihood thoroughly. In the other hand, traditional ecology knowledge is the long lived knowledge inherited from ancestor. Traditional ecological knowledge could become a useful warning system to warn people when should retreat and when should be prepared. As a whole, the purpose is to collect possible traditional ecological knowledge in areas suffered from disasters and improve such knowledge to become a feasible disaster mitigation approach.

Keywords: non-structural engineering measures, traditional ecological knowledge, extreme weather events, mitigation, adaptation

2 INTRODUCTION

Global climate change has intensified the frequency and intensity of extreme disaster events suchs as torrential rain, snow storm, drought and so on. Acoording to the scientific reports, the extreme weather events caused by climatic variability have already occurred in the past decades and it is very likely to emerge in the future (Pareek & Trivedi, 2011). In order to respond the increasing disasters, a four-phase disaster management strategy has been applied in the worldwide including (mitigation, preparedness, response, and recovery to cope with climate variabilaity (O'Brien et al., 2006; Alexander, 2002). Structural and non-structural enignnering measures are the two common approaches. Structural enginnering measures such as dikes, pump stations, dams are based upon engineering technologies to mitigate potential impacts. In the other hand, non-structural enginnering measures such as land use plan and insurance to lead human settlements away from the disaster risks areaas. Due to the frequent and intensified extreme disasters, the design standard of traditional structural engineering measures might not enough to cope with such disasters. Therefore, more attentions have been put on non-structural enginnering measures.

Among a suite of strategies, retreat from hazard-prone locations seems to be a great solution to reduce the risk posed by climate change (King et al., 2014). In fact, whether temporary, permanent, internal or international migration is recognized as a viable and sustainable adaptation strategy to reduce disaster risk and adapt climate change (King et al., 2014; Marino, 2012; Gemenne, 2011; IOM, 2011; Mayer, 2011; Black et al., 2011; Warner, 2010; Morton et al., 2008). However, such relocation and climatic migration might further result in the break down of couumities or unanticipated social chnges (King et al., 2014; Lizarralde & Boucher, 2004; UNDRO, 1982). In addition, involuntary outmigration involves changes in family commitment, livelihood opportunities, financial constraints and emotional ties and maladjustment is likely to occur (King et al., 2014; Oliver-Smith, 1991). The impacts of the society which has settled for centuries may cause devastating consequences and threat to its existence (Oliver-Smith, 1991). A great amount of research has indicated that relocation may levies high social cost, including impoverishment, social disarticulation, and decrease in livelihood security, social capital and cultural ties (King et al., 2014; Marino, 2012; Scudder, 2012; Usamah & Haynes, 2012; De Wet, 2006; Oliver-Smith, 2006; Cernea, 1996, 1997, 2000; Oliver-Smith, 1991).

In traditional disaster management systems, the long-term accumulated local knowledge has been one of indispensable components and is a significant tool today (Mavhura et al., 2013; Pareek & Trivedi, 2011). In order to adapt severe damages from climate change, traditional ecological knowledge (TEK) has been gradually recognized of the feasibility on coping disasters (Berkes, 1993). TEK refers to people's knowledge

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

of their local environments, and is derived from experience and traditions evolving by adaptive processes and has been passed down through generations by cultural transmission, about the relations of specific human societies to the local environments (Hernández-Morcillo et al., 2014; Leonard et al., 2013; Houde, 2007; Folke, 2004; Berkes et al., 2000; Berkes, 1999). TEK has enabled local communities to live in harmony with their environment for generations and included information necessary for survival (Folke, 2004; Mwaura, 2008; Pareek & Trivedi, 2011; Iloka, 2016). The long-term persistence of settlement can be seen as an evidence enough that the knowledge accumulated through trial and error over many years works (Folke, 2004; Freeman, 1992).

Past studies have showed that settlements located at hazard-prone areas might come up traditional ecological knowledge (TEK) including prevention and mitigation, early warning systems, preparedness and post-disaster recovery (Pareek & Trivedi, 2011). In fact, since the 1970s, a growing evidences show that TEK can improve disaster preparedness and practice (Hiwasaki, Luna & Shaw, 2014; Dekens, 2007). The inheritance of long live experiences and knowledge can be applied to possible disaster mitigation and adaptation in the future. Therefore, the knowledge acquired through perceiving disaster and respond to natural hazards can help understand environmental science and improve disaster mitigation and adaptation strategies (Dekens, 2007). Hence, this This study attempts to build up community resilience in hazard-prone area under traditional ecological knowledge. First of all, this study will review the nature, forms, and cases regarding traditional ecological knowledge. Afterwards, this study will apply GIS-based land suitability analysis methods to search for hazard-prone indigenous tribes in southern Taiwan. And then this study will apply a systematic literature review in indigenous tribes with hazard-prone area to collect traditional ecological knowledge. As a whole, the purpose is to integrate traditional ecological knowledge (TEK) into scientific knowledge and help human beings improve capacity to disaster adaptation and resilience strategies to adapt the changing environment.

3 LITERATURE REVIEW

3.1 Migration in high risk areas

Migration from high risk areas (post-disaster resettlement, post-disaster relocation, pre-disaster migration etc.) seems to be inevitable while it is much more complicated than expected. In fact, climatic migration might be related not only safety but also social and economic issues (King et al., 2014; Usamah & Haynes, 2012; Oliver-Smith, 1991). Although resettlement indeed could reduce direct exposures from disasters, individual vulnerability might be increased due to the process such as the loss of livelihood, loss of community context, loss of religious belief and so on (Usamah & Haynes, 2012; Gaillard, 2008; Cernea, 1997; Oliver-Smith, 1991; Quarantelli, 1984). An outmigration strategy in Mayon volcano in the Philippines shows that the area has successfully reduced risks from volcanic- and typhoon-related disasters. Instead, the community has lose the livelihood options. In order to make their livelihoods, people return to their old workplaces or commute great distances to maintain lifehood. The continuing mobility of resettles who travel for their livelihoods may cause the loss of community connections (Usamah & Haynes, 2012). The economic advantages which people have built in their original settlement are the main cause of failure. (Oliver-Smith, 1991). Thus, the consequences of migration can be more devastating than the disaster event (Usamah & Haynes, 2012; Oliver-Smith, 1991).

Formalizing outmigration into disaster policy may reduce resilience for those communities in the long term, thereby initiating unanticipated changes based on economic, political or sociocultural factor and expose people to greater risks (King et al., 2014; Hernández-Morcillo et al., 2014; Oliver-Smith, 1991). In most migration policies,in order to maximize efficiency, the location of migration are mainly determined by authorities. Land which government owned or controlled may be considered as a priority for migration. With the ignorance or lack of concern for social and economic, the resettlement in a top-down manner frequently cause the failure of migration (Oliver-Smith, 1991). In addition to socioeconomic issues caused by migration, people's attitude towards relocation is also a material concern. Evidence shows that people in hazard prone areas often show the reluctance to migrate. In the case of Antigua, suffered from severe earthquakes and a huge landslide, the city was relocated for the third time to safer terrain (Oliver-Smith, 1991). Although the citizenry refused to immigrate, a new capital, Guatemala City, was founded. However, people remained in the old city and repopulated it immediately. Today, the old city continues to exist and is

one of Guatemala's major tourist attractions (Oliver-Smith, 1991; Tobriner, 1980). Given such difficulties, it is suggested that migration should not be adopted as a strategy and efforts are make to rebuild original sites (Oliver-Smith, 1991; Aysan & Oliver, 1987).

3.2 Traditional Ecological Knowledge

Over the last two decades, traditional ecological knowledge (TEK) has increasingly recognized as a source of information for environmental science, policy, and management (Hernández-Morcillo et al., 2014). There is a growing awareness on TEK for to contemporary resource management problems in various parts of the world (Berkes, 1993; Freeman, 1992). For illustration, people in Uganda have forecasted seasonal weather in order to increase or stabilize crop yields (Okonya & Kroschel, 2013). It is quite common for people to use words such as "local," "indigenous," "folk," and "traditional" as synonyms to describe their local environments (Hernández-Morcillo et al., 2014; Mercer et al., 2010; Sillitoe, 1998).

TEK is holistic and dynamic in nature and is gathered over generations through accumulation of experiences, society-nature relationships, community practices and institutions, and observation in long term (Mercer et al., 2010; Berkes, Colding & Folke, 2000; Flavier et al., 1995). The knowledge based on tradition and non-industrial societies is ecology-oriented, it attempts to understand and explain the operation of ecosystems, containing many interacting species of animals and plants (Freeman, 1992). Evolved through trial and error, Traditional ecological knowledge has a unique living style to confront a variety of environments and transmitted to future generations by oral narrative and practical experiences (Berkes et al., 2000; Ohmagari & Berkes 1997). Therefore, TEK can be viewed as part of the adaptive strategies to dwell and survive (Hernández-Morcillo et al., 2014).

Since the 1970s, there is grown evidence that TEK can improve disaster preparedness and practice (Hiwasaki et al., 2014; Dekens, 2007). Those have settled in inhospitable environments may develop a capacity for the survival of whole groups and have collectively accumulated a vast number of knowledge on disaster prevention and mitigation, preparedness and response and post disaster recovery (King et al., 2014; Pareek & Trivedi, 2011; Freeman, 1992). The nature of the community affects the knowledge which those have acquired (Dekens, 2008). The region in Himalaya had often been suffered from landslides and flash floods. Through experience and accumulated knowledge of the generations, the people here develop the sensitivity to select habitation places that were relatively safe from these disasters.

Though people cultivate lands closed to areas affected by these disasters, they decided to settle down at the upslope locations where are less vulnerable to disaster (Rautela, 2005). During the December 26 tsunami which caused 163,795 death in Indonesia's northern Aceh province, the knowledge of the sea phenomenon and the behaviors of buffaloes helped people in the Simeulue community flee the shore for nearby hills (de León, Bogardi, Dannenmann & Basher, 2006). As mentioned previously, over the course of history and up to this day, it is demonstrated that traditional ecological knowledge is critical to save lives in the face of disasters (Pareek & Trivedi, 2011; McAdoo, Moore & Baumwoll, 2009). Traditional ecological knowledge gained from local experience and practices should be integrated into disaster mitigation and adaptation to further aim for sustainability.

4 RESEARCH DESIGN

4.1 Conceptual Model

The purpose of this study is to integrate traditional ecological knowledge (TEK) into scientific knowledge to improve disatser adpatation and resilient strategies under global climate change. Therefore, this study begins with the suitability analysis of overlaying disaster risk areas (such as flood-prone areas, soil liqifaction, Dip slope areas, landslide-prone areas, collapse-prone areas, fault zone areas, rockfall-prone areas and detritus sliding-prone area) and human settlements. Afterwards, the study conduct comparative analysis between disater risk and past disaster records to find out settlements located at hazard-prone areas and suffered with disasters. This study assumes that such hazard-prone settlements might have TEK to help them continue live in such high risk areas. Therefore, a systematic review will then be applied to collect possible TEK. Figure 1 is the conceptual model of this research.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

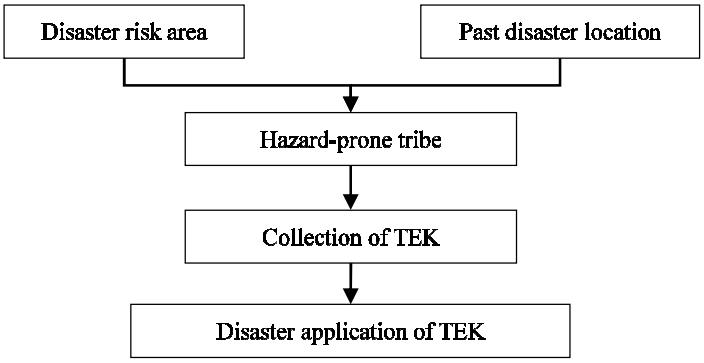

Fig. 1 Conceptual model

4.2 Suitability Analysis

This study applies geographic information system (GIS) as the main methodology to precede suitability analysis on hazard-prone settlements. GIS is a computer-based tool that analyses and visualizes geographic data on the map. There are various software could be used for analysing and visualizing geographic data such as MapInfo, ESRI ArcGIS, QGIS, GeoDa and so on. ArcGIS can visualize the features that can recognize the patterns and provide vital information to the users. It can demonstrate and convert numerous diverse data into a single visualization platform. In this study, we apply ESRI ArcGIS as the basic workstation to find out the spatial distribution of hazard-prone settlements.

4.3 Systematic review

Systematic literature review is one of the methods applied to summarize both present and past findings in specific topic. The main purpose is to integrate and categorise relevant research to collect information. It aims to assess the strengths and limitations of existing findings and integrate the fingings into conceptual framework (Uscher-Pines, 2009). In this study, systematic literature review enables us to understand how people in high risk area respond to disasters, and to reveal the application of traditional ecological knowledge related to disaster management.

5 HAZARD-PRONE SETTLEMENT

This study has applied suitability analysis via geograpgic information system to select settlements located at hazard-prone areas. Afterwards, the comparative analysis is conducted to further find out settlements which had disaster loss. Eventually, the results will be overlapped with historical disasters including flood, debris disaster and slope disaster. The purpose is to explore why people could continued live in such high risk areas and find out whether traditional ecological knowledge exists or not. After the screening process above, three settlements that located at landslide-prone areas and suffered from disasters are selected.

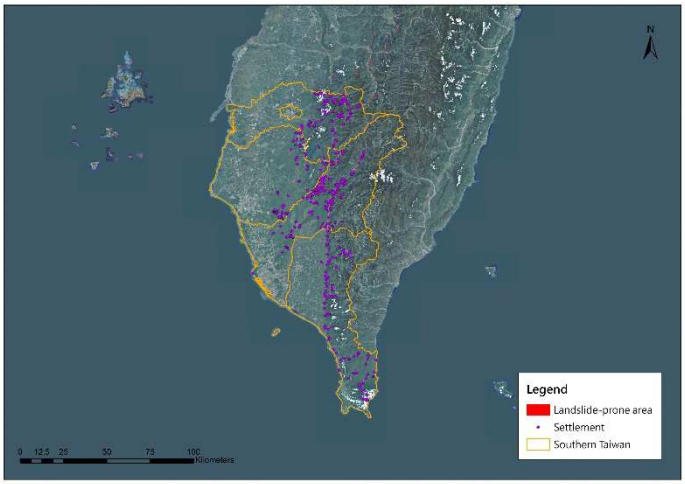

Fig. 2 Potential disaster risks. (A) Landslide-prone area

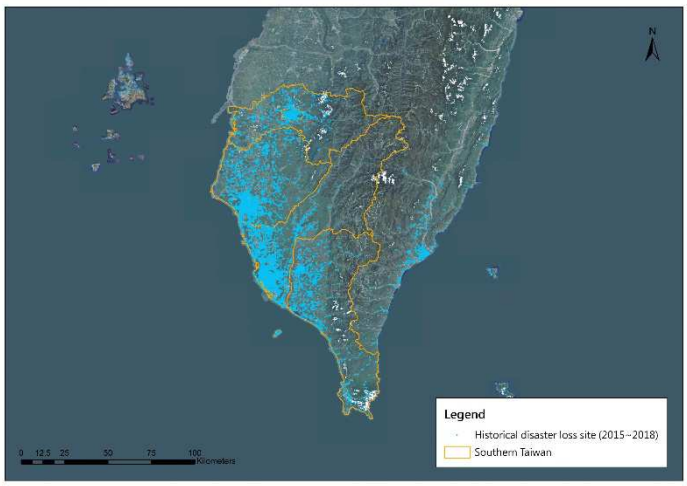

Fig. 3 Historical disaster loss site

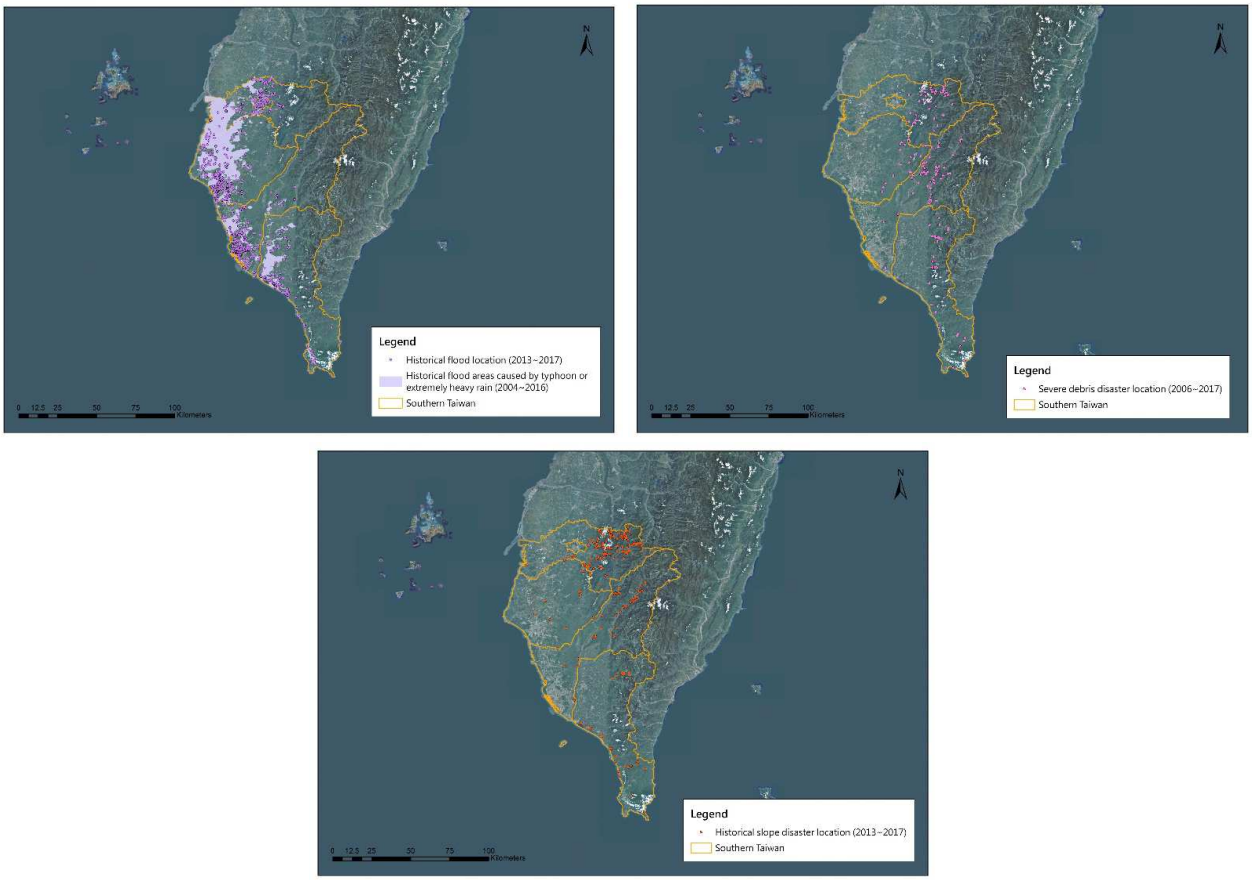

Fig. 4 Historical disaster records: (A) Historical flood disaster, (B) Severe debris disaster, (C) Historical slope disaster

According to the suitability analysis, three settlements of Paiwan peope have been selected including Yilin tribe is located in Laiyi Township, Siadanlu tribe and Chiaotung tribe had settled in Shizi Township. The historical disaster data shows that Yilin tribe was attacked by Typhoon Megi in 2016. In 2010, typhoon Fanapi brought extremely heavy rain and caused mudslide which buried roads and rivers and rushed into houses. Typhoon Trami in 2013 caused Siadanlu tribe suffering from slope disaster. Because of the debris accumulation affecting the waterway, the tribe was in urgent need of help from the government during typhoon Haitang and Nesat in 2017. During typhoon Nepartak in 2016, collapse of trees crushed high-voltage power lines and traffic was impacted in Chiaotung tribe because of the damage of electric pole. In addition, historical disaster records indicate that slope disaster occurred in neighboring area due to heavy rain in the winter of 2017. To sum up the above, disasters are very likely to occur repeatedly in the three settlements that located at hazard-prone area and made them suffered from disasters continuously. Therefore,

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

the study attempts to explore if there is any TEK among Paiwan people to keep them staying such high risk areas.

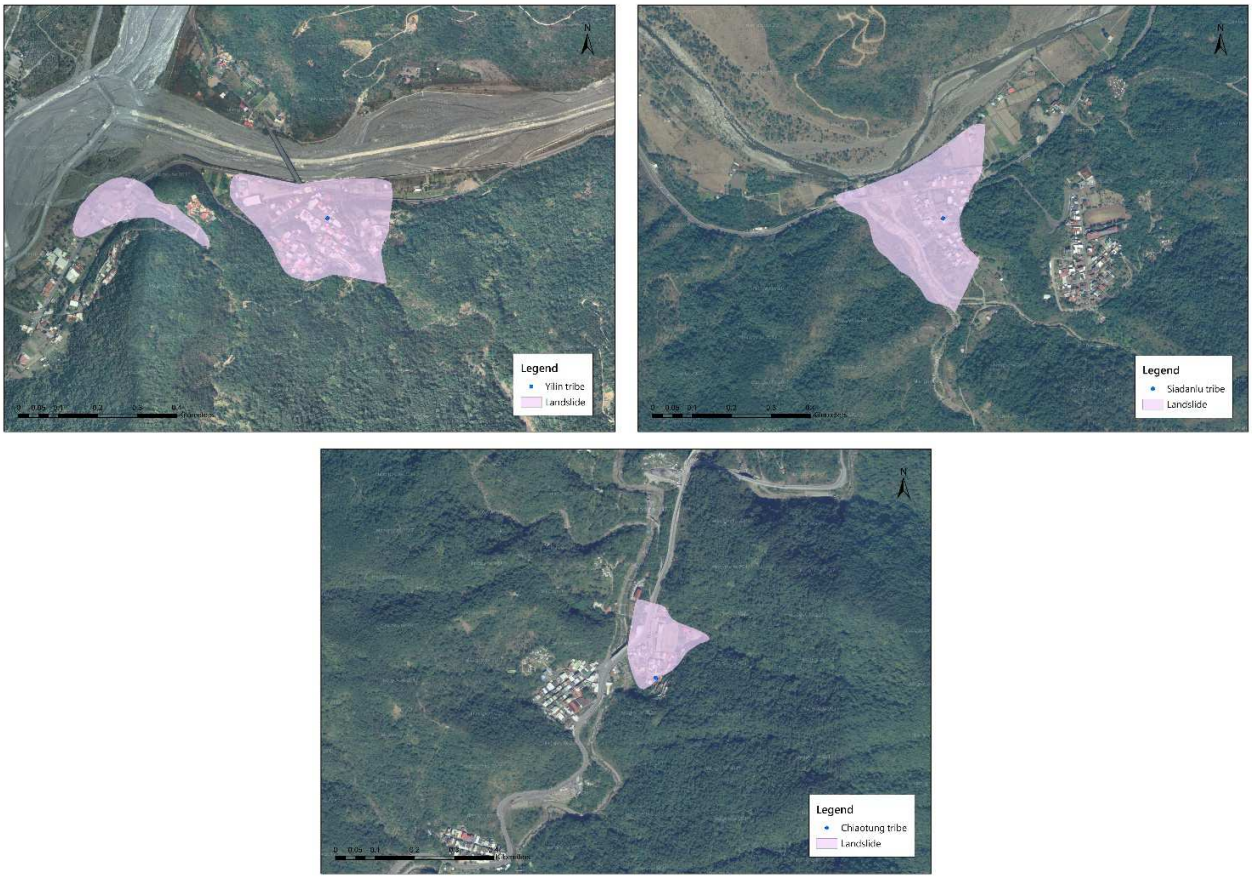

Fig. 5 Study area: (A) Yilin tribe, (B) Siadanlu tribe, (C) Chiaotung tribe

6 TRADITIONAL ECOLOGICAL KNOWLEDGE OF PAIWAN PEOPLE

Paiwan is one of the indigenious people in Taiwan. Paiwan people practice traditional social context and believe in Christianity, Catholicism and aboriginal traditional beliefs (Laiyi Township Office, 2020). The settlement pattern is collective village and mainly distributed in the southern part of Taiwan mountains in Pingdong and Taitung (the height is around 500 meters to 1,300 meters) and most of Paiwan people are located in Laiyi township, Pingtung county (Lin, 2010). Situated in the subtropical monsoon region, heavy rain and cyclones occur frequently in Taiwan. For Paiwan people, because of weather and geographical environment, is often affected by earth and rock disasters and floods. Hence, Paiwan people have extensive knowledge to cope with disasters.

Fig. 6 Landscape of Yilin tribe

Traditional ecological knowledge could be divided into various stages including days before disaster and during disaster. There are multriple signs could be applied to forecasting whether there is a storm coming or how bad will the storm is. In general, Paiwan people could predict a storm is coming by observing weather condition such as thunderstorm comes in summer afternoon and stops suddenly, feather shaped clouds or horsetail shaped clouds. or the color of the sky might be changed right before the storm. In addition to meteorological changes, unusual animal behavior can also be used to predict the onset of extremely heavy rain. Ant migration is believed to sense the nearness of heavy rains. There's a Paiwan nursery rhymes about it, "window in the sky, window in the sky, when does it rains, look at the ants climbing up (Guo & Chen, 2017)."

Fig. 7 Cloud signs

Landslide are predicted when it's raining. Paiwan people observe environmental conditions to judge whether landslide will happen. Depending on the environmental changes, Paiwan people will determine whether the disaster will happen and when to leave. It's mainly based on changes in rivers and indicators included the rising of water level and the rivers become turbid. It is noted that when the flow rate and velocity of rivers changes, accompanied by strong ground vibrations, and fog appears upstream, these signs represent the appearance of the landslide (Guo & Chen, 2017; Xiao, 2013).

7 CONCLUSION

Traditional ecological knowledge enables local people to adapt to their environmental problems for long periods of time. Although limited by the open data, only information in recent years has been collected. It is still revealed from the literature that indigenous tribes in high risk area have traditional ecological knowledge to cope with disasters. The study found that the application of traditional ecological knowledge in Paiwan is mostly used for disaster prediction or reducing disaster risk and less for disaster recovery. In this case, migration is not a necessary solution which may cause disruption of a society. In contrast, high risk areas without traditional ecological knowledge are more in need of migration strategies or require the traditional ecological knowledge from surrounding area. Traditional ecological knowledge should contribute to disaster application and help people in high risk improve their capacities to disaster adaptation and resilience strategies to adapt the changing environment. With the expansion of traditional ecological knowledge, it is highly possible to reduce the need for migration in high risk areas and the economic, political or sociocultural problems derived from migration.

1 ABSTRACT

Currently, the world is facing great challenges in terms of securing water, energy and food for all. With continuous increase in urbanisation and and changed lifestyles, the demand within the three sectors food, water and energy (FWE) in cities is increasing as well (Sukhwani et al., 2019). Due to the limited availability of natural resources, the pressure on urban land use is equally increased, thus more attention needs to be given to sustainability and resource efficiency. Furthermore, climate change and the related increased frequency of extreme weather events such as stormwater events and/or dry periods pose additional challenges for infrastructure and (agricultural) land use as well as for the quality of life. These challenges call for more systemic, integrated and cross-sectoral approaches helping to build resilient urban systems. These approaches should focus more on a holistic urban system transformation, rather than tackling problems within one sector. Thus, the main goal of reaching a sustainable future should be to create integrated, informed and well-coordinated interventions to support cities to become more climate resilient.

As a response to the problem setting, the concept of FWE Nexus emerged. The Nexus describes and analyses the interlinkages between the three sectors, with the goal to identify potential synergies and minimise trade-offs between the three sectors (Hoff, 2011).

The paper discusses a number of methods on how to describe the FWE system: Firstly, to show how different elements in the entire FWE system are interrelated and to create a common system view among the involved stakeholders, a qualitative system analysis, has been carried out. This qualitative system analysis enables experts (from FWE sectors, city authorities, urban planners) to understand the causal relations and the feedbacks between the system elements. Thus, to cope with the challenges and system immanent drivers, a basis for the discussion and development of strategies is established. The qualitative analysis was also used to gain a specific view on the differences between different case study regions. Secondly, based on this qualitative analysis, a more specific quantitative GIS-based analysis of land use changes and resulting water demand has been performed as input for a simulation model. This model will be used to analyse the impacts of spatial planning scenarios for the sustainable resources management and shall support urban planners to create more resilient cities and regions.

Keywords: FWE Nexus, population growth, land use change, urban agriculture, qualitative and quantitative system analyses and simulation

2 BACKGROUND AND OBJECTIVE

Rapid urbanisation, growing population and the evolving challenges posed by climate change are causing an increased need for security of supply of water, energy and food for all. Due to the limited availability of natural resources, the pressure on urban land is increasing and competition for land use is created. This requires a stronger focus on the sustainable and efficient use of the resource land. Bren d´Amour et al.(2017) concluded that the rapid expansion of cities will result in the loss of some 300,000 square kilometres of particularly fertile farmland worldwide by 2030. This arable land, which will probably disappear in the future, is almost the size of Germany. Furthermore, climate change and the related increased frequency of extreme weather events such as stormwater events and/or dry periods, pose additional challenges for infrastructure and (agricultural) land use as well as for the quality of life.

In this context, the Sustainable Urbanisation Global Initiative (SUGI)/FWE-Nexus call was jointly established by the Belmont Forum and the Joint Programming Initiative Urban Europe. Within this call, the AIT Austrian Institute of Technology GmbH is involved in the project IN-SOURCE (INtegrated analysis and modeling for the management of sustainable urban FWE ReSOURCEs), which aims at developing a joint urban data and modelling framework that will help cities and regions to analyse and characterise the FWE-Nexus interdependences. This framework is based on the extension of semantic 3D city models as well as on

geoinformation applications to be developed and applied in the three case study regions: Vienna, New York and the administrative district Ludwigsburg as a metropolitan region. The paper focuses on the case study region Vienna.

The objective of the qualitative system analyses, the causal relation analyses, are (i) understanding the system elements interaction and feedbacks in the entire FWE-System, (ii) building a joint vision of these system elements interactions between the project partners, (iii) supporting the discussion with stakeholders in interactive workshops.

3 QUALITATIVE SYSTEM ANALYSIS

Causal relations can be expressed by using the method of Causal Loop Diagrams (CLDs). The approach became famous during the 70ies as they have been used by the Club of Rome to explain the system structure of the developed World3 models (Meadows et al., 1972).

CLDs use a simple "language" to describe dynamic systems and can be used to analyse, communicate and discuss possible system behaviour. Interrelations between system elements expressed as arrows with polarities (+, -) and time delays are the components used to visualise the entire system. CLDs have no starting point or end point, they are rather closed circuits. The system elements are entities, which can increase or decrease. The arrow with the polarity indicates how an entity changes when the influencing entity changes. A link marked positive (+) indicates a positive relationship and a link marked negative (-) indicates a negative relation. A positive causal link means the two entities change in the same direction, i.e. if the entity in which the link starts decreases, the influenced entity also decreases. Similarly, if the entitiy in which the link starts increases, the influenced entity increases as well. A negative causal link means the two entities change in the opposite direction: if the entitiy in which the link starts increases, the influenced entity decreases, and vice versa. With these simple "rules" complex system structures can be visualised. For the CLDs developed in IN-SOURCE and shown in this paper we used coloured arrows (blue) and solid lines for "+" interrelations and red arrows and dashed lines for "-" to increase the readability in the paper.

The aim of the FWE CLDs which are specifically developed for each case study region is to get a more appropriate view about the most important interactions. The diagram neither consists of all possible system elements nor all connections as this would make it hardly manageable to interpret. For example, we didn´t differentiate between different water qualities which would have restricted use for different purpose only (drinking water, treated waste water, rain water etc.).

The decision of which element/parameter/factor is important, was met according to different information: expected system element changes, e.g. population changes (increases or decreases), effects of climate change, together with challenges the case study areas are currently facing, e.g., mitigation of heat islands, air pollution. Other important factors to identify important links were the interest of the relevant stakeholders and available tools to quantify the causal relations. Within the specific CLDs for each case study region we indicated the more important links by increasing the thickness of the arrows as the specific CLD for Vienna in Figure 1 shows.

3.1 Causal FWE relations in Vienna

The causal relations diagram for Vienna was established under the assumption of a growing urban population. According to forecasts, Vienna will grow moderately by 289.000 people (about 16%) over the next three decades and the population of the city will be about 2,200,000 in 2048 (MA23, 2018). Additionally, climate change has been taken into consideration as a determining factor that will change the future system logic. The CLD shows relations between the three systems of water, energy, and food and challenges Vienna is currently facing (e.g. heat islands, air pollution, urban land availability). Due to the high complexity of the topic, this analysis can only show a few relevant connections that are primarily connected to the Nexus. Figure 1 shows the causal FWE relations that have been assigned to the three systems using different colors.

3.1.1 Urban Food System

Population growth would also increase the related Food consumption which in return reduces the Food availability. To meet the increasing demand for food, importing food results in an increasing transportation demand which causes additional CO_2 emissions what can be called a Nexus effect with the energy system.

Another option to supply the city with sufficient food is to increase Urban Agriculture (UA) which again increases the traffic to transport the food and affects the energy used for UA. Not only can food be grown on the available farmland, but it can also be used as an energy source by producing biofuel. This of course means again a reduction of Food availability.

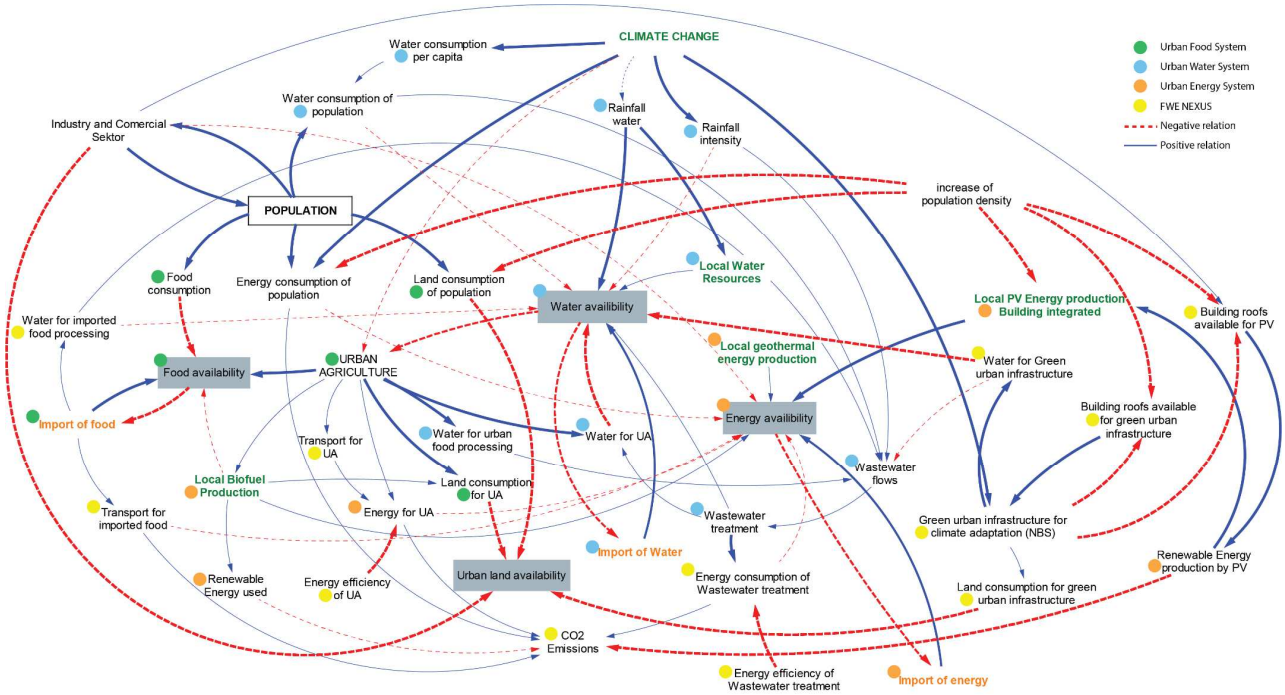

Fig. 1: Specific Causal food-water-energy relations for Vienna. ©AIT

The urban food production system is obviously closely related to the availability of urban land which creates conflicting interests. The main conflict due to population growth arises between urban food production and the construction of new dwellings and industrial areas including green urban infrastructure (e.g. parks). As construction activity for housing and industry increases, the availability of arable land decreases. Innovative forms of UA as vertical farming and aquaponic reduce this conflict but are currently not in the scope of the city of Vienna. To minimize the land consumption of the assumed population growth, the population density could be increased too (e.g. by increasing the building height). This would result in a decrease of the Land consumption of the population and might subsequently result in increased Urban land availability.

Another parameter that needs to be involved as a key impact factor in the future urban food production system is Climate Change. More than almost any other sector, agriculture depends on climatic influences. Even slight changes in temperature and precipitation have a noticeable impact on the level and annual variability of yields and agricultural incomes. Both in past and future growing seasons, heat waves result in dry and dusty fields and an unbalanced distribution of precipitation severly affects the agricultural yields (Mitter et al., 2014; BMLRT(a), 2019).

3.1.2 Urban Water System

Climate Change has also an important effect to the water availability. Increased Rainfall water would increase the local Water availability, whereas current climate models for Vienna make it very difficult to estimate the changes in the amount of rainfall. The Rainfall intensity is, according to the current climate models, easier to predict and will increase. This would increase the Wastewater flows and reduce the Water availability because the total amount of rainwater could not be stored by the environment – soil, lakes etc. – (the surface runoff will increase). Additionally to the more frequently occurring heavy rainfall, the climate models are predicting that heat stress/heat waves will also occur more frequently in the future. One of Vienna´s strategies to cope with this problem is to increase the green and blue urban infrastructure (e.g., on bulding roofs and facades or urban places (MA18(a), 2015)) which results in an increase of Water demand for Green urban infrastructure but will further reduce the Water availability due to the required irrigation needs. In general, the current water system for Vienna regarding drinking water and water for industry is

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

dominated by water import from outside of Vienna and a growing population will further increase the need for more imports to the system.

3.1.3 Urban Energy System

The energy system of Vienna is currently dominated by energy imported to the system. Almost 90 % of the energy consumed in Vienna is imported (MA20, 2019). In the future a higher share of renewable energy produced within the city as well as a more efficient use of energy is key to meet the 2050 targets regarding the reduction of CO_2 emissions. Energy efficiency in urban agriculture aims e.g. at increasing the utilisation of waste heat from other uses for example to heat the green houses during winter season. The above-mentioned conflict for urban land and the possible mitigation strategy to use vertical farms would increase the amount of energy needed to grow the plants in these facilities. The source of this additional energy demand is decisive. Photovoltaic (PV) systems producing electricity on the roofs of the vertical farms would for sure be a starting point to tackle the energy demand, especially during the winter season. In general, increasing the amount of building integrated PV is part of the Smart City framework strategy for the future (MA18(b), 2019).

The population growth resulting in an increased population density would also decrease the Building roofs available for either PV or green urban infrastructure due to limitations of urban land availability and the construction of high-rise buildings (which could affect the solar radiation). Thus, a more vertical development of Vienna (like New York City) would also have negative side effects on other resources (Renewable energy from PV) due to limited space availability for the installation of the necessary infrastructure.

Another important Nexus connection related to the water system is the Energy consumption of Wastewater treatment which will increase with the population growth. An increase in the Energy effciency of Wastewater treatment would decrease the energy needs. The increased amount of treated wastewater could be used in Urban Agricuture (UA) and increases therefore the Water availability in the system.

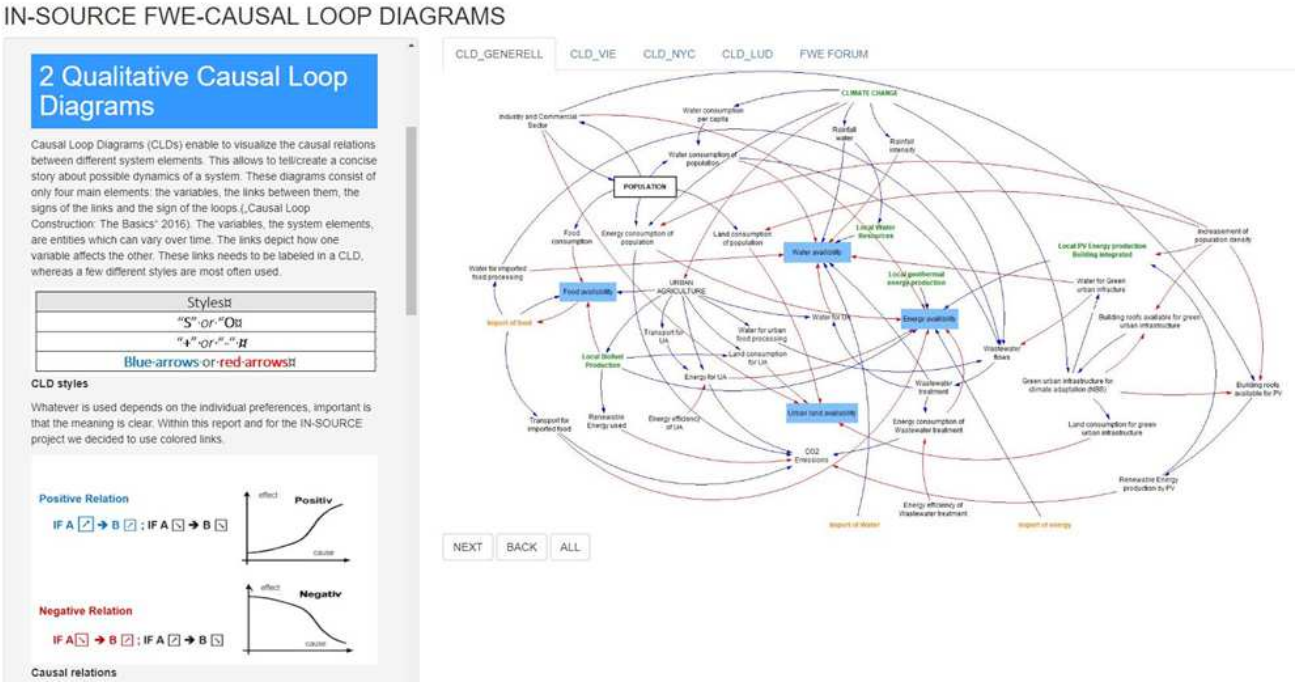

Fig. 2: Screenshot of the web-application to discuss the FWE-System – Specific CLD for Vienna, ©AIT

3.2 Story telling with CLDs

These causal relations discussed so far are only a part of the relations presented in the CLD (Figure 1). The aim was to present the use of the developed specific CLD to "tell a story" on what would happen if some of these causal relations would change (increase or decrease). During the discussion with the stakeholders (energy experts, urban planners, food related NGOs from Vienna) in the workshops, the CLD has been very valuable as the experts found important connections of their own domain to others and missing interrelations

could also be identified by the experts which improves the entire system knowledge. As Figure 1 shows, CLDs are often very complex in the sense which makes it difficult to follow and analyse. To increase the usability, a step by step introduction is recommended. For this purpose we developed within the IN-SOURCE project an interactive web-application to help users to understand the contex more easily by telling the story.

Figure 2 shows a screenshot of this interactive web application (AIT(a), 2020). For the other case study regions, that are considered in IN-SOURCE, New York City (NYC) and Ludwigsburg specific CLDs were also created, which also can be found in the web-application.

4 QUANTITATIVE ANALYSIS

As mentioned above, based on the qualitative FWE Nexus system analysis, a quantification for important causal relations was performed. Main part of this was a GIS-based water demand analysis for different land use categories in Vienna. As basis, the current land use in Vienna, as shown in the following Figure 3, was used. The map illustrates the spatial distribution of urban agriculture-related land use categories in the city of Vienna in the year 2016. The map was created using open-source data supplied by Open Government Data Austria (OGD, 2019).

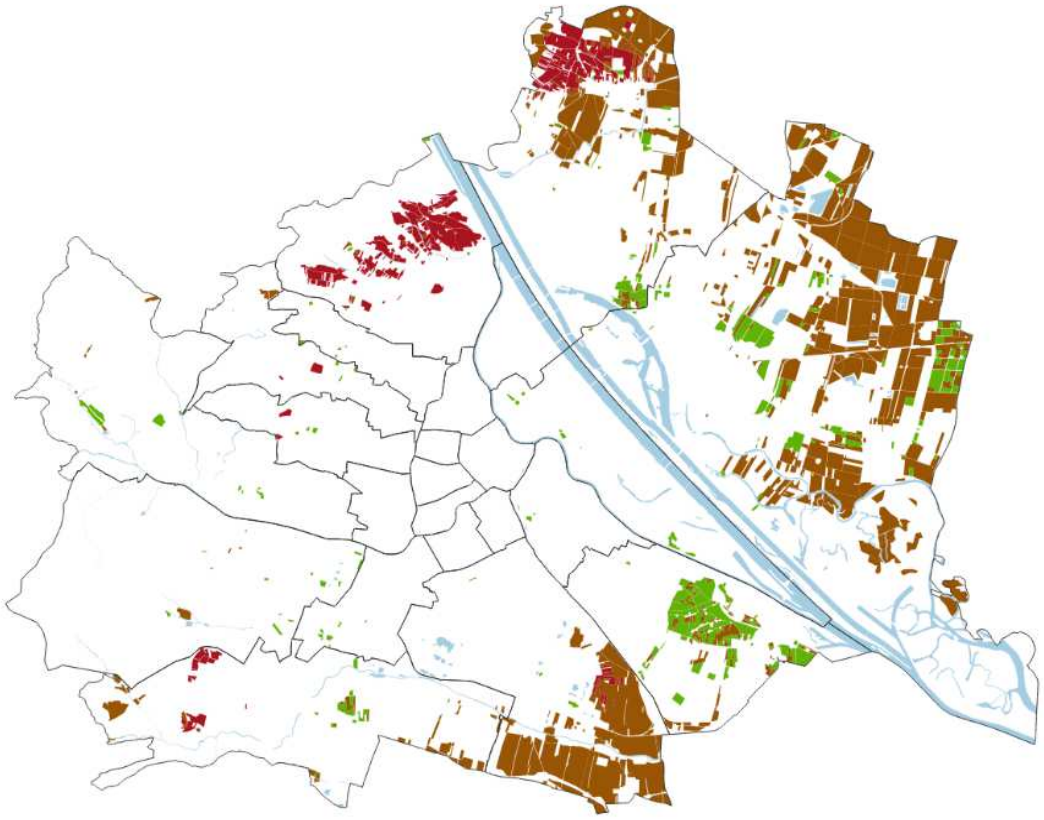

Fig. 3: Agricultural areas in Vienna 2016 (OGD, 2019), incl. water bodies and district boundaries of Vienna, ©AIT

There are 31 land use categories provided in the data set (OGD, 2019), while for this paper only so called "Urban Agricultural Areas" are of interest. These areas are divided into the three categories farmland, vineyard, nursery and orchard which cover 14% of the total area of Vienna. Farmland is most important because of the large proportion of urban agricultural area it occupies. Arable farming is mainly operated in the north, east and south of the city. Farmland corresponds to about 10% of the city's total area, which is significantly higher compared to e.g. 4% of agriculturally used area in Berlin. (UBA, 2019).

In 2016 almost 38,000 tons of field crops (grains, oil fruits, pulses, potatoes) have been cultivated on about 3,000 ha arable land (used for cultivation of field crops) in Vienna. Wheat accounts for around 50% of the total harvest. Nevertheless the level of self-suffiency for Vienna within these products is rather low – about 8% self-sufficiency for grains (Landwirtschaftskammer Wien, 2017). Table 1 gives an overview of the per capita consumption of different foods in 2017/18 for selected products.

Vegetables		**Grains**		**Others**	
	[kg/capita]		*[kg/capita]*		*[kg/capita]*
Tomatoes	29.0	Wheat	63.3	Sugar	33.3
Onions	9.4	Barley	0.5	Potatoes	49.0
Carrots	9.1	Maize	13.4	Legumes	0.9

Table 1: Per-capita consumption July 2017 to June 2018 of main foods in Vienna in kg (Statistik Austria, 2019)

For estimating the water demand for farmland, it was necessary to estimate the water demand of different field crops. For our approximation we used potatoes, tomatoes, wheat and sugar since they correspond to the biggest amount of herbal foods consumed per capita in Vienna. Thus, these crops were considered to simulate the water demand of the land use category farmland. For the calculation of the water demand of these crops, the simulation tool AquaCrop by FAO was used (AquaCrop FAO, 2019). AquaCrop is a crop growth model developed by FAO's Land and Water Division to address food security and assesses the effects of the environment and management on crop production.

AquaCrop uses the input parameters climate, crop information, irrigation and soil to calculate the water demand of certain crops. The crops wheat, tomatoes, potatoes and sugar beet chosen for Vienna were already implemented as default files in the simulation tool. Thus, it was only necessary to make adjustments regarding sowing and harvesting time for the considered crops according to common practice in Austria (Agrana, 2019; Laendle - Kartoffel, 2019; Vereinigung der Pflanzenzüchter und Saatgutkaufleute Österreichs, n.d.). It should be noticed that AquaCrop calculates the water demand for crops that are cultivated in open field production. In the case of tomatoes in Vienna, the results could differ from the real situation as the tomatoes are mainly grown in greenhouses. Since the per capita consumption of tomatoes in Vienna is rather high, the water demand of tomatoes nevertheless was simulated with AquaCrop, as a first approximation.

The software simulates the irrigation requirement for optimal crop development. This means that the plants are always supplied with sufficient water, naturally via precipitation or by additional irrigation, so that the plants do not suffer from water stress and can therefore develop optimally. Chernosem was defined as soil type, which is a common and suitable soil type for agriculture in Vienna (MA22, 2019; ViennaGIS, 2019).

For the simulation of Viennese crops, the local climate is of great importance. Climatic data provided by AIT (supported by high resolution dynamic simulations carried out with the regional climate model COSMO-CLM (AIT(c), 2019; Cosmo, 2020)) was used for present as well as for future climate. Therefore, it was possible to simulate the water demand of agricultural crops in the future. Table 2 illustrates the development of the average water consumed by typical Viennese crops in the climatic periods 2019-2048 (P1), 2049-2078 (P2), 2079-2098 (P3). Climatic periods were used to reduce the annual fluctuation in precipitation. The calculated water demand presented in the table below considers only water consumed by the crop growth. Water consumption for transport, processing or washing, etc. is not included.

	Water demand in mm/m²				
	P1: 2019-2048	P2: 2049-2078	Change (P1 to P2) [%]	P3: 2079-2098	Change (P2 to P3) [%]
Tomato	885	900	+1,7%	920	+2,2%
Spring wheat	1235	1265	+2,4%	1335	+5,5%
Sugar beet	1225	1235	0,8%	1245	+0,8%
Winter wheat	780	810	+3,8%	980	+21,0%
Potato	1045	1075	+2,9%	1145	+6,5%

Table 2: Development of the average total water demand of typical Viennese crop plants due to climate change

Although there is only little difference in total average water demand, the figures don't reveal the sources of water. As the changes show, the water demand remains rather constant for all considered crops except for winter wheat. However, there is a current trend towards increased winter wheat cultivation, which Austrian farmers are following. According to the Federal Ministry of Agriculture, Regions and Tourism (BMLRT), the cultivation of spring wheat is declining due to climate change and the resulting hot and dry summer months (BMLRT(b), 2019). Statistical data confirms this trend: From 2016 to 2019 the cultivation area for spring wheat declined by 57 % (2016: 101 ha; 2019: 43 ha) in Vienna (Statistik Austria(b), 2020).

To understand this trend, it is necessary to reflect upon the sources of water – from irrigation or precipitation – as mentioned above. Figure 4 seperates the sources of water into precipitation and irrigation for the same time period. It should be noticed, that the following figure exclusively shows water which is actually consumed and therefore necessary for plants to grow. The diagram shows the trend that in future the share of irrigation will increase continuously for all selected crops. Since all crops have different growing periods, the amount of precipitation, which can be used, differs. The best example is spring wheat and winter wheat. Whereas spring wheat is sown in spring and harvested in autumn, winter wheat is sown in the beginning of autumn. That is one of the reasons why the proportion of natural and water from irrigation differs between these two crops. Due to changing climate conditions, the distribution of precipitation during the year is shifting and can also be a reason for having to adapt the crop types.

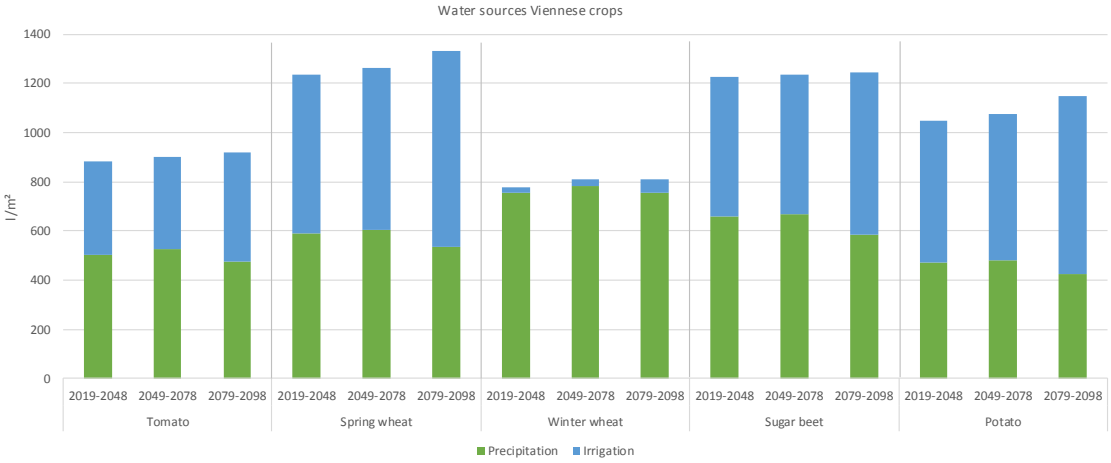

Fig. 4: Development of the average precipitation and irrigation requirement of typical Viennese crops 2019 to 2098, ©AIT

Focusing on spring wheat, the diagram illustrates that the irrigation requirement is sigificantly increasing: in the climate period 2079-2098, the proportion of irrigation will even be greater than that of natural precipitation. This development contributes to the conversion of the cultivation of winter wheat in Austria, as mentioned above. Whereas irrigation requirement represents the main share of the total average water demand for most of the considered crops, the share of irrigation requirement for winter wheat remains relatively low. The following figure 5 shows the monthly mean temperature and precipitation for the respective climate periods to compare the results with climate data.

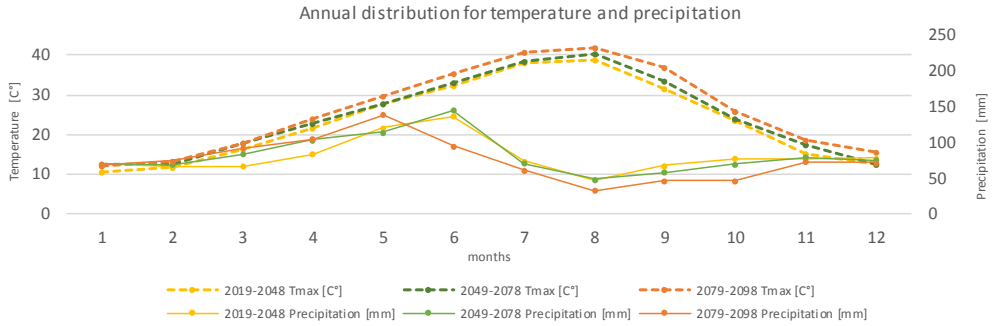

Fig. 5: Development of the monthly mean temperature and precipitation averaged over a 30-year span representing a time period from 2019 to 2098, ©AIT

As can be seen in the diagram, precipitation is steadily decreasing over time which is reflected in the irrigation demand for the considered crops. The climate model predicts a significant decrease of about 6% of precipitation for the period 2079-2098 compared to the previous period 2019-2048, as one factor leading to the required irrigation demand for the crops. In addition, the diagram shows an higher increase in temperature in the considered period during the entire year, which also increases the need for irrigation. The results of the climate model provide an outlook into the future, enabling to estimate the impact on the water demand for urban agriculture, in order to adapt to climate change. In summary, the results of the climate model show that a change is imminent in the next decades which will definitely influence the handling of resources.

As part of the IN-SOURCE project, these analyses shall lead to an estimation of water demand for Vienna, based on land use categories. In this context, additionally to the water demand for arable land, water demand factors have been investigated within the project for all relevant land use categories.

The research has shown that currently only limited (publicly available) data on water consumption in Austria, especially in Vienna, is available for different land use categories, or is difficult to obtain. For the residential category, an average daily water consumption of 130l/(capita*day) was used (wien.gv.at, 2019), whereby this was in turn divided into several density categories as distinguished in real use (OGD, 2019) (e.g. dense residential area, garden city, large-volume residential construction, loosely built residential area/single-family houses area), as the water consumption in these housing options differ considerably from one another (Neunteufel, 2010). For industrial, commercial and service-oriented areas, estimating the water demand is difficult due to several parameters. According to Neunteufel, 2010, on the one hand, there are no figures on what proportion of Austrian industrial companies cover their water needs from the public water supply and what proportion is covered by self-supply (e.g. from ground water). On the other hand, the processes in industry/trade are very heterogeneous, which makes it difficult to estimate on a general level. In the commercial sector, values are usually set which, depending on the commercial enterprise, are multiplied by the number of employees or the quantity produced in order to take account of the different consumers. Nevertheless, there are some data that was collected from different studies and used in the project.

	Land use category	Mio.m³/a
Infrastructure	Industry & Service	46
	Social Infrastructure	7
	Mixed use	3
	Streetscape	3
	Technical Infrastructure	1
	Total:	**60**
Residential	Residential & Mixed use	66
Agriculture and Natural area	Recreational and leisure facilities	21
	Agriculture	30
	Natural area	49
	Total:	**100**
Total		226

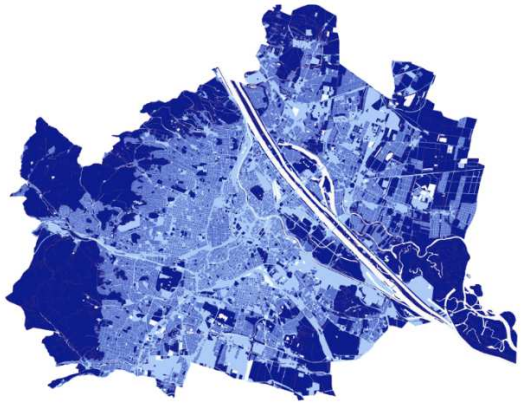

Fig. 6: Water demand by land use categories, ©AIT

The results of the water demand analyses show a total water demand of 226 Mio. m³ per year in Vienna (calculation base year 2018). The residential use accounts for the largest share. The average water consumption for industrial/commercial areas was calculated at approx. 31,000 m³/ha and year, the agricultural and natural areas are estimated to consume an average of 5,000 m³/ha per year, which corresponds to about 1/6 of the demand of industry. For residential areas, between 2,000 and 19,000 m³/ha and year are needed, depending on the density of the residential area.

5 SUMMARY AND OUTLOOK

The aim of the qualitative approach using CLDs to highlight important FWE relations was to get a more appropriate view about the most relevant interactions. And indeed, the multiple connections give an idea of the complexity of the topic. The specific quantitative GIS-based analysis of land use changes and resulting water demand has shown, that there is further need for research activities in this area. The influencing factor of climate change concerning the change in water consumption needs to be investigated in more detail. Besides climate change, many other factors need to be taken into account, but cannot be assessed and truthfully projected into the future due to unpredictable trends. For example, changes in lifestyles like dietary habits are difficult to foresee. Scenario simulations can at least help to prepare for different possible futures and enable to create adquate adaptation measures.

Another research question that was raised in the project deals with the topic on how do new forms of urban agriculture (vertical farming, insect breeding, aquaponics) affect the specific water and energy consumption? Besides that, the development of green and blue infrastructure will also become a crucial topic in the future in order to accelerate climate change adaptation and benefit from the positive cooling effects to improve quality of life and well-being of citizens.

Our analyses has shown that still high uncertainties exist, but this first estimation enables to get an idea of the most important leverage points to influence the water balance and existing FWE Nexus relations. The next steps in the project are to use the first results to simulate a future water demand using input data from the climate model. These results will be used as input for the simulation model URBANICA (Gebetsroither, 2014; Gebetsroither, 2015; AIT(b), 2020) which enables the user to analyse the impacts of spatial planning scenarios for the sustainable management of resources. The aim is to support urban planners in creating climate resilient cities and regions with regards to the FWE aspects.

6 ACKNOWLEDGEMENTS

The results in the paper were created as part of the IN-SOURCE project, funded under the framework of the SUGI Initiative in the Food-Water-Energy Nexus call, which was jointly established by the Belmont Forum and the JPI Urban Europe. In this context, we would like to give our acknowledgements to the Federal Ministry Republic of Austria Climate Action, Environment, Energy, Mobility, Innovation and Technology (BMK).

1 ABSTRACT

Der Anteil an Flächen in städtischen öffentlichen Räumen sind hauptsächlich zu Gunsten des motorisierten Individualverkehrs verteilt (Havemann, 2010; Knoflacher, 2009) – Fußgängerinnen, Fußgängern, Radfahrerinnen und Radfahrern bleiben meist nur die Restflächen (Notz, 2017). Während der Nutzungsdruck durch neue Mobilitätsformen weiter steigt und unterschiedliche Interessenslagen ausgehandelt werden müssen, rückt die Bedeutung und Umgestaltung des öffentlichen Raumes zunehmend ins Zentrum des Diskurses. Neue (urbane) Initiativen und Bewegungen fordern diese Räume und alternative Umgestaltungen vermehrt ein. Allerdings sind Prozesse der Stadt- und Verkehrsplanung starr und langfristig angelegt und reagieren meist zu langsam auf aktuelle Herausforderungen und Bedürfnisse. (Fugmann and Karow-Kluge, 2019). Dies wird zunehmend kritisch diskutiert und mehr Flexibilität, Experimentieren und Partizipation eingefordert (Savini et al., 2015), um eine „faire“ Verteilung des öffentlichen Raumes und eine nachhaltige Mobilitätskultur zu bewirken. Ein wesentlicher Ansatz für das neue Planungsverständnis ist die Herangehensweise des „Tactical Urbanism“. Dabei werden Interventionen als zeitlich begrenzte Veränderungen des öffentlichen Raumes sowie auch „als Instrument der prozessualen Stadtentwicklung, als Teil von Planungs- und Beteiligungsprozessen und als städtebaulicher Lösungsvorschlag“ (Drobek and Tran, 2017) herangezogen.

Der Forschungsansatz des „Tactical Urbanism“ wird im Projekt „Tactical Mobilism – Interventionen für eine nachhaltige Mobilitätskultur“ aufgegriffen mit dem Ziel zeitlich begrenzte, einfache und kostengünstige Interventionen zur Transformation von Mobilitätsräumen zu testen und zu etablieren. Das Projekt wird im Rahmen des Forschungsförderungsprogramms “Mobilität der Zukunft” durch das Bundesministerin für Klimaschutz, Umwelt, Energie, Mobilität, Innovation und Technologie (BMK) gefördert. Dieser Beitrag beschäftigt sich daher mit dem Begriff und Ansatz des „Tactical Urbanism/Mobilism“, verschiedenen Fallbeispielen aus der räumlichen Praxis und einen Einblick in den Use Case Villach.

Keywords: Urbanism, Mobilitätskultur, Tactical, öffentlicher Raum, Interventionen

2 HINTERGRUND – NUTZUNGSDRUCK UND STARRE PLANUNGSPRAKTIKEN

Im Zuge der Massenmotorisierung beginnend in den 60er Jahre hat die Stadtplanung und Verkehrsorganisation zunehmend die Ansprüche des PKWs gegenüber anderen priorisiert (Monheim, 2018) Dies wirkte sich nicht nur auf eine hohe Flächeninanspruchnahme auf Kosten der gemeinschaftsbildenden Funktion des öffentlichen Raums, des Zusammenlebens und nachhaltiger Mobilität, aus, sondern hat auch negative Umweltfolgen (VCÖ, 2018; Dover and Massengale, 2014).

Doch es findet ein Umdenken statt den motorisierten (Individual-)Verkehr in seiner Dominanz in der Stadt zurückzudrängen (Degros and Bendiks, 2019). In den letzten Jahren rückte eine Fülle von städtischen Aktivitäten in den Fokus wissenschaftlicher, aber auch planerischer Diskurse. Höhere Investitionen in Radinfrastruktur und Fußgängerzonen, die Förderung des öffentlichen Nahverkehrs und die Reduktion von Stellplätzen sind beispielhafte Maßnahmen in Städten (VCÖ, 2019). Dem gegenüber treten immer mehr teilkollektive Interessensgruppen, die nach heterogenen, zukunftsweisenden Gestaltungen öffentlicher Räume verlangen und ihre Ansprüche aus verschiedensten Phänomenen unserer heutigen Zeit, wie Klimawandel, Energiekrise, Strukturwandel und Mobilitätswende, ableiten (Lange, 2014: 16). Unter Begriffen wie "Tactical Urbanism", "Informeller Urbanismus", oder "Subversiver Urbanismus", sowie „Bottom-Up-Urbanism“, „Self-Made-City“ oder „Grassroots-Bewegungen“ (Saiko, 2013: 26) wird eine Reihe von diesen städtischen, kreativen Praktiken zusammengefasst, die eine Aneignung des öffentlichen Raums anstreben und häufig durch direkte Interventionen sichtbar werden (Sandholzer, 2019; Iveson, 2013; Saiko, 2013). Insbesondere das Konzept des „Tactical Urbanism“ hat zum Ziel zeitlich begrenzte, einfache

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

und kostengünstige Interventionen (z.B. Umbaumaßnahmen wie Parklets, temporäre Sperrungen, Begrünungsmaßnahmen) im Verkehrsbereich zu etablieren.

2.1 Nutzungsdruck in öffentlichen Räumen steigt

Zurzeit sind öffentliche Räume in Städten hauptsächlich zu Gunsten des motorisierten Individualverkehrs verteilt. Aufgrund des Zielkonflikts zwischen verkehrlichen und lokalen Nutzungen verlieren die öffentlichen Räume in urbanen Gebieten immer mehr an ihrer sozialen Funktion (Notz, 2017). Zum einen tragen die durch die autozentrierte Verkehrsplanung der letzten Jahrzehnte überdimensionierten Verkehrsflächen zur Einschränkung von Nutzungsmöglichkeiten und Reduzierung potentieller Aufenthaltsflächen im öffentlichen Raum bei (Degros and Bendiks, 2019). Zum Anderen sorgt die hohe Verkehrsbelastung für gesundheitsschädliche Lärm- und Stickstoffemissionen, wodurch das Wohlbefinden und die Lebensqualität der Bewohnerinnen und Bewohner sinkt und auch die Aufenthaltsqualität stark beeinträchtigt wird (Randelhoff, 2017). Der notwendige Wandel zur Umverteilung der Flächen in urbanen öffentlichen Räume zugunsten der aktiven Mobilität und ein Anstoß zu einer nachhaltigen Mobilitätskultur findet noch zu wenig statt. Insbesondere bei Parkplätze bzw. stehende Fahrzeuge nehmen den meisten Platz im öffentlichen Raum ein. Ob es sich dabei um „eine Privatisierung öffentlichen Eigentums“ (Notz, 2017) handelt, wird zunehmend diskutiert.

Großstädte und Metropolen stehen meist im Zentrum des Diskurses um die faire Aufteilung des öffentlichen Raums und sind Drehpunkt disruptiver Kräfte von Bottom-Up Initiativen. Aber „[e]s ist kaum bewusst und wird selten diskutiert, dass es noch ganz andere Formen urbanen Lebens gibt“ (Schmidt-Lauber, 2010), die sich nicht in den Großstädten und Metropolen abspielen. Auch Klein- und Mittelstädte fordern und fördern zunehmend ein Umdenken in Richtung nachhaltiger Mobilität und lebenswerter öffentliche Räume ein, sind offen für informelle Planung und verstehen ihre Rolle als wichtige Wirtschaftszentren und Wohnstandorte in der Region (Baumgart et al., 2011). Da in Österreich, als auch in Deutschland, ein großer Anteil der Bevölkerung in solchen Klein-und Mittelstädten leben, ist es nicht nur statistisch relevant, sondern sollte auch ins Blickfeld der Forschung rücken. Jede/r sechste Österreicherin oder Österreicher wohnt in einer Klein- oder Mittelstadt (Statistik Austria, 2020). In Deutschland sind es sogar fast jede/r Vierte (Destatis, 2018). Daher ist im hier beschriebenen Projektvorhaben die Stadt Villach Pilotstadt und in diesem Beitrag als Use Case aufgeführt.

2.2 Bottom-Up vs. Top-Down

Top-Down und Bottom-Up sind die zwei Gegenpole der Einflussnahme und Beteiligung, die in der Stadtplanung diskutiert werden (Breuer et al., 2014). Bottom-Up drückt sich im urbanen Handeln als Partizipation, Teilhabe und Offenheit sowie in der Stärkung der Rolle der Bürgerinnen und Bürger und der Identifikation innerhalb der eigenen Gemeinschaft in einem direkt-demokratischen Prozess aus. Top-Down sind zum Beispiel Gesetze, die von oben herab durch eine Institution, Verwaltung oder durch politische Entscheidungsträgerinnen und Entscheidungsträger auf die Bürgerinnen und Bürger und das Verhalten wirken (Jessop et al., 2013).

Traditionelle Planung und Steuerung äußert sich häufig durch starre Strukturen, die nicht dafür ausgelegt sind auf Änderungen und Anforderungen schnell zu reagieren, aber auch gleichzeitig Planungs- und Rechtsicherheit garantieren (Pogačar and Šenk, 2018; Hoelzel, 2015). Durch den Eintritt von „Grassroot“-Bewegungen oder anderen Bottom-Up-Initiativen in das Feld der urbanen Politik und Governance lässt sich eine Verschiebung im Verhältnis zwischen privaten Investoren und öffentlicher Verwaltung feststellen, was neue Strategien in Richtung vermehrter Kooperationen und Verschiebungen in klassischen Rollenzuschreibungen und –bildern auslöste (Domaradzka, 2019: 7). Es besteht dennoch die Gefahr, dass die langen Planungsprozesse die aktuell vorherrschenden Bedürfnisse der Bevölkerung verfehlen, da sie in einigen Jahren nicht mehr den Status Quo abbilden und/oder auch nur einen Teilaspekt behandelt haben.

2.3 Flexibilität in der Planung

Das Top-Down Prinzip in der Stadtplanung wird zunehmend kritisch diskutiert und gleichzeitig von Planerinnen und Planern mehr Flexibilität, Ausprobieren und Experimentieren eingefordert (Bertolini and le Clercq, 2003; Salet et al., 2013; Savini et al., 2015). Das gemeinsame, partizipative Erarbeiten und Ausprobieren im öffentlichen Raum in einem sogenannten Reallabor bzw. –experiment kann auch neue

Sichtweisen eröffnen, zum notwendigen Umdenken bei den Akteuren führen und positive Impulse in Richtung einer nachhaltigen Mobilitätskultur setzen (West, 2018). In der Praxis sehen Bergevoet und Tuijl (2016) eine zeitliche Flexibilität als einen stufenartigen Prozessablauf in dem die Resultate immer offen für Veränderungen oder Anpassungen sind (Bergevoet, Tom; van Tuijl, 2016: 39). Eine integrative Planung und Neukonzeption von städtischen Straßen erfordert ein neues Regelwerk zum Prozessablauf, zum Design der Straßenräume und zur damit verbundenen Neuverteilung des Raumes. Der Einsatz von partizipativen Prozessen und Werkzeugen hat einen noch geringen Stellenwert in der Verkehrsplanung und wird nur vereinzelt bisher angewandt (Scherz, 2018: 77). Vereinzelte Kultur-, Kunst- und Sozialprojekte lassen jedoch erahnen, welches Potenzial in einer gezielten Einbindung der Bewohnerinnen und Bewohner, Initiativen, Vereinen etc. und der Belebung des öffentlichen Raums als Lebensraum vorhanden ist. Wichtig ist es erstmal den Raum für Experimente sowie Flexibilisierung von Prozessen und Umsetzungsprojekten zu forcieren, was sich in temporären und kurzfristigeren Lösungen von „Tactical Urbanism“ widerspiegelt. Ein kurzer Vergleich zwischen dem deutschsprachigen Raum und Skandinavien macht dahingehend einen klaren Unterschied deutlich: Wohingegen in Dänemark die Planung eines Radweges nur zwischen 6-9 Monaten dauert, werden für diesen Prozessschritt in Deutschland 24 Monate veranschlagt (Reidl, 2019). Allein durch dieses Beispiel wird deutlich, dass Flexibilisierung und ein Umdenken in unseren aktuellen Planungssystemen dringend notwendig sind.

3 TACTICAL URBANISM UND VERWANDTE ANSÄTZE

In den letzten Jahren rückte eine Fülle von städtischen Bottom-Up-Aktivitäten in den Fokus wissenschaftlicher, aber auch planerischer Diskurse. Unter Begriffen wie "Tactical Urbanism", "Informeller Urbanismus", „Placemaking“ oder "Subversiver Urbanismus" wird eine Reihe von urbanen Praktiken zusammengefasst, die Interventionen im öffentlichen Raum anstreben. Diese Aneignungen sind begründet im Aufbegehren und dem Wunsch nach direkter Teilhabe seitens der Bürgerinnen und Bürger und haben ihre Ursprünge in Jane Jacobs einflussreichem Werk „The Death and Life of Great American Cities“ (Jacobs, 1961). Etwa zeitgleich wie Jane Jacobs’ Buch erschien auch jenes Werk in dem Henri Lefebvre erstmals von einem „Recht auf Stadt“ schrieb (Lefebvre, 1968). Ein wesentliches Stichwort in dieser Debatte ist die „Flächengerechtigkeit“ in der Stadt im Zeitalter nach den großen Plänen der „funktionalen Stadt“. Dieses Leitbild ging weiter über in die „Stadt der kurzen Wege“, die Idee der „Nahmobilität“ und jetzt die „Städte für Menschen“ und die „lebenswerte Stadt“ (Sabine Drewes, 2019) als zentrale Paradigma.

„Tactical Urbanism“ hat sich in diesem Diskurs als Überbegriff für unterschiedliche Interventionsansätze im städtischen, urbanen Raum entwickelt. Neben der Erstellung von Modellen zur Nutzung leerstehender Stadträume (Németh and Langhorst, 2014) und informellen Aktionen innerhalb rechtlicher Grauzonen (Bermann and Clough Marinaro, 2014) umfasst „Tactical Urbanism“ hauptsächlich Interventionen im öffentlichen Raum und auf Straßen zur Förderung nicht-motorisierter Mobilitätsformen (Birdsall, 2015). Tactical Urbanism Initiativen werden einerseits als neue Alternativen, andererseits auch als Herausforderungen für formelle, offizielle Planungsmethoden und -prozesse gesehen. Sie deuten jedoch darauf hin, dass Planungssysteme anpassungsfähiger und flexibler werden müssen. Ins Rollen brachte diese Bewegung das Duo Lydon und Garcia, die 2011 erstmals den „Tactical Urbanist Guide“ veröffentlichten und so auch den Begriff „Tactical Urbanism“ wesentlich mitprägten und versuchten zu definieren (Webb, 2018). Es gibt jedoch bereits die Angst, dass das radikale Potential von „Tactical Urbanism“ in klassischen Planungsprozessen verloren gehen könnte, da etablierte Demokratie- und Entscheidungsstrukturen in Verbindung mit wirtschaftlicher Macht diese zu ihren Zwecken nutzen könnten (Webb, 2018).

Generell sind taktische Interventionen kostengünstige, kurzfristige Aktionen, die auf eine langfristige, realistische Verstetigung und Umsetzung ausgelegt sind. Umsetzerinnen und Umsetzer können verschiedenste Akteurinnen und Akteure von Architektinnen und Architekten, Planerinnen und Planern, Künstlerinnen und Künstlern, öffentliche oder private Institutionen, aber auch hin zu lokalen Initiativen, sein. Diese Definition neuer Stadtmacherinnen und Stadtmacher geht also von einer transdisziplinären und kollaborativen Herangehensweise aus (Lydon et al., 2012; Lydon et al., 2011). Durch „leichte“ provisorische Maßnahmen können Lösungsansätze getestet werden, die in ihrer permanenten Umsetzung wesentlich kostenintensiver und komplexer wären (Leonard, 2015). Durch diese temporären Installationen wird außerdem das Bewusstsein für Probleme und alternative Lösungsansätze bei Politik und Verwaltung, sowie bei Bürgerinnen und Bürgern erhöht. Zusätzlich bietet sich die Möglichkeit potenzielle

Langzeitauswirkungen der Umsetzungen frühzeitig abschätzen und ungefähr evaluieren zu können. Diese können von kleinen Demonstrations- und Pilotprojekten mit geringen Projektkosten und einem kurzen Zeithorizont, bis hin zu kostenintensiven Langzeitvorhaben zur Neu- und Umgestaltung bestehender Räume, reichen. Dennoch finden sich Interventionen häufig nur in großen Städten bzw. ziehen dort die meiste Aufmerksamkeit auf sich.

Aktionen und Projekte des Tactical Urbanism lassen sich meist nicht ganz klar einem Begriff zuordnen und variieren in zeitlicher und räumlicher Ausprägung, sowie planerischen Aussrichtung (Top-Down, Bottom-Up, (in)formell) stark. Bis jetzt gibt es keine wirklich klare theoretische Abgrenzung in diesem Bereich. Die Begriffe und Theorien sind in ihrer Qualität und in ihrem Umfang unterschiedlich weit gefasst und können sich auf verschiedenen Maßstabsebenen abspielen (Marshall et al., 2016). Versuche diese verschiedenen, breit gefächerten und kleinräumlichen Aktionen zu beschreiben, führten meist zu einer Gruppierung in Überkategorien (Iveson, 2013) oder in einer Beschreibung von (Umsetzungs-) Methoden (Lydon and Garcia, 2015). Im Folgenden werden nun die wesentlichsten Überbegriffe in diesem Planungsfeld umrissen und in Relation zueinander gebracht. Im Bereich des „Tactical Urbanism“ gibt es weitere Ansätze bzw. Spielformen, die hier kurz skizziert und anhand eines Beispiels veranschaulicht werden. Die Abbildung 1 zeigt in welchem Verhältnis diese zu verorten sind – wobei die Bezeichnung „Tactical Mobilism“ (vgl Kapiel 4) darüber liegt und viele verschiedene Ansätze mit einbezieht.

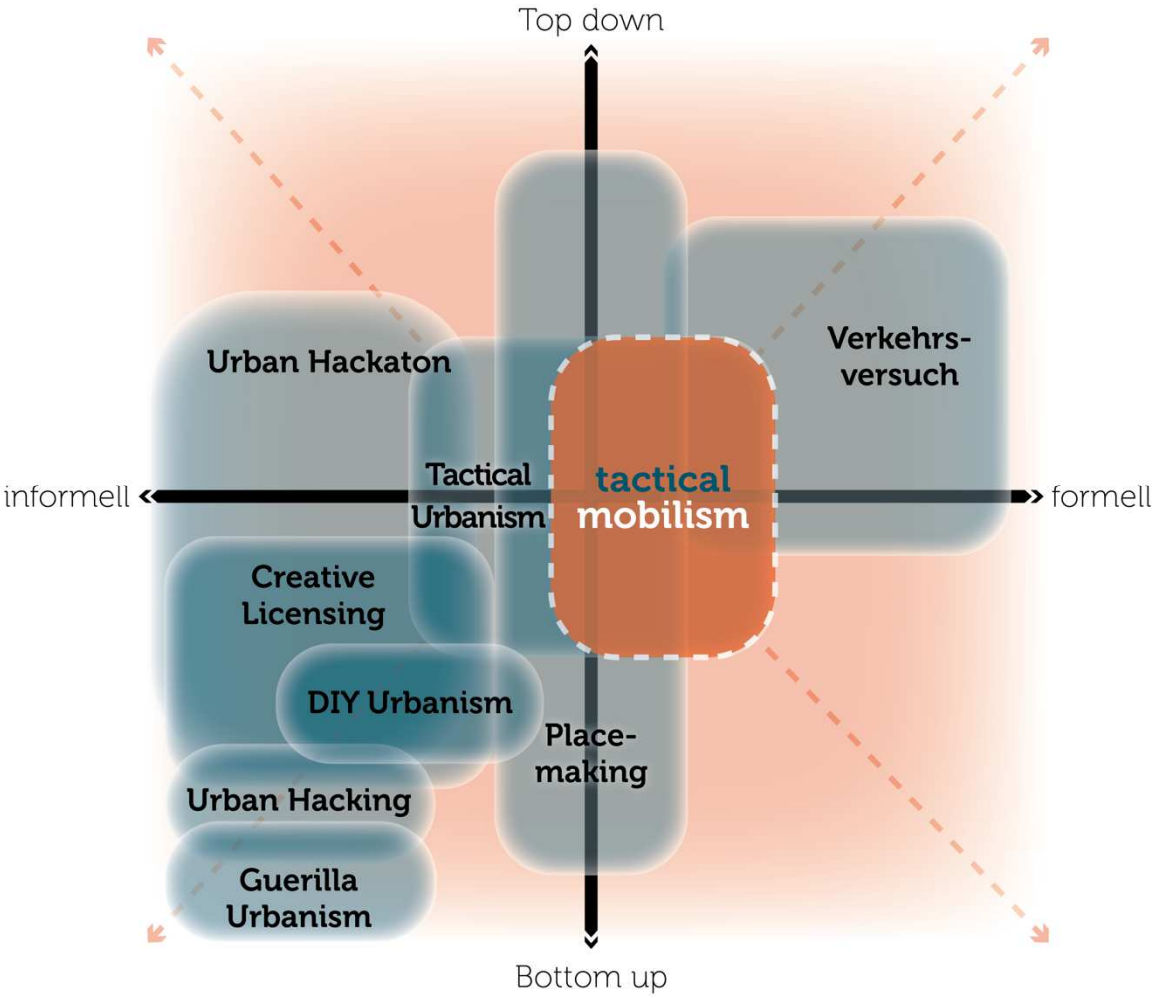

Abb. 1: Verortung der Theorien rund um „Tactical Mobilism” (eigene Darstellung)

3.1 Guerilla Urbanism und Urban Hacking

„Guerrilla Urbanism“ kämpft als Ansatz oftmals gegen die steigende Regulierung, Privatisierung und das Verschwinden alternativer Formen öffentlichen Raums (Hou, 2010: 1) in verschiedenen kaum fassbaren Ausformungen, wie Guerilla Gardening. Der öffentliche Raum wird von Bewegungen hierbei durch Guerilla Taktik regelrecht eingenommen (Eismann and Zobl, 2011). Urban Hacking als Form der Urbanen Intervention umfasst kleine, oft nicht genehmigte, räumliche Interventionen, die die „Einschränkungen” von Systemen aufbrechen wollen (Pogačar and Šenk, 2018; Gadringer, 2010). Diese Form der Aneignung beinhaltet einen klaren aktionistischen, selbstermächtigenden, Bottom-Up Ansatz (Schneider and Friesinger, 2009). Beide Handlungsweisen können nicht klar voneinander unterschieden werden, wobei Guerilla-Taktiken eher auf die Stärke der Überraschung setzen und Urban Hacking mehr die Nischen im System erforscht und ausmacht (Morandini, 2013: 102–103).

Der Urban Hackathon, der Begriff kommt ursprünglich aus der studentischen Hacker- und Computer-Szene, ist eine Spezialform von Urban Hacking und kann als Teil partizipativer Planung in Form eines Events beschrieben werden (de Waal and de Lange, 2019). Es werden teils definierte Problemstellungen in einem limitierten Zeitfenster (z.B. 24 oder 48 Stunden) gelöst. Informationstechnologien und Kollaboration sind zentrale Bestandteile (Pogačar and Žižek, 2016). Im Jahr 2015 wurden im Rahmen des Programms „Actors of Urban Change“ der Robert Bosch Stiftung drei Hackathons gefördert die „von unten“ im Bereich der Koroska Straße in Maribor (Slowenien) realisiert wurden. Ziel war es den jahrelangen Stillstand im Prozess zur Umgestaltung der Hauptstraße der Altstadt aufzubrechen und Anwohnerinnen und Anwohner zu motivieren am Prozess aktiv teilzunehmen (CityToolBox, 2020; Pogačar and Žižek, 2016)

3.2 DIY-Urbanism und Creative Licensing

DIY- und Tactical Urbanismus werden oft als synonyme (Über-) Begriffe verwendet. Sie unterscheiden sich jedoch fundamental darin, dass Tactical Urbanism darauf abzielt langfristige Veränderungen herbeizuführen, wohingegen DIY-Urbanism meist im kurzfristigen Umsetzen kleinräumiger Interventionen verharrt (Lydon and Garcia, 2015; Douglas, 2014). DIY (Do-it-yourself), oder oft auch DIWO (Do-it-with-others), zielt klar auf den Gedanken ab unabhängig von wirtschaftlichen und kommerziellen Zwängen eigene Wünsche und Ideen umzusetzen. Konkret bezogen auf den Raum zeigt sich dies in Form von Urban Gardening oder ähnlichen kleinräumigen, handwerklichen Projekten (Baier et al., 2013: 86). Creative Licensing kann hierfür ein nützliches Werkzeug sein, das ermöglicht bürokratische Hürden im öffentlichen Raum zu überwinden, beziehungsweise vorhandene Schlupflöcher zu finden und nutzen. Beispiele hierfür sind der alljährliche „Park(ing) Day” oder die Institution der Spielstraßen. (Pogačar and Šenk, 2018)

Parklets als ein Beispiel sind frei zugängliche, öffentliche Sitzplattformen, die sonst rein als Parkplätze für PKWs genutzte öffentliche Räume in nachbarschaftliche Treffpunkte verwandeln (können). Sie können das Ergebnis von Partnerschaften zwischen der Stadtverwaltung, lokalen Betrieben, Anwohnerinnen und Anwohner oder Nachbarschaftsgruppen sein. Verschiedene Nutzungen, wie Sitzmöglichkeiten, Begrünung, Bepflanzung oder Radabstellplätz, sind möglich (NACTO, 2013: 77–80). Teile des Parklet-Konzeptes entstanden aus einer Aktion des Design Studios „Rebar Group“ aus San Francisco. Sie transformierten 2005 einen Parkplatz in einen temporären öffentlichen Park. Nach Bezahlung der Parkgebühren bauten sie Bänke, Bäume und Rollrasen auf. Darauffolgend wurde auch der weltweite PARK(ing) Day ins Leben gerufen (Birdsall, 2013). Mit dem Hinweis auf vermehrten Bedarf an urbanen Erholungsflächen findet dieser alljährlich am dritten Freitag im Monat statt (Saitta, 2010: 78–79). 2010 wurde das erste offiziell genehmigte Parklet in San Francisco im Rahmen des städtischen Programmes „Pavement to Parks“ errichtet (Birdsall, 2013). In Wien gibt es seit 2015 die finanzielle Fördermöglichkeit durch das Aktionsprogramm „Grätzeloase“ der Lokalen Agenda 21 (Lokale Agenda 21 Wien, 2019).

3.3 Placemaking

Placemaking hat sich in den letzten Jahren als wachsende Bewegung etabliert, die zum Ziel hat Bürgerinnen und Bürger zu ermächtigen ihr eigenes Lebensumfeld zu gestalten und zu transformieren (Placemaking Plus, 2017: 6). Räume sollen sich mit diesem Toolset in Orte des Dialoges, der Inklusion und demokratischer Partizipation wandeln (Toolis, 2017; Project for Public Spaces, 2007). „Placemaking” kann als Bottom-Up, personen- und objektbezogener Prozess beschrieben werden, der großen Wert und Schwerpunkt auf Kollaboration und gemeinschaftliche Partizipation legt, um die Lebensqualität in Gemeinden und Städten zu

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

verbessern (Laven et al., 2019; Toolis, 2017). Die oftmalige Kritik spielt auf die apolitische Herangehensweise und die Exklusivität für manche Gruppen an. Die Revitalisierungsbestrebungen zielen oft auf Verschönerung und Verbesserung öffentlicher Räume für Investitionen ab. Ausgeschlossen werden oft Überlegungen zum Abbau wirtschaftlicher und sozialer Ungleichheiten (Toolis, 2017).

Beim Projekt Österreichischer Platz in Stuttgart wurde eine ehemalige, witterungsgeschützte Parkfläche für KFZ unterhalb einer Autobrücke als städtisches Experimentierfeld umgenutzt Der Prozess der gemeinschaftlichen Raum (-re-) produktion stand bei diesem vom Verein Stadtlücken initierten Prozess im Mittelpunkt. Die Vision der Initiatorinnen und Initiatoren war es Spielräume zu öffnen und ein Experimentierfeld für einen kooperativen Stadtraum zu schaffen und zwar gemeinsam mit den Bürgerinnen und Bürgern Stuttgarts. Von Frühjahr 2018 bis Herbst 2019 fanden hier unzählige Veranstaltungen, Workshops und Vieles mehr statt (Stadtlücken e.V., 2019). Die vorhergehend erwähnte Kritik der Exklusivität trifft bei diesem Beispiel von Placemaking nicht zu. Am Österreichischen Platz wurde nämlich auch ein „Stadtregal“ errichtet, was als Stadtmöbel zur Betreuung und Versorgung von und zum Austausch zwischen Wohnsitzlosen und Drogenabhängigen Menschen diente (Heißenbüttel, 2019). Für die kommenden beiden Jahre ist die Finanzierung des Projektes und dessen Verstetigung durch die Stadt Stuttgart mit 1,6 Millionen Euro finanziell garantiert (Gall, 2020).

3.4 Verkehrsversuche

Verkehrsversuche sind kleinmaßstäbliche Experimente, um eine zukünftige, verkehrliche Gestaltung auszuprobieren sowie Planungsvorhaben vor der finalen Realisierung temporär umzusetzen (Pogačar and Šenk, 2018). Oftmals scheitern visionäre und utopische Ideen an der fehlenden Vorstellungskraft betroffener Akteurinnen, Akteure, Entscheidungsträgerinnen und Entscheidungsträger und dem daraus resultierenden Widerstand und Unverständnis. In der temporären Übersetzung dieser Visionen in einem Experiment liegt die große Stärke des Verkehrsversuchs. Diese eher neuere Herangehensweise kann diesbezüglich zu mehr Verständnis und Akzeptanz führen und ist in Deutschland in der StVo in § 45 definiert und wie folgt festgeschrieben: „Die Straßenverkehrsbehörden können die Benutzung bestimmter Straßen oder Straßenstrecken […] beschränken oder verbieten und den Verkehr umleiten. Das gleiche Recht haben sie […] zur Erforschung des Unfallgeschehens, des Verkehrsverhaltens, der Verkehrsabläufe sowie zur Erprobung geplanter verkehrssichernder oder verkehrsregelnder Maßnahmen“ (Aichinger and Frehn, 2017; Bundesamt für Justiz, 2013). Diese „Erprobungsklausel“ in der deutschen StVo soll bald erweitert werden und somit die „Mitbestimmung der Kommunen gestärkt“ werden (Bundesministerium für Verkehr und digitale Infrastruktur, 2020). Getestet werden kann zum Beispiel die Errichtung neuer Radwege (Pogačar and Šenk 2018, 177) oder auch die temporäre Umgestaltung ganzer Straßenzüge, wie es in Potsdam, München oder anderen deutschen Städten bereits geschehen ist (Aichinger and Frehn, 2017). Die Methode der „Experimentellen Co-Production” kann hier als Schlüsselelement partizipativer Steuerung gesehen werden und hat das Potential beidseitig positive Synergieeffekte, sowohl für Bürgerinnen und Bürger als auch für Entscheidungsträgerinnen und Entscheidungsträger, zu schaffen. Vorteile dieser kooperativen Herangehensweise an Planungsaufgaben sind die Etablierung einer erhöhten Akzeptanz und eine erhöhte Legitimation von gemeinschaftlich getroffenen Entscheidungen. (Bartenberger and Sześcilo, 2016)

In München wurde ein Teil der Sendlinger Straße noch vor einer angedachten Erweiterung der Fußgängerzone temporär als verkehrsberuhigter Bereich für die Bevölkerung erlebbar (Aichinger and Frehn, 2017). Für ein Jahr wurde der Autoverkehr vollständig verbannt. Aufgrund der prominenten Lage und Bekanntheit der Gegend war dies ein sensibles Vorhaben. Über die gesamte Zeitdauer wurde deshalb dieser Versuch mit einer umfassenden Evaluierung und Bürgerbeteiligung begleitet. (Netzwerk Bürgerbeteiligung) Die Evaluation ergab die Empfehlung zur dauerhaften Umgestaltung der Maßnahme an den Stadtrat (Referat für Stadtplanung und Bauordnung, 2017). Bis Anfang 2020 sollen die letzten Arbeiten zur Umgestaltung in eine Fußgängerzone abgeschlossen sein (Portal München Betriebs-GmbH & Co. KG, 2019).

Die verschiedenen Ansätze unterscheiden sich stark in ihren Kosten, der Umsetzung, der Prozesse sowie im Maßstab. Auch ob eine Verstetigung angestrebt oder nur vereinzelt auf Bedürfnisse und auf Ansprüche an öffentliche Räume aufmerksam gemacht werden soll, ist ganz unterschiedlich. Tabelle 1 bietet hier zu eine knappe Übersicht und soll einen weiteren Diskurs in der Frage nach der Definition und Abgrenzung der genannten Ansätze von Interventionsmöglichkeiten im öffentlichen Raum anstoßen.

Ansätze	Gesamtkosten Umsetzung	Gesamtzeit Umsetzung	Verstetigung angestrebt?	Wer initiiert und setzt um?	Maßstab	Rechtliche r Rahmen
Tactical Urbanism	Niedrig angestrebt	Kurz – Mittel	Ja	Versch.	Versch.	Informell – formell
Guerilla Urbanism / Urban Hacking	Niedrig - Mittel	Kurz	Unklar	Privatpersonen, Vereine	Punktuell im öffentliche n Raum	Informell
DIY-Urbanism & Creative Licensing	Niedrig	Kurz	Nein	Privatpersonen, Vereine	Kleinräuml ich (z.B. Stellplatz)	Informell
Placemaking	Niedrig - Hoch	Mittel - Lang	Ja	Versch. – eher informell	Versch.	Informell - formell
Verkehrsversuch	Hoch	Lang	Ja	Politik, Verwaltung	Straßenabs chnitte, Grätzl	Formell

Tabelle 1: Tabellarische Einordnung der Theorien rund um "Tactical Mobilism"

4 USE CASE DES TACTICAL MOBILISM

Da Interventionen und Projekte im öffentlichen Raum nicht nur Implikationen auf diesen direkt besitzen, sondern in weiterer Folge auch auf den Verkehr und die verschiedenen Mobilitätsformen, die diesen nutzen, entstand die Wortschöpfung des „Tactical Mobilism". Dieser Ansatz ist zwischen Verkehrsversuch, Tactical Urbanism und Placemaking verortet (siehe Abb. 1) und weißt damit inhaltlich sowie prozessual Überschneidungen auf. Damit verbunden und unter dem Titel „Tactical Mobilism – Interventionen für eine nachhaltige Mobilitätskultur" wird beim BMK ein Forschungsvorhaben mit dem Ziel anhand von zeitlich begrenzten, einfachen und kostengünstigen Interventionen eingebettet in einen Partizipationsprozess ein Umdenken seitens der Bevölkerung, Politik und anderer Akteurinnen und Akteure anzuregen, gefördert. Neben dem Forschungsbereich der Verkehrssystemplanung (TU Wien) als Konsortialführung und der Stadt Villach, komplementieren das Institut für Städtebau (TU Graz), queraum. kultur- und sozialforschung, PLANUM Fallast Tischler & Partner GmbH sowie Artgineering das interdisziplinäre Team.

4.1 Methodischer Ansatz

Das adaptive und flexible Ausprobieren unterschiedlicher „Spielarten" des Tactical Mobilism stellt das Hauptanliegen des Projekts dar. Dabei wird Tactical Mobilism als integrativer Prozess verstanden, der von der Auswahl über die Konzeption bis hin zur Intervention und Wirkungsmessung reicht und mittels einer sehr umfassenden Evaluierung begleitet wird. Im Rahmen des Reallabors wird mittels der Methode des Community Organizing gewährleistet, dass unterschiedliche Bevölkerungsgruppen (z.B. Kinder, Jugendliche, Familien, ältere Menschen, Menschen mit Behinderung, sozial benachteiligte Personengruppen) einbezogen und empowert werden, ihre Sichtweisen einzubringen und ihre Lebenswelt aktiv mit zu gestalten. In Anlehnung an die Phasen des Community Organizing kommen unterschiedliche Methoden zum Einsatz (z.B. Befragungen, Begehungen, Raumbeobachtung). Das Reallabor und die darin stattfindenden Interventionen bzw. Experimente in den Testräumen unterstützen eine Bewusstseinsbildung in Bezug auf die räumliche (Ungleich-)Verteilungssituation zwischen den einzelnen Modi im öffentlichen Raum. Außerdem ist eine Verstetigung von temporären zu permanenten Maßnahmen und Projekten, also ein „pilot-to-permanent" Modell, angestrebt.

4.2 Der Ort

Innovativer Ort und Use Case ist darin die Stadt Villach - eine 60.000 Einwohner Stadt im österreichischen Südalpenraum, nahe des Dreiländerecks Österreich, Italien und Slowenien. Aufgrund der Lagegunst ist Villach ein attraktiver Ort für Unternehmen und bietet gleichzeitig spannende und attraktive öffentliche Räume in der Innenstadt. „Während die städtische Peripherie eine Zunahme verzeichnet, sieht sich das Stadtzentrum mit zunehmendem Leerstand konfrontiert. In diesem Zusammenhang hat sich die Stadt dazu entschlossen sich mit den möglichen Potentialen der öffentlichen Raumqualitäten der Stadt intensiv auseinanderzusetzen" (Fachkonzept Öffentlicher Raum Villach 2015, 2019).

Abb. 2: Konzept zur Umsetzung von "Tactical Mobilism" (eigene Darstellung)

Die Stadt Villach als Partner im Projekt eignet sich aus mehreren Gründen als Pilotstadt:

- Die Stadt gehört zu den österreichischen Mittelstädten. Die Erfahrungen im Projekt können somit für zahlreiche größenmäßig und strukturell ähnliche Städte in Österreich (z.B. St. Pölten, Wels, Dornbirn, Steyr) und auch europaweit als Vorbild dienen.
- Villach versteht sich als „innovativer Impulsgeber für soziale, technologische, wirtschaftliche und ökologische Innovationen" und verfügt über einige Vorerfahrungen und bereits umgesetzte Aktivitäten.
- Villach ist des Weiteren Mitglied im Netzwerk „Gesunde Städte" und bietet Angebote wie essbare Stadt, öffentliche Gartenbeete und gezielte Bewegungsangebote für verschiedene Zielgruppen.
- Die Stadt Villach beschreitet im Fokus der nachhaltigen Stadtentwicklung seit mehreren Jahren konsequent den Weg der Innovation. Im integrativ unter Beteiligung der Öffentlichkeit erarbeiteten Stadtentwicklungskonzept „Stevi :konzept 2025" wurde die Bedeutung einer innovativen urbanen Mobilität für Villach besonders hervorgehoben.
- Im Fachkonzept Öffentlicher Raum Villach ist im Aspekt der aktiven und smarten, urbanen Mobilität eine fairere Aufteilung von 13 urbane Achsen (urbanen Straßenräumen) strategisch festgelegt worden.
- Das Reallabor-Gebiet von Tac | Mob ist die Innovationsachse Hauptbahnhof – Innenstadt – Infineon. An dieser Achse liegen die wichtigsten öffentlichen Einrichtungen, die wichtigsten Mittelschulen und das größte und innovativste Unternehmen Kärntens, Infineon Villach.

Insbesondere der Klimawandel im Zusammenhang mit dem öffentlichen Raum sind der Stadt Villach ein Anliegen und sollen anhand von Interventionen sichtbar und greifbar werden. Es wird sich zeigen müssen, inwieweit und in welcher Ausprägung Tactical Mobilism Interventionen forciert und umgesetzt werden können. Interventionen sind im Sommer 2020 geplant und sollen Politik, Verwaltung, Bewohnerinnen und Bewohner gemeinsam auf die Straße und in den öffentlichen Raum bringen.

5 CONCLUSIO UND AUSBLICK

Auch wenn veschiedenste Fachrichtungen und Arbeitsfelder wie Architektur, Raumplanung, Kunst, Aktivismus und Initiativen, mit der Thematik der Intervention, insbesondere im öffentlichen Raum, eine längere Tradtion pflegen (Mohr and Landau, 2017; von Borries et al., 2012), ist der Ansatz Tactical Urbanism ein nicht klar umrissenes Feld, dessen Differenzierung und Definition nach wie vor schwierig ist. Dieser Beitrag hat den Anspruch einen Überblick zu verschiedenen Ausprägungen, die sich räumlich, zeitlich und prozessual stark unterscheiden, zu geben und deren starken Bezug zu Verkehr und Mobilität aufzuzeigen. Sowohl das Projekt, als auch die Wortneuschöpfung des Tactical Mobilism, konnte in die Reihe der Begrifflichkeiten eingeordnet werden. Das Projekt mit dem Fokus auf Klein- und Mittelstädte ist nicht nur ein wichtiger Beitrag das Konzept der „taktischen" Interventionen in der Planungspraxis bekannt zu machen und die Begrifflichkeit mehr zu schärfen, sondern auch langfristig neue Handlungsoptionen in der Planung aufzuzeigen und ein Umdenken „in den Köpfen" seitens der verschiedensten Akteure zu bewirken. Da urbanes Leben sich nicht nur in größeren Städten und Metropolen abspielt, ist es umso wichtiger das Experimentieren zu forcieren und aktivistische, informellen Kräfte außerhalb dieser zu erkennen und zu aktivieren. Villach als innovative Mittelstadt traut sich an das Experiment. Es wird sich zeigen, wie lokale Politik, Bevölkerung, verschiedene Initiativen und Vereine auf das Vorhaben reagieren, sich einbringen und weiter vorantreiben.

Is Green Infrastructure a Game Changer for Sustainable Regional Development? A Scenario Approach for Stuttgart Region

Till Jenssen

(Dr. Till Jenssen, Verband Region Stuttgart, Kronenstraße 25, 70174 Stuttgart, jenssen@region-stuttgart.org)

1 INTRODUCTION

There are numerous challenges for municipalities and regions: affordable housing, overburdened infrastructure, air quality, increasing pressure on open spaces, expansion of renewable energies, climate adaptation. Certainly, the list is not complete. Moreover, these issues – as a typical characteristic of complex situations – interact with one another in various ways.

As one of Germany's most dynamic and densely populated locations the Stuttgart Region is particularly affected by these challenges. Therefore, protecting and developing the landscape is a longstanding concern of its overall spatial planning strategy (e.g. development-axes, regional green corridors, landscape park, public transport policy). In view of the sheer number of tasks, the ongoing dynamics as well as strong sectoral policy instruments, the question can be raised as to how far green infrastructure can be a game changer for a substantive transformation towards sustainability.

Against this background, a scenario-approach is carried out aiming for the integration of various knowledge-areas into a supra-sectoral and strategic view on regional transformation. Taking the example of the Stuttgart Region, the diversity and interdependencies of land use are taken into consideration and synthesised in form of a qualitative system analysis.

The scenario development is part of the RAMONA-project, which is funded by the Federal Ministry of Education and Research (BMBF) in the framework of the "Stadt-Land-Plus"-measure. The project deals with the intervention regulation under the Nature Conservation Act[1] ("Eingriffsregelung") and inherent opportunities for urban and regional development. The scenario based approach therefore starts with open-space-indicators such as "degree of imperviousness", "compensation measures" as well as "green infrastructures" and puts them into a wider perspective of socio-technical development (e. g. settlement structure, infrastructure, traffic volume, agriculture or health) in order to obtain comprehensive pictures of the Stuttgart Region in the year 2050.

Keywords: impact regulation, great transformation, spatial development, landscape, system analysis

2 CONSTRUCTING CONSISTENT SCENARIOS – METHODOLOGY AND PROCESS

Scenarios describe alternative, consistent future developments (Kosow & Gaßner 2008). They provide a platform to reflect, communicate and discuss the openness of the future, the interdependence of developments as well as the steering effects of possible policy interventions. When selecting a suitable scenario-technique for the RAMONA-project it was essential that it offers a formalised system-analytic structure to interconnect a wide variety of drivers (as land use is a highly interdisciplinary issue) but at the same time is capable of handling qualitative information (as units, scale levels and calculability differ).

According to these requirements, cross-impact-balance-analysis (CIB) (Weimer-Jehle 2018) offers a viable option. It constructs impact networks based on expert surveys and finds plausible configurations by applying a mathematical algorithm. These plausible configurations are taken as scenarios. Thus, qualitative insights in interdisciplinary questions can be formulated, documented and synthesised into overall pictures.

Among others, the method has been used several times for scenario analyses in the field of energy supply and sustainability research (Jenssen & Weimer-Jehle 2012; Renn et al. 2007).

To put emphasis on the communicative and facilitating quality within the group-process CIB was closely blended with metaplan-technique. The current case-study involves fifteen regional practitioners and academics and is based on a five-step procedure:

(1) Identification of sectoral indicators (named descriptors), each assigned with a range of possible alternative developments (or variants) by 2050, in a moderated group discussion within workshop I (14

[1] RAMONA is an acronym for "Urban-regional compensation strategies as an engine of sustainable land use". For more information about the project and the institutions involved, see http://www.fona-ramona.de/

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

persons, September 2019). The descriptors are chosen in order to sufficiently describe the system of land use in Stuttgart Region.

(2) Building a common understanding within the group as well as specifying and defining the descriptors with brief descriptions in desk-work subsequent to workshop I.

(3) Assessment of direct impacts between the system elements in pairs and on an ordinal scale by the involved experts as well as providing the reasons for the evaluation in a written questionnaire (October – November 2019). "0" is used if one element does not have any influence on the other one. A strongly promoting influence is indicated by using "+3", whereas "+2" and "+1" are used for minor effects. Vice versa, restricting impacts are assessed by negative values.

(4) In case of strong deviations between the written assessments, a clarification-process was carried out via group work (3 groups à 3 to 4 persons) and moderated group discussions (10 persons) in workshop II (November 2019). Mostly, the group found consensus on the assessments, in a small number of cases majority decisions were taken.

(5) Examination of all theoretical combinations and computer-aided selection of consistent scenarios and interpretation of the results.

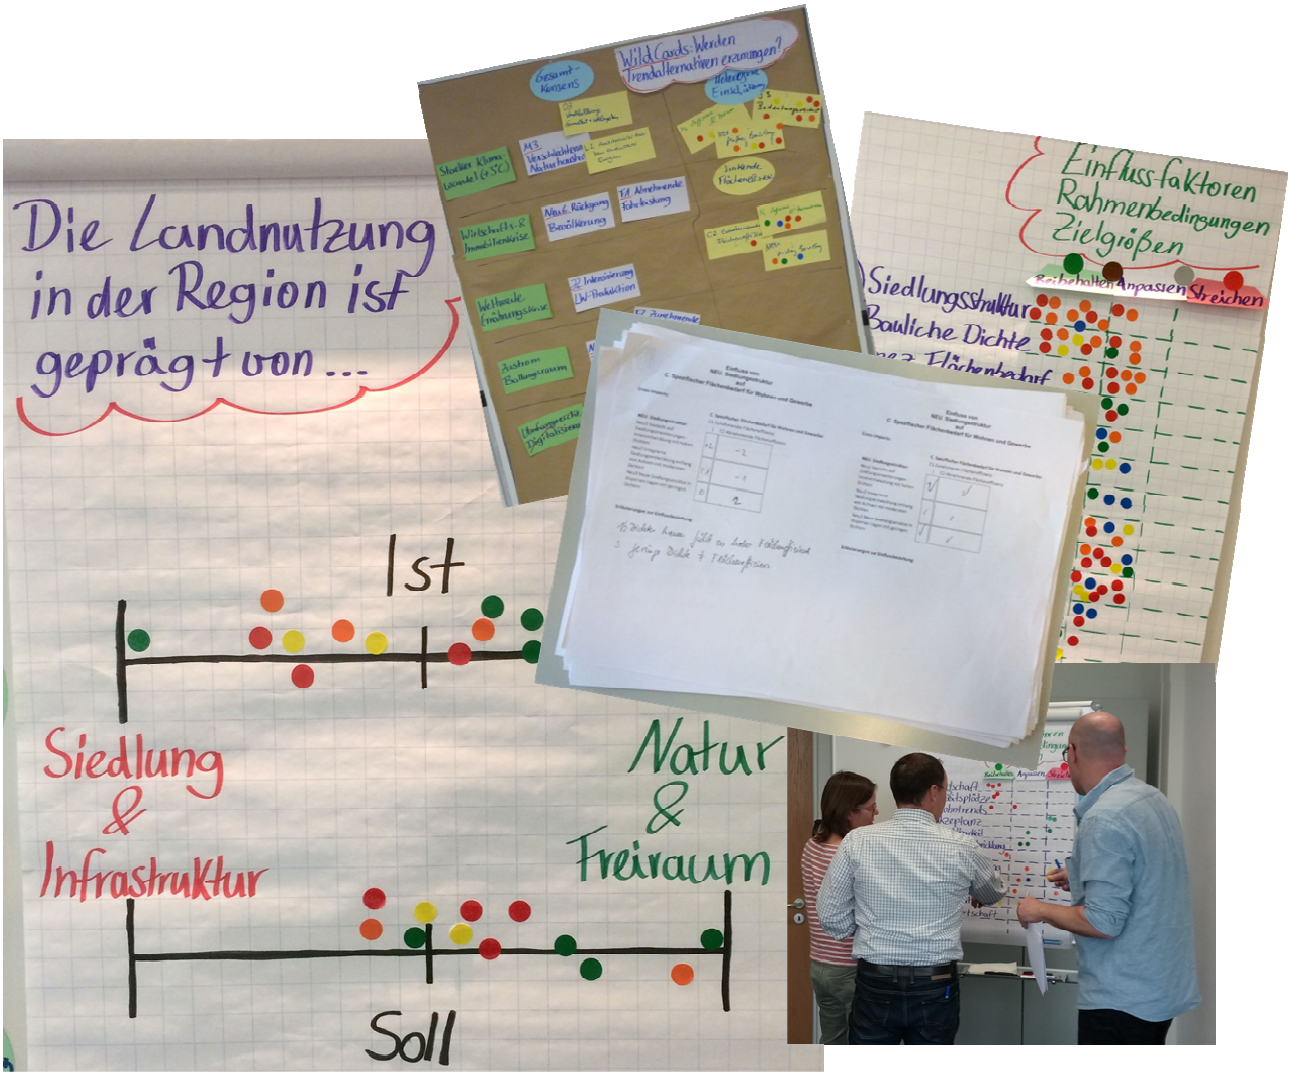

Fig. 1: Impressions of the scenario process

3 SYSTEM ELEMENTS AND THEIR ROLE – A FIRST GLANCE

Within the scenario-process 13 descriptors and 34 variants were identified as system variables for land use in 2050 by the involved experts. These variables are then arranged in a matrix-structure and produce a "morphological" box representing the mental mindset of the group. Examining each and every possible combination of the variants shown in table 1 would imply to check 186,624 assumption bundles by hand. As

this would be very time consuming and error-prone, the computer software “scenario wizzard” is applied to check each system state for possible contradictions and to finally to “eliminate” implausible solutions.

Descriptors	Variants
a. Settlement	a1. Re-development of existing built up areas with high densities
	a2. Development axes with moderate densities
	a3. Development in dispersed locations with low densities
b. Floor Space Demand	b1. Increasing floor-space-efficiency
	b2. Decreasing floor-space-efficiency
c. Population	c1. Population increase
	c2. Constant population
	c3. Population decline
d. Traffic Volume	d1. Decreasing traffic volume
	d2. Increasing traffic volume
e. Degree of Imperviousness	e1. Constant degree of imperviousness
	e2. Increasing degree of imperviousness
f. Compensation Measures (Impact regulation)	f1. Compensation at the intervention site
	f2. Pooled substitution or compensation (within the region)
	f3. Disjointed substitution or compensation (within the region)
	f4. Substitution outside the region
g. Landscape Development	g1. Local development of open spaces
	g2. Coherent System of green Infrastructures
h. Agriculture	h1. Extensification and provision of public services
	h2. Intensification of agricultural production
	h3. Marginalisation
i. Transport Infrastructure	i1. Operation / Maintenance
	i2. Traffic reduction and expansion of public transport
	i3. Traffic management and expansion of roads
j. Energy Infrastructure	j1. Stagnation in expanding renewable energy
	j2. Major progress in expanding renewable energy
k. Natural Environment and Ecosystem Diversity	k1. Significant improvement
	k2. Constant level
	k3. Significant deterioration
l. Social Values and Consumer Behaviour	l. Sufficiency and postmaterialism
	l2. Hedonism and materialism
m. Health and Well-Being	l1. Significant improvement
	m2. Constant level
	m3. Significant deterioration

Table 1: Overview on descriptors and variants for future development until 2050.

The working-principle of the automated consistency-check can be highlighted by the example of three descriptors shown in figure 2. A scenario consisting of (a1, b1 and i1, coloured in green) is considered as consistent according to the mental setting of the group as it has the highest positive sum in each column (+4, +2 and +2). This matches the discussions during workshop II: the group argued for example that a limitation to the exisiting settlements (a1) – as a physical boundary for habitation – gives an impuls to increase floor space efficiency (+2). Moreover, the group agreed that maintaining current transport infrastructure limits settlement development and thus supports a re-development within the existing built-up areas (2). In contrast to the above-mentioned configuration, a combination of a3, b1 and i1 has a negative balance in one column (-4 in column a3, highlighted in red) and is therefore classified as implausible.

	a			b		i		
	a1	a2	a3	b1	b2	i1	i2	i3
a. Settlement								
a1 Re-development of existing built up areas with high densities				+2	-2	+3	0	-3
a2 Development axes with moderate densities				+1	-1	0	+2	+1
a3 Development in dispersed locations with low densities				0	+2	0	+1	+3
b. Floor space demand								
b1 Increasing floor-space-efficiency	+2	+1	-2			0	+1	-1
b2 Decreasing floor-space-efficiency	-2	+1	+2			0	-1	+1
i. Transport innfrastructure								
i1 Operation /Maintenance	+2	0	-2	0	0			
i2 Expansion of Public transport	0	+1	-1	0	0			
i3 Expansion of roads	-2	0	+2	0	0			
Balance:	+4	+1	-4	+2	-2	+3	+1	-4

Fig. 2: Exemplary impact balances for three descriptors

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

In addition to the consistency-check it is worth to look at the general role of the descriptors in order to find out how much effect they have ("activeness") and how much influence they receive ("passiveness"). To do so, all impacts exerted by one descriptor in a row ("active sum") and all impacts exerted onto a descriptor in a column ("passive sum") are summed up and shown in a system grid (see figure 3).

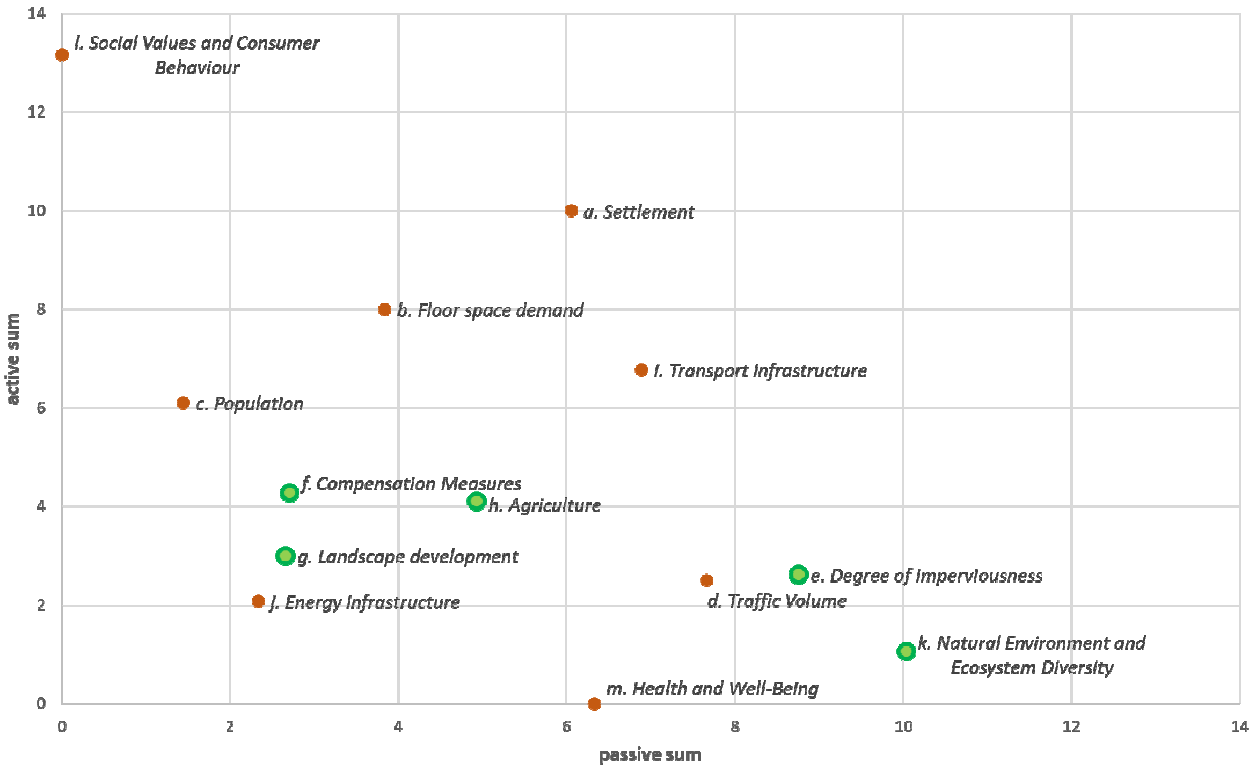

Fig. 3: System grid "land-use 2050 in Stuttgart Region"

The strongest position within the system grid holds descriptor l "social values and consumer behaviour" – a driver which is seen as independent from regional influences by the experts. Besides, the three most important forces in the grid belong to the built environment (settlement, floor space demand and transport infrastructure). In turn, open-space-indicators marked in green colour (imperviousness, compensation, landscape development, agriculture) have rather small effect. Descriptor k "natural environment and ecosystem diversity" is barely seen to exert activity at all but at the same time it is the descriptor receiving the highest influence. In summary, "land use" can be classified as a moderately complex system containing active, passive and bipolar elements.

4 A RANGE OF FUTURES – A DEEPER LOOK AT THE SCENARIO SPACE

Scanning the collected data for internal inconsistencies, twelve scenarios for land use by 2050 with completely consistent configurations in Stuttgart Region remain. These twelve descriptor-bundles leave a clearly reduced scenario space (compared to 186,624 possible combinations) but at the same time comprise a multitude of possible developments being determined systematically. They cover nearly all considered variants (e. g. increasing, constant and decreasing population levels), allthough in distinct combinations. Coming from an open space perspective it is, however, particularly noticeable that an improvement of natural environment (descriptor k1) does not appear at all in the scenario space of the consistent scenarios.

Taking settlement (descriptor a), floor space demand (descriptor b) and transport infrastructure (descriptor i) as the most influential and regionally internal drivers a scenario-taxonomy can be provided containing four fundamentally different types of regional development (see figure 4). This classification helps building a better understanding of the scenario-structure as well as uncovering similarities and differences in the scenario space. Type III- and IV-scenarios for example always co-occur with environmental degradation (k3) as well a significant deterioration in health and well-being (m3).

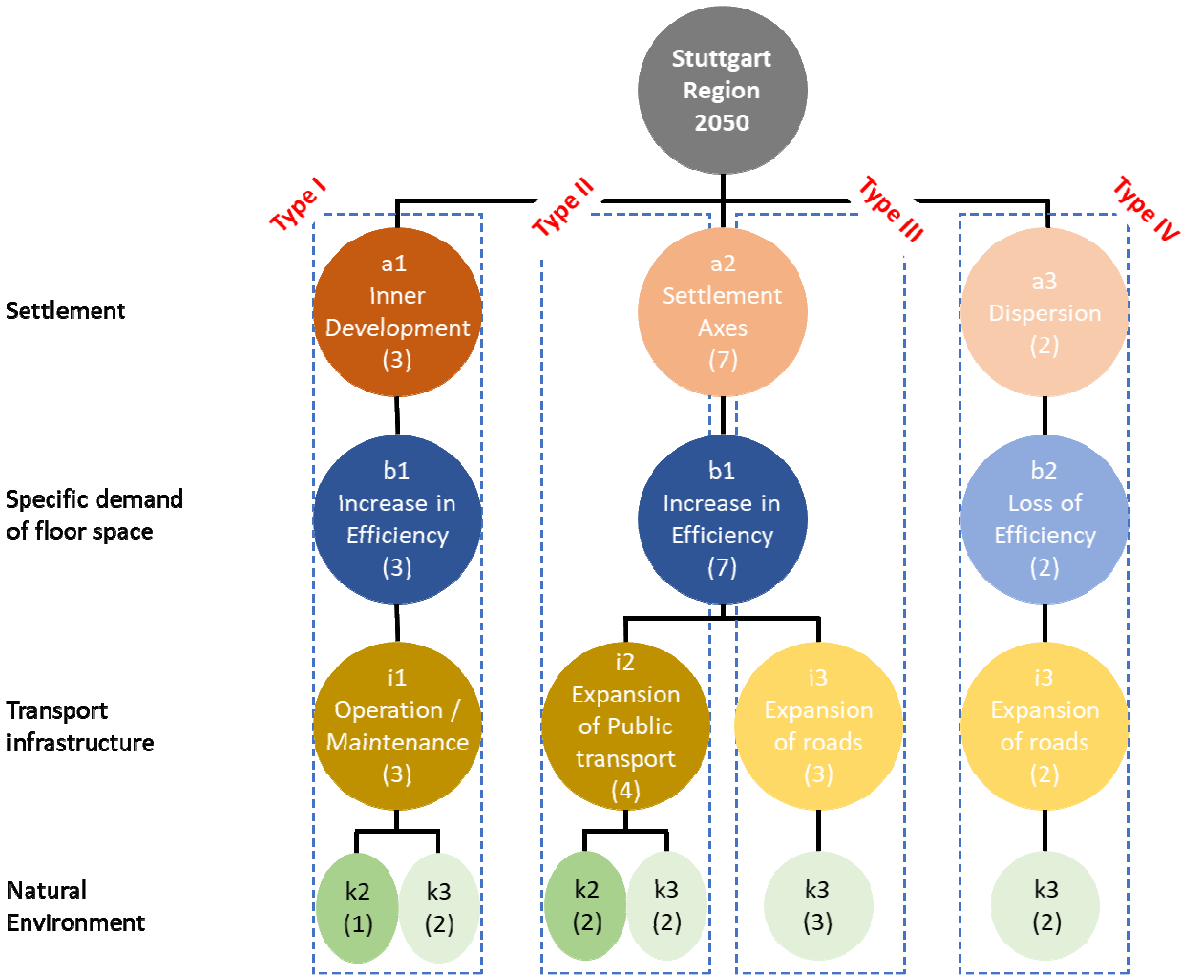

Fig. 4: Scenario tree of 12 completely consistent scenarios

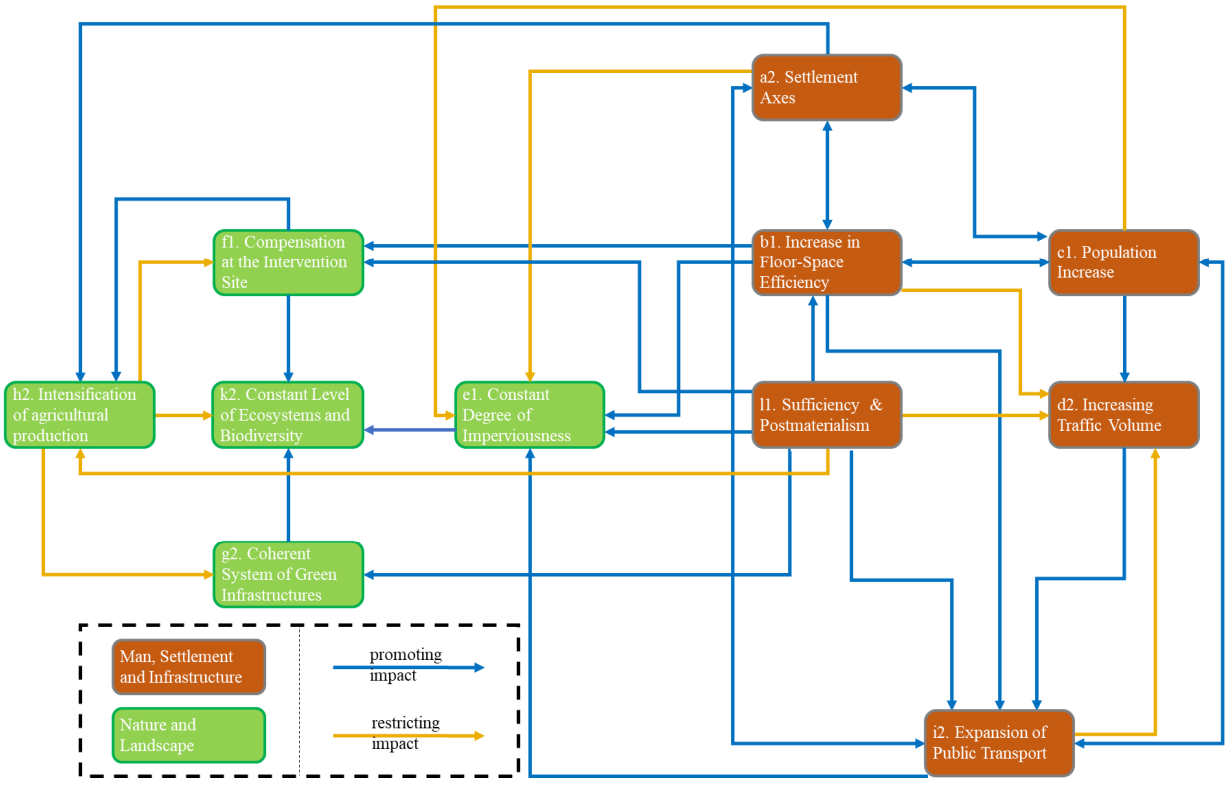

Fig. 5: Assortment of impacts within scenario # 9 “Unstable balance in the city region“ (type II)

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

In contrast, type I- and II-scenarios generate more heterogenous results consisting of constancy or deterioration of natural resources (k 2 and k3) as well as – in a few cases – even improvements in health and well-being (m1). Actually, three type I- and II-scenarios come along with a stable ecosystem (k2). According to the way of thinking expressed in the CIB-matrix they achieve this under two prerequisites only:

- when compensating ecological interventions within regional borders (f1 or f3) and
- when establishing a coherent system of green infrastructures (g2).

Moreover, the scenarios suggest that a constant ecological status can be further enhanced if agriculture provides ecosystem services (h1) and if boundaries are set for further settlement development (a1 or a2). This can be interpreted in such a way that open space governance – in the sum of its effects – can play a significant role in growing agglomerations if it is carried out in a stringent and coordinated manner.

As shown in figure 5 impact relations can be promoting or restricting and they can be one-sided or reciprocal. As a whole, the system tends to configurations in which promoting impacts outbalance restricting ones. Scenario # 9 “Unstable balance in the city region” (type II) is such a scenario, although it includes some ambivalent and restricting drivers. The reason is that at the same time it includes plenty of reinforcing loops, especially between settlement axes (a2), floor-space efficiency (b1) and population growth (c1). These drivers are mutually supportive and therefore help generating and stabilising type II-scenarios.

5 CONCLUSION – PLANNING IN THE FACE OF MULTIPLE FUTURES

In contrast to common scenario development CIB correlates different parameters by developing, analysing and interpreting impact networks in a multidisciplinary, discourse-oriented and transparent manner. The application of this heuristic method thereby contributes to understanding land-use as a dynamic system with mututal impact relations as well as increasing transformation-knowledge for a sustainable regional development.

As a communicative and transparent toolkit, CIB is a good starting point for reflections on the current state of land use as well as on political goals and appropriate strategies (for different frame conditions) as it helps illuminating the space of possibilities thoroughly with well-founded assumptions instead of guessing “random” scenarios.

Looking at the land use in Stuttgart Region in the year 2050, each open-space descriptor seen individually shows rather small impact (“active sum”). Nonetheless, in combination they trigger noticeable effects and within the context of their systemic-interactions they pan out to be a necessary – but not sufficient – prerequisite for a constant or improving level of natural environment and human well-being.

Within the scope of this work a huge variety of future pathways for regional development could be constructed. In view of the discourse on the great transformation, the created scenarios will now be further explored with regards to change agents (who?), normative issues (why?), disruptive forces (what if?) as well as the context adequacy and adaptabillity of policy options (how to?).

The task of the scenario-process for Stuttgart Region, however, is not to come up with one definitive future but multiple possibilities – may they be seen as positive, neutral or negative – as well as raising awareness for essential obstacles, catalysts or amplifier. Thereby, clarity in the face of uncertainty can be gained helping planners to prepare their plans for regional transformation as well as to adjust or change them over time.

1 ZUSAMMENFASSUNG

Aufgrund steigender Bau- und Bevölkerungsdichten und der Ausweitung des Siedlungsflächenanteils in urbanen Räumen, einer Verschiebung der Altersstruktur und einer durch den Klimawandel bedingten Zunahme von Extremwetterereignissen wird die Stadtbevölkerung zunehmend Umweltbelastungen ausgesetzt sein. Klimaindizierte Auswirkungen (u. a. Hitzeperioden, Starkregen) werden zudem innerhalb des Stadtkörpers in Folge hoher Versiegelungsgrade, einem verringerten Luftaustausch der urbanen Atmosphäre und einer steigenden lufthygienischen Belastung nochmals verschärft.

Um diese Herausforderungen in Städten zu bewältigen, bedarf es u. a. entsprechender Lösungsmöglichkeiten in der Bauleitplanung, die mit der Flächennutzungsplanung die gesamtstädtische Entwicklung und mit der Bebauungsplanung kleinräumige Bebauungs-, Erschließungs- und Freiflächenstrukturen rechtsverbindlich festlegt. Das Aufgabenspektrum der Bauleitpläne ist dabei vom Gesetzgeber u. a. mit der im Jahre 2011 in das Baugesetzbuch eingefügten Klimaschutzklausel in § 1a Abs. 5 BauGB (sog. Klimaschutzklausel) erweitert worden. Sie soll seither auch dazu beitragen, dem Klimaschutz und der Klimaanpassung, insbesondere in der Stadtentwicklung durch Konzeptionen und die konkrete Festlegung baulicher Maßnahmen angemessen Rechnung zu tragen.

Der Gesetzgeber hat dafür nach und nach auch konkrete Festsetzungsmöglichkeiten zur Klimaanpassung in den § 9 Abs. 1 BauGB integriert, der die Inhalte des Bebauungsplans regelt. Daraus ergeben sich grundsätzlich gute Möglichkeiten zur Umsetzung umfassend integrierter räumlicher Klimaschutz- und Klimaanpassungskonzepte in städte- und z. T. auch hochbaulicher Hinsicht. In der Planungspraxis wird allerdings, oftmals aufgrund fehlender Betroffenheit bzw. Unwissenheit, den klimatischen Belangen wenig Bedeutung beigemessen. Daher ist eine systematische und strukturierte Vorgehensweise von Nöten, um auf die gegenwärtigen und zukünftigen Herausforderungen reagieren und agieren zu können.

Keywords: Urban Planning, Urban Climate, Bauleitplanung, Stadtplanung, Stadtklima

2 EINLEITUNG

Die Bundesrepublik Deutschland nimmt im Rahmen des Klimaschutzes (Mitigation) und der Klimaanpassung (Adaption) im internationalen Vergleich eine vergleichsweise bedeutende Rolle ein. Bereits vor dem in Kraft treten der europäischen Richtlinie zur Nutzung erneuerbarer Energien (Richtlinie 2009/28/EG des Europäischen Parlaments) wurde in Deutschland das erneuerbare Energien Gesetz (EEG) im Jahr 2000 eingeführt. Hierin werden der Ausbau erneuerbarer, klimafreundlicher Energien sowie deren bevorzugte Einspeisung in das Stromnetz geregelt. Die Umsetzung dieser EU Richtlinie dient vornehmlich, ähnlich wie z. B. die Energieeinsparverordnung (EnEV) und das erneuerbare Energien Wärmegesetz (EEWärmeG), der Mitigation. Neben den Maßnahmen zum Klimaschutz existiert seit dem Jahr 2009 die „Deutsche Anpassungsstrategie an den Klimawandel“ (DAS). Darin sind u. a. folgende langfristigen Ziele definiert:

- Gefahren und Risiken benennen und vermitteln = Wahrscheinlichkeiten, Schadenspotentiale und Unsicherheiten transparent machen,
- Sensibilisierung der unterschiedlichen Akteure,
- Bereitstellung von Entscheidungsgrundlagen, die es den unterschiedlichen Akteuren ermöglichen Vorsorge zu treffen,
- Handlungsmöglichkeiten aufzeigen, Verantwortlichkeiten abstimmen, bzw. festlegen = entsprechende Maßnahmen formulieren und umsetzen.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Um konkrete Aussagen über die Anfälligkeit von Deutschland gegenüber dem Klimawandel treffen zu können, wurde im Zuge der Erarbeitung der DAS die nationale Vulnerabilität ermittelt. Dafür stellte das „Behördennetzwerk Vulnerabilität“ die Betroffenheit Deutschlands durch den Klimawandel thematisch und regional differenziert dar. In die Auswertung flossen neben meteorologischen Werten auch regionale Daten (z. B. die Bevölkerungs- und Wirtschaftsstruktur) ein und wurden miteinander verknüpft. Daraus entstand eine Klimaaussage mit regionalen Bezügen. Die Ebenen der Raum-, Regional- und Bauleitplanung werden in diesem Zusammenhang als besonders relevante Querschnittsbereiche im Hinblick auf die Anpassung an den Klimawandel eingestuft.

Zur Ausarbeitung und Umsetzung der angestrebten Maßnahmen folgte auf die DAS der sogenannte „Aktionsplan Anpassung“ (APA) im Jahr 2011. Hierin wird die Zusammenarbeit zwischen den Ebenen Bund, Land und Kommune sowie den verschiedenen Akteuren aus Politik, Wirtschaft und Gesellschaft bekräftigt. Dabei definiert der APA drei strategische nationale Säulen sowie eine Säule im Hinblick auf grenzüberschreitende, internationale Maßnahmen.

Säule 1: „Wissen bereitstellen, informieren, befähigen“ = Wissensgrundlagen werden ausgebaut, Informationen bereitgestellt und vermitteln

Säule 2: „Rahmensetzung durch den Bund“ = stärkere Berücksichtigung der Klimaanpassung durch gesellschaftliche Akteure mittels entsprechender rechtlicher Rahmenbedingungen

Säule 3: „Aktivitäten in direkter Bundesverantwortung“ = klimaangepasste Gestaltung bundeseigener Flächen, Immobilien, Infrastrukturen (z. B. Bundeswasserstraßen, Schienenwege) und Bauprojekte

Säule 4: „Internationale Verantwortung“ = Informationsbereitstellung über europäische und internationale Initiativen (Entwicklungs- und Forschungszusammenarbeit) zur Adaption durch den Bund

Auf Grundlage dieser Säulen wurden bis 2015 zahlreiche Aktivitäten, wie z. B. das Modellvorhaben der Raumordnung „Raumentwicklungsstrategien zum Klimawandel“ (Säule 1), die Anpassungen rechtlicher Regelungen im BauGB oder auch die Initiierung von Förderprogrammen (Säule 2) verwirklicht.

Die obigen Ausführungen zu den nationalen Vorschriften und Regelungen in Deutschland zeigen die stetig angepassten Aktivitäten und Maßnahmen entsprechend den dynamischen Prozessen des Klimawandels. Dies spiegelt sich auch im gesetzlichen Rahmen der Bundesrepublik wieder, in den die Raumordnung sowie die Regional- und Bauleitplanung eingebunden sind. Im Bezug zur Adaption durch die räumliche Planung ist vor allem die Säule 2 hervorzuheben. So basieren z. B. die Änderungen im BauGB (Aufnahme von § 1 Abs. 5 Satz 2 – Klimaanpassung als Planungsleitsatz und entsprechenden Festsetzungsmöglichkeiten) auf der Orientierung an den Inhalten dieser Säule.

3 KLIMATISCHE BELANGE IN DER (RÄUMLICHEN) PLANUNG

Das räumliche Planungssystem in Deutschland ist in Stufen aufgebaut, die sich an den bestehenden Verwaltungsebenen orientieren. An erster Stelle steht der Bund, der vor allem Grundsätze und Leitlinien (z. B. im Raumordnungsgesetz, ROG) vorgibt und nur für besonders ausgewählte Bereiche selbst konkrete planerische Aussagen trifft.

Darunter findet sich die Ebene der Länder. Die Bundesländer stellen entsprechende landesweite Raumordnungspläne auf, die im Sinne von § 1 Abs. 3 ROG die großräumlichen Ziele für die Entwicklung, Ordnung und Sicherung des jeweiligen Teilraumes festlegen. Auf Grundlage dieser stellt anschließend die zuständige Behörde auf regionaler Ebene Regionalpläne auf, die die Aussagen der übergeordneten Ebenen konkretisieren (gemäß § 8 Abs. 2 ROG). Die Vorgaben auf Landes- und Regionalebene erfolgen insbesondere in der Form von Zielen und Grundsätzen der Raumordnung (im Sinne von § 3 Abs. 1 Nr. 2 und 3 ROG). Ziele sind dabei abgewogene und verbindliche Vorgaben, die bei nachfolgenden Planungen im Sinne einer Anpassung zu beachten sind. Die Grundsätze sind Aussagen für nachfolgende Abwägungs- und Ermessungsentscheidungen, die im Rahmen weiterer Planungen (z. B. die Bauleitplanung) einer Berücksichtigung, Konkretisierung und weiteren Abwägung bedürfen.

Demzufolge sind auf kommunaler Ebene die landesweiten und regionalen Vorgaben im Zuge der Bauleitplanung zu beachten (gemäß § 1 Abs. 4 BauGB), z. T. bestehen auch unmittelbare Anpassungspflichten. Die zuständige Gemeinde muss Bauleitpläne aufstellen, sobald und soweit es für die städtebauliche Entwicklung und Ordnung erforderlich ist, und damit die bauliche und sonstige Nutzung der

Grundstücke in der Gemeinde nach Maßgabe des BauGB vorzubereiten und zu leiten. Somit liegt das Hauptaugenmerk der räumlichen Planung auf der Entwicklung, Ordnung und Sicherung des Siedlungsraumes. Dafür ist entscheidend, dass unterschiedliche Anforderungen an einen Raum aufeinander abgestimmt, auftretende Erfordernisse aufgenommen und letztlich potentielle Konflikte präventiv vermieden werden. Daraus folgt, dass die räumliche Planung hinsichtlich des Klimaschutzes und der Klimaanpassung ein wichtiges Instrument, insbesondere aufgrund des räumlichen Charakters zahlreicher Klimafolgen (z. B. urbane Überwärmung) sowie der Vulnerabilität bestehender Raumnutzungen und Strukturen, ist.

Um die Rolle der räumlichen Planung zu stärken, sind in der Vergangenheit u. a. Novellierungen der einschlägigen gesetzlichen Grundlagen die Folge, wodurch Inhalte in Bezug auf den Klimaschutz und der Klimaanpassung integriert werden. Dies tangiert alle Planungsebenen im deutschen Planungssystem. Diese sind in Tabelle 1 exemplarisch dargestellt.

Ebene	Planung	Planungsinstrument	Maßstab	Gesetzliche Grundlage
Bund	(Bundes-) Raumordnung	Leitvorstellung und Grundsätze der Raumordnung	-	Raumordnungsgesetz
Länder	Landesplanung	Landesentwicklungs-programm/ -plan	1:200.000 bis 1:100.000	Raumordnungsgesetz
Region	Regionalplanung	Regionalpläne	1:50.000 bis 1:25.000	Raumordnungsgesetz
Kommune	Bauleitplanung	Flächennutzungs- und Bebauungspläne	1:5.000 bis 1:500	Baugesetzbuch, Baunutzungsverordnung

Tabelle 1: Exemplarische Darstellung des deutschen (Raum-)Planungssystems.

4 FESTSETZUNGSMÖGLICHKEITEN FÜR KLIMAANPASSUNG IN DER BAULEITPLANUNG

In der Bauleitplanung als Instrument der räumlichen Planung auf kommunaler Ebene werden die Voraussetzungen dafür geschaffen, bestimmte Klimaanpassungsmaßnahmen rechtlich und verbindlich zu fixieren. Dies ist im Zuge der Aufstellung von Bauleitplänen möglich, da dort auf Grundlage des BauGB flächen- und maßnahmenbezogene Festsetzungen getroffen werden können. Der Flächennutzungsplan (vorbereitender Bauleitplan) deckt das gesamte Gemeindegebiet ab. Hierbei können die, die Gesamtstadt betreffenden klimatischen Erkenntnisse (z. B. aus informellen Planungen oder der Regionalplanung) aufgenommen werden. Die Darstellungen des Flächennutzungsplans sind flächenhaft – daran orientieren sich auch die Handlungsmöglichkeiten zu Klimaschutz und Klimaanpassung. So ist im Flächennutzungsplan z. B. die Flächenvorsorge für Kaltluftentstehungsgebiete und Luftleitbahnen (Freihalten von Bebauung), die Verteilung der baulichen Nutzung im Raum und auch die bereichsweise städtebauliche Dichte darstellbar. Diese Darstellungen stellen die Basis für quartiersspezifische Festsetzungen im Bebauungsplan dar, die nochmals deutlicher und konkreter ausgestaltet sind. Da sie städtebauliche Vorkehrungen, Anforderungen an die Gebäude und sonstige Maßnahmen zur Klimaanpassung rechtsverbindlich festsetzen, kommt ihnen hinsichtlich der Umsetzung konkreter Maßnahmen zur Klimaanpassung in Quartieren besondere Bedeutung zu. Im Festsetzungskatalog des § 9 BauGB findet sich in § 9 Abs. 5 Nr. 1 die spezifische Möglichkeit, für die Bebauung besondere bauliche Vorkehrungen oder Sicherungsmaßnahmen gegen Naturgewalten anzuordnen. Dies kann z. B. für die Sicherung gegen Hochwasser- oder Sturmgefahren genutzt werden. Flächen, die nach § 9 Abs. 1 Nr. 10 BauGB von der Bebauung freizuhalten sind, sowie Leitungsrechte nach § 9 Abs. 1 Nr. 21 können zum Beispiel, auch in Kombination mit Festsetzungen nach Nr. 16 (Hochwasserschutz und Regelung des Wasserabflusses), für die Rückhaltung von Starkregen und Notwasserwege eingesetzt werden. Allgemein können auch die Grundfestsetzungen des Bebauungsplans zu Art und Maß (Dichte) der baulichen Nutzung, Bauweise und überbaubaren Flächen gezielt zur Klimaanpassung genutzt werden, z. B. um die Durchlüftung von Quartieren zu sichern. Festsetzungen nach § 9 Abs. 1 Nr. 20 BauGB lassen sich beispielsweise zur lokalen Begrünung (auch von Fassaden und Dächern) einsetzen. Den Schwerpunkt bilden an dieser Stelle die Inhalte von Bebauungsplänen, denen hinsichtlich der verbindlichen Festlegung von Maßnahmen zur Klimaanpassung in Quartieren besondere Bedeutung zukommt.

5 BEISPIELHAFTE VORGEHENSWEISE FÜR DIE BERÜCKSICHTIGUNG ORTS- BZW. QUARTIERSSPEZIFISCHER KLIMATISCHER BELANGE BEI PLANUNG STÄDTISCHER QUARTIERE

Damit die Adaption im Rahmen der Planung städtischer Quartiere eine angemessene Berücksichtigung findet, ist ein ganzheitlicher Blick auf existierende Inhalte der verschiedenen Planungsebenen ratsam. Bereits zu einem frühen Zeitpunkt der Planung gilt es den Aspekt der Klimaanpassung aufzunehmen, um diesen möglichst nahtlos in das planerische Gesamtkonzept zu integrieren. Hierzu bietet sich eine exemplarische Vorgehensweise in Form eines zweigeteilten Prüfschemas an. Der Fokus liegt dabei auf den durch den Klimawandel indizierten Belastungen der urbanen Überwärmung, mangelnder Austauschbedingungen sowie Überschwemmungen durch Starkregenereignisse.

5.1 Vorgehensweise und Systematik

In der Realität findet das Thema Klimaanpassung häufig nur geringfügig Berücksichtigung (z. B. Pflanzungen von Bäumen, Schaffung von Ausgleichsflächen), obwohl es nach den Regelungen des BauGB umfassend zu behandeln ist. Darüber hinaus stellt bei der Planung städtischer Quartiere in der Regel ein städtebaulicher Entwurf oder ein Strukturkonzept die Grundlage für einen nachfolgenden Bebauungsplan dar, der im Sinne des § 1 Abs. 5 Satz 2 und § 1 Abs. 5 BauGB der Klimaanpassung Rechnung tragen soll. Jedoch fixiert der Bebauungsplan die Inhalte des vorgeschalteten Entwurfs im Zuge entsprechender Festsetzungen. Sofern nun letztgenannter Entwurf den Aspekt der Adaption bei der Anordnung verschiedener Nutzungen und baulicher Strukturen nicht berücksichtigt, spiegelt sich dies auch meist im darauf aufbauenden Bebauungsplan wieder. Dementsprechend ist es sinnvoll, die Thematik Klimaanpassung bei städtebaulichen Planungen bereits vor dem eigentlichen Bauleitplanverfahren zu berücksichtigen. Grundsätzlich sollte bereits im Stadium der grundlegenden Konzeptfindung bei der Beauftragung eines Planungsbüros bzw. bei eigenständiger gemeindlicher städtebaulicher Planung die Klimaanpassung aufgenommen werden.

Eine wichtige Voraussetzung ist zunächst die Feststellung, ob die jeweilige Gemeinde möglicherweise vom Klimawandel bedingten Folgen (Überwärmung, Starkregen, Sturm) betroffen ist bzw. sein könnte. Dementsprechend bedarf es einer Analyse verschiedener lokalklimatischer Informationen, die allerdings noch nicht so detailliert sein müssen. In diesem frühen Stadium gilt es lediglich, sofern vorhanden, einen Hinweis auf eine potentielle Belastung der Gemeinde zu eruieren. In diesem Zusammenhang ist es durchaus sinnvoll auf bereits existierende Quellen zurückzugreifen (z. B. den Aussagen von Planwerken verschiedener informeller und formeller Planungen).

In diesem Zusammenhang wird eine Vorgehensweise strukturiert, mit deren Hilfe ein potentieller Bedarf zur Adaption bereits zu einem frühen Zeitpunkt im Planungsprozess in der jeweiligen Gemeinde geprüft werden kann. Im Anschluss an die Überprüfung können entsprechend einem diagnostizierten Bedarf spezifische Inhalte in die grundlegenden Konzeptionen einfließen. Sollte ein grundsätzlicher Bedarf zur Klimaanpassung bestehen, würde im Rahmen der Aufstellung eines Bebauungsplanes nochmals die Behandlung der Thematik Klimaanpassung auf Grundlage der Inhalte im BauGB folgen. Neben den Regelungen in § 1 Abs. 5 Satz 2 und § 1 Abs. 5 BauGB ist dabei vor allem der Umweltprüfung im Sinne § 2 Abs. 4 BauGB Gewicht beizumessen. Im Zuge dessen sind neben Auswirkungen auf das Klima auch umweltbezogene Auswirkungen auf den Menschen und seine Gesundheit sowie die Bevölkerung gemäß § 1 Abs. 6 Nr. 7c BauGB zu berücksichtigen. Hierunter fallen die durch den Klimawandel bedingten Herausforderungen, die potentielle Gefahren für den Menschen und dessen Gesundheit darstellen. Ausgehend von dieser Problemstellung wurde daher ein Prüfschema entwickelt, das im Rahmen der Umweltprüfung Anwendung finden kann. Vergleichbare Prüfschemata existieren bereits für artenschutzrechtliche Belange. Mithilfe dieses Prüfschemas soll im Rahmen der städtebaulichen Planung ein konkreter Handlungsbedarf hinsichtlich Klimawandel bedingter Belastungen abgeleitet werden. Auf Grundlage der Identifizierung eines entsprechenden Handlungsbedarfs können nach der Verifizierung potentieller Belastungsbereiche angepasste Festsetzungen bzw. Festsetzungsvorschläge getroffen werden.

Die Struktur dieser Vorgehensweise zur Berücksichtigung orts- bzw. quartiersspezifischer klimatischer Belange bei der Planung städtischer Quartiere besteht aus zwei Modulen. Das erste Modul gibt Aufschluss über einen möglichen Bedarf zur Adaption in der jeweiligen Gemeinde. Es besitzt einen hinweisenden Charakter und sollte idealerweise bereits zu einem frühen Zeitpunkt innerhalb des Planungsprozesses, noch

vor dem eigentlichen Bauleitplanverfahren, eingesetzt werden. Die Überprüfung basiert auf bestehenden Planwerken formeller und informeller Planungen auf verschiedenen Ebenen hinsichtlich vorhandener klimatischer Inhalte und Informationen (s. Abb. 1).

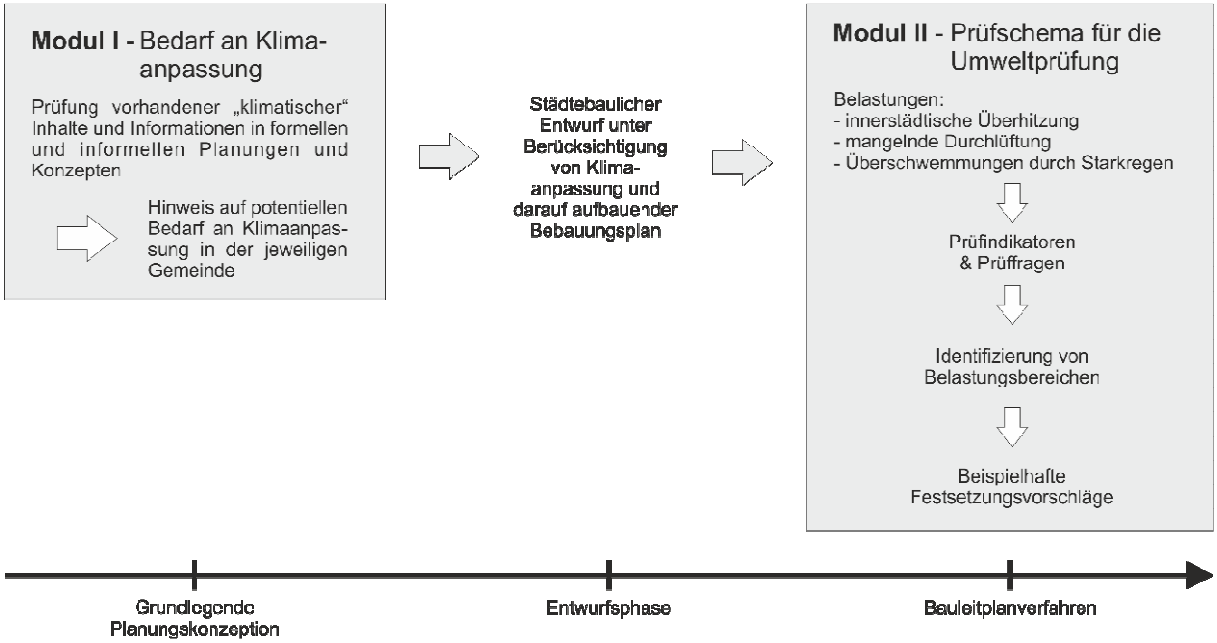

Abb. 1: Exemplarische Darstellung der Strukturierung und Systematik der analytischen Vorgehensweise zur Bewertung lokalklimatischer Belange in der Bauleitplanung.

Das zweite Modul beinhaltet ein Prüfschema zur urbanen Überwärmung, mangelnden Austauschbedingungen und Überschwemmung durch Starkregenereignisse. Die Prüfung unterschiedlicher Indikatoren und zugleich die Identifizierung potentieller Belastungsbereiche können angepasste Festsetzungsvorschläge unterbreiten. Wichtig ist, dass auch bei fehlenden Hinweisen im ersten Modul die jeweilige Gemeinde dennoch durch Klimawandel bedingte Folgen belastet sein kann. Modul 2 stellt lediglich einen Ausschnitt möglicher zu prüfender Inhalte dar. Durch die Überprüfung von Inhalten bereits vorhandener Planungen greift das Modul gewissermaßen dem Bauleitplanverfahren vor, während für dessen Durchführung ebenfalls die Inhalte übergeordneter Planungen sowie Fachplanungen Berücksichtigung finden müssen (vgl. u. a. § 1 Abs. 4 BauGB). Aufgrund der Schwerpunktsetzung des ersten Moduls auf lokalklimatische Inhalte unterschiedlicher Planungen soll dieses eine frühzeitige Beachtung von Klimawandel und -anpassung im Planungsprozess unterstützen. Das zweite Modul, als ein in die verbindliche Umweltprüfung integrierbares, kann und sollte auch unabhängig vom ersten Modul Anwendung finden (s. Abb. 1).

5.2 Modul 1

Modul 1 besteht insgesamt aus fünf verschiedenen Teilbereichen, die sich von der Ebene des Bundes bis zur kommunalen Quartiersebene erstrecken. Für jeden der Teilbereiche ist eine bestimmte Anzahl an Fragen formuliert, die mit „Ja" oder „Nein" beantwortet werden können. Dabei wird keine spezifische Gewichtung der Teilbereiche vorgenommen. Insgesamt ergeben sich somit für das gesamte Modul achtzehn Fragen. Je mehr Fragen mit „Ja" beantwortet werden, desto mehr verdichtet sich die Annahme, dass bei der angestrebten städtebaulichen Planung der Aspekt der Klimaanpassung im Hinblick auf urbane Überwärmung, mangelnde Austauschbedingungen und/ oder Überschwemmungen durch Starkregenereignisse Berücksichtigung finden sollten (s. Abb. 3). Zugleich ergibt sich daraus, dass sofern noch nicht vorhanden, detaillierte ortsspezifische Untersuchungen zu empfehlen sind. Insbesondere Gemeinden, die bisher noch keine oder kaum Ansätze zur Klimaanpassung initiiert haben, können durch die Aufnahme vorhandener lokalklimatischer Informationen im Rahmen der Durchführung des Moduls erste Hinweise auf einen möglichen Adaptionsbedarf gegeben werden.

Allerdings ist an dieser Stelle nochmal explizit darauf hinzuweisen, dass das Resultat aus diesem Modul lediglich einen hinweisenden Charakter besitzt und somit weitere ortsspezifische Untersuchungen zu Klimawandel bedingten Folgen zu empfehlen sind.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Der erste Teilbereich des Moduls dient der großräumigen Einordnung der Gemeinde. Hierfür werden die Lage in Verdichtungsräumen und die Lage an Fließgewässern bzw. Küsten zur jeweiligen Gemeinde abgefragt. Dies erfolgt auf Grundlage der durch DAS ermittelte nationale Herausforderungen und deren thematische sowie regionale Verwundbarkeit (urbane Überwärmung in Ballungsräumen, Gefährdung durch Starkregenereignisse und Sturmfluten, Gefährdung durch Flussüberschwemmungen).

Ob die zu untersuchende Gemeinde innerhalb eines Ballungsraumes liegt, kann z. B. über den frei zugänglichen Online Kartendienst INKAR abgefragt werden. Durch die Verortung der Gemeinde hinsichtlich der Lage in Verdichtungsräumen, an Flüssen oder der Küste wird somit ein erster Anhaltspunkt für eine potentielle Belastung durch die genannten Belastungen gegeben.

Der zweite Teilbereich in Modul 1 umfasst die Angaben zu verschiedenen regionalen Klimadaten (Lufttemperatur, Luftfeuchte, Niederschlagsmenge, etc.). Frei zugängliche Klimadaten sind u. a. über den Klimaatlas des Deutschen Wetterdienstes erhältlich.

Der dritte Teilbereich in Modul 1 thematisiert die Überprüfung möglicher vorhandener Informationen bzw. Vorgaben zur Klimaanpassung auf Landes- bzw. regionaler Ebene (Abb. 2). Dabei wird geprüft, ob derartige Festlegungen im landesweiten und/ oder regionalen Raumordnungsplan existieren und, ob durch andere Fachplanungen (z. B. Landschaftsplanung, Hochwasserschutzplanung) entsprechende Aussagen vorliegen. Darüber hinaus stellen auch informelle Planungen (Klimaanpassungsstrategien), eine potentielle Informationsquelle dar. Sofern in den genannten Bereichen bereits klimabezogene Inhalte existieren, können diese für die gemeindliche Planung genutzt werden. Zudem kann eine bereits erfolgte Berücksichtigung der Klimaanpassung auf einen entsprechenden Bedarf in der Region hinweisen.

Der Aufbau des vierten Teilbereiches aus Modul 1 ist kongruent zum dritten Teilbereich. Der Unterschied liegt in der Bezugsebene. In Teilbereich 4 erfolgt eine Überprüfung des Flächennutzungsplans und anderer Fachplanungen sowie informeller Planungen auf mögliche Inhalte zur Klimaanpassung. Auch hier gilt, dass eine entsprechende Festsetzung und Inhalte eines lokalklimatischen Anpassungsbedarfs innerhalb der Gemeinde existieren.

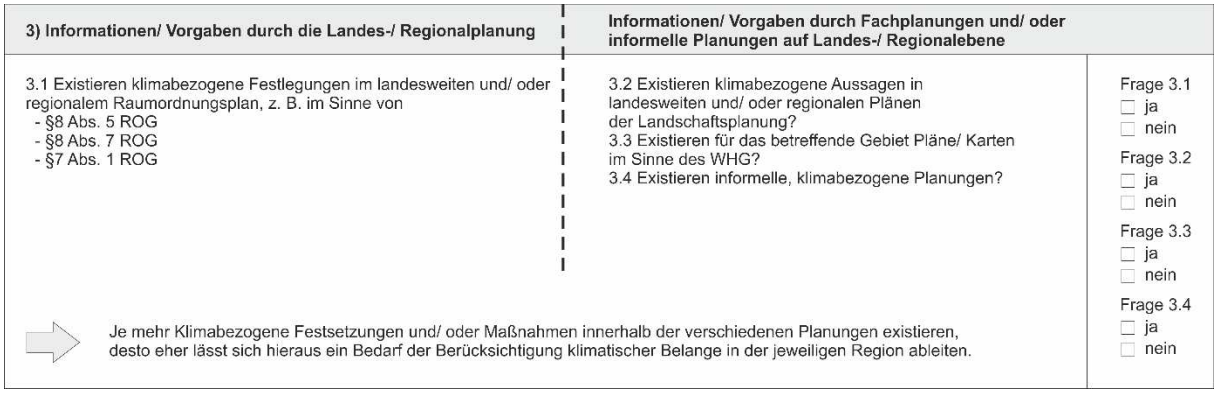

Abb. 2: Exemplarische Darstellung eines Fragenpaketes aus Teilbereich 3 „Informationen/ Vorgaben auf landesweiter und regionaler Ebene“ in Modul 1.

Der fünfte Teilbereich des Moduls 1 befasst sich mit ausgewählten Fragen direkt zum Plangebiet. Auf Grundlage der Abfrage der Lage des Gebietes innerhalb der Gemeindestruktur und ob bebaute oder versiegelte Bereiche angrenzen, kann ein Hinweis auf eine mögliche lokalklimatische Belastung geben. Das Potential der Belastung des Plangebietes kann allerdings auch durch geomorphologische Besonderheiten auftreten.

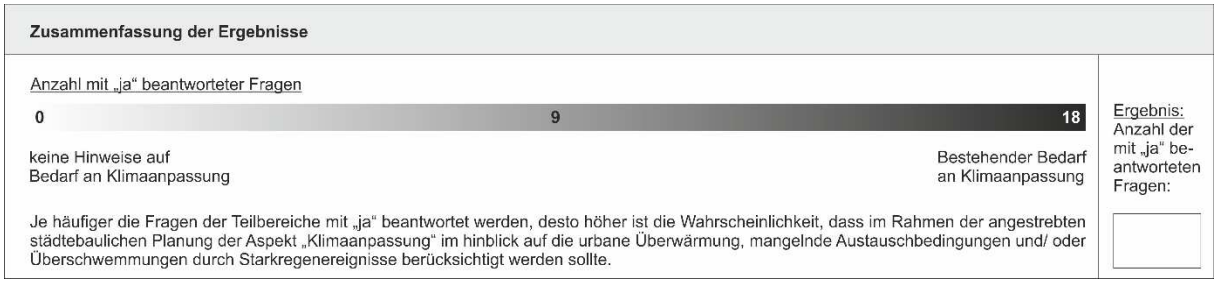

Abb. 3: Exemplarische Darstellung der Ergebnisse zur Bewertung der Inhalte aus Modul 1.

Die Bearbeitung von Modul eins mündet schließlich in der Zusammenfassung der Ergebnisse aus den einzelnen Teilbereichen (s. Abb. 3).

5.3 Modul 2

Das zweite Modul stellt ein Prüfschema dar, das im Rahmen der Umweltprüfung Anwendung finden kann. Die zentral zu überprüfenden potentiellen Belastungen sind urbane Überwärmung, mangelnde Austauschbedingungen und Überschwemmung durch Starkregenereignisse. Für jede der drei potentiellen Risikofaktoren sind entsprechende Prüfindikatoren definiert und für die entsprechende Gemeinde zu prüfen. Je nach Resultat der Analyse der Prüfindikatoren kann daraus eine Vulnerabilität des Bezugsraumes durch die überprüfte Belastung abgeleitet werden. Wichtig ist, dass durch die Bearbeitung der einzelnen Prüfpunkte eine lokale Belastung jedoch nicht abschließend und eindeutig nachgewiesen werden kann. Das Prüfschema deckt immer nur einen Teil des zu prüfenden Themenbereiches ab. Bei einer Aussage, die auf eine potentielle Belastung schließen lässt, empfehlen sich weitere ortsspezifische und detaillierte Untersuchungen. Für jede der drei Belastungspotentiale sind entsprechende Belastungsbereiche definiert, die von möglichen Auswirkungen in besonderem Maße betroffen wären. Der der Gemeinde vorliegende städtebauliche Entwurf ist dann auf diese Belastungsbereiche hin zu prüfen. Diese können letztendlich im städtebaulichen Entwurf bzw. im Bebauungsplanentwurf gekennzeichnet und darauf basierend ein Verweis auf angepasste Festsetzungen als Lösungsansätze gegeben werden.

Für eine das Lokalklima berücksichtigende Darstellung der Bestandssituation mithilfe von Prüfbögen für jede der drei genannten Belastungsbereiche wird in der Folge eine Erläuterung der definierten Prüfindikatoren dargestellt:

5.3.1 Urbane Überwärmung

Für den Belastungsbereich „Urbane Überwärmung“ sind insgesamt acht Prüfindikatoren definiert. Die durchschnittliche Jahrestemperatur und deren temporäre Entwicklung geben Aufschluss über die grundlegende lokalklimatische Situation hinsichtlich der Lufttemperatur des jeweiligen Untersuchungsraumes. Eine Überprüfung der Anzahl meteorologischer Ereignistage (warmer/ heiße Tage, Tropennächte) gibt Aufschluss darüber, ob es eine ortsspezifische Wärmebelastung gibt. Warme Tage sind gekennzeichnet durch eine maximale Lufttemperatur von mindestens 25°C. Deren Anzahl beinhaltet gleichzeitig die heißen Tage. Letztgenannte sind charakterisiert durch eine Höchsttemperatur von mindestens 30°C. Tropennächte entwickeln sich, wenn sich die während der Tagstunden „aufgebaute“ Wärmebelastung in nächtlichen Lufttemperaturwerten $\geq$ 20°C (18:00 bis 06:00 Uhr) äußert. Dieses Phänomen kann insbesondere bei länger anhaltenden sommerlichen autochthonen Wetterlagen beobachtet werden. Mithilfe der Analyse der Entwicklung der Lufttemperaturverhältnisse und einem Trend hinsichtlich der Anzahl warmer/ heißer Tage sowie Tropennächte wird eine Prognose möglich, wie sich die Belastungssituation vor Ort und zukünftig entwickeln kann.

In Bezug zur urbanen Überwärmung sind vier potentielle Belastungsbereiche definiert, die im besonderen Maße von Klimawandel bedingten Modifikationen betroffen wären. Dabei handelt es sich u. a. um Blockinnenbereiche. Durch die isolierte Lage im Bestand ist der bodennahe atmosphärische Austausch nahezu ausgeschlossen. Darüber hinaus wird die Lufttemperatur innerhalb des Blocks durch die Oberflächentemperatur der Gebäude beeinflusst. Dieser Effekt wird verstärkt durch die umliegenden versiegelten Flächen.

Öffentliche Plätze weisen meist einen hohen Versiegelungsgrad auf, wodurch sich diese Räume deutlich erwärmen, vor allem bei fehlendem Schattenwurf durch fehlende Module und Strukturen (z. B. Bäume). Jedoch stellen solche Plätze oftmals öffentliche Räume dar, die von einer Vielzahl von Menschen frequentiert werden, die in der Folge einer lokalen Wärmebelastung ausgesetzt sind.

Auch Verkehrsflächen (Straßen, Stellplätze, etc.) stellen versiegelte Flächen dar, die aufgrund der verwendeten Materialien ebenfalls zu einer lokalen Überwärmung beitragen. Vergleichbar mit dem Effekt der o. g. Verkehrsflächen zeigen sich auch versiegelte Gebäudeflächen. Je höher die Bebauungsdichte ist, desto deutlicher zeigen sich die Auswirkungen der physikalischen Eigenschaften künstliche Baumaterialien.

Nachdem eine potentielle Belastung festgestellt und identifiziert wurde, können im betroffenen Gebiet Strukturen angepasst und spezifische Festsetzungsvorschläge getroffen werden.

5.3.2 Bodennahe atmosphärische Austauschbedingungen

Zur Überprüfung der bodennahen atmosphärischen Austauschbedingungen bedarf es zunächst der Bestimmung der übergeordneten Windrichtung. Hinzu kommt eine Analyse hinsichtlich bestehender bzw. potentieller gebietsrelevanter Kalt- bzw. Frischluftentstehungsgebiete und deren möglicher Ventilationsbahnen. Deren potentiell siedlungsrelevanter Belüftungseffekt gilt es im Hinblick auf die urbane Überwärmung zu nutzen. Zusätzlich erfolgt eine Abfrage der vorhandenen Belastung durch Luftinhaltsstoffe und existierender, den Luftaustausch behindernder Barrieren. Beide Punkte spiegeln sich nochmals in den definierten Belastungsbereichen wieder. Abschließend werden, sofern vorhanden, topographische, das Lokalklima beeinflussende Geländegegebenheiten hervorgehoben. Auch in Bezug auf die unterschiedlichen Prüfindikatoren für einen mangelnden Luftaustausch empfehlen sich bei fehlenden Kenntnisse detaillierte Untersuchungen. Dies gilt insbesondere bei einer nachgewiesenen Belastung durch Überwärmung und/ oder Luftschadstoffe (s. Abb. 4).

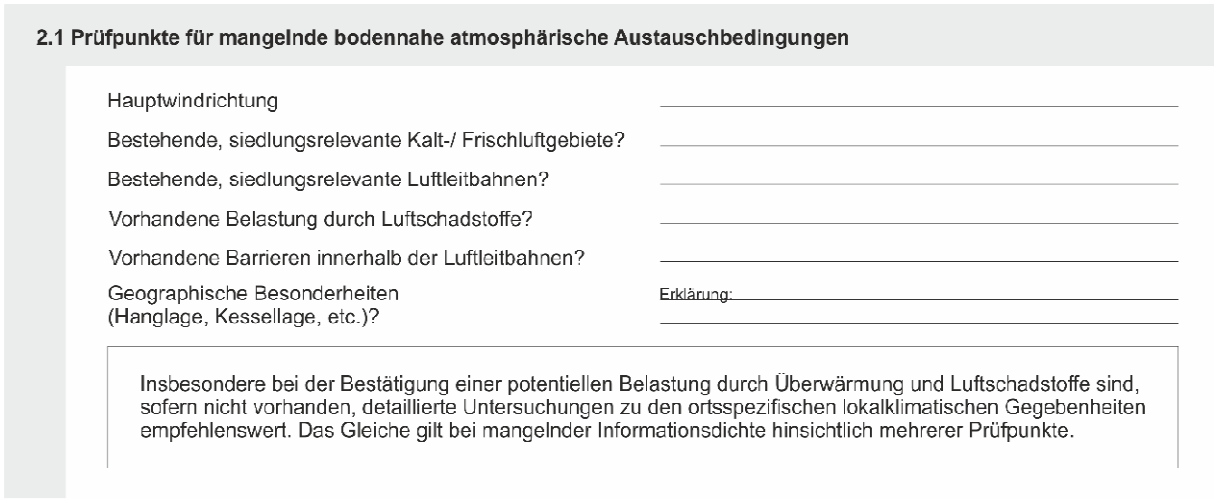

Abb. 4: Exemplarische Darstellung des Prüfschemas für potentielle Belastungsbereiche aufgrund des mangelhaften bodennahen atmosphärischen Austauschs.

Hinsichtlich der mangelnden bodennahen Austauschbedingungen sind insgesamt drei Belastungsbereiche definiert. Vor allem Räume mit potentieller Belastung durch Luftschadstoffe bedürfen entsprechender Austauschmöglichkeiten, um eine Verdünnung ebendieser zu gewährleisten.

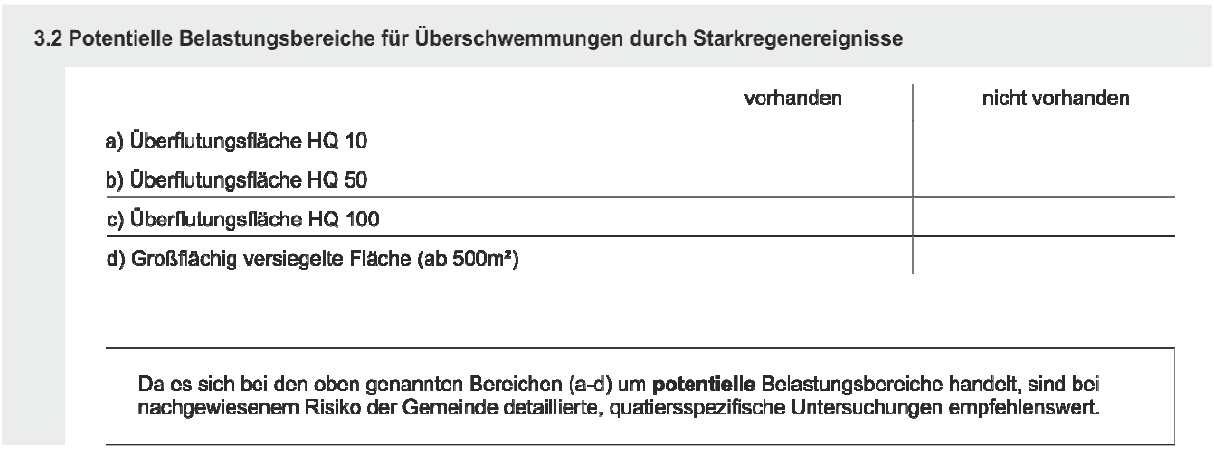
Gleichsam dem zuvor erläuterten Prüfschema „Urbane Überwärmung“ können auch hier, nachdem eine potentielle Belastung festgestellt und identifiziert wurde, die beschriebenen Belastungsbereiche im betroffenen Untersuchungsgebiet strukturell angepasst und entsprechende Festsetzungsvorschläge gemacht werden.

5.3.3 Überschwemmungen durch Starkregenereignisse

Zur Überprüfung einer potentiellen Belastung durch Überschwemmungen in Folge von Starkregenereignissen werden primär die durchschnittlichen Jahresniederschlagsmengen und die relative Feuchte sowie deren Entwicklung in den letzten zehn Jahren berücksichtigt. Zudem erfolgt eine Abfrage der Anzahl der Starkregenereignisse sowie deren voraussichtliche Entwicklung. Leider existieren für Starkregenereignisse oftmals noch keine gebietsbezogenen Statistiken. Allerdings lässt sich aus überdurchschnittlich hohen/ zunehmenden Niederschlagsmengen ein potentielles Risiko durch Starkregen ableiten. Auch hier gilt es, dass bei fehlenden Angaben ortsspezifische, detailliertere Untersuchungen zu empfehlen sind.

Bei Belastungsbereichen aufgrund von Überschwemmungen handelt es sich u. a. um Flächen, die im Rahmen der Aufstellung von Hochwassergefahrenkarten als Überflutungsflächen deklariert wurden. Dabei werden drei Kategorien unterschieden: Flächen, die statistisch einmal in zehn Jahren überflutet werden (HQ10), einmal in fünfzig Jahren (HQ50) und einmal in hundert Jahren (HQ100). Je höher dieses Zeitintervall ist, desto größer ist die potentielle Überflutung. Angezeigt werden hierbei Flächen, die durch über die Ufer getretene Gewässer überschwemmt werden (s. Abb. 5).

Darüber hinaus sind auch großflächig versiegelte Flächen durch die Überschwemmung in Folge von Starkregenereignissen gefährdet, da der anfallende Oberflächenabfluss nicht abfließen kann und die Kanalisation für derartige, kurzfristig auftretende Wassermengen oftmals unterdimensioniert ist. Nach der abschließenden Identifizierung der oben beschriebenen Belastungsbereiche, können die vorhanden Strukturen im Idealfall angepasst und entsprechende Festsetzungsvorschläge empfohlen werden.



3.2 Potentielle Belastungsbereiche für Überschwemmungen durch Starkregenereignisse

	vorhanden	nicht vorhanden
a) Überflutungsfläche HQ 10		
b) Überflutungsfläche HQ 50		
c) Überflutungsfläche HQ 100		
d) Großflächig versiegelte Fläche (ab 500m²)		

Da es sich bei den oben genannten Bereichen (a-d) um **potentielle** Belastungsbereiche handelt, sind bei nachgewiesenem Risiko der Gemeinde detaillierte, quatiersspezifische Untersuchungen empfehlenswert.

Abb. 5: Exemplarische Darstellung des Prüfschemas für potentielle Belastungsbereiche für Überschwemmung durch Starkregenereignisse.

6 FAZIT

Seit Anfang der 1990er Jahre ist der Klimawandel eine fortwährend diskutierte Thematik. Durch erste internationale Abkommen, wie z. B. die Klimarahmenkonvention, wurde die Grundlage für nachfolgende und darauf aufbauende Regelungen geschaffen. Hierbei lag der Fokus zunächst vornehmlich auf Klimaschutzmaßnahmen (Reduktion industrieller Emissionen, Förderung erneuerbarer Energien). Der Klimaschutz geht der Klimaanpassung zeitlich voraus. Somit hat sich das Thema der Klimaanpassung aus dem Klimaschutz auf der Basis verschiedener internationaler und nationaler Abkommen/ Regelungen entwickelt. In Deutschland kommt der räumlichen Planung bei der Anpassung an den Klimawandel eine entscheidende Rolle zu, da sie die unterschiedlichen Anforderungen an den Raum aufeinander abstimmt, um auf der jeweiligen Planungsebene auftretende Konflikte auszugleichen. Der Regional- und Bauleitplanung ist dabei eine besondere Bedeutung beizumessen, da sie konkrete und verbindliche Aussagen treffen. Die Voraussetzungen für derartig verbindliche Regelungen werden durch entsprechende Inhalte in den gesetzlichen Grundlagen geschaffen, die wiederum unter anderem auf die verschiedenen internationalen und nationalen Vereinbarungen zurückzuführen sind.

Da Klimawandelfolgen eine zunehmend ausgeprägte städtebauliche Dimension erreichen, steigt auch die Handlungserfordernis einer angepassten Stadtentwicklung. Diese Erkenntnis unterstreicht nochmals die Bedeutung der Bauleitplanung bei der Anpassung an den Klimawandel. Durch die nach § 2 Abs. 4 BauGB vorgeschriebene Umweltprüfung bei der Aufstellung von Bauleitplänen ist die grundlegende Voraussetzung für eine Berücksichtigung des Aspektes Klimaanpassung bei der Planung städtischer Quartiere bereits gegeben. Jedoch wird der Adaption oftmals nicht ausreichend Gewicht beigemessen – dazu trägt auch bei, dass der Gesetzgeber zur Planungsbeschleunigung mit den §§ 13a und 13b BauGB bei einer Vielzahl von Bebauungsplänen von der Pflicht zur Umweltprüfung wieder abgerückt ist. Hier besteht Optimierungsbedarf. Bei einer adäquaten Berücksichtigung der Maßnahmen zur Klimaanpassung enthält der bestehende Festsetzungskatalog des Bebauungsplans gemäß § 9 BauGB zahlreiche Möglichkeiten, um potentiellen Klimawandel bedingten Belastungen zu begegnen.

Um im Rahmen der Planung städtischer Quartiere die Adaption angemessen zu berücksichtigen, ist eine ganzheitliche Sichtweise auf existierende Inhalte auf den verschiedenen Ebenen der räumlichen Planung anzustreben. Dabei gilt es bereits zu einem sehr frühen Zeitpunkt der Planung den Aspekt der Klimaanpassung aufzunehmen, um diesen letztlich möglichst nahtlos in das planerische Gesamtkonzept zu integrieren.

Hinsichtlich der Berücksichtigung des Themas der Klimaanpassung in Regionen und Städten existieren gegenwärtig verschiedene informelle Planungen oder Programme. Diese oftmals in Form von Rahmenplänen

ausgearbeiteten Aussagen sind jedoch häufig ohne einen konkreten Umsetzungsbezug und treffen lediglich allgemein gültige Aussagen. Darüber hinaus beschränken sich derartige Planungen häufig auf Räume, die strukturstark und bereits in besonderem Maße von Klimawandelfolgen betroffen sind. Aufgrund des rezenten Klimawandels, der zunehmenden Verdichtung/ Versiegelung sowie steigender Einwohnerzahlen in urbanen Räumen nimmt zukünftig die Zahl belasteter Bereiche zu. Folglich bedarf es angepasster Lösungsstrategien, die bestenfalls im Rahmen der bestehenden gesetzlichen Regelungen Anwendung finden können.

Mit der Erarbeitung der aus zwei Modulen bestehenden Vorgehensweise ist ein beispielhafter Ansatz aufgezeigt, wie die Klimaanpassung bei der Planung städtischer Quartiere integriert und innerhalb des herkömmlichen Planungsprozesses adäquat berücksichtigt werden kann. Entscheidend ist hierbei die Einbeziehung der Adaption zu einem frühen Zeitpunkt des Planungsprozesses. Ebenso gilt es zu gewährleisten, dass diese angemessen im Rahmen der Umweltprüfung Berücksichtigung finden. Insbesondere hinsichtlich der Bearbeitung in Bezug zur Umweltprüfung erscheint mit Blick auf die voraussichtlich lokalklimatische Entwicklung die Notwendigkeit eines Prüfschemas gegeben. Da die grundlegenden Voraussetzungen für eine angemessene Berücksichtigung lokalklimatischer Belange, insbesondere von Klimaanpassungsmaßnahmen, durch die bestehenden Inhalte im Baugesetzbuch bereits gegeben sind, ist die Integration eines strukturschaffenden Prüfschemas in die Umweltprüfung als äußerst sinnvoll einzustufen.

Ko-produktive Stadtentwicklung? Steuerungsansätze und Steuerungsprobleme mit kreativen Wertschöpfungsprozessen

Sarah C. Schreiner

(Dr.-Ing. Sarah C. Schreiner, Urban Research and Development, Margaretenstraße 39, 20357 Hamburg, dr.ing.schreiner@gmx.de)

1 ABSTRACT

In den wissenschaftlichen Diskussionen über die Kulturalisierung der Ökonomie oder Kreativquartiere lässt sich erkennen, dass für raumgestaltende Prozesse die Eigenlogiken kreativer Unternehmen von grundlegender Bedeutung sind. Zur Gestaltung einer kreativen Stadt sind flexible und projektbasierte Konstellationen notwendig. Hierarchische Organisationsmodelle und formelle Instrumente der Stadtplanung verlieren in diesem Kontext an Bedeutung. Horizontale Steuerungsformen und vor allem ko-produktive Aktivitäten sind dafür geeignet. Wichtige Akteure sind dabei natürlich Stadtplanungsämter und städtische Wirtschaftsförderungsgesellschaften. Diese Akteure setzen in der Praxis die damit verbundenen Aufgaben jedoch nur selten in Beziehung zu der Frage nach adäquaten Formen der räumlichen Planung oder Steuerung.

Anhand eines bedarfsorientierten Forschungsansatzes habe ich dieses Phänomen planungswissenschaftlich untersucht und dazu die Wertschöpfungsprozesse kreativer Kleinstunternehmen in der Stadt Hamburg als Beispiel genommen. Dabei zeigen sich vielfältige Formen betrieblicher Entwicklungspfade sowie zielgruppenorientierte Unterstützungsmaßnahmen der lokalen Institutionen der Stadtplanung und Wirtschaftsförderung.

Der Artikel beschreibt Steuerungsansätze und -probleme mit kreativen Ökonomien von unterschiedlichen Akteuren der öffentlichen Hand hinsichtlich gesamtstädtischer Entwicklungsperspektiven. Möglichkeiten und Grenzen ko-produktiver Stadtentwicklung werden konkret am Beispiel der Stadt Hamburg skizziert. Der Artikel endet mit Handlungsvorschlägen für eine Qualifizierung planerischer Ko-Produktion und Übertragungsmöglichkeiten für andere Städte.

Keywords: Planungskultur, Gewerbeflächen, Kreativwirtschaft, Kooperation, Kommunikation

2 EINLEITUNG: KO-PRODUKTION ALS SPEZIFISCHE ART DER STADTGESTALTUNG

Aktuell wird in der deutschen Stadtentwicklung, die ja vor komplexen Anforderungen an die Bevölkerungs- und Wirtschaftsentwicklung sowie der städtebaulichen Erneuerung von Kommunen steht, vermehrt über Planungskulturen, akteursspezifische Interaktionsweisen und kommunikationsbasierte Zielerreichung diskutiert.[1] Über die Art des Umgangs mit gegenseitigen Erwartungen, mit Teilhabe sowie mit Vertrauensbildung können neue Formen der Kooperation erprobt und Lerneffekte generiert werden.[2] Vertreterinnen und Vertreter privatwirtschaftlicher, intermediärer oder zivilgesellschaftlicher Interessen sind nicht mehr nur Adressaten staatlicher Verfahren, Programme und Projekte. Vielmehr gestalten sie als Ko-Produzenten städtische Räume aktiv mit und werden zu relevanten Kooperationspartnern für die Stadtplanung und Wirtschaftsförderung. Sie übernehmen daher selbst Steuerungsfunktionen und Verantwortung für raumbildende Prozesse.[3]

Mit Ko-Produktion werden hier gemeinschaftliche Produktionsprozesse mit wechselseitigen Austauschbeziehungen auf überwiegend horizontaler Ebene bezeichnet. Ko-Produktion kann somit in ökonomischen Wertschöpfungsprozessen oder in der Raumentwicklung stattfinden.[4] Ko-Produktion verläuft niemals linear, sondern in vielfältigen Diskussionen und Abwägungsschritten, und beinhaltet keine zentralen Entscheidungspositionen. Daher vollziehen sich solche Prozesse jenseits der – unter anderem baugesetzlich oder finanzpolitisch verankerten – formalen Verfahren der Stadtplanung und Wirtschaftsförderung.

Der Hype um die kreative Klasse[5] und die Räume kreativer Milieus[6] als Treiber für die sozio-ökonomische Gesamtentwicklung von Städten und Regionen hält schon seit ein paar Jahren an. In kreativen

Wertschöpfungsprozessen[7] sind ko-produktive Aktivitäten insbesondere bei Kleinstunternehmen der Kreativwirtschaft – aufgrund von deren spezifischer Alltagsbewältigung – weit verbreitet.[8] Ihre Fähigkeit schöpferischen Denkens und Handelns basiert auf individuellen, kollektiven und auch städtebaulichen (urbanen) Ressourcen.[9] Kreative Kleinstunternehmen agieren vor allem in kreativen Milieus. Sie nutzen Stadträume nicht nur als Bühne, sondern gestalten sie aktiv mit.[10] Diese Akteure müssen als Raumproduzenten beachtet werden. Für die Entwicklung einer kreativen Stadt[11] werden solche Unternehmen und ihre Wertschöpfungsprozesse daher zu wichtigen Handlungsfeldern der lokalen Stadtplanungsbehörden und Wirtschaftsförderungsorganisationen.

Vor diesem Hintergrund beschäftigt sich der Artikel mit folgenden Forschungsfragen:

- Wie agieren lokale Planungsbehörden und städtische Wirtschaftsförderungsgesellschaften in Prozessen der Quartiers- und Stadtentwicklung mit kreativen Kleinstunternehmen?
- Welche Voraussetzungen benötigt ko-produktive Stadtentwicklung?
- Welche Instrumente und Umgangsformen sind für die Stadtplanung und Wirtschaftsförderung geeignet bzw. notwendig, um kreative Wertschöpfungsprozesse in einer Stadt überhaupt zu beeinflussen oder adäquat zu unterstützen?

3 WIE REAGIEREN STADTPLANUNG UND WIRTSCHAFTSFÖRDERUNG AUF KREATIVE ORTE UND MILIEUS?

Diverse Stadtplanungsämter sowie städtische Wirtschaftsförderungsgesellschaften versuchen mittlerweile gezielt, eine spezifische Attraktivität von Stadtgebieten als Arbeitsorte für kreative Ökonomien, wie Architekten, Grafiker und Filmproduzenten, zu initiieren oder zu unterstützen.[12] Dabei setzen sie sowohl städtebauliche als auch kommunikative Steuerungsinstrumente ein. Das zeigt sich zum einen an der Ausrichtung kommunaler Flächennutzungsplanungen auf die Ansiedlung kreativer Unternehmen. Zum anderen demonstrieren das kommunikative Maßnahmen zur Vernetzung kreativer Ökonomien sowie spezifische Beratungsangebote und Öffentlichkeitsarbeit für die lokale Kreativwirtschaft.

3.1 Städtebauliche Steuerungsansätze

Strategisch eingesetzte infrastrukturelle und bauliche Restrukturierungsmaßnahmen, bei denen Kultur und Kreativwirtschaft für sozialräumliche Entwicklungsprozesse eingesetzt werden, gibt es in europäischen Großstädten seit Anfang unseres Jahrtausends. Das geschieht vor allem über die lang- oder mittelfristige Planung großer Projekte oder Kreativquartiere zur Revitalisierung ehemaliger Areale der Industrieproduktion, Hafenflächen oder Kasernen.[13] Die kommunalen Bauverwaltungen steuern solche Vorhaben strategisch mit Mitteln der Baulandvergabe, der Flächennutzungsfestlegung, der Förderung bestimmter Gewerbebauvorhaben oder der Gestaltung öffentlicher Freiflächen.

An zahlreichen Orten werden zudem Unterstützungsfonds aus öffentlichen Mitteln für „Kreativ-Immobilien“ eingerichtet oder Wirtschaftsförderungsgesellschaften damit beauftragt, Gewerbe-Immobilien an kreative Ökonomien sowie Kulturschaffende zu vermitteln. Das betrifft sowohl Zwischennutzungen als auch langfristige Nutzungen von Flächen. So werden bestimmte Grundstücke und Immobilien bevorzugt oder besonders kostengünstig an Kreativunternehmen vergeben. Die zentral organisierte Vergabe der Flächen soll dazu beitragen, Leerstand zu verringern oder kreative Unternehmen an bestimmten Orten anzusiedeln, um diese zu transformieren.[14]

---

[6] Vgl. Lange 2007, Frey 2009
[7] Vgl. Schreiner 2018:70
[8] Im Vergleich zu anderen Wirtschaftsbereichen sind Kleinstunternehmen in der Kultur- und Kreativwirtschaft überproportional vertreten (Dapp & Ehmer 2011:4). Im Jahr 2016 betrug ihr Anteil fast 97% (Bertschek et al. 2019:43).
[9] Vgl. Frey 2009:36ff., Overmeyer 2011:68
[10] Vgl. Hesse 2011:40ff.

[12] Vgl. Hesse 2011, Kunzmann 2009
[13] Beispiele sind die IBA Hamburg 2013, die ehemalige NDSM-Werft in Amsterdam-Noord und die ehemalige Linzer Tabakfabrik.
[14] Vgl. Hesse 2011, 43ff.

Seit einigen Jahren werden verstärkt auch kurz- bis mittelfristige Unterstützungsmaßnahmen durch öffentliche Institutionen umgesetzt. Das betrifft vor allem Neubauvorhaben für Standortgemeinschaften wie Gründerzentren, Inkubatoren oder Coworking Spaces für bestimmte Teilökonomien der Kreativwirtschaft. Das erstreckt sich außerdem auf Umbauten von Bestandsimmobilien für spezifische Nutzungen durch wissensbasierte und/oder oder kreative Unternehmen sowie kulturelle Einrichtungen.[15] Solche Einzelprojekte können als direkte Eingriffe zur Herausbildung von kreativen Milieus beitragen. Sie ergänzen die strategischen, städtebaulichen Entwicklungsvorhaben von kreativen Orten und Quartieren.

3.2 Kommunikative Steuerungsinstrumente

Städtische Akteure begleiten Aufwertungsmaßnahmen urbaner und kreativer Quartiere zunehmend mit Informations- und Dialogaktivitäten. Dazu gehören Angebote zur Kooperationsförderung, gezielte Öffentlichkeitsarbeit und Standortmarketing. Sie setzen dafür Formate wie Informations-, Beratungs- und Vernetzungsveranstaltungen für kreative Unternehmen ein. Außerdem unterstützen sie die Wirtschaftskraft und Sichtbarkeit ortsansässiger Kreativökonomien durch Imagekampagnen oder Marketingstrategien auch mit Branchenhearings, Messen, Publikationen und Ausstellungen.

Die kommunikativen Angebote können einerseits eine Ansiedlung und lokale Konsolidierung von kreativen Unternehmen sowie deren potentielle Kooperationspartner unterstützen. Andererseits wird damit die Hoffnung verbunden, mit einem entsprechenden Image als erfolgreiche Stadt zur sozialen und ökonomischen Transformation von Stadtgebieten und/oder zur Neudefinition regionaler bzw. städtischer Identitäten beizutragen.[16]

Oft nutzen städtische Wirtschaftsförderungsgesellschaften bzw. -behörden oder Kammern diese kommunikativen Steuerungsinstrumente, eher selten sind es die Planungs- oder Baubehörden. Die verschiedenen Maßnahmen können dauerhaft und langfristig oder temporär und kurzfristig umgesetzt werden.

3.3 Probleme und Kritik

Problematisch sind dabei folgende Aspekte: Sogenannte kreative Orte benötigen ein gewisses Maß an Offenheit, damit sich kreative Milieus herausbilden können. Sie entstehen, indem kreative Akteure bestimmte Gebäude oder Flächen entdecken, aneignen und gestalten können.[17] Eine durch staatliche Aktivitäten forcierte oder initiierte Imageprägung als kreative Orte bzw. Quartiere geht jedoch oftmals einher mit einer Vermarktung durch die Werbebranche und die Immobilienwirtschaft. Außerdem lösen die professionellen Angebote selbstorganisierte Formen einer kollektiven Aneignung preisgünstiger Immobilien mit schlechtem Bauzustand ab. Damit schrumpfen Möglichkeiten zur kreativen Gestaltung von Stadträumen und die freie Bühne wird kommerzialisiert.

Folgen sind Preisanstiege und eine höhere Nachfrage nach den noch verfügbaren Flächen. Das führt zu Verteilungskonflikten mit angestammten Bewohnerinnen und Bewohner, Initiativen und Unternehmen – und einem Verlust offener Orte.[18] Von daraus resultierenden Abwanderungen können nicht nur kreative Kleinstunternehmen selbst betroffen sein. Es kann auch diejenigen Betriebe betreffen, die für Lerneffekte und Wertschöpfungsprozesse kreativer Milieus relevant sind, ähnliche Standortanforderungen haben und auf eine räumliche Nähe mit kreativen Kleinstbetrieben angewiesen sind. Das berührt wissensarme und wissensintensive Unternehmensdienstleistungen, kleinere Produktionsunternehmen, Künstlerinnen und Künstler, Handel und Gastronomie (vgl. Abb. 1).[19]

[15] Beispiele hierfür sind die Themenimmobilie Designxport als Vermittlungsort für Design in Hamburg sowie das Dortmunder U als Zentrum für Kunst, Kultur, Kreativität und Wissenschaft auf ehemaligen Flächen der Union-Brauerei.

Abb. 1: Schnittstellen für Wertschöpfungsprozesse und Lerneffekte kreativer Kleinstunternehmen (Quelle: Schreiner 2018:81)

4 VERÄNDERTE ROLLEN UND STEUERUNGSFORMEN

Die Ballung kreativer Kleinstunternehmen an bestimmten Standorten vollzieht sich also überwiegend spontan und als selbstorganisierte Prozesse.[20] Daher treten Fragen der Steuerungsmöglichkeit der Kreativwirtschaft und der Planbarkeit kreativer Orte auf.[21] Für die Stadtplanung und Wirtschaftsförderung entstehen damit neue Herausforderungen: Ihre herkömmlichen Handlungstrategien sowie Verfahrens- und Regelungsarten müssen modifiziert werden, um Einfluss auf kreative Ökonomien zu erlangen.[22] Die geringe hierarchische Organisation kreativer Kleinstunternehmen erfordert kooperatives Verwaltungshandeln in netzwerkartigen Konstellationen.[23]

Die spezifischen Kommunikations- und Kooperationsformen kreativer Unternehmen erfordern also veränderte Rollen und Steuerungsformen von Vertreterinnen und Vertretern der Stadtplanungsämter und städtischen Wirtschaftsförderungsgesellschaften. Um eine Ansiedlung und Etablierung kreativer Ökonomien zu unterstützen, ist es zunächst relevant, deren Eigenlogiken und Interaktionsweisen zu verstehen. Das betrifft sowohl ihre Selbstgestaltungskräfte, als auch Formen vertikaler sowie horizontaler Kooperation bzw. Ko-Produktion.

4.1 Zielgruppenspezifische Ansprache durch Beraterinnen und Berater

Der Arbeitsalltag von Einzelselbständigen und Kleinstbetrieben der Kreativwirtschaft ist von einem hohen Maß an Selbstregulierung und Autonomiebestreben gekennzeichnet. Ökonomischen Unsicherheiten der Unternehmensorganisation wird über kulturell und sozial determinierte Arbeitszusammenhänge in temporären Kollektiven und phasenweiser Projektarbeit begegnet. Als Grundlage dienen dafür sozialräumlich verankerte Netzwerke und kreative Milieus.

Eine formalisierte Interessenvertretung ist für einen großen Teil der Erwerbstätigen innerhalb der Kreativwirtschaft nicht üblich. Zwar gibt es diverse Berufsverbände – und im Fall der Architektur auch Kammern auf der Landes- und Bundesebene. Jedoch sind viele Kleinstunternehmen anderer kreativer Tätigkeitsbereiche nicht in Berufsverbänden organisiert. Daher fehlen offizielle Ansprechpersonen oder Delegierte, wenn gemeinsame Ziele, Programme oder Projekte mit Planungsbehörden oder städtischen Wirtschaftsförderungsgesellschaften ausgearbeitet werden sollen.

[20] Vgl. Hesse 2011:45ff., Frey 2009
[21] Vgl. Lange et al. 2011:12ff., Frey 2009
[22] Vgl. Overmeyer 2011:68, Hesse 2011:46ff.
[23] Vgl. Kunzmann 2009

In diesem Kontext können staatliche Akteure mit einer offenen Ansprache bestimmter Zielgruppen (wie bspw. Existenzgründerinnen und Existenzgründer in der Kreativwirtschaft) über die in den kreativen Milieus üblichen Kommunikationsmittel agieren. Sie sollten bei Informationsveranstaltungen eine beratende Rolle einnehmen.

4.2 Dialog und Kooperationstreffen mit Moderatorinnen und Moderatoren

Außerdem treffen immer wieder individuelle Selbstorganisationsformen und Entscheidungen von kreativen Unternehmen auf kooperative Steuerungsformen innerhalb gemeinsamer Projektbearbeitung sowie Aspekte der hierarchischen Steuerung.

Beispiele für hierarchische Steuerungsformate sind Stipendien oder Messefinanzierungen für kreative Unternehmen, die von lokalen Behörden sowie staatlich eingesetzten Agenturen des Bundes oder Landes vergeben werden. Außerdem sind Förderungsvoraussetzungen bei Kredit- oder Investitionsprogrammen des Bundes für kreative Kleinstunternehmen oftmals inhaltlich unpassend oder die Beantragung kann aufgrund des hohen bürokratischen Aufwands nicht bewältigt werden. Die besonderen Rahmenbedingungen der Kreativwirtschaft oder spezifischer kreativer Teilbranchen werden dabei nicht explizit beachtet. Diese Steuerungsformen scheinen also nicht mit den Alltagspraktiken der Zielgruppe zusammen zu passen und daher nur bedingt wirksam zu sein. Hier kann es helfen, bedarfsforientierte Förderangebote mit geringerem formalem Antragsaufwand zu ermitteln und aufzustellen.

Um die Vernetzung von kreativen Kleinstunternehmen mit potentiellen Geschäftspartnern auf horizontaler Ebene zu unterstützen, sind spezifische Kooperationsveranstaltungen geeignet. Das kann erfordern, dass solche Aktivitäten nicht auf einzelne Branchen der Kreativwirtschaft begrenzt werden, sondern fallspezifisch auch Vertreterinnen und Vertreter aus Handwerk, Industrie, Handel und Wissenschaft mit einbeziehen. Dabei sollten planende und fördernde Akteure eher eine moderierende Rolle einnehmen, um auf horizontaler Ebene agieren zu können. Ihre Einflussnahme sollte sich in dem Kontext auf partnerschaftliche Zusammenarbeit konzentrieren.

4.3 Ortsspezifische Mischung

Die Herausbildung kreativer Orte vollzieht sich jeweils im Zusammenspiel der Alltagspraktiken kreativer Unternehmen mit den Planungspraktiken kommunaler/städtischer Akteure. Das verläuft in jeder Stadt etwas anders, da es dafür keine nationalen Vorgaben oder einheitliche Zuständigkeiten gibt.[24] Somit können Vorgehensweisen und Ziele der lokalen Kreativunternehmen sowie der Organisationseinheiten der öffentlichen Hand – die in diesen Bereichen raumwirksam handeln – unterschiedlich sein, sich ergänzen oder überlagern.

Die literaturbasierte Diskussion verdeutlicht: Sowohl kontextbezogene als auch direkte Steuerungsaktivitäten beeinflussen bzw. unterstützen die lokale Kreativwirtschaft, kreative Milieus und die gesamtstädtische Entwicklung. Hierfür kann eine Bandbreite an städtebaulichen und kommunikationsbasierten Steuerungsansätzen eingesetzt werden (vgl. Abb. 2).

Abb. 2: Bandbreite der Steuerungsansätze für kreative Ökonomien und Milieus (eigene Darstellung)

[24] Vgl. BBSR & BBR 2016:22f.

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Sollen diese Ansätze fruchten, sind vor allem prozessuale Formen des kooperativen Umgangs notwendig: Stadtplanung und Wirtschaftsförderung sollten die ortsspezifischen Kommunikationsarten und temporären Projektkonstellationen der handelnden Individuen respektieren und als Rahmenbedingungen für gemeinschaftliche Interaktionen akzeptieren. Die ortsspezifische Planungskultur speist sich demnach aus dem individuellen Handeln, dem Selbstverständnis, dem Vernetzungsgrad sowie der Außenwirkung der jeweiligen Delegierten aus der Stadtentwicklung.

Ansätze für eine Stadtentwicklung, die kreative Ökonomien und ihre Milieus ins Zentrum stellen, sollten sich außerdem am spezifischen Bedarf der fokussierten Gruppen orientieren. Daraus folgt, dass stadträumliche Effekte, die durch Unterstützungsmaßnahmen für Kreativorte entstehen, beachtet werden müssen, um negative Auswirkungen auf andere Gruppen, Stadtquartiere oder die Region zu begrenzen.

5 ERGEBNISSE AUS HAMBURG

Eine detaillierte Untersuchung der Wertschöpfungsprozesse von Kleinstunternehmen des Produktdesigns und der Architektur in der Stadt Hamburg zeigt:[25] Es gibt vielfältige Formen kreativwirtschaftlicher Alltagsgestaltung, deren Muster sich auf gesamtstädtischer Ebene ablesen lassen. Die lokale Stadtplanung und Wirtschaftsförderung hat dezidiert Steuerungsansätze darauf ausgerichtet, zum Beispiel die Entwicklung von Kreativquartieren und diverse Beratungsangebote.

Dennoch haben die untersuchten Unternehmen Probleme in ihrer betrieblichen Entwicklung. Abwanderungen in andere Großstädte oder Regionen sind eine Folge davon. Das ist zum Teil der fehlenden Unterstützung bzw. unzureichenden Steuerung durch unterschiedliche Akteure der öffentlichen Hand geschuldet.

Mit Bezug auf die oben genannten Forschungsfragen werden ortsspezifische Untersuchungsergebnisse im Folgenden kurz skizziert.

5.1 Konkrete Bedarfe als Voraussetzungen für ko-produktive Stadtentwicklung

Interaktionen von Hamburger Kleinstunternehmen des Produktdesign oder der Architektur verlaufen überwiegend in informellen Koordinationsmechanismen jenseits institutioneller Steuerungseingriffe.[26] Je nach Organisationsform, Entwicklungsphase und Ortsressourcen sind ihre Austausch- und Zulieferbeziehungen sowie Absatzmöglichkeiten und Innovationsfähigkeiten eingeschränkt.

Zunehmend problematisch ist für diese Betriebe der lokale Gewerbeflächenmarkt: In Hamburg favorisieren die untersuchten Kleinstunternehmen vorrangig diejenigen Stadtgebiete als Unternehmensstandorte, die von einer heterogenen und kleinteiligen Nutzungsmischung geprägt sind (vgl. Abb. 3). Das zeigt sich sowohl in temporären Raumaneignungen als auch in dauerhaften Manifestationen der kreativen Kleinstunternehmen in bestimmten Quartieren. Relevant für die Standortwahl der befragten Unternehmerinnen und Unternehmer ist, dass sie dort ideal Wohnen und Arbeiten verbinden können. Außerdem gibt es in diesen Lagen ein lebendiges Umfeld, das einerseits spannend und inspirierend ist, und andererseits persönliche Austauschbeziehungen mit Kundinnen, Kunden, Geschäftspartnerinnen und Geschäftspartnern erleichtert. Daher ist bei den untersuchten Kleinstunternehmen ein großer Bedarf zum Kauf und zur langfristigen Anmietung bzw. Erbpacht urbaner Gewerbeflächen vorhanden. Städtische Gewerbeflächen und -immobilien in geeigneten Lagen stehen jedoch de facto kaum für diese Interessenten zur Verfügung. Die vielfältigen Zuständigkeiten für einen Verkauf oder eine Erbpacht städtischer Grundstücke und Immobilien machen Abstimmungsprozesse außerdem nicht nur sehr unübersichtlich, sondern auch langwierig. Aufgrund des Fehlens übergeordneter Ansprechpersonen auf kreativwirtschaftlicher Seite sind Verhandlungen zwischen den einzelnen Akteuren nicht strukturell, sondern nur fallspezifisch zu lösen.

Außerdem werden die vorhandenen Informations- und Kooperationsangebote der staatlichen Wirtschaftsförderungsorganisationen wie der Hamburg Kreativ Gesellschaft mbH oder des Regionalberater des Kompetenzzentrum Kultur- und Kreativwirtschaft des Bundes von den untersuchten Kleinstunternehmen nur partiell genutzt. Vor allem die öffentlichen Veranstaltungen zu Themen digitaler Produktion, Vertrieb und Marketingstrategien wurden zum Zeitpunkt der Untersuchung gut besucht. Dabei ist das Interesse bzw.

[25] Vgl. Schreiner 2018:103ff.
[26] Da das typische Organisationsmerkmale in der Kreativwirtschaft darstellen, sind sie hierin mit anderen kreativen Ökonomien vergleichbar.

der Bedarf von Existenzgründerinnen und Existenzgründern aus den Kreativökonomien größer als von den etablierteren Unternehmerinnen und Unternehmern. Insgesamt ist die Wahrnehmung des Angebots sowie die Teilnahme von Produktdesignerinnen, Produktdesignern, Architektinnen und Architekten jedoch eher gering, was auf ein nicht ausreichendes bzw. bedingt geeignetes Angebot an Informations-, Kooperations- und Beratungsangeboten schließen lässt.

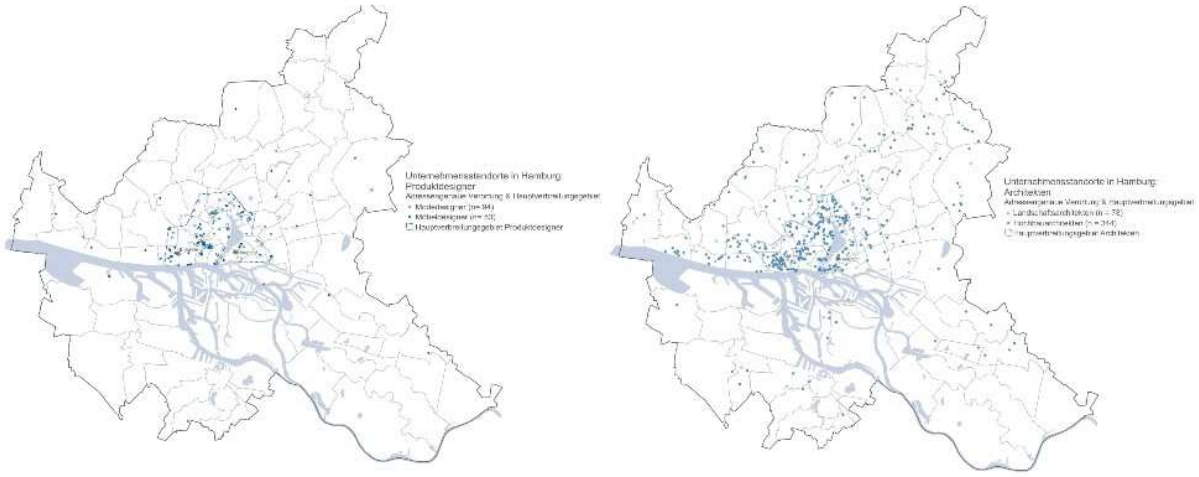

Abb. 3: Unternehmensstandorte und Hauptverbreitungsgebiete von Produktdesign- und Architekturbüros in Hamburg (Quelle: Schreiner 2018:107, 109)

Dass die Hamburger Kleinstunternehmen des Produktdesigns und der Architektur bedarfsgerechte Unterstützungsangebote benötigen, ist eine logische Schlussfolgerung aus den Forschungsbefunden.

5.2 Steuerungsansätze der lokalen Stadtplanung und Wirtschaftsförderung

Die Stadtplanungs- und Wirtschaftsbehörden führen kaum kontextbezogene und direkte, städtebauliche und kommunikative Steuerungsaktivitäten für Produktdesign und Architektur in Hamburg durch. Jedoch bieten verschiedene stadteigene Wirtschaftsförderungs-, Quartiersentwicklungs- und Immobiliengesellschaften sowie die Architekten- und Handelskammer an, kreative Unternehmen zu standort- und betriebsrelevanten Themen zu informieren, zu beraten oder zu vernetzen.

Ausgehend von den internationalen Diskussionen über den Wettbewerb von kreativen Städten wird auch in Hamburg seit einiger Zeit die Entwicklung von Kreativquartieren zur Vitalisierung von Stadtgebieten in Betracht gezogen. Dabei versuchen Quartiersentwicklungs- und Wirtschaftsförderungsgesellschaften wie die HafenCity Hamburg GmbH oder die Hamburg Kreativ Gesellschaft mbH, kreative Aktivitäten und Unternehmen in den Stadtgebieten anzusiedeln, die für Gewerbe, Freizeit- und Wohnnutzungen qualifiziert werden sollen. Das wird über die Vermittlung temporärer Gewerbeflächen für bestimmte Kreativunternehmen oder entsprechende Kriterien bei Konzeptvergaben für Immobilienverkäufe durchgeführt. Bei diesen formalisierten Verfahren kommt es für kreative Kleinstunternehmerinnen und Kleinstunternehmer darauf an, die richtigen Ansprechpartnerinnen und Ansprechpartner der städtischen Institutionen sowie die relevanten Fristen, Gelegenheiten, Voraussetzungen und Abläufe zu kennen.

Die eingesetzten Kommunikationsmaßnahmen sind durchaus vielfältig. Sie zielen auf betriebswirtschaftliche Unternehmensentwicklung, Vernetzung von kreativen Unternehmen sowie Marketing von Hamburg als kreative Stadt. Insgesamt erweisen sich die allgemeinen dialogorientierten Aktivitäten auch für Unternehmen des Produktdesigns und der Architektur als ausreichend. Die gefundenen Lücken betreffen spezifische und direkte Formate zur Stärkung transdisziplinärer Kooperationen zwischen diversen Unternehmen, von Existenzgründerinnen und Existenzgründern bis zu etablierten Unternehmen, sowie Öffentlichkeitsarbeit für bestimmte Tätigkeitsfelder und den dazugehörigen Wertschöpfungsprozessen.

Die lokal vorhandenen Steuerungsansätze der Planungsbehörden und Wirtschaftsförderungsgesellschaften zur Förderung von Produktdesign und Architektur in Hamburg sind – unterm Strich – eher hierarchisch aufgestellt, stark sektoral ausgerichtet, selten bedarfsgerecht und basieren auf "behördlichen" Umgangsweisen staatlicher Institutionen. Daher sind sie für die untersuchten Kleinstunternehmen, die vorrangig in kreativen Milieus mit funktionalen Wertschöpfungsprozessen und persönlichen

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Kooperationsbeziehungen agieren, wenig geeignet. Die auf sie angewendeten Instrumente sind also hinsichtlich einer ko-produktiven Stadtentwicklung kaum wirksam.

5.3 Anpassungsbedarf für lokale Steuerungsformen

Von ko-produktiver Stadtentwicklung sind staatliche Organistaionseinheiten in Hamburg, sofern es um kreative Wertschöpfungsprozesse der fokussierten Ökonomien geht, noch weit entfernt. Viele Akteure der öffentlichen Hand tun sich schwer damit, für die kreativen Kleinstunternehmen als Partnerinnen und Partner auf Augenhöhe und mit adäquaten Unterstützungsformen zu agieren. Die existierenden Aktivitäten zur Unterstützung kreativer Ökonomien in Hamburg bergen jedoch großes Potenzial, genauer auf die lokalen Charakteristika konkreter Tätigkeitsfelder und -formen ausgerichtet zu werden.

Um Einfluss auf die Ansiedlung und Etablierung kreativer Unternehmen des Produktdesigns und der Architektur nehmen zu können, sollten die staatlichen Delegierten der öffentlichen Organisationen stärker auf die zugrundeliegenden, spezifischen Anforderungen und Umgangsweisen eingehen. Ganz grundsätzlich erscheint dafür eine stärker zielgruppenorientierte Adressierung mittels der richtigen Sprache als enorm förderlich und möglich. Das trifft ebenso auf eine flexible, inhaltliche und heterarchische Koordination zwischen den Unternehmen sowie den Stadtplanungsämtern, Wirtschaftsbehörden, städtischen Entwicklungsgesellschaften und Kammern zu.

Weniger institutionalisierte und hierarchische Strategien können sektorübergreifende Impulse für Stadtquartiere bringen und durch offene Angebote umgesetzt werden. Als Impulsgeberinnen, Impulsgeber, Vermittlerinnen, Vermittler, Moderatorinnen oder Moderatoren zwischen den unterschiedlichen Sprachen und Sphären kommen hierfür fachlich versierte und gut vernetzte Personen, zum Beispiel aus einer der zahlreichen Kulturstiftungen, Baugenossenschaften, Unternehmervereinigungen oder Fachverbänden, in Frage.

Konkret sollten flächennutzungsbezogene Steuerungsformen dahingehend modifiziert werden, dass dynamisierte Festlegungen und Vergaben kommunaler Gewerbeflächen stattfinden, die frühzeitig öffentlich bekannt gemacht werden und die hybride Flächennutzungen zulassen. Auch sollten dringend Aktivitäten zur Potenzialerkennung und Sicherung von urbanen Gewerbeflächen stadtweit koordiniert durchgeführt werden.

Ein weiterer adäquater Steuerungsansatz ist, Dialogformate für bestimmte kreative Wertschöpfungsprozesse stärker branchenübergreifend auszurichten. Damit können Informationsaustausch und Kooperationsanbahnungen auch über die Stadtgrenzen hinaus gefördert werden und somit lokal-regionale Unternehmensbeziehungen gestärkt werden.

6 FAZIT

Allgemein gibt es für die Stadtentwicklung und Wirtschaftsförderung verschiedene Optionen, kreative Orte, Ökonomien und Milieus in Großstädten zu unterstützen – und zu behindern. Welche Eingriffsmöglichkeiten bestehen und welche Rolle dabei staatlichen Organen zukommt, hängt von den jeweiligen Kooperations- und Koordinationsformen der relevanten Akteursgruppen ab. Wenn kreative Kleinstunternehmen für städtische Gestaltungsprozesse fokussiert werden, sollten die recht spezifischen Umgangsweisen sowie Standortanforderungen der entsprechenden Teilökonomien beachtet werden.

Urbane Standorte und lokal verankerte Interaktionen stellen, wie am Hamburger Beispiel ersichtlich ist, Aushandlungsarenen kreativer Ökonomien dar. Soziokulturelle Gemeinsamkeiten, Vertrauen sowie das Verständnis unterschiedlicher Rollen und Sprachen bilden eine Grundlage des betrieblichen und somit des alltäglichen Handelns in kreativen Milieus. Kreative Kleinstunternehmen kooperieren und koordinieren ihre Beziehungen auf horizontaler und vertikaler Ebene. Staatliche Organisationen können, neben Produktions- und Vertriebspartnern, in diese kreativen Wertschöpfungsprozesse integriert sein, müssen es aber nicht.

Die Bindeglieder zwischen kreativen Unternehmen und den Vertreterinnen und Vertretern der öffentlichen Hand sind die ökonomischen, sozialen und kulturellen Erwerbs- und Entwicklungsziele, die über das Medium der Kommunikation gegenseitig vermittelt und über die Methode der Kooperation erreicht werden. Je besser die jeweiligen Wünsche und Bedürfnisse, Möglichkeiten und Restriktionen, Ziele und Vorlieben einander bekannt sind und respektiert werden, umso genauer gelingen Aktivitäten, die die Beteiligten in ihren Gemeinsamkeiten und Unterschieden voranbringen. Mit dialogorientierten Prozessen raumbezogener Steuerung bieten sich also Möglichkeiten für gemeinschaftliches, temporäres Handeln und für

projektorientierte Konsensfindung verschiedener Akteure. So können städtische Entwicklungsvorhaben prozessual umgesetzt werden, deren Ziele und Ergebnisse inkrementell sind.

Für eine ko-produktive Stadtentwicklung sind also – in dem hier dargestellten Handlungsfeld – vielfältige Fachkenntnisse zu den jeweiligen kreativen Wertschöpfungsprozessen, gegenseitiges Vertrauen und Offenheit für Neues bei allen Beteiligten notwendig. Hierfür bedarf es einer spezifischen Planungskultur, die örtliche Eigenheiten reflektiert, auf einer gemeinsamen Sprache aufbaut sowie sich ständig fortentwickelt.

Insgesamt betrachtet kommt es jeweils auf das projekt- und ortsabhängige Zusammenspiel von formeller und informeller, hierarchischer und heterarchischer Koordination zwischen den staatlichen und privatwirtschaftlichen Akteuren an. Planungsaktivitäten mit Top-down-Ansätzen sowie kontextbezogene Steuerung sind dafür weniger geeignet als Bottom-up-Prozesse und direkte Unterstützungsaktivitäten. Steuerungsinstrumente sollten zwar dynamisch, aber auch komplementär eingesetzt werden und zu gemeinsamen Entscheidungen führen. Das bringt allerdings einen intensiven, ressort- und themenübergreifenden Abstimmungsaufwand mit sich. Außerdem ist dafür notwendig, dass die Vertreterinnen und Vertreter der öffentlichen Hand ihre Handlungsfähigkeit hinsichtlich ihrer Stadtentwicklungsziele hinterfragen und adäquate Rollen als Vermittlerinnen, Vermittler, Moderatorinnen, Moderatoren, Kooperationspartnerinnen oder Kooperationspartner einnehmen bzw. diese Aufgaben an geeignete Akteure delegieren.

(Prof. Dr.- Ing. Petra von Both, KIT- Building Lifecycle Management, Karlsruhe, petra.vonboth@kit.edu)

1 ABSTRACT

Können an unterschiedlichen Orten angesetzte Reallabore anhand ihrer Rahmenbedingungen verglichen werden? Lassen sich aus einer Umfeldanalyse sogar generalisierbare Faktoren extrahieren, die helfen können für eine in der spezifischen Situation eines Reallabors erfolgreich getesteten Konzeption Randbedingungen zur erfolgreichen Übertragbarkeit des Ansatzes an andere Orte zu definieren? Diese Fragen stehen im Ausgangspunkt eines Forschungsvorhabens, das sich mit dem Aufheben der dogmatischen Trennung von scheinbar gegensätzlichen urbanen und ländlichen Planungssichten beschäftigt. Gemeinsame Methodik der von unterschiedlichen Projektpartnern angesetzten Konzepte an verteilten Orten bildet ein Fokus auf die Bevölkerung(sstruktur) sowie gesellschaftliche Veränderungsprozesse als verbindendes Element zwischen den traditionell isoliert behandelten Planungsräumen Stadt und Land.

Anhand von Analysemethoden aus abgeschlossenen Forschungsprojekten, die sich mit Konzepten zur energieeffizienten Stadtentwicklung mehrerer räumlich verteilten Kommunen befassten, werden in einem laufenden Vorhaben hierfür räumliche Kontexte erfasst und deren nur auf die „dem Land“ oder „der Stadt“ zugeordneten gesellschaftlichen Veränderungsprozesse auf Gemeinsamkeiten hin überprüft. Dabei wird das Ziel verfolgt die Projektpartner methodisch zu unterstützen, die an verschiedenen Orten lokale Konzepte gemäß eines Konstrukts der Transformativen Zelle zur Untersuchung von Projekten und Vorhaben mit transformativer Wirkung umsetzen. Der Beitrag stellt entwickelte Methoden sowie ihre Veranschaulichung an generellen Randbedingungen der lokalen Situationen vor, die den Partnern ein Instrument zur Umfeldanalyse bereitstellten.

Keywords: Kommunale Vergleichbarkeit, Übertragbarkeit lokaler Konzepte, Integrale Planung, Umfeldanalyse, Stadtentwicklung

2 EINLEITUNG

Eine verstärkte Tendenz zur Förderung der Übertragbarkeit von Forschungsergebnissen in die Praxis kann derzeit festgestellt werden. Dabei werden unter dem Begriff eines Reallabors oftmals das Erforschen von Fragestellungen im realen Umfeld eines Areals, Quartiers oder einer ganzen Stadt verstanden. Lassen sich Reallabore durch Rahmenbedingungen vergleichen? Können mittels Umfeldanalyse sogar generalisierbare Faktoren extrahiert werden, die helfen können lokal spezifische Lösungen an andere Orte zu übertragen? Dies steht im Ausgangspunkt eines Forschungsvorhabens, das tradierte, scheinbar gegensätzliche urbane bzw. ländliche Planungssichten zu Überwinden versucht. An verschiedenen Orten angesetzte Quartierskonzepte unterliegt eine auf Bevölkerung(sstruktur) sowie gesellschaftliche Veränderungsprozesse zielende Methodik als verbindendes Element zwischen traditionell isoliert behandelten Planungsräumen Stadt und Land.

Unter dem Begriff der Transformative Zelle (TZ) wird in einem laufenden Forschungsprojekt ein Konstrukt untersucht, um Projekte, Vorhaben und Gemeinschaften mit transformativer Wirkung besser verstehen zu können. Das Modell der TZ dient hierbei selbst als Untersuchungsgegenstand und gleichzeitig als strategisches Hilfsmittel für Transformationsakteure. Prinzipiell wird mit der TZ die Erarbeitung eines methodischen Planungsinstruments auf kommunaler Ebene verfolgt. Einerseits geht es dabei um die Entwicklung methodischer Ansätze einer TZ, die dann andererseits praktisch an verschiedenen lokalen Quartierskonzepten in Reallaboren mit verschiedenen Handlungsfeldern (Ernährung, Bildungslandschaften, etc.) angewendet und evaluiert werden (vgl. LandStadt 2019 sowie Graf 2019).

Im Beitrag wird ein methodischer Teil des untersuchten Gegenstandes der TZ vorgestellt, der den Partnern Instrumente einer Umfeldanalyse zur Untersuchung der Orte ihrer Reallabore an die Hand gibt. Diese dienen dabei zum einen dazu die lokale Situation vor dem Hintergrund der konzeptionell fokussierten Handlungsfelder zu durchleuchten. Zum anderen sollen sie im Sinne einer Generalisierbarkeit des Prinzips einer TZ eine Vergleichbarkeit bzw. mögliche Übertragbarkeit lokal angesetzter Quartierskonzepte ermöglichen. Der der Entwicklung der zusammengestellten Untersuchungsmethoden zugrundeliegende

ISBN 978-3-9504173-8-8 (CD), 978-3-9504173-9-5 (print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI, Clemens BEYER, Judith RYSER, Christa REICHER, Canan ÇELIK

Ansatz, zielt auf das Aufzeigen von gesellschaftlichen Veränderungen als ein wichtiges Charakteristikum der lokalen Situation ab. Es wird damit versucht tradierten Planungssichten entgegenzuwirken, die noch den Kontext starr wahrnehmen und das Umfeld vornehmlich gemäß der Lage innerhalb einer Stadt als „urban“ bzw. auf dem Land als „rural“ einteilen und damit oftmals bei sich immer weiter angleichenden Lebenswelten zu kurz greifen. Zur bedeutungsvollen Umfeldmessung setzt der im Beitrag vorgestellte Lösungsansatz auf eine Überwindung dieser eingeschränkten Planungssichten. Anhand von Analysemethoden aus abgeschlossenen Forschungsprojekten, die sich mit Konzepten zur energieeffizienten Stadtentwicklung mehrerer räumlich verteilten Kommunen befassten, werden dann gemäß dem vorgeschlagenen Lösungsansatz räumliche Kontexte erfasst und deren bisher vornehmlich auf die „dem Land“ oder „der Stadt“ zugeordneten gesellschaftlichen Veränderungsprozesse auf Gemeinsamkeiten hin überprüft.

3 METHODIK

Wie können eigendynamische Entwicklungen, beispielsweise bezüglich kultureller, sozialer, wirtschaftlicher oder baulicher Veränderungen, im lokalen, kommunalen oder regionalen Maßstab analysiert werden?

Zunächst bedarf es hierfür der fallbezogenen Identifikation und Qualifikation der lokalen Rahmenbedingungen, welche die Entwicklung und den Fortbestand möglicher Konzepte zur Stadtentwicklung unterstützen oder auch hemmen können. Durch Vergleich zu ähnlich veranlagten Orten können die Rahmenbedingungen dann iterativ auf ihre Generalisierbarkeit weiter untersucht werden. Eine praxisnahe Rückkopplung ermöglicht es entsprechend angesetzte Untersuchungsmethoden schrittweise zu erproben. Daher steht der Untersuchungsgegenstand vor dem Hintergrund konkreter Fallbeispiele zu den im Forschungsprojekt angesetzten Reallaboren, in denen jeweils ein Quartierskonzept von den Projektpartnern umgesetzt wird. Der Beitrag behandelt drei der vier Städte, in denen die Reallabore ansässig sind und untersucht deren unterschiedliche Rahmenbedingungen. Kennzahlen und Informationen zu Handlungsfeldern beleuchten kommunale äußere sowie innere Entwicklungsbedingungen. Ziel ist es ein einheitliches strukturiertes Vorgehen in Form einer Erstellungsmethode sowie Umfeldanalysen als entsprechende exemplifizierte kommunale Profile für die drei Städte bereitzustellen, mit denen grundlegend zum entwickeln lokaler Konzeptionen die im Kontext wirkenden Herausforderungen und Potentiale der Entwicklung aufgezeigt werden. Anderen Kommunen soll damit eine Beurteilung der möglichen Übertragbarkeit von Strategien oder Strategiebausteinen auf den eigenen Kontext erleichtert werden, die im Rahmen des Forschungsvorhabens von den Projektpartnern für die lokale Situation gemäß dem Leitziel zum Aufbrechen der starren Trennung von Land- und Stadtsicht auf die Planung entwickelt werden. Als eine Vorlage zur Anwendung auf die lokale Situation werden im Beitrag Methoden an den Fallbeispielen exemplifiziert, die den Untersuchungsgegenstand im (regionalen) Kontext an gängigen soziodemografischen Kennwerten durchleuchten. Dabei werden zunächst die (regional) wirksamen Rahmenbedingungen untersucht, um darin dann die folgend weiteruntersuchten Randbedingungen der lokalen Situationen einordnen zu können. Die somit generell als Handlungsanleitung zu lesende methodische Hilfestellung des Beitrags soll es den Projektpartenern im konkreten Anwendungsfall ermöglichen, über die im Beitrag allein zur Veranschaulichungszwecken anhand genereller Randbedingungen erfassten kommunalen Profile hinausgehend, in weiterführenden Detaillierungen ihres lokalen Profils die aufgegriffenen Handlungsfelder im angesetzten Quartierkonzept situationsspezifisch auszuleuchten. Mittels geeigneter Kennwerte kann dazu der Bezugsrahmen inhaltlich weiter an die lokal spezifischen Entwicklungskonzepte angepasst werden. Ein Abschätzen der Übertragbarkeit lokaler Strategien kann darauf aufbauend dann durch den Abgleich dieser im Profil thematisch auf das Handlungsfeld abgegrenzten bzw. konkretiserten, spezifischen Randbedingungen mit den entsprechenden Werten am Zielort ermöglicht werden. Im Rahmen der Umfeldanalysen geht es um das Betrachten von Randbedingungen der lokalen Situation sowie das Herausarbeiten charakteristischer Kriteren, die einerseits Entwicklungen in skaleneübergreifende Zusammenhängen vor dem Hintergrund gesellschaftlicher Veränderungsprozesse miteinbeziehen. Und die andererseits derart aufgeschlüsselt sind, damit ähnliche (Referenz-) Situationen vergleichend hinzugezogen werden können. Die Fallbeispiele werden daher skalenbasiert „von außen nach innen“ durchleuchtet. dabei werden iterativ, ausgehend von den äusseren Randbedingungen der übergeordneten Ebene, jeweils die Kennwerte der inneren Maßstabsebene tiefergehend untersucht und eingeordnet. Dieser Schritt zeigt für die Methodenanwendung an, wie eine thematische Zusammensetzung lokal angesetzter Quartierskonzepte in den einzelnen Reallaboren als Beitrag zur Definition einer TZ dann in eine (generalisiert) untersuchte Umfeldbedingung eingeordnet werden kann.

4 UMSETZUNG

Von einer Skalenebene der Region bis zur lokalen Situation werden im Folgenden als Fallbeispiele die Reallaborstandorte untersucht. Diese übergeordnete Untersuchungsebene bezieht sich dabei auf eine prinzipielle Verortungs- bzw. Vergleichsmöglichkeit der Standorte. Die im Kapitel zusammengestellten Analysen bilden die Basis der im Kapitel 5 dann anschliessend bezüglich der konreten inneren Randbedingungen weiterführend untersuchten und zusammengestellten lokalen Profile.

4.1 Großmaßstäbliche Betrachtung

Für eine generelle Einordnung der tiefergehend untersuchten Orte ist die Betrachtung der regionalen Kontexte wichtig, in denen sie sich befinden. Insbesondere die (relative) Nähe zu Metropolen, die sichtbare direkte wie auch indirekte Wechselwirkungen auf die Orte ausüben, wird dabei a priori der kleinräumlichen Analyse gegenübergestellt. Dies ermöglicht es auch die vor Ort erkennbaren Gegebenheiten besser den anderen Orten vergleichend gegenüber zu stellen. Im Folgenden werden daher zunächst die drei Agglomerationszonen betrachtet in denen bzw. in deren Einzugsgebiet sich die Fallbeispiele einordnen.

4.1.1 Ostdeutschland – Metropolregion Berlin

Charakteristisch für die Umfeldbeziehung der Metropole Berlin erscheint die Sogwirkung ihrer wirtschaftlichen Stärke in einer ansonsten recht wirtschaftsschwachen Region. Am deutlichsten wird diese Anziehungskraft an Pendlerströmen, die beispielsweise für die Beziehung zum Berlin umgebenden Bundesland Brandenburg in der Studie „Pendleratlas“ des RBB auf Basis statistischer Daten von 2015 aufbereitet wurden . Diese Wechselbeziehung auf sein Umfeld hat sich in den letzten Jahren weiter verstärkt. Neben den sichtbaren Faktoren wie den Pendlerströmen, die nicht zuletzt auch auf die sich stetig verteuernden Mieten in Berlin zurückgehen, können in den Detailanalysen zu den Fallbeispielen auch indirekte Wirkungen wie die Bildungswanderung der jungen Bevölkerung nach Berlin aufgezeigt werden.

In Abbildung 1 wird schematisch die großmaßstäbliche Beziehung der Metropolregion Berlin zu den im Umfeld liegenden Gemeinden der Fallbeispiele dargestellt (Abbildung 1). Aufgrund seiner räumlichen Nähe wirken auf Angermünde dabei starke Anziehungskräfte. Dies äußert sich neben den oben angedeuteten Pendlerzahlen in einer breiteren Palette an entwicklungsbedeutsamen Faktoren, wie Bildungswanderung etc.. Beim Betrachten der lokalen Situationen von Gemeinden im (größeren) Umfeld der Metropole Berlin, sollten die großräumlich wirkenden Rahmenbedingungen mit einbezogen werden. Hieraus lassen sich bereits im Vergleich der in unterschiedlicher Entfernung liegenden Fallbeispiele erste Differenzierungen der Metropolwirkungen auf die „anziehenden“ Entwicklungstendenzen erkennen, die bei den Analysen vorort wertvolle Erläuterungsansätze bieten können.

4.1.2 Metropolregion Zürich

Die Metropolregion Zürich ist eine der am dichtesten besiedelten Agglomerationszonen in der Schweiz. Mit einer Bevölkerungsdichte von über 4400 Einwohner pro Quadratkilometer stehen dabei die 12 Kreise der Stadt Zürich im Kern dieser Zone. Davon ausgehend dehnt sich das Ballungsgebiet flächig in nördlicher Richtung sowie nach Süden lediglich durch die Zäsur der Topografie und dem Zürichsee unterbrochen in das weitere Umfeld aus. Im Vergleich zu Berlin ist der einfließende Pendlerstrom mit 213000 (Stadt Zürich 2013) in Bezug auf die Bevölkerungszahl mehr als 50% gegenüber unbedeutend erscheinenden 7%. (Stadt Zürich 2013).

Das heißt die Bevölkerungszahl in Zürich verändert sich täglich um knapp die Hälfte gegenüber der ansässigen (Wohn-) Bevölkerung. Diese Dynamik bildet somit einen der charakteristischen Wesenszüge der Stadtgesellschaft in der das Reallabor Zürich ansetzt, das sich von dort ausgehend über verschiedene Standorte in das nähere Umfeld erstreckt. Die großräumigen Rahmenbedingungen der Metropolregion wirken durch das Ansetzen dieses Fallbeispiels in dessen Kern direkt auf das Reallabor. Bezüglich einer Übertragbarkeit sollten daher die Entwicklungstendenzen der Stadt Zürich in ihrem Zusammenspiel mit der Metropolregion mit betrachtet werden. Durch die Lage innerhalb einer in sein Umfeld wirkendes urbanes Gefüge ist zu erwarten, dass eine Übertragung eher schwierig sein dürfte, da die Rahmenbedingungen mit den lokal spezifischen Situationsmerkmalen übereineinstimmen und das vorhandene Gefüge die untersuchten Lösungsansätze prägen dürfte.(vgl. Abbildung 1)

4.1.3 Metropolregion Ruhrgebiet

Der umgangssprachlich kurz als „Pott“ bezeichnete Agglomerationsbereich des Ruhrgebietes ist das größte und zusammenhängend am dichtesten besiedelte Gebiet innerhalb Deutschlands. An seinem Rand schließt das Rheinland mit dem Raum Köln an, zusammen bilden sie die nördliche Einflusszone des Fallbeispiels in der Stadt Bonn. Diese durch zahlreiche dicht aneinander liegende Großstädte geprägte Region stellt aufgrund der guten Erreichbarkeit ein beim Betrachten der lokalen Situation Bonn’s gewichtigen, einzubeziehenden Faktor dar. Zur nördlichen Seite ebenfalls gut per Bahn bzw. Autobahnen erschlossen liegt die Agglomerationszone Rhein-Main mit Frankfurt als gewichtigem Kern. Auch hiervon sind Wechselwirkungen bezüglich großräumiger Randbedingungen von Bonn zu erwarten (vgl. Abbildung 1).

4.1.4 Zusammenfassung

Die in diesem Kapitel beleuchteten großmaßstäblichen Rahmenbedingungen haben sich für die einzelnen Fallbeispiele als sehr unterschiedlich dargestellt. Generell erscheint die Lage in Bezug zu den umliegenden Metropolen dabei ein für die Untersuchung wichtiges Merkmal darzustellen (vgl. Abbildung 1).

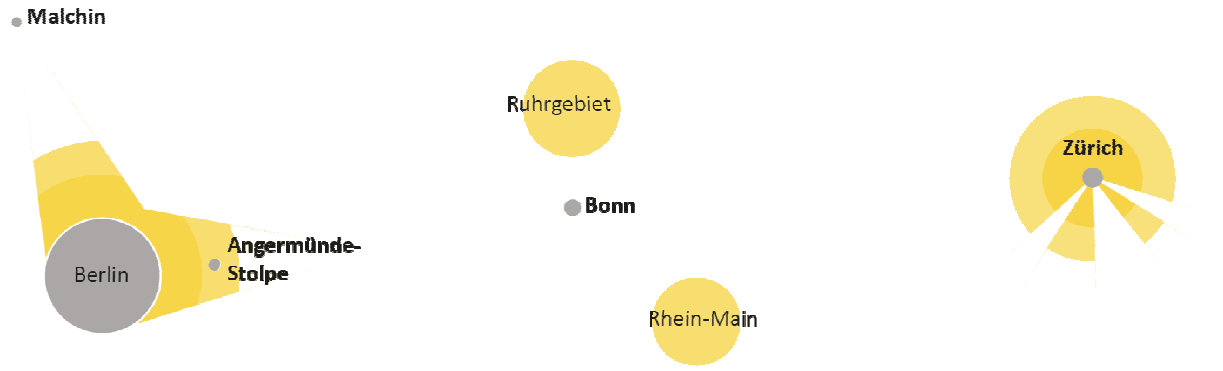

Abbildung 1: Metropolregionen im grafischen Vergleich; eigene Darstellung.

Tabelle 1 zeigt die weiteren unterschiedlichen Arten an identifizierten Rahmenbedingen. Ähnlich zur Situation Berlins, ist allerdings anstelle eines einzelnen Anziehungspunktes die Stadt Bonn von polyzentrischen Agglomerationszonen umgeben. Dadurch sind diffuse Wirkungen zu erwarten, die nicht direkt mit einem Zentrum in Verbindung gebracht werden können. Hinzu kommt, dass die Stadt Bonn selbst als Großstadt in dieses großräumige Gefüge mit ihren Randbedingung. eingreift und dieses mit beeinflusst. Gesteigert wird dies im Fall der Stadt Zürich, in dem sich ihre Randbedingungen als Kern der Metropolregion mit den großräumigen Rahmenbedingungen der Region direkt überlagern.

Bezugnehmend auf den Aspekt möglicher Übertragbarkeit (ggf. als Vorstufe einer Generalisierbarkeit der in den Reallaboren untersuchten lokalen Gegebenheiten) lokaler Quartierskonzepte sollte ein Augenmerk bei der Betrachtung auf die großmaßstäblichen Rahmenbedingungen gelegt werden. Eine Fokussierung auf die lokalen Randbedingung allein könnte wichtige (großräumige) Wirkungen sonst außer Acht lassen, die für das Gelingen einer Übertragung in andere lokale Situationen unabdingbar sind.

4.2 Statistische Einordnung der Entwicklungen

Die unterschiedliche Ausgangssituation und die Rahmenbedingungen der regionalräumlichen Entwicklung der drei Fallbeispiele. unterliegen der Fragestellung, welche relativen Unterschiede in der Entwicklungsdynamik zwischen den Standorten der einzelnen Reallabore bestehen. Mit Darstellung entsprechender sozio-räumlicher Entwicklung(stendenzen) kann ein Bezugspunkt für die Abschätzung einer

Übertragbarkeit (und somit Anhaltspunkte bezüglich einer möglichen Generalisierbarkeit) darin angesetzter Stadtentwicklungskonzepte geschaffen werden.

Da gängige sozialdemografische Klassifizierungen über Bevölkerungsgröße (Klein-, Mittel- oder Großstadt) oder zentralörtliche Funktionen (Unter-, Mittel-, Oberzentrum) keinen Aufschluss über standorttypischen Entwicklung geben, müssen mehrere Perspektiven zu den Standorten der Reallabore eingenommen werden um ein vielschichtiges Bild der Region zu erzeugen. Dabei steht die Bevölkerung durch ihre Schlüsselstellung bei sämtlicher Entwicklung immer im Brennpunkt der Betrachtungen. Als Ausgangspunkt und Orientierungsrahmen der Untersuchung dient die Empfehlung des „Wegweiser Kommune" der Bertelsmann Stiftung [BER2018]. Auf Basis der darin umfangreich zusammengestellten kommunalen Daten sind durch clusteranalytische Ableitungen verschiedene (generalisierte) Demographie-Typen bestimmt und jeweils mit eigenen Profilen beschrieben worden. Die Hinweise zu den demographischen Herausforderungen wurden den Fallbeispielen zugeordnet (siehe Tabelle 2). Da im Wegweiser Kommune jedoch nur Daten zu deutschen Städten erfasst werden, nimmt hinsichtlich der Datenerfassung (sowie deren in Bezug setzen zu den deutschen Reallaboren), das sich im Großraum Zürich befindliche Reallabor eine Sonderstellung ein. Durch Hinzuziehen verschiedener artverwandter Untersuchungen zur schweizerischen Demografie konnte Zürich gemäß dem Bertelsmann Demographietyp 2 „Zentren der Wissensgesellschaft" als prosperierendes Wirtschaftszentrum von den Verfassern plausibel zugeordnet werden.

Die Gegenüberstellung der einzelnen Standorte zeigt den gesamtgesellschaftlichen Trend einer alternden und schrumpfenden Bevölkerung. In den Typ-2-Städten wird diese Entwicklung durch die Zuwanderung junger Bevölkerungsgruppen überlagert, wohingegen dieser Trend in den Typ-9-Kommunen durch die Abwanderung der jungen Bildungsbevölkerung sogar noch verstärkt wird. Die Bevölkerungsentwicklungen in den Fallbeispielen weisen somit konträre Entwicklungstendenzen auf. Dies impliziert die Annahme, dass die jeweiligen Entwicklungen so zu unterschiedlichen Auswirkungen auf die soziokulturellen und räumlichen Strukturen führen.

Kommune	Demographietyp	Merkmale	Herausforderungen
Bonn Zürich	Typ 2: Zentren der Wissensgesellschaft	sozial heterogenes Zentrum der Wissensgesellschaft ökonomischer + demographischer Wachstumsraum funktional verflochtene Stadtregion	negativer Familienwanderungssaldo bezahlbarer und qualitativer Wohnraum familiengerechte Quartiere soziale Exklusion und Polarisierung regionale Betrachtung der Entwicklung
Angermünde-Stolpe	Typ 9: Stark anpassende Kommunen mit Anpassungsdruck	stark schrumpfende Kommune mit besonderem Anpassungsdruck	tiefgreifende sozioökonomische Verwerfungen radikale Neupositionierung in vielen Bereichen ehrliche Einschätzung der Leistungsfähigkeit der öffentlichen Hand neue Formen der Beteiligung initiieren

Tabelle 2: Kommunen geordnet nach Demografie-Typen. Quelle. Bertelsmann Stiftung; eigene Darstellung.

4.3 Klassifizierung der Standorte

Zur weiteren Verdeutlichung der räumlichen und soziokulturellen Unterschiede sowie zur besseren Differenzierung der sich abzeichnenden verschiedenen Entwicklungstendenzen (vgl. Kap. 4) der Fallbeispiele, werden sie im Weiteren spezifischer klassifiziert. Dazu sind in einem Kennzahlenvergleich die Daten zur Bildungswanderung (18-24jährige) mit Indikatoren zum wirtschaftlichen Wohlstand der Bevölkerung (Kaufkraft) und zur regionalen Dynamik (Pendlersaldo, Gesamtpendleraufkommen) zusammengeführt. Die Kennwerte zur Bildungswanderung und zur Kaufkraft sind den Daten des Wegweiser Kommune entnommen, und über einen Zeitraum von 2012-2017 gemittelt [BER2018]. Die Pendlerdaten entstammen der Regionaldatenbank Deutschland der Statistischen Ämter des Bundes und der Länder mit dem Bezugsjahr 2011 [REG2012]. Die entsprechenden Zahlen für die Stadt Zürich sind dabei basierend auf den Stadtstatistiken [STA2018] aufbereitet worden.

Zur besseren Einordnung der Entwicklungstendenzen in den Fallbeispielen untereinander sind diese durch eine vereinfachte Clusteranalyse anhand einheitlicher Merkmale tiefergehend charakterisiert. Die Grundlage ihrer Einordnung bilden dabei die 5 Cluster, die in ihren wesentlichen Merkmalsausprägungen an der Vorarbeit von Rexroth [REX2016] angelehnt sind (vgl. Tabelle 3). Die ursprünglichen Charakteristika der einzelnen Cluster sind auf einer breiteren Basis an Fallbeispielen aufgebaut, die somit in die Betrachtung einbezogen und gemäß den lokalen Spezifika der drei Kommunen weiter geschärft werden konnten.

Charakteristika	hoher Lebensstandard, Zuwanderung junger Bevölkerung, starke regionale Vernetzung	mittlerer Lebensstandard, hohe Zuwanderung junger Bevölkerung, geringe regionale Vernetzung	einfacher Lebensstandard, geringe Wanderungsdynamik, geringe regionale Vernetzung	Einfacher Lebensstandard, Abwanderung junger Bevölkerung, wirtschaftlich unselbstständig	hoher Lebensstandard, Abwanderung junger Bevölkerung, wirtschaftlich unselbstständig
Neue Typisierung	I	II	III	Zusammengefasst zu IV	

Tabelle 3: Clustereinteilung. Quelle Rexroth; eigene Darstellung.

Als Ergebnis stellte sich trotz einer Reduzierung auf wesentliche Charakteristika (vgl. Tabelle 4) heraus, dass die Fallbeispiele jeweils in einem eigenen Cluster lagen. Damit kann vor dem Hintergrund dieser Analyse bezüglich der Randbedingungen nicht auf ähnliche Entwicklungstendenzen geschlossen werden. Diese Einordnung anhand der lokal spezifischen Charakteristika, die insbesondere die Bevölkerung durchleuchten, weist auf stark abweichende regionale Dynamiken der einzelnen Fallbeispiele hin.

Cluster	Kommune	Kaufkraft	Pendlersaldo	Gesamtpendler	Bildungs-wanderung
I	Zürich	1,5	1,27	-0,49	0,15
II	Bonn	0,85	0,19	-0,43	1,40
III	Angermünde-Stolpe	0,31	-1,10	1,50	-0,84
