REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

PREFACE

Manfred SCHRENK,

Conference Director,
President CORP – Competence Center of Urban and Regional Planning

WELCOME to REAL CORP 2023, the
28th International Conference on Urban & Regional Development and Spatial Planning in the Information Society!

A constantly growing world (around 8 billion people now, 9.7 billion to be expected by 2050) with constantly expanding cities and urban agglomerations is facing various challenges such as scarcity of resources, infrastructure provision security, risk of disasters, global warming or ageing of the population. These topics have to be seen as global challenges which are unevenly distributed across the world regarding the dynamics of those phenomena and their geogeaphic location. Are Nature-Based Solutions the key to liveable, sustainable, resilient cities even under the threats of climate change? Is it just about greening the cities and their green and blue infrastructures? What is the context of their technological developments and social innovation?

Nature-Based Solutions are definitely being understood well beyond greenery or only biotic nature. There are strong relations with topics such as liveability, social cohesion and human activities, and urban planning, architecture and design as key disciplines. Thus, beside green and blue (water) infrastructure as currently the most often addressed manifestation of Nature-Based Solutions in cities, REAL CORP 2023 suggests to reflect also on the physical processes and materials (abiotic nature) as inevitable parts of nature. These can bes seen in connection with parameters of urban planning, such as morphology, land use, availability of space for (land) use occupancy etc. These physical world processes are also part of nature, especially as the properties of locations and sites that may well dictate their further development as well as the selection of suitable Nature-Based Solutions for implementation at these specific locations.

Nature-Based Solutions that directly use natural processes (e. g. natural terrain with high vegetation, which in urban areas is most often associated with a park), especially in dense urban patterns, are generally more difficult to implement due to spatial as well as economic constraints. Nature-Based Solutions that may be more appropriate in such situations may come from a set of ideas and proposals that "mimic" nature. Here, it is important to note that nature is made up of both biotic and abiotic components. For example, in terms of reducing the occurrence of heat islands in cities, solutions can be found in the selection of suitable building materials and their appropriate treatment, appropriate physical characteristics of the components of abiotic nature, optimum orientation of buildings and their compositions on the sites, as this can influence the natural ventilation of the rooms (micro scale) or area (macro scale).

Other open questions include ways in which Nature-Based Solutions can be addressed in various spatial planning documents and processes and how can the capabilities of Nature-Based Solutions be used in effective policy making and implementation.

This year we brought together some 200 participants from more than 30 countries worldwide. The main goal of the REAL CORP conference series is to bring together leading experts in the field of spatial planning, geoinformation and related disciplines to exchange their knowledge, share their ideas, discuss current developments and get together for face to face networking leading to the development of new thoughts, partnerships and projects.

The success of the REAL CORP conferences is – clearly without doubt – the result of the efforts of participants, reviewers, and the conference organising team. We would like to acknowledge the Reviewer Team and Programme Committee members for their valueable voluntary help with the review process. Our thanks go to all participants and authors of the submitted papers as well.

The proceedings of this year's conference contain around 110 scientific papers; 92 of them were selected after a double-blind, double-stage (for both abstracts and full papers) peer-review process for publication and presentation at REAL CORP 2023. The non-reviewed papers were accepted by the programme committee after a double-blind abstract review.The conference is held from 18 to 20 September 2023 in Slovenia's capital Ljubljana as well as in virtual space.

Welcome to Ljubljana! Have a great conference!

1 ABSTRACT

The report provides an overview of AI methods and tools and of their applicability for creation of robot's intelligence. By a term "robot" we simultaneously refer to a decision support system in a form of an autonomous device (a traditional robot) and to some system presented in the form of special software that implements the functions of an intelligent assistant. The totality of works on AI can be divided into two areas, two types:

- imitation of human intellectual activity;

- decision support, autonomous decision making based on inference (usually first-order predicate algebra), or other tools.

Our company deals exclusively with systems of the second type.

Structure of the paper:

(1) An overview of AI: pattern recognition, machine learning, data meaning, neural networks, singular value decomposition (SVD). Here we discuss the advantages and limitations of the most well-known approaches in the field of applied AI methods today.

(2) Our experience in AI: knowledge base, ontology, inference machine, scenario approach, ontomodeller, Protege 2000. A brief history of the application of AI methods in our company since the late 90s of the last century is presented.

(3) Tactical situation analysis. In our systems, the concept of a tactical situation is the basis for the application of AI in real-time systems and in monitoring systems for various purposes. A tactical situation is a basic concept for determining the reaction to external circumstances and conditions that have arisen for a robot that ensures the fulfilment of a certain mission.

(4) Smart city applications. Developed within the framework of the European CRISALIDE project, an intelligent decision support system in the interests of a smart city, is one of the options for implementing basic AI technologies in the interests of urban governance.

(5) Future work: RIC technology, discussion: a "Green Button" idea. Based on our experience of theoretical and technological research, a technology system is proposed, a technological platform that can be called a core of robotics intelligence (RIC). This platform allows you to form a full cycle of intelligent control of the robot:

- obtaining data on the external environment (robot environment) from various sources, own and external;

- evaluation of options for fulfilling one's own mission and making a decision (close to the optimal solution);

- monitoring the implementation of the decision;

- proofreading of the solution if necessary;

- making a decision on the completion of a mission formed for a robot, or a general system for which a decision is made on automatic control without involving (directly) a person.

Accumulation of experience and self-training based on the analysis of tactical situations and the results of decisions made. We call this idea a "Green Button" idea.

Keywords: robotics, planning, artificial intelligence, smart city, green button idea

2 INTRODUCTION

The history of the practical application of AI methods and tools in our company goes back more than 20 years. During this time, we have formed a system of technologies, including in the field of AI, implemented applications in the interests of marine monitoring systems and Smart City. Among the AI tools used by our company, the following should be noted first of all: ontology system, expert systems (knowledge bases, inference machines), scenario system and singular value decomposition (SVD) method. According to our experience, the application of AI was carried out in two stages: during the development of applications and during their operation. All this allowed us to form a relatively small set of AI technologies in the form of a platform on which you can develop applications of various scale and purpose.

Currently, the entire set of works united by one name — AI, can be divided into two large groups. The first group – which formed this scientific direction – is an attempt to replicate the intellectual functions of the human brain. Despite great efforts in this direction, the progress is very modest. The second group is the endowment of applications or robotic complexes with intellectual functions based on formal logic and other approaches. It is safe to say that all of our AI developments belong to the second group.

During the period of our company's activity, which is since the early 2000s, we have developed a number of hardware and software systems, including tools and methods of artificial intelligence. Based on our experience in the development, production and exploitation of our products, it was concluded that there was a need to create some kind of intellectual core, which could be scaled over a wide range, namely from a micro-robot to large organizational and technical systems. For such a wide range of manufactured systems, we have an invariant representation of our technologies and development tools. Therefore, we can say with confidence that we have some basic core, which is the intellectual basis of all our products. The main motivation and the main idea behind the development and implementation of RIC is the maximum automation of the application of our products in the interests of the end user, a "Green Button" Idea. Let's take a look at the main elements of RIC and some examples of its implementation.

3 AN OVERVIEW OF AI

In the last decade, AI has received a "second wind" after decades of oblivion, when hopes for its widespread use and replacement of people's intellectual activity actually failed (70s of the last century). The revival of AI is due to the following factors: the sharply increased computing capabilities of modern computers and the rapid development of the global Internet. The modern power of computers has made it possible to implement complex algorithms and process large amounts of data. Widespread access to the Internet has dramatically increased the number of users of AI applications, such as voice analysis, pattern recognition, and search for useful information. The whole set of works that is of interest to us can be reduced to the following, fairly well-known, areas in the field of AI: Pattern recognition, machine learning, data meaning, neural networks, singular value decomposition (SVD). It is not possible to analyse the whole variety of works and applications in AI within the framework of this article. We will briefly review only those that we have explored as a platform for practical applications.

3.1 Pattern Recognition

Pattern recognition is the automated recognition of patterns and regularities in data. It has applications in statistical data analysis, signal processing, image analysis, information retrieval, bioinformatics, data compression, computer graphics and machine learning. Pattern recognition has its origins in statistics and engineering; some modern approaches to pattern recognition include the use of machine learning, due to the increased availability of big data and a new abundance of processing power. These activities can be viewed as two facets of the same field of application, and they have undergone substantial development over the past few decades" [Wikipedia]. This idea works well when we have a large statistical sample of initial data. Typically, millions of test images are required. Difficulties arise for rare phenomena when one attempts to use expert, formalized knowledge.

3.2 Machine Learning

Machine learning (ML) is a field of inquiry devoted to understanding and building methods that "learn" – that is, methods that leverage data to improve performance on some set of tasks.[1] It is seen as a part of artificial intelligence. [Wikipedia]. Just like Pattern recognition, this idea works well for cases where we

have a large statistical sample of initial data. The main drawback is the lack of interpretation of the results obtained. The main advantage of this method is that a decision is made that was not predetermined in advance.

3.3 Big Data

"Big data primarily refers to data sets that are too large or complex to be dealt with by traditional data-processing application software. Data with many entries (rows) offer greater statistical power, while data with higher complexity (more attributes or columns) may lead to a higher false discovery rate.[2] Though used sometimes loosely partly because of a lack of formal definition, the interpretation that seems to best describe big data is the one associated with large body of information that we could not comprehend when used only in smaller amounts" [Wikipedia].

3.4 Neural Networks

"A neural network is a network or circuit of biological neurons, or, in a modern sense, an artificial neural network, composed of artificial neurons or nodes.[1] Thus, a neural network is either a biological neural network, made up of biological neurons, or an artificial neural network, used for solving artificial intelligence (AI) problems" [Wikipedia]. This approach is now very widely used in various subject areas and is very popular. However, we do not use this approach in our applications due to a key drawback – the lack of interpretation of the results obtained. As an alternative, we use the singular value decomposition of matrices.

3.5 Singular Value Decomposition

"In linear algebra, the singular value decomposition (SVD) is a factorization of a real or complex matrix. It generalizes the eigendecomposition of a square normal matrix with an orthonormal eigenbasis to any matrix. It is related to the polar decomposition" [Wikipedia]. This approach allows us to solve the same problems as neural networks, but here we can explicitly control the accuracy of the solution and confidence in adequate results. The use of SVD in our applications has shown its high efficiency. Recognition of tactical situations using SVD gives this method a high degree of versatility.

4   OUR EXPERIENCE IN AI

Knowledge base, ontology, inference machine, scenario approach, onto-modeller, Protege 2000. A brief history of the application of AI methods in our company since the late 90s of the last century is presented.

4.1 System of Ontology

The main motivation for the development of the concept of ontology was an attempt to combine software from different subject areas (domains), and, above all, to form a system of non-intersecting sets of concepts. The first tool for developing ontologies was our OntoModeler software product, Fig. 1, developed in the late 90s of the last century. To describe the logic and business intelligence, a special scripting language with Pascal syntax was developed. These technologies were the basis for the development of knowledge bases and logical scenarios. Also, OntoModeler was integrated into a GIS of its own design, see Fig.2.

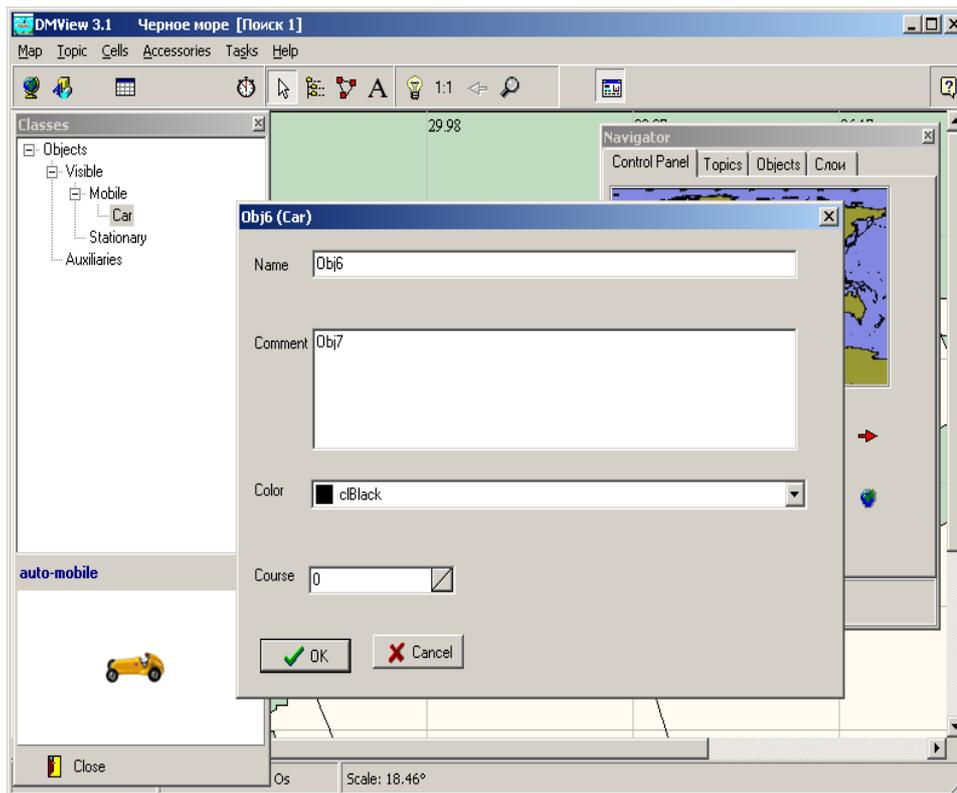
The increasing complexity of GIS, the emergence of modern web technologies and technologies of distributed heterogeneous systems have dramatically increased the cost of maintaining and upgrading our key technologies. In the mid-2000s, a decision was made to switch to the JEE platform as the main software development environment and Protege 2000 as the main tool for developing and maintaining ontologies, see Fig.3. A special Plug-in was developed to create scripts based on the Drools language.


Fig. 1: Ontology editor main window
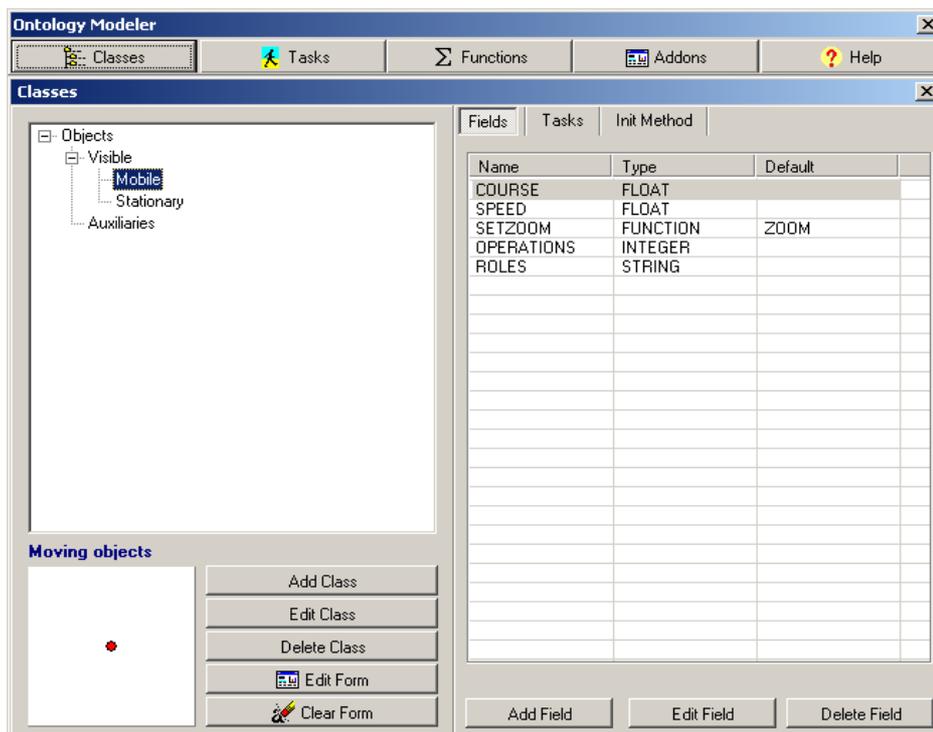

Fig. 2: Integration OntoModeler in to GIS

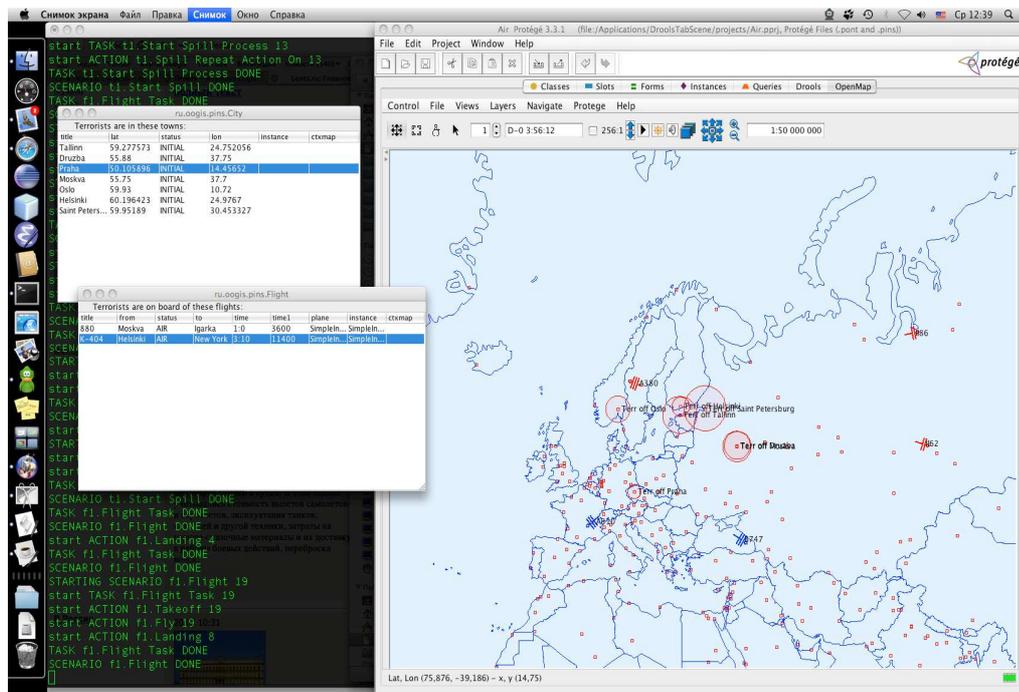
The application of the Protege 2000 system made it possible to speed up the development of an ontology system and to integrate various software components, such as GIS for various purposes, databases and knowledge bases, to implement a fairly powerful scripting system that allows implementing fairly complex business analytics without involving programmers. This approach made it possible to reduce the application development time, its cost, reliability and maintainability during exploitation by dozens of times.


Fig. 3: Protege 2000 Applications

4.2 Scenario Approach

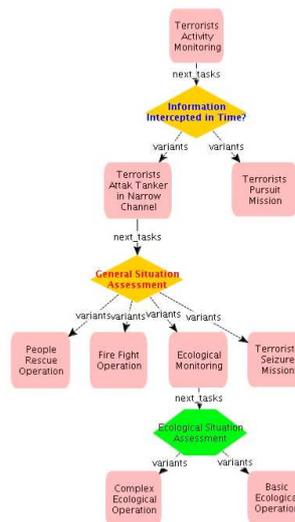
A scenario is the same as algorithm, but with the possibility of executing 2 or more parallel development branches that are executed simultaneously. A fully-fledged scripting system was developed in the Protege 2000 system as a special Plug-in, which implemented a visual script editor that allows you to implement business intelligence in a visual representation, which drastically reduced the time for its implementation, since the work was performed directly by subject matter experts without involving programmers. Note that there are two approaches to visual computer modelling: a scenario approach – when the content and sequence of steps to implement some business intelligence are known, and a rule-based approach for the case when the business intelligence or process is not known in advance. We use both approaches. An example of a simple scenario, its scheme, is shown in Fig. 4.


Fig. 4: A simple Scenario

The scenario scheme is a two-dimensional graph, the vertices of which are the stages (phases) of decision making, and the arcs are the transitions from one phase of decision making to another. The difference between a scenario and an algorithm is visually demonstrated, where the stages are performed in strict sequence one after another.

4.3 Micro Service Architecture

The expansion of the scope of our solutions has led to the fact that scaling has fairly wide limits: from smartphone applications to large heterogeneous distributed systems. The technology system that uses Protege as an ontology editor is a rather heavy solution and can not be universally applied. In this regard, we have developed a system of technologies for which a lightweight ontology editor and a scripting system in the Drools language have been created, which allows the user to create flexible and lightweight development tools based on scenario approach in almost any integrated software development environment, for example, in JetBrains products.

5 TACTICAL SITUATION ANALYSIS

In our systems, the concept of a tactical situation is the basis for the application of AI in real-time systems and in monitoring systems for various purposes. A tactical situation is a basic concept for determining the reaction to external circumstances and conditions that have arisen for a robot that ensures the fulfilment of a certain mission.

5.1 JDL Model as a Spiral Processing of Information

In our systems, the concept of a tactical situation is the basis for the application of AI in real-time systems and in monitoring systems for various purposes. A tactical situation is a basic concept for determining the reaction to external circumstances and conditions that have arisen for a robot that ensures the fulfilment of a certain mission. The levels of this model correspond to such fundamental concepts as measurements, data, information, knowledge and understanding. At the same time, these concepts are not absolute, but relative. It all depends on the scale of the model. For example, on micro-robot level, unmanned device, manned vehicle, weather monitoring centre or other purpose.

Measurements, data and information can be interpreted as some attributes of a certain entity (robot), real (physical world), or abstract (digital world). Knowledge is a direct clarification, the work of "artificial consciousness", "intelligence" at the level of such a concept as "phenomenon". This is the level of a "simple" robot that performs a set of embedded business intelligence, its activities are quite well regulated, despite the fact that it can be performed using an inference machine.

"Understanding" is the clarification of the essence of occurring phenomena on the basis of self-learning, i.e. it is the rectification of embedded business intelligence in the form of scenarios based on self-learning or on-the-fly revision by a supervisor.

5.2 Cycle of Control

The control cycle (CC) is the logical basis of any control, artificial or physical entity, including decision support systems. CC is inherent in human nature from the very beginning and, according to the hypothesis of I. Kant [], is pre-established. It is simply not always realized and is often realized fragmentarily and probably not consciously. The control centre is implemented by some system consisting of two parts: Command&Control. This is military terminology, but recently it has been directly applied when considering such concepts as a decision support system (DSS) and the analysis of tactical situations. From the point of view of technical cybernetics, "command" is a given control function, and "control" itself is a technical implementation of the control function, i.e. issuance of a control action and, through feedback, control of its execution.

5.3 Tactical Situation Definition

The basis of the analysis of the tactical situations (TS) is the situation. The situation is not formed arbitrarily, but taking into account a certain class of vehicle. In turn, the TS does not arise without a specific task (tasks), which is solved by the monitoring system, DSS and/or decision maker. That is, TS is closely related to the concept of "task". In human activity, it is quite natural to solve a number of problems almost continuously. DSS is also developed to solve a certain set of problems, and not in general for any problems. Therefore, we can say with confidence that the starting point for starting the analysis of the TS is the formation of a list of tasks that the decision maker solves and the DSS supports their solution. The process of fulfilling (solving) the task takes place against the backdrop of a changing environment and the emergence of new TS. The analysis and evaluation of the TS allows the decision maker to make the following types of decisions:

20

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

(a) continue the task according to the previously developed plan; (b) adjust the plan; (c) make a new decision in connection with such a change in the situation, which led to a change in the TS.

TS analysis is carried out by processing the input stream of measurements, data and information and evaluating the problem being solved. If the performance indicators of the problem being solved do not correspond to the specified (expected), we say that the TS has changed. But this is only for those cases when we can set the criterion and performance indicators. The decision on a "specifically new" vehicle may be done in two ways:

(a) logical, or scenario, based on the logic of first-order predicates; (b) mathematical, or imitative conclusion. Having identified a new vehicle, a new cycle begins.

To clarify, let us give a simple everyday example: various situations can lead to the threat of a car tipping over on the road in motion: – slippery road (rain, snow, ice, etc.); – high speed of movement; – sharp turn; – sharp movements of the steering wheel; – poor pavement of the road surface (clay, sand, gravel), etc. and so on. Therefore, it is advisable to create a list of threats and associate them with possible TS.

6 SMART CITY APPLICATIONS

Developed within the framework of the European CRISALIDE project, an intelligent decision support system in the interests of a smart city, is one of the options for implementing basic AI technologies in the interests of urban governance. In the CRISALIDE project an Innovative Decision-Making Tool has been developed for Contributions on:

- Urban Information Systems;
- Urban Decision Support Systems;
- Geo-Information-Infrastructures, Data availability;
- Urban Planning.

We consider the CRISALIDE as an instrument for end users. Decision making support system (DMSS) can help CRISALIDE users to satisfy human's demand for space. CRISALIDE is a software and hardware complex based on intelligent GIS, which provides the ability to integrate maps of various formats, implement a scenario approach in urban development modelling, 3D modelling, support for 2D + t modelling, support for 3D + t modelling, support for decision-making based on expert knowledge, the ability to monitor changes and assess the possible impact of decisions on the urban environment.

The software and hardware complex provides the consumer with a universal set of technological and functional solutions within the framework of the basic configuration with the possibility of expanding functional tasks in accordance with the requirements of the customer and the subject area, multi-platform and the absence of mandatory additional paid software.

The main end users of the developed CRISALIDE system are state authorities and local self-government, public and private enterprises and organizations directly related to the functioning and development of the urban environment. The introduction of the CRISALIDE system allows us to solve the following tasks: to develop e-government, to improve the quality of public administration through the creation and implementation of modern information technologies. The proposed system of intellectual decision-making support makes it possible to predict the development of urban infrastructure both within the city as a whole and in selected districts and quarters, to identify a deficit or surplus of construction facilities and/or infrastructure, as well as to take into account the socio-economic aspects of the development of municipalities and regions. Main services can be presented by text, graphics and voice forms. A list of services is very big and covers all of city life routines. Most of the services are presented by Internet through different gadgets. But, as was noted by Erich Fromm, today people would like to know and can to do primitive operations, especially how to use gadgets, but do not wish to understand things. It is the biggest demand of our civilization. According to this evidently fact our proposal is to include in to a plan of CRISALIDE project next generation a systems of services, pointed to understanding process. So, understanding should be as a service from Internet. The CRISALIDE project will be consists next main parts as follows:

(1) Knowledge clouds as services for individuals.

(2) Private business analytics for understanding development.

(3) An intelligent social networks development as a platform or environment for knowledge and understanding existences and processes.

7   A "GREEN BUTTON"

In this article, we have presented a far from complete list of technologies that can be used to develop the intelligent core of a robotic complex. A robotic complex can be either completely autonomous or automated, i.e. with human participation. The main feature of RIC is the ability of the installed software to provide decision support, both in stand-alone and automated versions. At the current time, our technologies allow us to form a relatively simple logic of the robot's behaviour, which can act autonomously. But when solving more complex problems, such as, for example, in the CRISALIDE project – the operation of a decision support system for managing the urban environment, the participation of a whole team of people of various specialties is required.

A reasonable question arises: is it possible in automated systems to entrust the formation of proposals for making decisions offline? Theoretically, such a possibility exists, but what about practice? Let's translate these questions into a technological plane. The very first step is confidence in the chosen technological solutions. What does it mean, for example. TS analysis can be considered as a problem of pattern recognition, or simply recognition. Stereotypically suggests the idea of using neural networks. But, the main drawback of neural networks is immediately remembered – the lack of interpretation of recognition results. Believing in such an autonomous decision generation system becomes a matter of faith, which will not fully suit pragmatically minded people who are ultimately responsible for the decision made.
The use of SVD eliminates this drawback, since we can control the accuracy of decision making. Why are we discussing this issue at all? We are discussing, because here, maybe. two extremes: the first is that we do not need an automated DSS, we only need well-trained decision makers. The second extreme is the need to create DSS, which will eventually replace a person in any decision-making process. Our arguments are as follows: even if the decision maker is well prepared and has extensive experience, he is not immune from mistakes. It is a human trait – to make mistakes. DSS, even if it cannot offer the optimal solution, it can protect against making a misguided decision in advance.

At the current level of development of AI technologies, it is impossible to create a DSS that will always make optimal decisions. But you can set up the DSS so that it will not make gross mistakes and make decisions that are close to optimal. We will not consider the concept of "close to optimal" in this article, since this is a separate special topic. The local conclusion that we can draw now is that there is a set of technologies that allows you to automate the DSS as much as possible. We call this hypothesis the "Green Button" idea. The general scenario for implementing the Green Button idea is as follows.

7.1 Access to Environment Data

This is a connection with the outside world in real time. To do this, we have created a whole family of different servers that receive data from a variety of meters and interacting external systems, providing heterogeneity and distribution. The RIC must have access to external information, preferably in real time or near real time. The more channels for obtaining information about the external situation, the better for the adequate behaviour of RIC and, ultimately, the successful completion of the assigned mission. Our experience with real-time systems shows that practically the entire set of information about the external environment can be formed in the form of typical channels, regardless of the type of physical field that needs to be registered. The first and the simplest option is geographic (spatial) coordinates and one physical measurement: temperature, relative humidity, atmospheric pressure, etc. The second option is associated with the processing of data from the analysis of a certain plane or volume, associated with the registration of objects in various environments: the surface of the earth, the air atmosphere, the aquatic environment. For these systems, integrated processing can be reduced to the problem of pattern recognition on a plane or in a volume. As a result, we get an abstract representation of the surrounding world in some functions and arrays of measurements, as well as selected physical objects.

22

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

7.2 System of Ontologies

A set of technologies allows you to formalize the subject area and form a number of non-intersecting concepts and relationships between them. Such a system is also called a knowledge base system. The system of ontologies and/or knowledge bases is a way of interpreting the environment (paragraph 6.1) and business intelligence, which ultimately determines the mission of RIC. Thus, a system is obtained that can be interpreted by different logics. As a rule, we use first-order predicate logic and generic tools that support it. The most important property of ontology (in our opinion) is a unified system of concepts for such different entities as decision makers, applications and databases. This significantly reduces the development time of such intelligent systems, their maintenance, scaling and modernization.

7.3 Scenario System

The scenario system allows you to formalize the customer's business analytics, which is the basis of the DSS. Actually, with the help of this idea, the "Green Button" is implemented. Those. automation from an automated system (with human participation) to a fully autonomous system (without human participation). This idea is very productive for cases when, for various reasons, the decision maker cannot make a decision under the circumstances and conditions.

7.4 Tactical Situations Processing

This is the basis of the DSS, which connects a number of fundamental concepts: the tasks (mission) of the object and/or system in whose interests the DSS was developed, the current situation (data, geography and time), the system of restrictions. The technical basis of TSP are: SVD classifier (recognition) and script interpreter. The implementation of TSP allows you to abstract from the elements of what is happening (data, measurements, information) and operate with such concepts as knowledge and understanding. Either the decision maker, or the decision maker + RIC, or RIC evaluates what is happening from the point of view that the mission is feasible, or not, needs to be corrected, or should be replaced by another, or cancelled completely. To understand what we are talking about, very roughly TSP can be interpreted as a pattern recognition process, but! The images here are abstract and have no direct physical interpretation. Plus, many of these "images" refer to cases of "rare events". In this case, a number of well-established AI methods, in particular neural networks, are not applicable. In this regard, we apply the SVD method, which can be applied to large statistics (like neural networks), as well as to "rare events", the abstract images of which are formed by experts.

7.5 Web interface

Interacting RIC system with decision makers and other DSS users. Interaction through touch and through voice communication.

The proposed idea of the "Green Button" has been tested in our systems since the mid-2000s. In the current conditions, a mechanism is being developed to control the degree of automation of the decision support process: from complete autonomy to the participation of the decision maker or the decision maker team in the decision selection process. Our current solutions do not directly evaluate or manage the degree of automation. When solving this issue, we will be guided by the fact that the degree of automation will be determined by the decision maker.

8 CONCLUSION

Development of RIC technology, discussion of it led to a "Green Button" idea. Based on our experience of theoretical and technological research, a system of technology is proposed, a technological platform that can be called a core of robotics intelligence. This platform allows us to form a full cycle of intelligent control of the robot and decision making process for large scale systems:

- obtaining data from the external environment (robot environment) from various sources, own and external;
- evaluation of options for fulfilling one's own mission and making a decision (close to the optimal solution);
- monitoring the implementation of the decision;

- proofreading of the solution if necessary;

- making a decision on the completion of a mission formed for a robot, or a general system for which a decision is made on automatic control without involving (directly) a person.

Accumulation of experience and self-training based on the analysis of tactical situations and the results of decisions has been made. In general we call this idea a "Green Button" idea.

Our next step is to provide a set of real work applications with embedded such system. The firs one will be an extension of CRIALIDE project, maritime monitoring systems, autonomous mobile devices of different types for ground, aerial and maritime purpose.

(Professor Mohamed Fikry, Alexandria University, mfikry2004@yahoo.com)

1 ABSTRACT

Rapid urbanization among many factors contribute to elevate air temperature inside city's urban fabric that causes urban human discomfort. Natural ventilation in urban canyons is one of the measures that can limit that effect and minimize the air temperature of urban areas. Benefits range from pedestrian comfort in the urban environment, to efficiency of natural ventilation systems in urban streets. Studies have covered different urban forms and their impact on pedestrian comfort, others have investigated the role of built-up density on pollutants dispersion, some have studied the role of urban configurations on natural ventilation in buildings, while some studied different physical characteristics which also affect the urban heat island. What is yet to be defined is the effect of those physical characteristics on shaping the building regulations, especially in Egypt, and their efficiency regarding natural ventilation systems in urban canyons to eliminate the raised temperature. Spreading green architecture in Egypt requires reshaping current legislation and codes, starting by revising the existing local building laws and regulations. The aim of this work is to assess and analyse the main building code in Egypt by studying and analysing theories on natural ventilation and its physical characteristics.

Keywords: building regulations, urban canyon, pedestrian comfort, natural ventilation, urbanisation

2 INTRODUCTION

The world is currently experiencing the largest wave of urbanization in history. According to World Urbanization Prospects, by 2050, nearly two out of three of us will live in cities (Santamouris, 1997, Mei et al., 2018, Nazarian and Kleissl, 2016). Global urbanization includes the rapid growth of high-rise buildings, superstructures and increased buildings density. They continue to cause concerns about city breathability by blocking the prevailing wind and are associated with microclimate variations in urban districts. They are causing deterioration of pedestrian thermal comfort, increasing energy consumption and are causing several negative environmental impacts such as urban air pollution and urban warming (Juan et al., 2017, Omrani et al., 2017, Lin et al., 2014). For those reasons, we can easily notice the significant difference in microclimate when we are moving between urban areas and rural areas.

Outdoor urban ventilation is very important for a healthy and liveable urban environment -as it is one of the most effective passive cooling techniques- which is strongly affected by urban morphology (Ramponi et al., 2015, Santamouris, 1997). The interaction between urban morphology and airflows needs to be considered in new urban developments since their effects on human life may be beneficial or detrimental. Such effects do not only depend on the characteristics of the wind as a natural phenomenon – intensity, speed and direction- but also on the features of the obstacles and environments that the wind encounters along its path (Palusci and Cecere, 2022). Baruch Givoni states in (Givoni, 1989), that "Of all the climatic elements the wind conditions are modified to the greatest extent by urbanization". There is a clear need for basic scientific understanding of the airflow process in urban area morphologies for improving outdoor thermal comfort and lowering energy consumption (Mei et al., 2018).

Numerous studies have demonstrated that it is possible to improve urban air ventilation and urban climate by manipulating the building configurations during the early stages of planning and regulations. Countries such as United Kingdom, America, France, Germany and others made energy efficiency strategies a priority in building regulations (Omrani et al., 2017, Juan et al., 2017).

In recent decades, a large number of investigations have been conducted for the assessment of natural ventilation in urban areas. This paper aims to analyse the natural ventilation behaviour and its physical characteristics and assess the Egyptian regulations - Building Law No.119 of year 2008 – regarding natural ventilation aspects.

3 NATURAL VENTILATION

Ventilation generally is the process of delivering fresh air. It could be natural, mechanical or hybrid. Natural ventilation relies on natural forces; it can be described as a process for providing fresh air movement. Natural ventilation can be used basically inside buildings to: improve indoor air quality (IAQ), achieve thermal comfort, reduce energy consumption and reduce pollutants inside spaces. Meanwhile, natural ventilation plays a very important role in the urban environment -as wind flow- to: control the humidity, adjust pedestrian thermal comfort, dilute pollutants and for summer cooling (Arup et al., 2002, Fordham, 2000, Krarti, 2018, Schulze and Eicker, 2013, McConnell, 1926).

3.1 Wind flow

The wind flow in the urban environment is complicated to follow. Small differences in land topographies cause irregular flows; as the wind flow is completely different in rural areas and urban environments (E. Bozonnet, 2006, Azizi and Javanmardi, 2017). Wind flow has many characteristics to be analysed and measured; its direction, velocity and pattern and all those characteristics change significantly from one place to another.

3.1.1 Wind direction

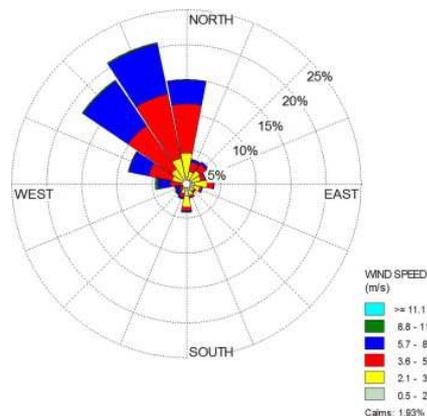
Wind direction is generally defined as where the wind blow or by the direction from which the wind originates (for example, a south wind blows from the south to the north). Any obstacles as buildings or land topography directly affect the wind direction ((NWS, 2021, Kutz, 2016, Serway and Jewett, 2018). Wind direction is usually reported in cardinal directions, or in degrees. A wind rose is a simple way to read wind direction as well as its velocity. For example, as shown below in Alexandria's wind rose (Figure 1), the prevailing wind direction -where the wind blows most often- is North North West (El-Geziry, 2013, (NWS, 2021). Wind direction can be measured by the windsock/wind vane or by ultrasonic Anemometer/thermal Anemometer (more sophisticated) (Hawkins and Sutton, 2009).


Figure 1: Alexandria's wind rose. (El-Geziry, 2013)

3.1.2 Wind velocity

Wind velocity (wind flow speed) is a fundamental atmospheric quantity caused by movement of the air from high to low pressure (Hogan and Monosson, 2010). Wind velocity is affected by a number of factors and at different scales as the pressure gradient. Where the air pressure differs between two points in the atmosphere or on the surface of the Earth the wind flow become faster or slower to balance out the variation in pressure (Chua et al., 2010, Garrison et al., 2002, Justus et al., 1978). The Beaufort wind force scale was known as the first measurement technique of wind velocity. Nowadays, meters per second (m/s) is the international system unit for velocity (Saucier, 1955, McIlveen, 1991, Hay, 2016). Wind speed could be measured with the same instruments that measure wind direction mentioned in the last section.

3.1.3 Wind flow pattern

Generally we can define wind flow pattern as how wind moves horizontally between different areas. The large global wind pattern is the result of the differential Earth's heating. This difference is created because of the uneven heat by the rays of the sun which happened because of Earth's rotation, its ellipsoid shape and its twenty three and half tilted axis (Dashamlav.com, 2021, Bu and Kato, 2011, Perry, 2004). When it is about

cities and urban areas, wind interacts differently with the surrounding urban areas with different behaviour and characteristics that will be discussed in the next section.

3.2 Urban wind flow

Allard and Ghiaus, (2006) mention that the general aspects of wind patterns in the urban environment - as compared to those of undisturbed wind - are: mean speed due to differences in terrain roughness reduced by 20 to 30%; turbulence increased in intensity by 50 to 100%; and greater incidence (20%) of weak winds. It is also agreed that the mean wind speed above and inside the canopy height is closely related to certain urban dimensions. For roof-top speeds above 4.0m/s, mean velocity decreases by about 33%, while for speeds below 1.5m/s this coupling between the external main and internal secondary flow is considerably reduced or is lost. The centre of a city is warmer than its outlying areas. Daily minimum temperature readings at related urban and rural sites frequently show that the urban site is 6° to 11° C warmer than the rural site. This phenomenon called "urban heat island" (UHI) could be defined as the maximum temperature difference between the city and its surrounding area (Rafferty, 1998).

3.2.1   Urban wind flow pattern

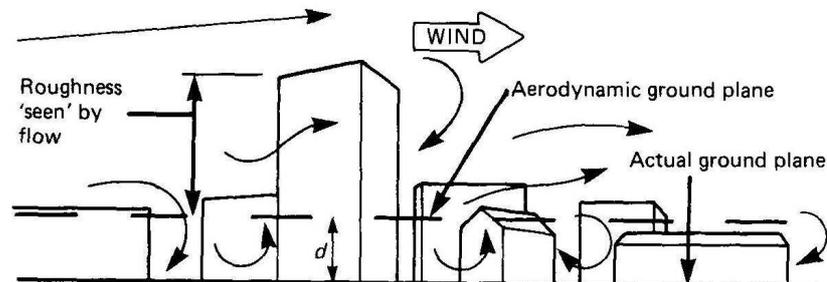
Once the wind flow from the suburban surroundings reaches an urban area it tends to skip over the roofs and sides of buildings and its momentum is transformed into pressure on the windward surfaces of solids, creating several types of effect, such as acceleration, down-flow, flow detachment, low wind speed, high and/ or low pressure zones, sheltered areas and leeward wakes of turbulent vortices (as shown in Figure 2). This unsteady behaviour tends to diminish the flow's momentum due to the drag and viscous forces caused by the friction produced between surfaces and air flow. The Atmospheric Boundary Layer -the lowest 1 or 2 km of the atmosphere which is directly influenced by the presence of the earth's surface and responds to surface forces- is then set by the energy spent in overcoming the shear stress due to the roughness of the terrain, which is determined by the canopy height. Below this height, the free airflow momentum is transformed into wind pressure on vertical surfaces. Above this height the flow tends to stabilize slowly until reaching the gradient speed (Oke, 1978b, Oke, 1988, Cook, 1986, Faria, 2012).


Figure 2: Flow in the interfacial layer (Both canopy layer and surface layer together create the interfacial layer which is extending up to one tenth of the total height of the ABL). (Cook, 1986)

3.2.2   Wind flow pattern around isolated structure

As shown in (Figure 3), when the wind is approaching a structure, it gradually diverges. At the windward facade a stagnation point with maximum pressure is situated at approximately 60–70% of the structure height. From this point, the flow is deviated to the lower pressure zones of the facade: upwards, sidewards and downwards. The upward and sideward flow separate at the upwind facade edges and create a separation bubble or recirculation zone characterized by a low velocity and high turbulence level intensity. Depending on the dimensions of the structure and the turbulence of the oncoming flow, the separated flow can reattach to the side facades and roof (as illustrated by the dotted lines in Figure 3). A considerable amount of air flows downwards from the stagnation point and produces a vortex at ground level. The main flow direction of the standing vortex near ground level is opposite to the direction of the approach flow. Where both flows meet, a stagnation point with low wind speed values exists at ground level, upstream of the structure. The standing vortex stretches out sideways and sweeps around the structure corners creating corner streams with high wind speeds. At the leeward side of the structure, an under pressure zone exists. As a result, backflow or recirculation flow occurs in a cavity zone that consists of vortices with horizontal and vertical axes. The mean cavity reattachment line downstream of the structure marks the end of the cavity zone. After this

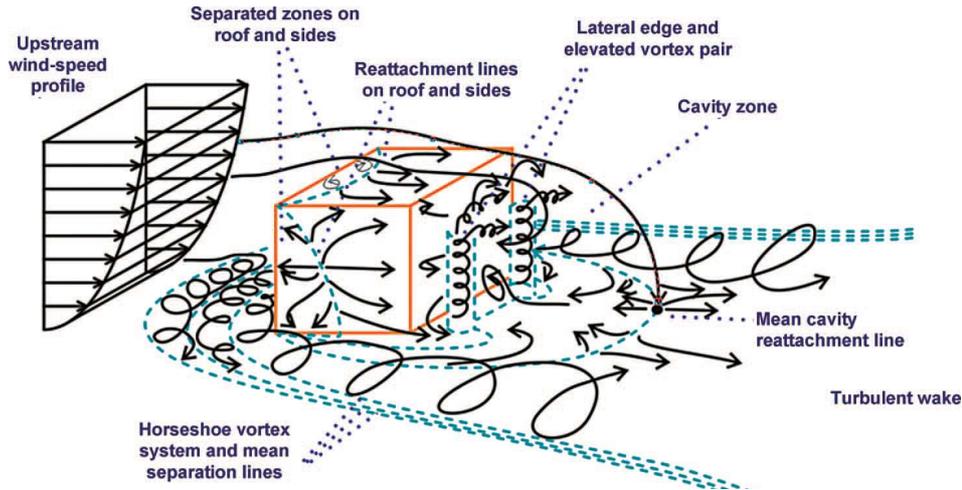
structure, the flow resumes its normal direction but wind speed stays low for a considerable distance behind the structure until the wake flow (Bert Blocken 2011).


Figure 3: Schematic representation of wind-flow pattern around an isolated structure. (Hosker, 1985)

3.2.3   Wind flow pattern in urban canyons

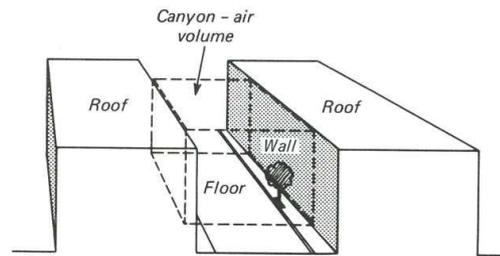
Urban canyon is the volume lying between buildings, and the urban canyon volume is the volume between road surface and the roof tops of buildings (Figure 4) (Vardoulakis et al., 2003). Urban canyons are characterized by three main parameters: H, the mean height of the buildings in the canyon, W, the canyon width, and L the canyon length. (Georgakis and Santamouris, 2008)


Figure 4: Schematic cross-section of an urban canyon-urban conyon's volume represented with doted line. (Oke, 1978b)

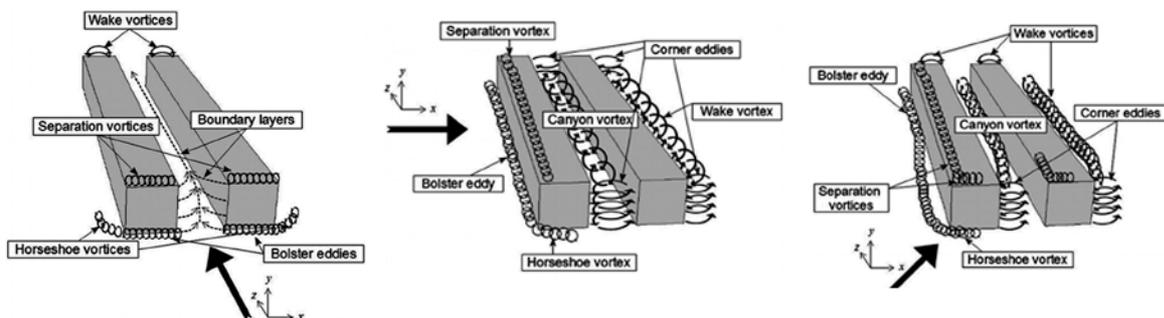
As shown in (Figure 5), Wind flow speed and direction modify as a result of the urban canyon's geometry; parallel, perpendicular or angled.


Figure 5: wind flow in different canyon's geometry; parallel (left), perpendicular (middle) and angled (right). (Yazid et al., 2014)

When the wind flow is parallel to the canyon's axis or nearly parallel (deviation of less than thirty degrees), a mean wind component is created along the canyon's axis. The wind speed is reduced due to friction and there is also a possibility of uplifting near the vertical and ground surfaces. In this case the vertical components of velocity tend to be much decreased and in the stream wise direction, if only wind drive forces are applied. Further, the flow inside the canyon is copying the free flow behaviour, but with reduced intensity (Nakamura and Oke, 1988).

28

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

An important aspect observed in the perpendicular wind flow is the production of vortices rotating in the mainstream direction below the canopy height and between the two structures shown in (Figure 5). The vortex occurs as a result of pressure differences between the leeward side of the upstream structure and the windward side of the downstream structure. The flow separates at the edge of the leeward surface creating a large wake of low pressure behind the front structure. Then the flow is diverted upwards due to its mass conservation and rises, though with a weaker vertical component. The vortex created in the canyon space therefore presents wind components near the surfaces but little air movement at its centre (Georgakis and Santamouris, 2008, Cook, 1986, Faria, 2012).

Skewed flows usually create a vortex alongside the main axis. The mean flow along the canyon axis presents vertical downwards components causing spiral vortices along the length of the canyon in the upward stream direction but with reduced velocity (Nakamura and Oke, 1988).

4   WIND FLOW PARAMETERS

Many parameters are affecting the urban wind flow. To define those parameters, this study analysed previous studies and the articles published in the field of natural ventilation in the urban environment, whether in individually published articles, or in previous review papers. Thr study investigated relevant publications in related journals regarding natural ventilation and the urban environment, including in particular: Building and Environment, Energy and Building and Journal of Wind Engineering and Industrial Aerodynamics. Among these numerous publications, this paper further focused on studies conducted in the years from 2008 to 2018 with the following keywords: natural ventilation, urban, canyon, airflow and air change rate (ACH). References are analysed according to: relations, methods, type of natural ventilation, wind direction, measurement unit, sensibility analysis, model and limitations of the study. As shown in (Table 1) studies are classified by building typology (high-rise, low-rise, compact, single block or others), scale (urban, canyon or building), measurement unit (Q, ACH, age of air or Cp), type of natural ventilation (pressure or buoyancy) and type of study (coupled or uncoupled). The next five graphs (Figure 6, Figure 7 and Figure 8) show the percentage of studies that discussed each type of classification.

Model					Scale of study			Measurement's unit				Type of NV		Type of study	
high-rise	low-rise	compact	single block	others	urban	Street canyon	Building	Q	ACh	Age of air	Cp	Pressure	Buoyancy	Coupled	Uncoupled

Table 1: previous studies classification. Source: the research

Figure 6: study's model (left) - study's scale (right). Source: the research

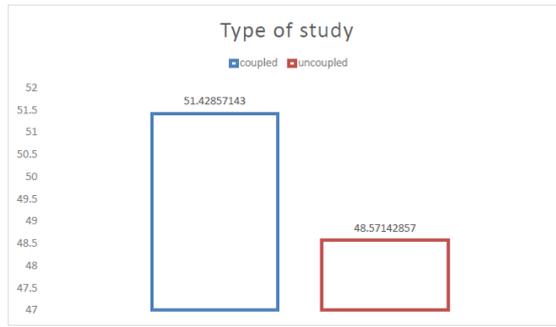
Figure 7: measurement unit (left) - type of natural ventilation (right). Source: the research


Figure 8: type of study. Source: the research

From previous studies a number of physical parameters were identified that affect the wind flow pattern in urban areas and related phenomena as urban temperature and pollution. The parameters are: Aspect ratio (AR), floor area ration (FAR), packing density (ΛP) and setbacks. The studied ranges of each physical factor are presented in (Table 2). Studied AR ranges vary from 0.5 to 6, FAR ranges vary from 1 to 4, ΛP ranges vary from 0.25 to 0.6 and setbacks were vertical or horizontal and their values depend on road width and buildings height.

Physical factor	Studied ranges
Aspect ratio (AR)	0.5 to 6
Floor area ratio (FAR)	1 to 4
Packing density (Λ_P)	0.25 to 0.6
Setbacks	varied

Table 2: The four physical factors studied ranges. Source: the research

The four parameters and their definitions, importance and relation to urban wind flow will be discussed in next sections.

4.1 Aspect ratio (AR)

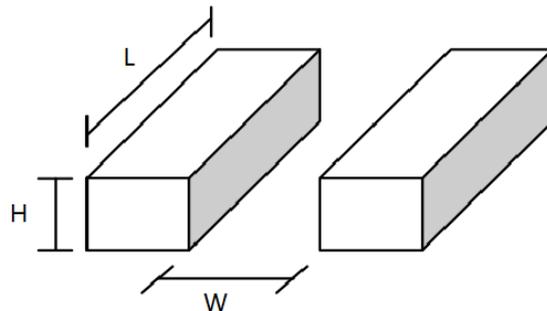
Generally as defined in Webster (1907), the aspect ratio is a ratio of one dimension to another. In urban studies, aspect ratios are related mainly to dimensions of urban canyons; they are H/W, L/H and W/L (Figure 9). Those ratios identifies the built aspect ratio and the type of volumetric canyon within it. It is expected that the resultant wind flow speed and direction below the canopy height are connected to variations in these aspect ratios (Hunter et al., 1990, Nakamura and Oke, 1988). A canyon can be considered accoording to the mentioned ratios: for example, uniform or regular when its H/W ratio approximates to 1.0; deep or narrow when this ratio increases to 2.0; and wide or shallow when it drops to 0.5. Also, the L/H ratio is considered short, medium or long for respective ratios of 3.0, 4.5 and 6.0. Regarding the height, a canyon is considered symmetrical when height is relatively constant and asymmetrical when there is large variation in height (Vardoulakis et al., 2003, Nakamura and Oke, 1988, Oke, 1978a).


Figure 9: A simple urban canyon. Block's height (H), canyon's width (W) and canyon's length (L).(Afiq et al., 2012)

Comparative analysis of previous AR studies shows that wind speed inside a canyon does not necessarily increase with the increase of canyon AR. Apart from AR, there are other important factors governing the flow field inside a canyon. For example, thermal effects, finite length canyon effects, traffic induced turbulent effects and other physical parameters play important roles in shaping the flow characteristics inside a canyon (Ai and Mak, 2015).

4.2 Floor area ratio (FAR)

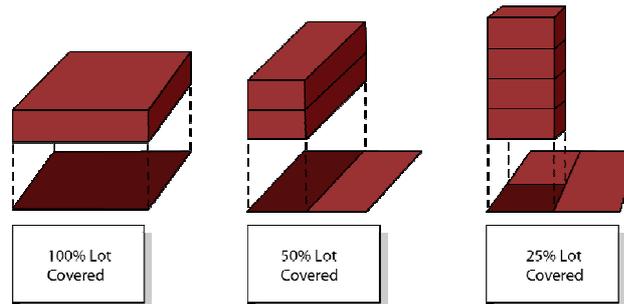
Floor area ratio (FAR) is the ratio of a building's total floor area (gross floors areas) to the size of the piece of lot upon which it is built. FAR is sometimes called floor space ratio (FSR), floor space index (FSI), site ratio or plot ratio. The difference between FAR and FSI is that the former is a ratio, while the latter is an index. Index numbers are values expressed as a percentage of a single base figure. Thus a FAR of 1.5 is translated as a FSI of 150% (Birch, 2009, Spikowski, 2006). FAR is often used as one of the regulations in city planning along with the packing density (ʌp) (block covering ratio BCR) as well as zoning to limit urban density. While it directly limits building density, indirectly it also limits the number of people that a building can hold, without controlling a building's external shape. (Figure 10) shows three different plot options with the same FAR (1); by decreasing the lot covering ratio and increasing number of floors. Thus, many authorities have found it unnecessary to include height limitations when using FAR calculations in building regulations. (Birch, 2009, Spikowski, 2006)


Figure 10: Floor area ratio (FAR=1). (DCOZ, 2022)

Previous FAR studies are wide ranging and vary from effects on environmental aspects such as solar radiation, day lighting. human comfort and natural ventilation, to business studies on land values, city character, regulations and laws.

4.3 Packing density (ʌP)

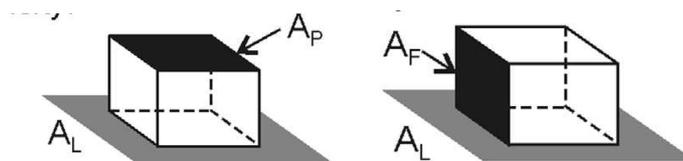
Packing density (ʌP) is the ratio between the block coverage area (ground floor area) and its total plot area (Hu and Yoshie, 2013). It is also known as; block covering ratio (BCR), plan area density, planar area density, building area density and building to land ratio (SÜMEGHY, 2007). Ramponi et al. (2015) agreed that urban density can be described with geometric parameters like the packing density (ʌP) and the frontal area density (ʌF) (the ratio of the frontal area- front façade that facing the wind - and the total surface area) (Figure 11).


Figure 11: packing density (left) and frontal area density (right). (Ramponi et al., 2015)

Previous studies agreed that building packing density is the key factor to influence the flow adjustment and urban ventilation capacity in the city model; and that lowering the building packing density within a city could reduce the pollutant concentrations at street level and result in higher ventilation efficiency in most cases.

4.4 Setbacks

Setback in architecture, is a step-like recession in the profile of a block. Could be from a wall (other building frontage), a road or a water stream. In regulations, a setback is the minimum distance which a block must be set back from any place which is deemed to need protection (Davis, 1994, Allen, 1995). A setback as a minimum one-bay indent across all stories is called a recessed bay or recess and is the more common exterior form of an alcove. Setbacks were used by people to increase the height of masonry structures by distributing gravity loads produced by building materials. This was achieved by regularly reducing the footprint of each level located successively farther from the ground. The most marked example of a setback technique is the step pyramids of ancient Egypt (Figure 12).

Figure 12: Djoser's Step Pyramid in Saqqara. (egymonuments.gov.eg, 2019)

In previous aforementioned studies setbacks are studied with different parameters to analyze how it could affect the natural ventilation efficiency. Pablo J. Rosado (2017) compared the change in solar flux reflected from the simple narrow (no setbacks) canyon to that of the simple wide (with setbacks) canyon. The simple wide canyon was able to reflect from 2.90 (summer) to 4.52 (fall) times more solar flux than the simple narrow canyon. These multipliers are the scaling factors for adjusting air temperature changes obtained with the simple narrow canyon to the simple wide canyon which directly affect the efficiency of natural ventilation.

5 EGYPTIAN REGULATIONS AND LAW

Law No.119 of 2008 (and its executive regulations) - called unified building law - is the only law used for planning and construction. The Egypt Green Building Council (EGBC) was established by 2009 and introduced a national green building rating system called the green pyramid rating system (GPRS) (Elfiky, 2011). Regarding the law and GPRS, we cannot find obvious planning criteria to be followed to enhance city breathability or outdoor air quality as a result of good natural ventilation penetration through the urban fabric. At present in Egypt, any new constructions are subjected to the proposed planning strategies (for example the proposed strategies of the city of Alexandria 2025, 2032 and 2050) and the unified building law. In the next sections, the unified building law (law No.119 for 2008) will be analysed, based on the four natural ventilation factors mentioned in previous sections.

5.1 Aspect ratio (AR)

In the Law No 119, aspect ratios are not mentioned directly. However, building height is defined as the distance between the surface of the sidewalk (from the centre of the frontal elevation) and the top surface of the concrete slab. Parapets and service rooms at roof level are not considered. The total building height is the distance between the surface of the sidewalk (from the centre of the frontal elevation) and the highest point in the building.

The law states that the building height shall not exceed one and a half times the width of road which means: AR=1.5- with a maximum height of 42 m, The legal rule for the height of the building on two different roads stipulates that: if the building is located at the intersection of two opposite sides with different width, the width of the building height is equal to one and a half times the width of the wider road with a maximum height of 36 meters.(Ministry of Housing, 2009).

5.2 Floor area ratio (FAR)

In the Law No 119 floor area ratio is defined as: the ratio of total built up areas of all floors to the total plot area. According to article 26, FAR is determined by the strategic plan for each part of the city with maximum FAR equal 4 in the case of absence a strategic plan.(Ministry of Housing, 2009).

5.3 Packing density (ʎP)

In the Law No 119 packing density ia defined as: the ratio of the ground floor built up area to the total plot area. According to article 26, ʎP is determined by the strategic plan for each part of the city (Ministry of Housing, 2009).

32

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

5.4 Setbacks

In the Law No 119 setbacks are mentioned in different terms and definitions.The Regulation Line is the line that defines the street and creates boundaries between public and private properties; it could be within, wider or narrower than the plot boundaries. The Construction Line is the line within which it is allowed to build on; it could be the street edge, the same as the Regulation Line or recessed from both. Finally, setbacks are mentioned in three other terms: frontal setback, side setback and rear setback which are defined as: the distance between the Property Line and the Construction Line in all directions (Ministry of Housing, 2009). Article 26 states that, in the case of existing streets, the Regulation Line is set back by half the difference between the width of the current road and the proposed width when building or reconstructing the plots (Ministry of Housing, 2009).

6 CONCLUSION

The rapid urbanization we are living nowadays is causing a number of problems, starting from pedestrian discomfort to the blockage of city breathability. Urban ventilation is strongly affected by urban configuration, therefore it is important to be considered as a mandatory element in building regulations and laws.

By comparing the building codes included in the Unified Building Law No.119 of 2008, and its executive regulations released in April 2009 by the Minister of Housing, and the GPRS document released by the HBRC in the same year; there are serious contradictions between both documents, as the Unified Building Law and its executive regulations allow building designs and procedures that do not comply with the GPRS. Moreover, there is no reference in the Unified Building Law to the GPRS or green building in general, nor is there any reference to the Unified Building Law in the GPRS documentation released by the Ministry of Housing, Utilities and Urban Development. Thus, it is clear that the GPRS is an isolated document that does not fit into the current building regulations, nor represent a law on its own (Ayyad and Gabr, 2012, Ammar, 2012). The most important thing - more than the relation between the law and the GPRS - is the existence of natural ventilation as concept, importance and consideration in the law. As studied and mentioned in the last section, when analyzing the law and the GPRS, there is no direct mention to natural ventilation related to the urban environment. Nor do the four main physical aspects affecting the natural ventilation have restricted requirements to enhace urban natural ventilation.

It is important to investigate urban ventilation further, its physical factors and its relation to laws and to specify the requirements in law to be followed to optimize urban natural ventilation and make it obligatory. Now that there are a lot of new developments in the construction field in Egypt, it is a perfect time to regenerate the building regulations to support the concept of natural ventilation in the built environment.

An Assessment of Urban Decay in Rural Towns: a Case of Building Dilapidation in Thohoyandou Town, South Africa

Comfort Ndou, Shylet Nyamwanza

(Comfort Ndou, University of Venda, Urban and Regional Planning; Thohoyandou, South Africa, ndoucomfort970@gmail.com)
(Shylet Nyamwanza, University of Venda, Urban and Regional Planning; Thohoyandou, South Africa, shylet.nyamwanza@univen.ac.za)

1 ABSTRACT

Urban decay is a global dilemma that can severely weaken the image, livability, and productivity of most cities due to its negative impacts on the built environment. Building dilapidation is one form of urban decay which can pose a risk to public health, safety or well-being . The impact of urban decay cannot be overemphasized particularly in South Africa's historically disadvantaged rural towns such as Thohoyandou. The aim of this study was to assess the status of building dilapidation in Thohoyandou Central Business District (CBD) in Limpopo province of South Africa. The objectives of the study were to map building dilapidation in Thohoyandou CBD; to investigate the causes of building dilapidation in Thohoyandou CBD and to suggest recommendations towards addressing persisting building dilapidation. This study adopted a qualitative research approach through conducting 20 key informant interviews and field observations. The study revealed that building dilapidation in Thohoyandou CBD is caused by factors such as lack of municipal by-laws to deal with derelict buildings, irregular planning procedures in the construction of buildings; lack of building maintenance, illegal occupation of buildings; negligence of buildings by property owners, incapacity of the municipality to render services to overpopulated buildings as well as lack of enforcing building occupant capacity by-laws. These findings highlight the complexity of the issue and the need for a holistic approach to address urban decay. Based on the research findings, the study puts forth several recommendations to mitigate building dilapidation in rural towns like Thohoyandou. The study suggested recommendations which include formulating municipal by-laws to deal with derelict buildings, stricter enforcement of regular planning procedures in construction projects; establishing a dedicated CBD building maintenance plan, conducting Thohoyandou CBD building audits, and regulation of building occupants' capacities. Collaboration among stakeholders, including the municipality, property owners, and the community, is essential for the successful implementation of these strategies. The study contributes to the existing knowledge on urban decay and revitalization. The research findings have significant implications for policy and decision-making in Thohoyandou CBD and other similar contexts, aiming to promote sustainable urban development and improve the overall quality of life.

Keywords: central business district, building dilapidation, urban decay, rural towns, spatial planning

2 INTRODUCTION

Urban decay and building dilapidation pose significant challenges to the sustainable development and revitalization of cities and towns worldwide (Ndlebe, 2017). In the context of developing countries, rural towns often face unique circumstances and complexities in combating urban decay (Phillips, 2017). Thohoyandou CBD, a rural town in South Africa, exemplifies these challenges, where the deterioration of buildings has become a pressing issue, negatively impacting the town's overall aesthetics, economy, and residents' quality of life.

This research aimed to investigate the causes and implications of building dilapidation in Thohoyandou CBD and to propose strategies for addressing this issue. By examining this specific case, the study contributed to the broader understanding of urban decay and provides valuable insights for similar rural contexts facing similar challenges.

According to Saranya and Mewa (2017), building dilapidation refers to the progressive deterioration and decay of structures, resulting from neglect, inadequate maintenance, or other contributing factors. In Thohoyandou CBD, the phenomenon of building dilapidation has been escalating, with a growing number of abandoned or rundown buildings becoming a common sight (Thulamela Municipality IDP, 2019). The consequences are multi-fold, including reduced property values, increased crime rates, decreased economic activities, and a decline in community morale (Phillips, 2017).

While the literature on urban decay and building dilapidation predominantly focuses on urban centers in developed countries, there is a dearth of research examining this issue in rural towns, especially in the context of developing countries. Thohoyandou CBD provided an ideal case study due to its unique characteristics, including a predominantly rural setting, limited resources, and a history of inadequate urban planning and management.

This study adopted a qualitative research approach, utilizing a case study research design to explore the causes and implications of building dilapidation in Thohoyandou CBD. By employing key informant interviews, field observations, and secondary sources, the research sought to uncover the underlying factors contributing to building dilapidation and understand their interconnectedness. Thematic content analysis was employed to analyze the collected data, identify recurring patterns and themes, and draw meaningful conclusions.

The findings of this study offered valuable insights into the complexities of building dilapidation in rural towns like Thohoyandou and inform the development of strategies and interventions to mitigate urban decay. Ultimately, the research aimed to contribute to the existing knowledge base on urban revitalization efforts in developing countries and promote sustainable urban development for the betterment of Thohoyandou CBD and similar contexts.

3 LITERATURE REVIEW

3.1 Introduction

Urban decay is a significant issue that affects cities worldwide, leading to numerous social, economic, and environmental challenges (Saranya and Mewa, 2017). Understanding the causes and consequences of urban decay is crucial for policymakers, urban planners, and researchers to develop effective strategies for revitalization and sustainable urban development (Phillips, 2017). This literature review aims to explore the various dimensions of urban decay, analyze its underlying causes, and highlight the importance of comprehensive interventions.

Urban decay encompasses a range of interconnected problems, including physical deterioration, social disintegration, economic decline, and inadequate infrastructure (Mireku, 2021). Dilapidated buildings, high crime rates, unemployment, poverty, and spatial inequalities are common manifestations of urban decay (Aubakari, 2021). According to Martinez (2021), the consequences of urban decay are far-reaching, affecting the quality of life for residents, hindering economic growth, and exacerbating social inequalities.

This literature review serves as a critical component of a broader thesis focusing on urban decay and its remediation. By examining existing research, theories, and practical interventions, the review aims to provide a comprehensive understanding of urban decay, its causes, and potential solutions. The review draws upon a range of scholarly works, including academic articles, books, and policy reports, to ensure a comprehensive analysis of the topic. By synthesizing the existing literature, this review seeks to identify common themes, knowledge gaps, and emerging trends in the field of urban decay. It also aims to highlight the significance of urban planning, policy interventions, and community engagement in addressing urban decay and promoting sustainable urban development. The findings of this literature review will contribute to the broader thesis by providing a solid theoretical foundation and informing the subsequent empirical research and analysis.

Overall, this literature review will play a vital role in understanding the complexities of urban decay and formulating effective strategies for its mitigation. By examining the existing body of knowledge, it will provide insights into the causes and consequences of urban decay and offer recommendations for policymakers, urban planners, and community stakeholders to foster vibrant and sustainable cities.

3.2 Urban Decay: Definition and Causes

Urban decay refers to the progressive deterioration of urban areas, characterized by physical, social, and economic decline (Martinez, 2021). It encompasses a wide range of manifestations that collectively contribute to the degradation of cities and communities. Physical decay is often visible through dilapidated buildings, crumbling infrastructure, and abandoned spaces (Suite, 2023). Social disintegration involves the breakdown of social networks, increased crime rates, poverty, and social inequalities (Lombardo, 2017).

Economic decline manifests as unemployment, decreased investment, and a shrinking tax base (Ndlebe, 2017).

Urban decay is the result of a complex interplay of various factors, including economic, social, and planning-related aspects (Philip, 2017). Economic factors play a significant role in the deterioration of urban areas. The decline of traditional industries, such as manufacturing, can lead to high unemployment rates and poverty, creating a cycle of disinvestment and decline (Letlape, 2019). Global economic forces, such as deindustrialization and globalization, have also contributed to the decay of certain cities and neighborhoods (Suite, 2023).

According to Glaeser and Gyourko (2005), social issues, including crime, social inequality, and social dislocation, are intertwined with urban decay. High crime rates, often associated with urban decay, create an atmosphere of fear and insecurity, discouraging investment and economic activity (Attwood, 2013). Social inequalities, such as unequal access to quality education, healthcare, and housing, further perpetuate urban decay (Davis, 2018). Social dislocation, caused by factors such as migration, racial segregation, and gentrification, can disrupt social cohesion and exacerbate urban decay (Fahey, 2017).

Inadequate urban planning and governance contribute significantly to urban decay. Poor land-use planning, zoning regulations, and lack of comprehensive urban development strategies can result in mismatched land uses, uncontrolled sprawl, and neglect of certain neighborhoods (Kandžija et al., 2017). Insufficient investment in infrastructure maintenance and renewal leads to the physical deterioration of buildings and public spaces (Lewis, 2013). Additionally, inadequate community participation and lack of accountability in decision-making processes can hinder the revitalization of decaying areas (Nassaji, 2015).

The impacts of urban decay are detrimental to both communities and cities as a whole. Decaying neighborhoods often experience a decline in property values, making it difficult for residents to sell their homes and move elsewhere (Onuoha, 2014). This exacerbates residential segregation and hinders social mobility. Urban decay can also lead to decreased tax revenues for local governments, limiting their capacity to provide essential services and invest in infrastructure (Vera, 2015).

Furthermore, the negative impacts of urban decay extend beyond economic and social realms. Deteriorating physical environments contribute to poor health outcomes, as decaying buildings may contain health hazards such as lead, asbestos, or mold (Zack, 2015). The lack of green spaces and the degradation of the natural environment further exacerbate health disparities in decaying neighborhoods (Kweon et al., 2017). Urban decay also perpetuates a negative cycle, as it discourages private investment and perpetuates a sense of hopelessness and disengagement among residents (Bess, 2008).

In conclusion, urban decay is a multifaceted phenomenon with profound impacts on communities and cities. Its manifestations encompass physical, social, and economic decline. Economic factors, social issues, and inadequate urban planning all contribute to the emergence and persistence of urban decay. The negative impacts of urban decay include reduced property values, diminished tax revenues, health hazards, and social disintegration. Understanding the causes and impacts of urban decay is essential for formulating effective strategies for revitalization and sustainable urban development.

3.3 Importance of Addressing Urban Decay

Addressing urban decay is of utmost importance for achieving sustainable urban development and ensuring the well-being of communities (Bess, 2008). Neglecting urban decay can have severe consequences that extend beyond the physical deterioration of neighborhoods (Awumbila, Owusu, and Teye, 2014). By understanding the significance of addressing urban decay, policymakers, urban planners, and community stakeholders can work towards implementing comprehensive strategies to revitalize declining areas (Branas et al., 2011).

One of the potential consequences of neglecting urban decay is the increase in crime rates. Decaying neighborhoods often experience higher levels of criminal activities due to the lack of social control, disinvestment, and limited economic opportunities (Crentsil and George, 2018). The presence of vacant and abandoned properties creates a breeding ground for criminal behavior and contributes to a sense of insecurity among residents (Galeser, 2011).

Environmental degradation is another consequence of urban decay. Neglected areas are more likely to suffer from poor environmental management, including inadequate waste disposal, pollution, and the loss of green

spaces (Harrison, 2002). This not only negatively impacts the quality of life for residents but also contributes to health hazards and the degradation of ecosystems (Phillips, 2017).

Furthermore, neglecting urban decay can result in declining property values, exacerbating economic inequalities and hindering economic growth. Deteriorating neighborhoods face challenges in attracting investments and businesses, leading to a downward spiral of disinvestment and limited job opportunities (Taipale, 2011). The decline in property values also affects homeowners and can lead to financial instability and limited mobility for residents (Ndlebe, 2017).

To effectively address urban decay, comprehensive strategies are required. Piecemeal approaches are often insufficient and fail to tackle the root causes of decay (Okrent, 2009). Comprehensive strategies should encompass physical, social, economic, and environmental dimensions of urban development (Onuoha, 2014). This may involve targeted investments in infrastructure, affordable housing, and community facilities, as well as promoting community engagement and participation in decision-making processes (Parab et al., 2020).

In summary, addressing urban decay is crucial for sustainable urban development. Neglecting urban decay can have detrimental consequences, including increased crime rates, environmental degradation, and declining property values. It is imperative to adopt comprehensive strategies that address the underlying causes of urban decay and foster revitalization. By doing so, cities can promote social equity, environmental sustainability, and economic growth, ensuring vibrant and inclusive communities for the future.

3.4 Approaches to Urban Decay Remediation

Urban decay remediation requires a multifaceted approach that encompasses urban renewal programs, community development initiatives, and effective land use management frameworks (Smith and Sarah, 2008). This section explores these approaches and their role in addressing urban decay.

3.4.1 Urban Renewal Programs

Urban renewal, a concept rooted in the post-World War II era, aims to revitalize deteriorating urban areas through comprehensive redevelopment strategies (Squires and Kubrin, 2005). These programs emerged in response to the challenges of blight, substandard housing, and social dislocation (Bess, 2008). Urban renewal initiatives have been implemented worldwide, such as the regeneration efforts in London's Docklands and the revitalization of New York City's Times Square (Vera, 2015). However, the effectiveness of urban renewal strategies has been a topic of debate. While they can rejuvenate declining areas and attract investment, they often face criticism for causing displacement, eroding local cultures, and neglecting social inclusivity (Zach, 2015).

3.4.2 Community Development Initiatives

Community-based approaches play a vital role in addressing urban decay by empowering residents and fostering social cohesion. Such initiatives involve active participation from community members, grassroots organizations, and local authorities (Wilkerson et al., 2014). Successful examples of community-led efforts can be found worldwide, including the establishment of community land trusts in the United States and the creation of self-help housing projects in Brazil (Squires and Kubrin, 2005). These initiatives not only address physical decay but also promote social capital and empowerment. However, challenges exist, including limited resources, unequal power dynamics, and the need for sustained community engagement (Parab et al., 2020).

3.4.3 Land Use Management Frameworks

Land use management systems (LUMS) are essential tools for regulating land use and preventing frictional blight. LUMS encompass various mechanisms, such as land use policies, framework plans, and land use schemes, which guide decision-making processes and promote harmonious land development (Okrent, 2009). The Thulamela district in South Africa provides an example of a comprehensive LUMS. In this district, the Land Use Management System (LUMS) plays a crucial role in managing land use and development, aligning with the Integrated Development Plan's policy and strategic-based decisions (Mavhunga et al., 2019). Such frameworks help mitigate conflicts between incompatible land uses, ensuring sustainable urban development and avoiding the detrimental effects of urban decay (Onouha, 2014).

40

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3.4.4   Spatial Planning and Land Use Management Act (SPLUMA)

The Spatial Planning and Land Use Management Act (SPLUMA) serves as a comprehensive framework for spatial planning and land use management in South Africa. It requires the preparation of Spatial Development Frameworks (SDFs), which lay out a clear vision for long-term development goals (Vera, 2015). SPLUMA addresses the causes of urban decay by providing regulations for spatial planning, land use schemes, and urban management. It aims to promote spatial sustainability and efficiency. For instance, SPLUMA emphasizes sustainable land use, limits urban sprawl, and encourages the redevelopment of existing structures (Taipale, 2011). By adopting SPLUMA and adhering to its goals, municipalities can effectively tackle urban decay and promote sustainable urban development (Nassaji, 2015).

In conclusion, addressing urban decay requires a comprehensive approach that includes urban renewal programs, community development initiatives, effective land use management frameworks, and adherence to relevant legislation such as SPLUMA. Urban renewal programs can rejuvenate deteriorating areas, but they must consider social inclusivity and avoid displacement. Community development initiatives empower residents and promote social capital, although challenges of resource constraints and power dynamics exist.

3.5 Integrated Development Planning

Integrated Development Planning (IDP) is a crucial concept in addressing urban decay as it provides a comprehensive framework for coordinating various planning processes and promoting sustainable development (Zach, 2015). The municipality of Thulamela's IDP plays a significant role in addressing urban decay within its jurisdiction.

IDP refers to a strategic planning process that integrates various sectors and stakeholders to guide the development of a municipality or district (Vera, 2015). It serves as a primary instrument for informing planning, management, and decision-making processes (Smith and Sarah, 2008). The IDP recognizes the interconnectedness of social, economic, and environmental factors, aiming to create inclusive and sustainable communities (Bess, 2008).

The municipality of Thulamela's IDP is crucial in addressing urban decay within its region. It provides a framework for aligning national and provincial legislation with local planning requirements (Kandžija et al., 2017). The IDP identifies the plans and planning requirements that are binding on the municipality and outlines the principles and procedures for consultation and coordination with local municipalities (Republic of South Africa, 2000). By integrating various planning processes, the IDP ensures a holistic approach to urban development and helps overcome the challenges associated with urban decay (Branas et al., 2011).

The Thulamela municipality's IDP encompasses both rural and urban issues, addressing the declining built form and physical environment in the region. Urban decay often results in a lack of coherence and functionality in cities, hindering their overall development (Crentsil and George, 2018). The integration of various activities, guided by the IDP, enables the municipality to address urban decay by promoting effective land use, infrastructure development, and social inclusion (Thulamela Local Municipality, 2018).

The IDP's strategic planning approach ensures that all decisions related to planning, management, and development are informed by a shared vision and goals (Republic of South Africa, 2000). It enables the municipality to prioritize interventions and allocate resources effectively, taking into account the specific challenges associated with urban decay (Awumbila Owusu, and Teye, 2014). By integrating spatial development frameworks, land use management systems, and community-driven initiatives, the IDP contributes to a coordinated and comprehensive response to urban decay (Craig and Dougla, 2005).

In summary, integrated development planning plays a vital role in addressing urban decay by providing a holistic and coordinated approach to urban development. The municipality of Thulamela's IDP serves as a strategic planning instrument, aligning national and provincial legislation with local planning requirements. Through the integration of various planning processes, the IDP enables the municipality to address urban decay challenges and promote sustainable and inclusive development in both rural and urban areas.

3.6 Conclusion

This literature review has examined the concept of urban decay, its causes, impacts, and the approaches to remediation. The review highlighted the significance of addressing urban decay for sustainable urban development and emphasized the need for comprehensive strategies.

Urban renewal programs have been identified as a key approach to revitalizing deteriorating urban areas. However, it is crucial to consider their effectiveness and limitations, as well as the importance of community development initiatives. Community-based approaches play a vital role in empowering local communities and fostering sustainable change. Additionally, the review explored the role of land use management frameworks, such as the LUMS in the Thulamela district, and the Spatial Planning and Land Use Management Act (SPLUMA) in guiding land use and development. These frameworks provide regulatory mechanisms to prevent frictional blight and promote harmonious land use.

Moreover, the municipality of Thulamela's integrated development plan (IDP) emerged as a significant tool for addressing urban decay by integrating various planning processes and promoting sustainable development. To combat urban decay effectively, future research should focus on evaluating the outcomes of urban renewal programs, analyzing the long-term impacts of community development initiatives, and exploring innovative approaches within land use management frameworks. Additionally, interventions should prioritize the implementation of comprehensive strategies that integrate multiple approaches, including urban renewal, community development, land use management, and integrated development planning.

4 RESEARCH METHODOLOGY

4.1 Introduction

This section provides an overview of the research methodology, highlighting its significance in addressing the research objectives. The research design, approach, and key components are briefly discussed, setting the stage for the subsequent sections. The chosen qualitative research approach is justified based on its ability to capture human expressions, experiences, and observations. The case study research approach is explained as suitable for conducting a thorough and in-depth study of urban decay. The section also establishes the context for the research methodology and its importance in generating genuine and authentic results.

4.2 Research Approach

A qualitative research approach was chosen to capture the nuances and insights of the human mind in relation to urban decay. Qualitative research allows for open and transparent expression of opinions, experiences, and observations. It enables a deeper understanding of how individuals make sense of their urban environment (Neumen, 2013). By adopting a case study research approach, the study aims to conduct a comprehensive and in-depth examination of urban decay, narrowing down complex issues into manageable and investigable problems. This approach is particularly suitable for qualitative research and facilitates the application of theories or models to real-world phenomena (McLeod, 2014). It also addresses the need for researchers to gain insights into urban collapse and its implications.

4.3 Study Population

The study population consists of key stakeholders involved in the building dilapidation of Thohoyandou CBD. This includes municipal officials, property owners, and tenants within the CBD. Selecting the right participants is crucial for the accuracy and relevance of the study. Understanding the characteristics and preferences of the target audience helps in obtaining precise and meaningful research outcomes (Murphy, 2016)

4.4 Sampling Procedure

The sampling procedure for this study involved the selection of a sample group to be studied instead of attempting to study the entire population (Creswell, 2013). Non-probability sampling methods were adopted due to the qualitative nature of the research. Purposive sampling was used to select municipal officials involved in spatial planning issues within Thohoyandou CBD, while convenience sampling was employed to identify property owners and tenants within the CBD. The choice of sampling techniques aimed to gather information from relevant individuals who had knowledge and experience related to the research topic. By using a combination of purposive and convenience sampling, the study ensured the inclusion of key stakeholders who could provide valuable insights into the building dilapidation in Thohoyandou CBD (Reddy, 2017).

4.5 Data Collection

The data collection process for this study involved both primary and secondary data sources. Primary data collection methods included key informant interviews and field observations. Key informant interviews were conducted with 13 municipal officials, 2 property owners, 4 tenants, and 1 informal trader within the Thohoyandou CBD. These interviews provided valuable insights into the perspectives and experiences of key stakeholders involved in the building dilapidation issue. Field observations were carried out to map dilapidated buildings within the CBD using an observation checklist and capture photographs of the buildings.

Secondary data collection involved gathering information from various sources such as local government documents including the Thulamela Vision 2030 document, the Thulamela Integrated Development Plan (IDP) 2021/2022, and the Thulamela Spatial Development Framework (SDF). Additionally, previous studies such as journal articles and papers were reviewed to gain a better understanding of the research problem and explore existing knowledge on urban decay and revitalization efforts.

The collected data, both primary and secondary, served as the basis for the analysis and interpretation of the research findings. Thematic content analysis was applied as the method of data analysis, which involved identifying patterns and common themes in the interview data (Braun and Clarke, 2006). This analysis approach allowed for a comprehensive exploration of the data and facilitated the achievement of the research objectives.

4.6 Qualitative Data Analysis

Qualitative data analysis plays a crucial role in uncovering patterns, themes, and meanings within the collected data, providing valuable insights into the research topic. In this study, thematic content analysis was chosen as the method for data analysis (Creswell, 2013). Thematic content analysis is a systematic approach that involves identifying, organizing, and interpreting patterns or themes in qualitative data (Braun & Clarke, 2006).

Thematic content analysis was selected due to its suitability for analyzing rich textual data and its ability to uncover common themes and patterns across the interviews and observations (Reddy, 2017). By using this method, the research team aimed to identify recurring ideas, concepts, and perspectives related to building dilapidation in Thohoyandou CBD.

The process of analyzing the raw data involved several steps. First, the transcripts and field notes were read and re-read to gain a comprehensive understanding of the data (Shareia, 2016). Then, meaningful units of information were coded, assigning labels to segments of data that captured important concepts or themes. These codes were then grouped together to form broader categories or themes. Through an iterative process, the research team refined and revised the themes until a coherent and comprehensive set of themes emerged (Robson and McCartan, 2016).

Rigor and reliability were maintained throughout the analysis process by employing strategies such as intercoder agreement, member checking, and peer debriefing (McMillan and Schumacher, 2014). Intercoder agreement involved multiple researchers independently coding a subset of the data to ensure consistency and agreement in the coding process (Hadi and Closs, 2016). Member checking allowed participants to review and validate the interpreted findings, ensuring their perspectives were accurately represented ((Theofanidis and Fountouki, 2018). Peer debriefing involved seeking feedback from other researchers to enhance the credibility and trustworthiness of the analysis.

By employing thematic content analysis and maintaining rigor in the analysis process, this study aimed to provide a robust and comprehensive understanding of the causes and recommendations for building dilapidation in Thohoyandou CBD.

4.7 Ethical Considerations

The study adhered to a set of ethical considerations to ensure the rights and well-being of the participants. Approval was obtained from the university's research and innovation policy committee, ensuring that the study met ethical standards. Voluntary participation was emphasized, allowing participants to choose whether or not to take part in the study without coercion. Informed consent was obtained from participants, ensuring they were fully informed about the purpose, procedures, and potential risks involved. Anonymity

and confidentiality were maintained to protect participants' identities and ensure their responses remained confidential. Potential for harm was minimized by conducting the study in a sensitive manner and providing support resources if needed. Finally, results communication involved sharing findings with participants and the wider research community, ensuring transparency and accountability.

The ethical considerations followed in this study align with established guidelines and principles for conducting ethical research (Polit and Beck, 2017). By upholding these ethical standards, the study aimed to protect the rights and well-being of the participants and ensure the integrity and trustworthiness of the research process.

4.8 Conclusion

This research methodology section has discussed the key elements of the study's research design, data collection methods, and data analysis techniques. The emphasis has been placed on the adherence to ethical considerations, including voluntary participation, informed consent, anonymity, confidentiality, and potential for harm. Rigorous data collection and analysis methods, such as key informant interviews, field observations, and thematic content analysis, were employed to ensure the reliability and validity of the study's findings. The relevance of the research methodology in achieving the research objectives has been highlighted, as it provides a robust framework for understanding and addressing the issues related to urban decay. By following ethical guidelines and employing rigorous research methods, this study aims to contribute valuable insights and recommendations for addressing urban decay effectively.

5   RESULTS AND DISCUSSION

5.1 Introduction

This section aims to present and interpret the findings of the study. This chapter begins by summarizing the research questions or hypotheses addressed and providing a concise overview of the collected or analyzed data. The presentation of results focuses on the key findings, organized in a logical manner from the most important or significant to the least. The discussion of findings involves interpreting and analyzing the results in relation to the research questions or hypotheses. Throughout the discussion, reference is made to existing literature to compare and contrast the current study's findings with previous research. Emphasis is placed on identifying patterns, trends, and relationships observed in the data, while offering explanations or potential reasons for the observed results.

5.2 Research objective 1: Which buildings have dilapidated in Thohoyandou CBD?

Name of dilapidated building	Privately owned/ Owned by the municipality
Noorani complex	Privately owned
Gole complex	Privately owned
Thohoyandou inter-modal taxi rank	Owned by municipality
Matidza complex	Privately owned
NTK Thohoyandou	Privately owned
Post office	Owned by Municipality
Jjays Bottle store	Privately owned
Mutsindo mall	Owned by municipality
Luvhengo Complex	Privately owned

Table 1 Dilapidated buildings in Thohoyandou CBD.

The study found that that there are dilapidated buildings around Thohoyandou CBD. Some of these buildings include Noorani complex, Matidza complex, Mutsindo mall, Gole complex, NTK, Post Office, Luvhengo complex and are presented in table 4.1. above. Observation of the Noorani complex showed that the ceiling was decaying, the wall were peeling off and there were some electrical cables hanging on the balcony steels which are rusting. Findings of the study suggested that this was a result of a lack of maintenance in this building. The findings show that the building is dilapidating and may be contributing to urban decay in Thohoyandou CBD. Observation of the Thohoyandou intermodal taxi rank showed a razor wire abandoned on the stairs of the structure to show that the place is not in use. Further observation of the NTK and Thohoyandou Post office building showed that the buildings were in very poor condition, most windows of the buildings were broken and their roofing was rusting and striping off along with the interior wall of the buildings.

5.3 Research question 2: What are the causes of building dilapidation in Thohoyandou CBD?

Through interviews with key informants, the study identified various factors contributing to building dilapidation, including the lack of bylaws, irregular planning procedures, inadequate building maintenance, illegal occupation of buildings, neglect by property owners, the municipality's incapacity to render services, non-regulation of building capacities, and overcrowding. This following highlights the key findings:

Lack of Bylaws: One significant cause of building dilapidation in Thohoyandou CBD is the absence of bylaws to deal with derelict buildings. According to Key Informant A, "The absence of bylaws to deal with derelict buildings is a major challenge. We lack regulatory instruments to enforce compliance and ensure building maintenance." Bylaws serve as crucial regulatory instruments for creating inclusive, accessible, and safe cities (Ndlebe, 2017). According to Van dijk (2007), they enforce compliance and have the potential to bring positive change to the city's safety profile over time. However, the lack of effective bylaws hinders the municipality's ability to control human and corporate behavior, contributing to the deterioration of buildings (Luyt, 2008).

Irregular Planning Procedures: The irregular planning procedures in the construction of buildings, such as the intermodal taxi rank, have also played a role in building dilapidation. Key Informant B stated that, "Poor planning and budgeting, coupled with inadequate monitoring, have led to structural issues and improper provision of housing." Poor planning and budgeting, coupled with inadequate monitoring by local municipalities, lead to structural issues and improper provision of housing (Boraine, 2010). These factors negatively impact the condition of buildings, resulting in urban blight and aesthetic degradation (Wakely, 2014).

Lack of Building Maintenance: The lack of building maintenance exacerbates the problem of dilapidation. Key Informant C emphasized the following, "Building owners often display ignorance and a delayed response to maintenance issues." Building owners often display ignorance and a delayed response to maintenance issues, leading to the worsening of problems such as sanitation, electricity, and water (Ndlebe, 2017). Additionally, the absence of bylaws regulating derelict buildings allows mismanagement by landlords, affecting both revenue and the overall city aesthetics (Andile, 2018).

Illegal Occupation of Buildings: The illegal occupation of buildings, particularly by foreign business owners seeking better living standards, contributes to overcrowding and strain on municipal services. Key Informant D pointed out the following, "The illegal occupation of buildings by foreign business owners seeking better living standards has led to overcrowding and strain on municipal services." The influx of people increases the demand for services, including water, electricity, and solid waste disposal, which the municipality struggles to provide (Chen et al, 2014). According to Graham (2020), this influx further leads to the deterioration of buildings in the CBD.

Neglect by Property Owners: A significant issue in Thohoyandou CBD is the neglect of buildings by absentee property owners who prioritize rent collection over property maintenance. Key Informant E highlighted the following, "Absentee property owners prioritize rent collection over property maintenance." As absentee owners often reside elsewhere, they disregard the condition of the buildings, leading to decay and a decline in the aesthetic appeal of the CBD (Mantzaris, 2014).. According to Murimoga and Musingafi (2014), the lack of control over tenants and a disregard for building upkeep contributes to neighbourhood decline and blight.

Municipal Incapacity to Render Services: The municipality's inability to effectively deliver services, such as water, electricity, and sanitation, exacerbates building dilapidation. Key Informant F stated the following, "The municipality's inability to effectively deliver services exacerbates building dilapidation." Overcrowding caused by illegal occupants puts pressure on these utilities, leading to inadequate service provision (Andole, 2016). Poor leadership, governance, and financial mismanagement further contribute to the ineffective delivery of services (Routhe, 2018).

Non-regulation of Building Capacities: Thohoyandou CBD faces the challenge of large buildings with limited maintenance and insufficient space. According to Key Informant G, "The lack of regulation regarding building capacities affects the cleanliness, health, and overall functionality of the CBD." Overcrowding, especially due to the presence of illegal traders, obstructs proper infrastructure development and service provision (Phillips, 2017). The lack of regulation regarding building capacities affects the cleanliness, health, and overall functionality of the CBD (Graham, 2020).

Overcrowding: The rapid population growth in Thohoyandou CBD, driven by people seeking access to services, intensifies the pressure on buildings. Key Informant H explained the following, "Rapid population growth in Thohoyandou CBD intensifies the pressure on buildings." Small offices in rental buildings accommodate more people than the municipality's targeted capacity for service provision. Overpopulation leads to inadequate maintenance, strain on utilities, and ultimately, the dilapidation of buildings.

The causes of building dilapidation in Thohoyandou CBD are multi-faceted and interconnected. The absence of bylaws, irregular planning procedures, inadequate building maintenance, illegal occupation, neglect by property owners, municipal incapacity, non-regulation of building capacities, and overcrowding all contribute to the deteriorating state of the buildings. Addressing these issues requires a holistic approach, including the implementation of effective bylaws, improved planning processes, increased maintenance efforts, and better service provision. It is imperative for stakeholders, including the municipality, property owners, and the community, to work collaboratively towards revitalizing the CBD and ensuring its long-term sustainability.

5.4 Research question 3: Which recommendations can be suggested to address building dilapidation in rural towns such as Thohoyandou?

This section focuses on several key strategies to address the challenges related to derelict buildings and urban decay. These strategies include formulating bylaws, enforcing planning procedures, establishing a dedicated CBD building maintenance plan, evicting illegal occupants, conducting building audits, and regulating building capacities.

One crucial strategy identified is the formulation of bylaws to deal with derelict buildings. The responsible person or persons who violate these bylaws would be held liable for damages and costs incurred by the local authority to address the issue (Bess, 2008). By developing and enforcing these bylaws, Thulamela municipality can ensure accountability and promote the proper maintenance of buildings (Thulamela Municipality, 2023). To ensure compliance with the bylaws, authorized officials would be appointed by the municipal manager or relevant authority. These officials would have the right to enter any building or property at any time to assess compliance and issue notices as necessary. This approach aims to prevent hindrances to the authorized officials' authority and enable effective enforcement of the bylaws (Thulamela Municipality, 2023).

Another strategy involves stricter enforcement of planning procedures in the construction of buildings. Clients would be required to prepare baseline risk assessments for construction projects, and the municipality would enforce planning procedures based on these assessments (Phillip, 2017). This would ensure that health and safety specifications are incorporated into the design phase and that contractors comply with regulations. The goal is to enhance the longevity and sustainability of buildings while prioritizing safety (Karrin, 2011).

Establishing a dedicated CBD building maintenance plan is also crucial for overcoming building depreciation (Taipeli, 2011). This plan would focus on energy-efficient and adaptable buildings that have long-term value and longevity. By implementing technical systems and services that are easily replaceable and maximizing passive methods, buildings can become more sustainable (Lambardo, 2017). Additionally, water collection, purification, and energy generation should be integrated into building designs. Retrofitting public buildings can serve as examples of sustainable practices (Karrin, 2011).

The eviction of illegal occupants from buildings is another key strategy to address urban decay. The municipality would take action against illegal land occupiers with the property owner's permission (Zack, 2015). This includes submitting charges of trespassing, issuing eviction notices, and demolishing unfinished or unoccupied structures (Vera, 2015). Agreements with significant landowners would also be pursued to enable swift response to land invasions (Thulamela Municipality, 2023).

Conducting building audits in the Thohoyandou CBD is essential to ensure that buildings are used in accordance with their intended purpose. Many buildings in the area are occupied by businesses that may not align with their original designation (Bess, 2008). Conducting audits and comparing the information in land use applications with actual usage can help identify discrepancies and enforce appropriate zoning regulations (Thulamela Municipality, 2023). Lastly, the regulation of building capacities is crucial for efficient and effective building regulation (Vera, 2015). Thulamela municipality can implement a building regulatory capacity assessment strategy to gather essential information, identify gaps, and establish a baseline for

improvement (Andole, 2016). This assessment can aid in streamlining product certification, design, construction, and approval processes, ultimately enhancing the market's efficiency (Thulamela Municipality, 2023).

In summary, the strategies presented above offer a comprehensive approach to addressing derelict buildings and urban decay. By formulating bylaws, enforcing planning procedures, establishing maintenance plans, evicting illegal occupants, conducting building audits, and regulating building capacities, Thulamela municipality can promote accountability, sustainability, and revitalization in urban areas. These strategies emphasize the importance of compliance, safety, adaptability, and efficient building management to achieve long-term improvements in urban environments (Thulamela Municipality, 2023; Karrin, 2011).

6 CONCLUSION

This research shed light on the challenges posed by building dilapidation in Thohoyandou CBD, a rural town in South Africa. The study explored the causes and implications of this issue and proposed strategies for addressing urban decay in similar contexts. Through a qualitative research approach and a case study design, the research uncovered the underlying factors contributing to building dilapidation and highlighted their interconnectedness.

The findings of this study have significant implications for urban revitalization efforts in developing countries, particularly in rural towns facing similar challenges. By understanding the causes of building dilapidation and its consequences, policymakers, urban planners, and community stakeholders can devise targeted interventions to reverse the decay and promote sustainable development. Moreover, this research contributed to the existing knowledge base on urban decay by providing insights from a rural perspective, which has been largely overlooked in previous literature. The study emphasized the need for tailored strategies that address the unique circumstances of rural towns, such as Thohoyandou CBD, including limited resources and inadequate urban planning and management.

By implementing the proposed strategies, such as community engagement, capacity building, and strategic partnerships, Thohoyandou CBD can reclaim its vibrancy and become a model for sustainable urban development. Additionally, the lessons learned from this study can be applied to similar contexts worldwide, fostering inclusive and resilient communities.

1 ABSTRACT

The automation in the transportation and mobility sector, particularly the use of autonomous systems in public transportation, presents novel challenges for various user groups despite offering numerous positive aspects. Autonomous vehicles, particularly in the domains of micro-public transportation and car sharing, have the potential to serve as a flexible mobility solution for individuals without a driver's license or those who are physically or mentally incapable of operating a vehicle. To ensure equitable access to this potential of independent and flexible mobility for all individuals, the design of autonomous transportation modes must be inclusive.

The Austrian "AM4Kids" project (August 2020 to October 2023) imparts knowledge on mobility and transport system planning to children and juveniles in the context of the progressive automation of transportation and mobility modes, focusing on the principles of inclusive mobility offerings. Children and juveniles have attended several workshops on mobility and inclusion for over three years. In the final stage of the workshop series, the children and juveniles develop their visions and ideas for automated mobility, discussing the opportunities, risks, and consequences for themselves and other groups.

One way to better understand and visualise the wide range of everyday lives of people with disabilities, their mobility patterns, and mobility options is to use the persona concept. This method aims at packaging real users' motivations, needs, wishes and ambitions in a model to better integrate future research and technology development of automated mobility with the wants and needs of users. Personas do not represent the whole range of user diversity. However, they enable planners and developers to deal realistically with the situations and mobility needs of the relevant groups of people and allow specific analyses to implement user-oriented transport solutions.

This paper outlines the methodology applied and the results achieved to make them accessible to a broad professional audience. The project demonstrates that knowledgeably selected personas provide added value in developing technologies. They can also be employed in the further education and sensitisation of children and juveniles.

Keywords: awareness, persona, inclusion, automated mobility, children

2 INITIAL SITUATION

This paper is a follow-up to the 2022 paper entitled "Automated Mobility and Inclusion as Educational Topics for Children and Juveniles and as Tasks and Responsibilities of Mobility Planning: Work-Report on the Project AM4Kids" (Hohenecker et al. 2022).

The project assumes that people with disabilities do not have some "special needs" which would set them apart from non disabled transport participants. Instead, and in line with the social model of disabilities, the design of environments, infrastructures and vehicles neglects them as potential and actual users. They need awarness to be represented in the mindsets of traffic planners, traffic engineers and decision-makers. Exclusion, therefore, is not a consequence of bodily impairments but of failing to upgrade and to generalise chances of participation, e.g. in terms of universal design or design for all principles. The project aims to broaden the scope of reflection on how traffic systems, including infrastructures, vehicles and environments, are planned, designed and built and how human creativity can intervene and change these human-made structures. Contemporary (interface) design approaches must address these issues on a general and abstract level. They emphasise the diversity of road user groups by constructing "personas" (Cooper et al. 2007),

which are fictional but realistic characters with concrete situations and specific aims in their daily lives as well as broader biographical perspectives (see Chapter 3 in this paper). Personas are a fruitful starting point for pedagogical work as they are a dialogue partner in developing ideas for a future mobility system. They help children and juveniles in educational settings to develop forward-looking responsibility when they imagine future traffic systems and transport modes.

The focus is on children and juveniles who gain insight into transportation planning and the associated research fields and research processes within the framework of the project. The guiding statement is "Today's children and juveniles will be tomorrow's users and decision makers of automated mobility" (Hohenecker, Knoll et al. 2022). Children and juveniles shall learn about the wants and needs of diverse traffic participant groups, to deal in particular with the prospects for the development of automated mobility, and to develop and reflect their visions of the future in the subject area of mobility.

The project consortium of AM4Kids[1] is composed of sociologists, transportation planners, landscape architects, civil engineers and legal experts focusing on the needs of people with disabilities. Six different schools with fourteen overall classes participated in the project. Age groups from primary school to secondary school level 2 are represented. The classes vary in terms of school levels and in terms of pupils with disabilities involved as well as educational specialisation. Table 1 gives a brief overview of the numbers of participating school classes. For example, one school has some children with visual impairments and another school focuses on technical and engineering education.

school level	school classes and timeline	summarising unique characteristics
primary school (age group 6-10 years)	eight classes: in three different schools from 08-2020 until 10-2023	inclusive school and all-day school, volatile school, classes with special educational needs (integrative class)
secondary school level 1 (age group 10-14 years)	two classes: one school since 08-2020 until 10-2023 and two classes: one school from 01-2023 until 10-2023	school for children with visual impairment, classes with special educational needs (integrative class)
secondary school level 2 (age group 14-20 years)	two classes: one school from 08-2020 until 10-2023	vocational college, juveniles with technical & engineering education

Table 1: Overview of participating school classes per school level

The AM4Kids project comprises three phases. Children and juveniles went through all phases using age-appropriate teaching materials developed in the corse of the project.

Phase one focused on knowledge building about mobility and inclusion. Workshops conducted in phase 2 aimed at reflecting on their own mobility behaviour and learn about the needs of diverse traffic participant groups. In phase three, the children and juveniles develop their vision of the future of mobility.

The current paper refers to the project´s third phase and presents workshop materials and the results of this phase. Chapter 2.1 gives a summary of the project activities to date.

2.1 Previous project activities

The children and juveniles receive insight into mobility research within the project. They learn to observe mobility from different perspectives and reflect on their mobility patterns. The aim is to learn about mobility demands, needs and situational requirements of various traffic participant groups.

2.1.1   Phase 1 - Building knowledge

Phase one consists of expert lectures (task 1), sensitisation workshops about inclusion (task 2) and a time travel into the history of mobility (task 3). The expert lectures and workshops aim at explaining mobility and traffic system planning, give insight into our daily work and shall trigger curiosity about transport planning and inclusion in general. Moreover, the key figures and indicators of mobility and their meaning in practice are explained. In the sensitisation workshops, the needs and demands of visually impaired and blind people are addressed. The workshop started with a theoretical introduction to assistive devices and accessibility. The second part of the workshop was practical training where different kinds of visual impairments were

---

simulated, such as blindfolds or special glasses. Task three includes time travel, in which the children reflect on the film "Towards the year 2000 - a preview of Tomorrow's World", produced about 50 years ago. It shows how the producers at this time thought the world could look like 30 years later. The film should stimulate creativity of thinking about future scenarios. Past visions of future mobilities are reflected and analysed by asking what was predicted, discussed, implemented, and established back then for today.

2.1.2 Phase 2 – Reflection on mobility behaviour

In phase two, the reflection on mobility behaviour (task 4) took place. The children acted as transportation system planners, and they worked with age-appropriate mobility logbooks. We organised walks and spatial explorations in the course of which we analysed their school environment together and conducted transport planning methods such as surveying, counting, mapping and measuring. In task five, we developed three logbooks depending on the participating school and the age of the children and juveniles.

Tasks within the mobility logbooks were: documenting trips on three consecutive days, elaborating on the development of different modes of transport in the last decades and conducting interviews with familiar grown-ups about their mobility behaviour. Further, there was a task to design an imagined mode of future transport and to visualise their way to school in a drawing.

2.2 Autonomous driving and its impacts on people with disabilities

Accessibility is an essential prerequisite for the equality of people with disabilities. The unrestricted, barrier-free use of services, facilities and objects determines the radius of action and enables self-determined participation in society. To shape a sustainable and inclusive development of automated mobility, discussing this complex and multi-layered topic with children and young people today is essential. With a focus on inclusion, the aim is to understand how automation and digitisation enable or restrict the mobility of people with disabilities.

To develop inclusive mobility solutions a Design for All approach as an analytical lense. Following this basic idea for the planning and design of products, services and infrastructures, it should be possible for all people to use products, services and infrastructures without individual adaptation or special assistance. Design for All describes a design process that aims to achieve accessibility, usability and experienceability for as many people as possible.

With a focus on inclusion and automated mobility, the AM4Kids project deals with tomorrow´s traffic planning and mobility research. Automated mobility has much potential to increase independent mobility of people with disabilities, if various offerings address the needs and situations of people with disabilities. The following issues have to be adressed:

- The preparatory activities for a trip (pre-trip), such as obtaining information about the AM offer, the ordering, booking and payment process, the reservation of assistance services, etc., are to be carried out as far as possible on the person's own responsibility.

- All stages of the journey (on-trip) are barrier-free for people with disabilities. This starts when leaving the house door and concerns the access to the AM offer, the wait or stop, the change of inter- and multimodal means of transport, equipment, information on and around the route, stage or vehicle, the stay in the AM means of transport, stay qualities and equipment in the vehicle and ends when getting off near the destination as well as the departure to the destination address to the house door.

- The appropriate provision of information during the journey, as problems might occur during the journey. This involves a reflection of the experience (post-trip), any payment as well as any complaints to the operating company or the provision of services for the vehicle (e.g. charging the battery, luggage collection, etc.).

A central question is to what extent AM or a concrete AM offer is able to meet the specific requirements of people with disabilities to enable their independent mobility? For one, this is a question of technological development, but also of the socially acceptable costs of automated mobility for the different groups of people with disabilities. It is important that these groups can actively participate in the development of automated mobility to meet their needs sufficiently. The current situation is still way behind this requirment.

3 PERSONA CONCEPT IN THE AM4KIDS PROJECT

Personas are fictional characters that represent the target audience of a product or service. They help designers and developers understand the needs, goals, and behaviours of their (potential) users and provide a „human face" to the data and insights gathered during research. Personas are a valuable tool in user-centred design. (Cooper et al. 2007). However, the creation of personas can be influenced, e.g, by gender bias, leading to inaccurate or stereotypical representations of users. For example, a persona based on gender stereotypes may not accurately represent the needs and behaviours of the imagined target group, leading to a product that is not inclusive or accessible to all. (Marsden et al. 2015).

To create effective personas, designers and developers must be aware of their biases and strive to create inclusive and diverse representations of their target audience. With reference to gender, they have to address a range of gender identities and other factors such as age, ethnicity, and socioeconomic status. In the context of mobility, personas can be used to understand the diverse needs of different users, such as people with disabilities, older adults, commuters, tourists, and families with children.

For example, a persona for a person with a disability may include information about their mobility limitations, such as the need for accessible transportation and priority seating. They may also have specific needs for information, such as real-time updates on service disruptions or accessible route planning tools. A persona for a commuter may include information about their daily routine, such as the need for reliable and efficient transportation options. They may also have preferences for specific modes of transportation, such as biking or public transit, and may prioritise cost, convenience, and environmental impact.

Ten personas were developed in the R&D project "AM inclusive!" (Knoll et al. 2021). The goal of the personas is to package the motivations, needs, desires, and usage goals of real users into a model that decision-makers, responsible parties, developers, etc., can use to empathise with people with disabilities and develop user-centred decisions or technology developments accordingly. With the support of project partner Austrian Disability Council (ÖBR), feedback from people with disabilities was incorporated into the persona descriptions. The personas were constructed carefully to be typical and credible and contain as few gender stereotypes as possible. In the context of the project theme, Automated Mobility, the following information was used for the description of the personas:

- Name
- Sociodemographic information and background
- Mobility behaviour (regular routes, professional routes, etc.)
- Requirements for the mobility system (information, vehicle, accessibility, etc.)
- Technology and automation in everyday life today
- Wishes, needs, barriers

In the following, we present an example of a blind person using a guide dog:

Example of a persona: Michael - Blind person with a guide dog

Michael, now 30 years old, lost his vision at age 20 due to retinopathy pigmentosa, an inherited retinal degeneration. He relies on a guide dog for safety and assistance when navigating public spaces, particularly for using public transportation. While he has learned Braille, Michael finds standard tactile print with raised letters more accessible for reading. His guide dog accompanies him to work in an office, providing the support he needs to be spontaneous and independent during his daily commutes. When taking the bus, the dog helps Michael locate the entrances and exits, as the bus stops at different points within the bus stop. Michael requires a priority seat on the bus to accommodate himself and his guide dog, but the need for a quiet space for the dog is often overlooked in planning. He appreciates loudspeaker announcements, although they can be challenging to understand. Michael benefits from having an annual pass for public transportation, eliminating the need to worry about finding suitable tickets. However, he faces difficulties with the validation machines, which can be tricky to locate and insert the ticket correctly, especially as the bus wobbles during the journey.

Technology and automation in everyday life today: At home, Michael relies on a smartphone app to search for mobility information. The app helps him find the best time and connections for his commute using public

transportation. There are certain barriers that Michael encounters in public spaces and when using public transportation. When faced with new and unfamiliar routes, Michael usually looks for a companion to accompany him and his guide dog. While using his navigation app, Michael sometimes needs clarification for directions like left or right, and announcements may come too late. Accurate descriptions are crucial in these situations. Having his guide dog by his side would have helped Michael avoid obstacles caused by incorrect announcements. In Vienna's 22nd district, Seestadt Aspern, there has been a self-driving bus operated by Wiener Linien in test operation for some time now. Michael believes that automation will have a similar impact on him as long as he travels with his guide dog. The dog assists him in boarding and exiting the bus and helps him find a vacant seat that allows space for both himself and the guide dog without blocking others' way. Michael doesn't foresee significant changes due to self-driving vehicles. It's crucial for Michael that his guide dog is recognized as an assistance dog so that he cannot be denied entry to hospitals, doctor's offices, or stores with the animal. One significant concern for Michael is electric cars, as he has difficulty hearing them. He shares this concern with his colleagues who also have visual impairments.

This example demonstrates that, overall, individuals with disabilities have similar end goals and life aspirations as those without disabilities. However, the means and conditions to achieve these goals must be adapted to accommodate different sensory and motor abilities.

4 METHODOLOGY

The design of project phase three aims to sensitise children and juveniles to the topic of mobility in the context of current technical developments and inclusion. Hohenecker et al. (2022) described that the AM4Kids workshops promote creative and networked thinking among children. In phase three, the focus is on examining automated mobility from different perspectives. For this purpose, the project consortium developed Future Council workshops in an age-appropriate manner, depending on the participating school classes. Using personas, children and juveniles learn about the importance of developing mobility offers in a future-oriented and socially sustainable manner. The acquired knowledge enables the pupils to experience mobility from different perspectives and allows them to understand the implication of scientific concepts. It shows that in the course of childrens´ participation processes, the age-appropriate and step-by-step development of knowledge is indispensable for sustainable learning experiences.

The idea of Future Councils is based on the following goals:

- To impart knowledge about the automation of transportation system elements: Lectures, the lecturers explain the stages of automation and the term transport system. It is essential to convey the interaction of people, means of transport and the associated infrastructure. The diversity and heterogeneity of the users of a transport system are addressed, and the children and juveniles are sensitised to the different needs and demands. In an interactive exchange, the children and juveniles elaborate on which tasks in a transport system or means of transport have been automated throughout time and reflect on the advantages and disadvantages of these developments. Finally, driverless autonomous vehicles are presented, and their current and future application areas are discussed.

- Changing perspectives with the persona concept: After a short theoretical introduction to the persona concept, the children and juveniles read the description of their assigned persona in small groups. They learn about the persona's transport needs and requirements and identify barriers and difficulties. They reflect on the mobility system affordances to be entirely usable by the persona.

- Develop future scenarios and solutions for the persona: Pupils develop visions of the future and scenarios for automated mobility and discuss where the opportunities, risks and consequences lie for themselves and other groups of people and the environment. They work independently in small groups to develop means of transportation and elements of a transportation system that they believe will improve the persona's mobility situation.

- Reality Check of our Future Scenarios: Finally, a dialogue happens on eye level with researchers about their elaborated ideas within the workshop. The experts of the project consortium give feedback and discuss the relevance of their project ideas using the categories of society, politics, industry and users (results see chapter 5).

4.1 Change of perspectives with the persona concept

The personas created within the project "AM Inklusive!" (Knoll et al. 2021) and used in the current project "AM4Kids" promote a change in perspective within the working groups. Personas help pupils understanding the needs of others, as well as provide insight into the everyday challenges of persons with disabilities in the transport system. The goal is to encourage pupils to develop mobility solutions for personas from an inclusive design perspective, followed by discussing visions and ideas in a Future Council. Scientists and planners accompany the children and juveniles in this process, offer feedback and insight into the interdisciplinary, multi-level exchange between disciplines. In the following, the used personas are outlined:

4.1.1   Michael – blind person with a guide dog

Michael is a blind person who uses a guide dog for safety and support in public spaces. Michael finds reading the standard tactile script with raised letters easier than Braille. He works in an office and usually takes the bus, with his guide dog showing him the next entry and exit points. Michael uses an app on his smartphone to find the best time and connection for his public transportation routes. He often seeks a companion to walk new and unfamiliar routes with him and his guide dog. Michael emphasises the importance of recognising his guide dog as an assistance animal, allowing him to enter hospitals, doctor's offices, or shops. He finds electric cars dangerous as he cannot hear them, which is also challenging for his visually impaired colleagues.

4.1.2   Amina – a person who is blind from birth

Amina is a 47-year-old blind woman who lives with her partner and works in an office. She uses public transportation to get to work and relies on an assistant to help her with tasks. Amina faces challenges when using public transportation, such as needing help to see which line or end station the vehicle is heading to. She uses a long cane to navigate and prefers to orient herself to linear structures. Amina uses apps on her smartphone to find the best connections when travelling alone and asks for help when buying tickets. She uses a Braille display and a screen reader to work on her computer at home. Amina wishes for more automated communication and announcements in public transportation and at stops to help her navigate.

4.1.3   Aleksandar – blind person with an affinity for technology

Aleksandar is a 28-year-old blind man who lives in a city with his wife and two children. He is interested in technology and has tried many different products. He discovered a new technology at a fair - shoes with sensors that warn him of obstacles through vibrations on his smartphone. Despite the sensor, he still needs to be attentive as it cannot detect downward stairs or obstacles at chest or head height. Aleksandar always carries a long cane with him. He is now a representative for the manufacturer of the sensor technology. He travels to work alone and uses a screen reader to navigate new routes. In his free time, he travels with his family using public transportation. Aleksandar wishes for better communication with vehicles and for electric vehicles to make more noise. He has tried a self-driving bus but found it challenging to locate the entrance and exit. He also uses a navigation app on his smartphone and wishes for better communication with traffic lights. He uses an acoustic signal at intersections to know when the light turns green. He is happy that future traffic lights will be operated by pressing a button instead of using a Euro-Key.

4.1.4   Maria – a person with visual impairment

Maria is a 67-year-old retired woman living alone in the countryside with a visual impairment. She needs help recognising contrasts, doing reading and locating bus stops difficult. While urban areas support the visually impaired, the countryside needs such infrastructure. Maria uses call-and-collect taxis to travel and recently acquired a smartphone to help with navigation and reading. However, she needs help with GPS accuracy and the need for large font sizes. Improving and expanding support systems for people with visual impairments is crucial to make their daily lives easier.

4.1.5   Justin – a person who uses an electric wheelchair

Justin is a 19-year-old who lives with his parents in the countryside and has had problems feeling and moving his legs and arms since birth. Over time, his mobility has decreased, and he now uses an electric wheelchair. While his home has been modified to accommodate his wheelchair, Justin faces challenges when using public transportation. Bus and train ramps can be difficult to access, and he often needs assistance from

54

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

other passengers or transportation staff. Justin wishes for more accessibility in vehicles, including easier-to-use ramps and better communication systems for signalling entry and exit. He also hopes for technological advancements in electric wheelchairs to make them more lightweight and suitable for off-road use. Despite these challenges, Justin remains optimistic and looks forward to finding employment and continuing to explore the world around him.

4.1.6   Jana – a person using a mechanical wheelchair

Jana is a 38-year-old woman who has been using a manual wheelchair for 23 years since an accident left her unable to walk. She is skilled with her wheelchair and uses public transportation, including the subway, tram, bus, and rapid transit systems. However, she faces limitations in many buildings and needs help to cross the streets. Jana uses an app on her smartphone to find traffic information and the fastest connections for her routes. She also buys her tickets through the app. Jana has not been able to try the self-driving bus yet, but she is interested in how the ramp works and where the emergency button and wheelchair space are located.

4.1.7   Franz – a person with a phobia

Franz has claustrophobia and experiences anxiety and panic in crowded and enclosed spaces. This fear affects his mobility, and he prefers to drive his car instead of public transportation. Franz's employer does not have a company parking lot, so he must pay for parking. He avoids rush hour and schedules his work freely to avoid crowds. Franz would like to use public transportation more often, but he needs to catch up on information about the occupancy of the vehicles. He prefers a driver who can intervene and support in certain situations rather than relying solely on technology.

4.1.8   Cecilia, a deaf person

Cecilia relies on lip-reading and sign language to communicate. She prefers to be accompanied by an interpreter when dealing with authorities or doctors. Cecilia uses a video conferencing service to communicate with her sister and has downloaded several smartphone apps to help her stay informed and communicate better. Public transportation has improved for people with disabilities, but important information may still be announced over the loudspeaker before appearing on the display. Cecilia and her partner own a car but mainly use it to shop or get to the nearest train station.

4.1.9   Ali, a person with hearing impairment

Ali relies on hearing aids and induction loop systems to communicate. Ali avoids speaking to people or asking for directions in public places due to his difficulty in hearing. He uses an app on his smartphone to find the fastest route for public transportation and is grateful for digital screens displaying information about public transportation disruptions. Ali also uses a car-sharing service to borrow a car and prefers to walk instead of using e-scooters, which he finds too dangerous.

4.1.10   Sarah, a person with learning difficulties

Sarah lives in a supervised shared apartment and works in a supervised workshop. Sarah finds it challenging to understand information and prefers to be accompanied by a friend or caregiver when travelling on new routes. She records spoken words to remember things and asks for help when buying tickets or navigating her smartphone. Sarah finds it overwhelming to use transportation apps and prefers to ask other people for directions. She wishes there was only one app for public transportation with information in easy language.

4.2 Future Council in secondary levels 1 and 2

The tasks of the Future Council differ between secondary level 1 (A) and 2 (B) in complexity and scope. The persona's characteristics are first collected in a profile in both workshop versions. Version A asks about the persona's challenges in public transport, whereas version B generally asks about mobility behaviour. This builds on knowledge about mobility and transport generated in the previous project phases.

In version A, the pupils collect ideas for a means of transport or elements of a future transport system, which could be helpful for the persona. From these, implementation possibilities are derived and recorded in writing and graphically.

In version B, they think about how the persona would feel when travelling in a public transport system with autonomous buses a) with an operator and b) without an operator. The task here refers to the requirements of

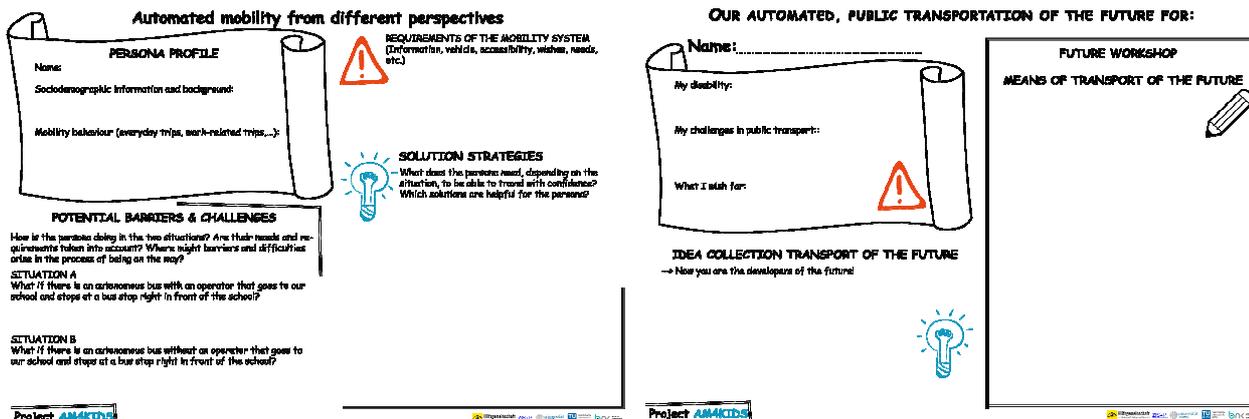
the public transport system so that the persona can travel confidently in the given scenarios. From this, solution strategies are derived and discussed in plenary, commented by the project consortium. The children and juveniles document their process step by step on prepared Flipcharts as shown in Figure 1.


Fig. 1: Flipcharts with the Future Council's assignment for elaborating the content in small groups. Version A secondary level 1 (left), Version B secondary level 2 (right)

4.3 Future Council in primary school

The Future Council workshops have also been adapted to the needs and capabilities of children in primary school. Pupils had the opportunity to develop their ideas for means of transport for the future in a very creative and open setting. After the expert´s input, means of transport, the related developments in the course of history, automated and autonomous mobility as well as inclusion – adapted to the age group and prepared for easy understanding – the children were enabled to take researcher roles. Their work output was drawings and collages for fantasy-based ideas for future mobility modes. As the persona concept is too complex for this age group, it was not used explicitly in this context. As an alternative, the expert team prepared the following questions to give some instructions and to reflect the ideas and inventions together with the students:

- For WHOM did you develop the means of transport of the future?
- WHAT should your means of transport be able to do? What should be better than the means of transport you already know?
- HOW are your means of transport controlled? Is it automated?
- WHO can use your means of transport? Is it suitable for blind people? Is it suitable for people who cannot see/hear/walk well? Are there any helping tools?

In this way, the persona concept – in terms of putting oneself in the position of someone else and create solutions that help the needs of a particular user group – was integrated into the workshop format to sensitise the pupils accordingly.

5   RESULTS

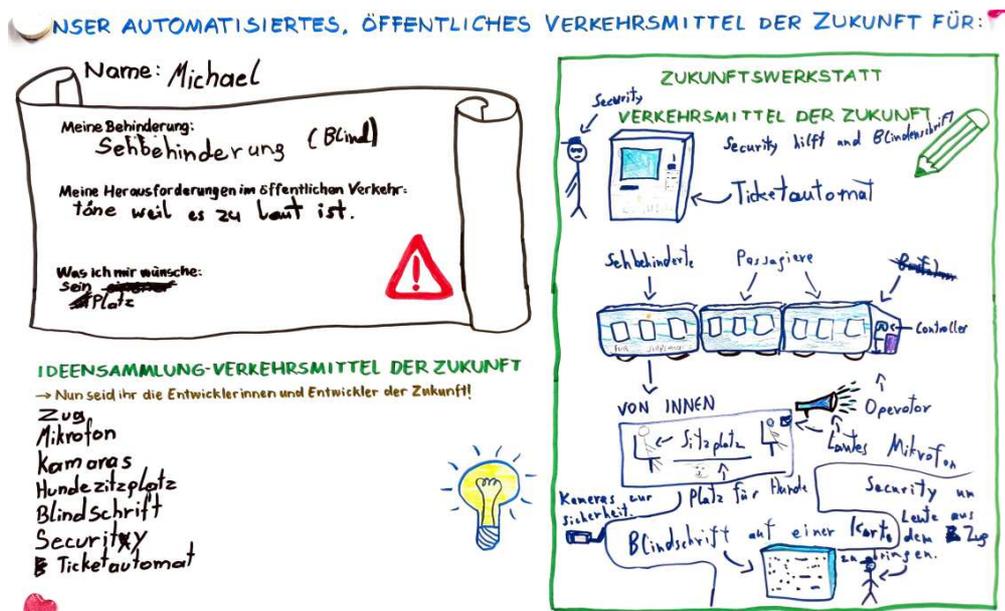
The children of secondary level 1 presented their ideas mainly graphically with short notes for the explanation on their flipcharts. Figure 2 shows the persona "Michael" as an example of the result of one of the working groups. Michael has a visual impairment, and his assistance dog accompanies him. The children recognise some challenges, such as the need of sufficient space for Michael and his dog in public transport. Therefore, one focus of their reflections is that public transportation should also include space reserved exclusively for assistance dogs. In addition, they suggest that securities help with the ticket machines and that these are also provided with tactile Braille. It is important to them that a contact person is always available for the passengers. In addition, information about the current location and the route should be available for people with visual impairments in public transport, e.g. in the form of maps with Braille.


Fig. 2: Example of a flipchart about the persona Michael - created by secondary level 1 students

The task for the students of secondary level 2 is linked to a given process, which refers to the scenario of the autonomous bus in the surrounding area of the school as a mobility offer. The students initially identify barriers and challenges, derive requirements for the mobility system, and develop solution strategies. For example, they used the perspective of the persona "Ali," (impaired hearing). The group suggests that warnings at bus stops (especially platforms) are given via light signals on the ground. Using vibration to alert people to events or last-minute changes in public transportation is also part of the solution strategy. These additional information channels would be beneficial for all passengers, not only for people with hearing impairments. In the workshop, the secondary level 2 students focus on actual technical implementations and discuss them intensively in groups. They propose various apps for the different personas, tailored to their needs. The persona "Franz" avoids public transportation because he is claustrophobic and feels uncomfortable when too many people are in the vehicle. The students follow the solution strategy to equip public transport with weight sensors and light barriers to estimate occupancy in real-time. The resulting information will be stored in the routing apps of the public transport. The persona "Franz" would thus be able to plan his routes better even in new routes about which he has no experience. Figure 3 below shows an example of the flipcharts about the persona "Jana" and a section about the persona "Ali".

Fig. 3: Example of flipcharts about the personas "Jana" (left) and "Ali" (right) - created by secondary level 2 students

Personas helped pupils to consider the practical problems of traffic participants with disabilities and to develop practical solutions. In the case of Michael, for example, they found the following elements to be included in a more inclusive traffic system:

- Louder and clearer announcements
- Recognition of the dog

- Improvement of the navigation app
- Tactile standard font.

The solutions developed by pupils in the workshops crystallised around two basic ideas. The first idea addressed realistic ways of adapting environmental conditions to the situation of persons with disabilities. Technical devices replaced or worked around the sensory impairments and broadened accessibility to traffic situations. On the other hand, pupils in technical schools integrated realistic design ideas with the technical devices they knew from their education. Blind persons need non-visual communication channels; wheelchair users need broader entrance and exit areas to access vehicles, etc. The second strategy used by younger pupils was developing less realistic (science fiction) vehicles and infrastructures like flying wheelchairs or highways for wheelchairs. These solutions projected known solutions of traffic participation for non-disabled people on people with disabilities and created a specific traffic system around their situation. From a pedagogical point of view, both strategies are meaningful and relevant and help pupils see the complexities of design problems regarding traffic participation.

6 DISCUSSION

The aim of an inclusive mobility system is to enable all people to move around on an equal footing and to participate fully in society. To this end, it is necessary to ensure a seamless, inclusive mobility chain from door to door.

- A mobility chain is schematically composed of the following elements:
- Pre-mobility: information + information + planning + implementation/ticket purchase.
- First mile: from the starting point to the 1st station or parking lot.
- First station: arrival to boarding + interactions on the spot/ such as ticket purchase, replacement transport, etc.
- In transit
- Intermediate/final station: exit mode of transport 1 to board mode of transport 2 or leave station
- Last mile: Final station to the actual destination
- Follow-up: Report problems encountered, reclaim, save the route for later trips, etc.

In between, waiting times and waiting places occur. Every mobility chain must meet the requirement of complemteness and inclusion. In reality, however, a large number of different and incomplete mobility chains occur. Therefore, the involvement of people with disabilities in planning mobility chains is essential. These considerations have to be taken into account in the context of the development of an inclusive offer for Automated Mobility and one should:

- Subject existing traffic information services to an inclusion usability check.
- Consistent implementation of the multi-sense principle: Reliable information transfer (pre-/post-trip) for passengers through analogue and digital functional diversity so that a transparent exchange of information between (automated) vehicle and passenger can be enabled.
- In developing applications for traffic information, pay attention to the needs of various people with disabilities.
- Barrier-free design of the road infrastructure, for example, utilising the comprehensive installation of tactile guidance systems, so that safe orientation to and from the (automated) vehicle is possible.
- Optimise physical design of (automated) vehicles; this refers to the need to design a vehicle that enables people with disabilities to get in and out independently
- Conduct regular usability tests and field checks with different groups of people with disabilities in public spaces and along the entire mobility chain

7 CONCLUSION

To conclude: Beyond its use in a design context, the personas concept is also a valuable device in pedagogical settings. Instead of reflecting on the situation of people with disabilities on an abstract level,

pupils learn to understand the situations of concrete traffic participants with their abilities and restrictions, their aims and demands. These aims and demands are not different from non-disabled traffic participants. Instead, the means and conditions must be adapted to meet their situations. To be sure, the solutions developed by the pupils, depend on their developmental and educational levels. Solutions developed by pupils from technical schools are much more realistic and geared towards working around sensory or bodily restrictions. Younger pupils tend to develop imaginary vehicles and infrastructures and create traffic systems for people with disabilities. While the first strategy adds communication channels and situational modifications to increase accessibility, the second strategy emphasises visions of mobility systems from the standpoint of other types of traffic participants (e.g. a highway seen from the perspective of wheelchair users). Both strategies bring design problems to the fore which can be further discussed and developed. Personas promote the attention of future mobility planners (more precisely: of pupils in the role of mobility planners of future traffic systems) to the diversity of user groups and the awareness of accessibility. Nevertheless, inclusive personas must not be misused as a substitute for the involvement of people with disabilities. The creed of participatory traffic planning says: "Nothing about us without us" and in this vein, traffic planning has to be done by people with and without disabilities together. Personas are an excellent educational tool to develop an inclusive mindset as it orients imagination to specific problems that open more ways to develop viable and sustainable solutions.

1 ABSTRACT

Städtische Baumkataster werden aus vielfältigen Gründen erstellt und gepflegt: Die Standorte und Arten der Bäume auf öffentlichem Grund spielen bei der Pflegeplanung - vor allem mit Blick auf die zu erwartenden Effekte durch den Klimawandel - eine zunehmende Rolle. Insbesondere der Zustand ist relevant für die Kommune, um ihrer Verkehrssicherungspflicht nachzukommen. Des Weiteren sind Bäume in der Bauplanung wesentlich und nicht zuletzt auch im Naturschutz von hoher Relevanz.

Die Digitalisierung städtischer Baumkataster hat in den letzten Jahrzehnten weitere Vorteile mit sich gebracht: Der Prozess der Datenerfassung und -bearbeitung kann einfacher und effizienter gestaltet werden. Durch die leichtere Zugänglichkeit ist eine bessere Planung, deren Koordination und eine Weitergabe relevanter Daten schneller realisierbar. Dies trägt auch zu einer transparenteren Kommunikation bei. Der Export von Daten ermöglicht zudem Analysen und automatisierte Anwendungen.

Allerdings stellt es die Kommunen vor eine große Herausforderung, das Baumkataster aktuell, vollständig und fehlerfrei zu halten, da es sich um eine sehr große Datenbasis handelt, die sich regelmäßig ändert.

Verschiedene (meist proprietäre) Anwendungen unterstützen die Mitarbeitenden von Kommunen durch intuitiv nutzbare Eingabemasken, um das städtische Baumkataster zu bearbeiten. Es bleibt jedoch immer die Herausforderung, dass die verschiedenen Merkmale einzelner Bäume oder Baumgruppen händisch angelegt oder bearbeitet werden müssen. Dies ist umso aufwändiger je mehr Merkmale ein Baumkataster enthält und birgt die Gefahr, dass durch mitunter mangelhafte fachliche Kenntnisse fehlerhafte Einträge vorgenommen werden. Es gibt zwar technische Hilfsmittel wie Bestimmungs-Apps, die bei nicht-trivialen Merkmalen wie bspw. Höhe herangezogen werden können, aber manche Eigenschaften, wie z.B. das Alter, können oft nur geschätzt werden.

Alle diese Gründe führen dazu, dass die Datenqualität städtischer Baumkataster oft unbefriedigend ist und die Daten nicht ohne Bedenken genutzt werden können. Im Rahmen des Klimawandels werden überdies Merkmale relevant, die bisher nicht erfasst wurden. Beispielsweise können ergänzende Angaben zum Standort (bspw. Baumscheibe oder Park) dazu dienen, einen potenziellen Trockenstress besser vorauszusagen. Eine Klassifizierung des Allergenpotenzials kann darüber hinaus Menschen mit Allergien eine adäquate raumrelevante Information zu „Allergen-Belastungsgebieten" zur Verfügung stellen.

Um den großen personellen und zeitlichen Aufwand der Pflege des städtischen Baumkatasters in Zukunft zu minimieren und weitere für die Planung und Wissenschaft relevante Merkmale großflächig integrieren zu können, wird in Kaiserslautern ein transdiszplinärer Ansatz erprobt, der auf Grundlage verschiedener Datenbasen und mit Einbezug unterschiedlichster Akteursgruppen arbeitet.

Ausgangslage sind das vorhandene Baumkataster der Stadt, das lückenhaft ist und nur wenige Merkmale enthält, allerdings wegen der präzisen GPS-Standorte eine gute Datenbasis bildet. In Kombination mit Luftbildern kann ein Deep-Learning-Modell trainiert werden, das die fehlenden Bäume erkennt. Ein weiteres KI-Modell, das mit Panoramabildern und LiDAR-Daten aus Straßenbefahrungen arbeitet, soll zudem eine Artenbestimmung ermöglichen. Die Ergebnisse werden von Fachkundigen stichprobenartig evaluiert, sodass eine Feedback-Schleife entsteht, mit der die Modelle sukzessive verbessert werden.

Gleichzeitig wird eine Web-Anwendung entwickelt, die eine nutzerfreundliche Oberfläche bereitstellt, auf der Forschende und interessierte Bürgerinnen und Bürgern weitere Merkmale ergänzen können - auf diesen

Daten können weitere Modelle trainiert werden. Andere Merkmale, wie etwa Höhe des Baumes, können automatisiert aus den vorhandenen Datensätzen extrahiert werden. Im Rahmen des Prozesses sollen unterschiedliche Datenbasen unter Berücksichtigung der rechtlichen Rahmenbedingungen, der Kosten und der Verfügbarkeit als Trainingsdaten dienen und eine Aussage über die Qualität der jeweiligen Ergebnisse getroffen werden. Des Weiteren ist es ein erklärtes Ziel, die KI-Modelle übertragbar zu gestalten, so, dass sie in Regionen mit ähnlichem Baumbestand direkt angewendet werden können. Eine weitere Anwendung kann die Aktualisierung des Baumkatasters und das Monitoring der Datenqualität desselben sein, sobald neue Daten zur Verfügung stehen.

Keywords: artificial intelligence, machine learning, künstliche Intelligenz, Datenqualität, Baumkataster

2 EINLEITUNG

Bäume sind für die Aufenthaltsqualität im öffentlichen sowie privaten Raum sehr wichtig. Sie beeinflussen das lokale Klima und die Luftqualität, werten Straßen, Plätze und Parks optisch auf und bieten zudem einen Lebensraum für Tiere.

Im Zuge der Verkehrssicherungspflicht, aber auch im Hinblick auf die Baumkontrollen, die Bauplanung und den Naturschutz, ist es für Kommunen von hoher Relevanz, die Lage und den Zustand der städtischen Bäume auf öffentlichem Grund zu kennen und zu erfassen. Hierbei spielen Baumkataster eine große Rolle. Dort werden Informationen zu den Bäumen gesammelt und gespeichert. Dazu gehören neben der Position des jeweiligen Baumes die Art und/oder die Gattung, die Höhe, der Kronendurchmesser, der Stammumfang sowie, falls bekannt, das Pflanzjahr und das Alter. Das Baumkataster stellt somit ein Hilfsmittel für die Baum- und Grünflächenpflege dar. Jedoch ist der Aufbau, die Ergänzung weiterer Merkmale und die Pflege eines solchen Katasters eine aufwändige Aufgabe, die viele Ressourcen beansprucht. Die Digitalisierung städtischer Baumkataster hat in den letzten Jahrzehnten vielerlei Veränderungen mit sich gebracht: Der Prozess der Datenerfassung und -bearbeitung kann einfacher und effizienter gestaltet werden. Durch die leichtere Zugänglichkeit ist eine bessere Planung, deren Koordination und eine Weitergabe relevanter Daten schneller realisierbar. Dies trägt auch zu einer transparenteren Kommunikation bei. Der Export von Daten ermöglicht zudem Analysen und automatisierte Anwendungen.

Jedoch haben nicht alle Kommunen digitale Baumkataster beziehungsweise sind diese oft unvollständig oder nicht aktuell. Weiterhin sind in den kommunalen Baumkatastern häufig nur die Bäume erfasst, die im öffentlichen oder halböffentlichen Raum stehen und in die Sorgfaltspflicht der Kommune fallen. Allerdings sind auch private Bäume für Aussagen über die Lufthygiene relevant und sollten für Anwendungsfälle in diesem Bereich aufgeführt sein [vgl. Albert et al. 2022]. Im Rahmen des Klimawandels werden überdies Merkmale von Bedeutung, die bisher nicht dokumentiert wurden. Unter anderem können ergänzende Angaben zum Standort (z.B. Baumscheibe oder Park) dazu dienen, einen potenziellen Trockenstress besser vorauszusagen. Eine Klassifizierung des Allergenpotenzials kann darüber hinaus Personen mit Allergien eine adäquate raumrelevante Information zu „Allergen-Belastungsgebieten" zur Verfügung stellen.

Anhand dieser Problemfelder entstand die Idee, die Datenqualität städtischer Baumkataster zu verbessern. Um den großen personellen und zeitlichen Aufwand der Pflege des städtischen Baumkatasters in Zukunft zu minimieren und weitere, für die Planung und Wissenschaft relevante Merkmale, großflächig integrieren zu können, wird in Kaiserslautern ein transdisziplinärer Ansatz erprobt, der auf Grundlage verschiedener Datenbasen und mit Einbezug unterschiedlicher Akteursgruppen arbeitet. So soll es ermöglicht werden, dass die vorhandenen, aber unvollständigen Daten ergänzt und weitere Merkmale wie Baumart, Höhe und Kronendurchmesser sukzessive hinzugefügt werden.

Im Rahmen des Prozesses sollen unterschiedliche Datenbasen unter Berücksichtigung der rechtlichen Rahmenbedingungen, der Kosten und der Verfügbarkeit als Trainingsdaten dienen und eine Aussage über die Qualität der jeweiligen Ergebnisse getroffen werden. Des Weiteren ist es ein erklärtes Ziel, die KI-Modelle übertragbar zu gestalten, sodass sie in Regionen mit ähnlichem Baumbestand direkt angewendet werden können. Interessierten Bürgerinnen und Bürgern soll es durch die Entwicklung einer nutzerfreundlichen Web-Anwendung ermöglicht werden sich an der Evaluation der Ergebnisse zu beteiligen und ergänzende Merkmale zu erfassen. Sobald neue Daten zur Verfügung stehen, kann ein weiterer Einsatz darin bestehen, das Baumkatasters regelmäßig zu aktualisieren und die Qualität der Daten zu überwachen.

Die Vorteile eines solchen Vorgehens sind vielfältig. Durch Nutzung von Luftbildern können auch private Bäume erfasst werden, die für die Öffentlichkeit nicht ohne Weiteres zu sehen und häufig nicht kartiert sind. Dies ist u.a. für die potenzielle Bewertung von Bereichen mit hohen Allergiepotenzialen durch (Baum-)Pollen sowie das Ozonbildungspotenzial durch biogene Kohlenwasserstoffemissionen von Interesse [Albert et al. 2022].

Es gibt einige Initiativen in deutschen Städten und Regionen, die sich bereits für eine Verbesserung des Baumkatasters einsetzen. Unter anderem in der Metropole Ruhr werden Baumstandorte auf Grundlage ähnlicher Daten und unter Anwendung von KI detektiert [Metz et al. 2023]. Da die Modelle Open-Source zur Verfügung gestellt werden sollen, könnten diese in den hier verfolgten Ansatz integriert werden. Es gibt des Weiteren bereits Deep-Learning-Modelle, die Bäume detektieren, bspw. Ventura et al. [2022] und Weinstein et al. [2019], auf die im nächsten Abschnitt näher eingegangen wird.

Ein erfolgreicher Anwendungsfall eines gut gepflegten Baumkatasters, kann der Einbezug der Bevölkerung bei der Bewässerung sein. Unter anderem in Berlin [Technologiestiftung Berlin] und Leipzig [OKF 2023] werden Plattformen genutzt, um das Gießen von Stadtbäumen zu koordinieren und nachzuvollziehen. In Magdeburg [Winter 2023] finden sich darüber hinaus noch Informationen zu gefällten Bäumen.

Im Folgenden werden zunächst der Projektkontext und die beteiligten Akteurinnen und Akteure vorgestellt. Die Vorgehensweise wird im Allgemeinen erklärt und die vorhandenen Datengrundlagen erklärt und evaluiert. Es wird Bezug auf bereits existierende KI-Modelle zur Positionsbestimmung und Eignung in diesem Anwendungsfall genommen. Zusätzliche mögliche Merkmale werden priorisiert und Möglichkeiten bzw. Grenzen ihrer Bestimmung aufgezeigt. Zuletzt werden die Maßnahmen zur Einbeziehung der Zivilbevölkerung dargelegt.

3 ANSATZ UND PROJEKTKONTEXT

Um das Vorhaben erfolgreich umzusetzen, bedarf es einer Zusammenarbeit verschiedener Akteursgruppen, die ihre jeweilige Expertise zur Verfügung stellen: es ist ein breites Fachwissen zu den Themengebieten Umwelt und Klima, Stadtplanung, Datenverarbeitung, Web-Design und KI gefragt, das durch die Forschenden abgedeckt wird. Mitarbeitende der öffentlichen Verwaltung kennen die vorhandenen Daten, stellen diese bereit und liefern Use-Cases aus der Praxis. Des Weiteren bestehen dort bereits Kommunikationskanäle, um mit der Zivilbevölkerung in Kontakt zu treten und diese für Crowdsourcing-Aktionen zu gewinnen. Hierbei sollen an Aktionstagen interessierte Bürgerinnen und Bürger mit Unterstützung der Forschenden Merkmale von Bäumen möglichst großflächig digital erfassen bzw. die Ergebnisse aus den KI-Modellen validieren.

Das Forschungsvorhaben ist aus dem durch die Carl-Zeiss-Stiftung geförderten Verbundprojekt „Ageing Smart – Räume intelligent gestalten" entstanden. Im Fokus des Gesamtprojektes stehen die Babyboomer, also die geburtenstarken Jahrgänge von 1955 bis 1969, durch deren Eintritt in das Rentenalter Kommunen vor Herausforderungen gestellt werden. So sind diese oftmals damit konfrontiert, neben altersgerechten Wohnstandorten auch passende Versorgungs- und Freizeitstrukturen zu schaffen. Das Gesamtprojekt hat sich als Ziel gesetzt, ein datengestütztes Entscheidungsunterstützungssystem (Decision Support System) zu entwickeln, das Mitarbeitenden der öffentlichen Verwaltungen in ebendiesen Planungsprozessen unterstützt. Insgesamt zehn Teilprojekte aus den Fachbereichen Raum- und Umweltplanung, Informatik und Mathematik der RPTU am Standort Kaiserslautern bearbeiten interdisziplinär diese Fragestellung. Ebenso involviert ist das Fraunhofer-Institut für Experimentelles Software Engineering (IESE) sowie das Deutsche Forschungszentrum für Künstliche Intelligenz (DFKI) GmbH (siehe dazu Abb.1).

Das Teilprojekt der Physischen Geographie untersucht bestehende, lokale, öffentliche Grünflächen im Hinblick auf die Frage, ob diese relevanten Rückzugsräume von allen Personengruppen gleichermaßen nutzbar sind. Ein besonderer Blick liegt hierbei auf den meteorologischen Rahmenbedingungen sowie lokalklimatischen und lufthygienischen Fragestellungen. Im Rahmen der Weiterentwicklung des Baumkatasters liefert das Teilgebiet mögliche Use-Cases und bietet die fachliche Expertise. Im weiteren Verlauf des Teilprojektes soll das methodische Vorgehen, das bereits im Jahr 2022 von Albert et al. vorgestellt wurde, auf Siedlungsräume übertragen werden. Hierbei ist ein (nahezu) vollständiges digitales Baumkataster erforderlich.

Das Team des SmartCity Living Lab des DFKI befasst sich im Rahmen des Forschungsprojekts, dessen Erkenntnisse und Umsetzungen auf vielfältigen Datenquellen fußt, mit der Data Governance und dem Daten-Management, um eine ausreichende Datenqualität zu gewährleisten. Diese ist ausschlaggebend für die Güte automatisierter Anwendungen und Methoden der Künstlichen Intelligenz. KI kann umgekehrt aber auch wie in diesem Fall genutzt werden, um eine gewünschte Datengrundlage zu schaffen oder zu verbessern.

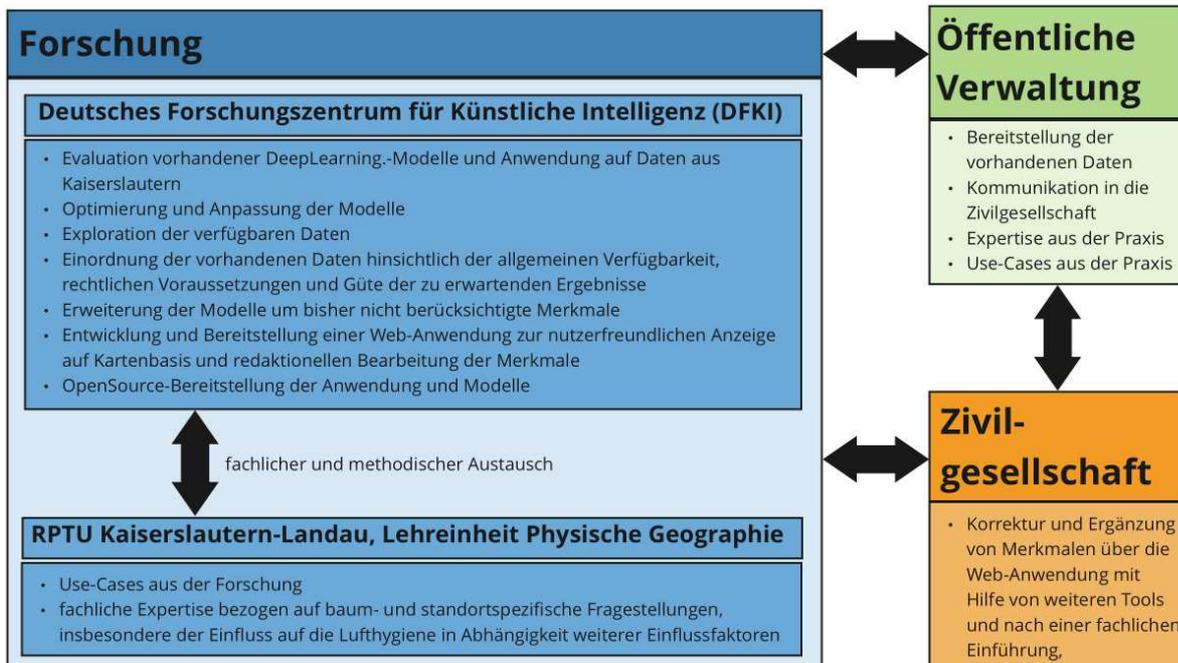
Die Stadt Kaiserslautern wurde als eine von sieben Modellkommunen im Projekt ausgewählt und arbeitet zudem im Rahmen der MPSC-Förderung (Modellprojekte Smart Cities) des BMWSB schon seit einigen Jahren eng mit Forschenden des DFKI und der RPTU zusammen. Sie stellt Daten zur Verfügung und nutzt ihre Kommunikationskanäle mit der Zivilbevölkerung, um diese aktiv miteinzubeziehen.


Abb. 1: Kooperationsnetzwerk zum Verbessern, Ergänzen und Nutzen des städtischen Baumkatasters

4 VORGEHENSWEISE

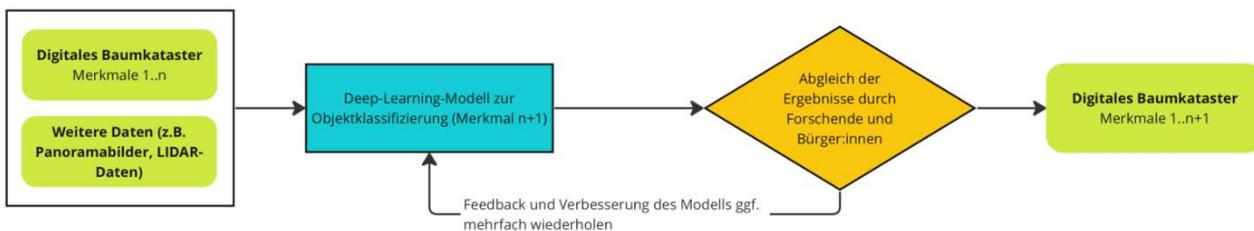
Zunächst werden die verfügbaren Daten auf ihre Qualität und Nutzbarkeit in diesem Anwendungsfall hin untersucht. Sie dienen als Grundlage, um das aktuelle Baumkataster mit den Merkmalen Position und Spezies unter Anwendung von vorhandenen und ggf. angepassten Deep-Learning-Modellen, um fehlende Positionen von Bäumen zu ergänzen. In einem weiteren Schritt wird ein weiteres Modell angewendet oder ggf. selbst trainiert, das die Gattung der neu detektierten Bäume ergänzen soll. Um die Qualität der Ergebnisse einordnen zu können, ist hier eine Kontrolle von fachkundigen Personen nötig. So können die Modelle sukzessive verbessert werden.


Abb. 2: Generalisierte Vorgehensweise zur Ergänzung des Digitalen Baumkatasters unter Einbezug der Bevölkerung

Des Weiteren soll das Baumkataster um weitere Merkmale, wie bspw. Höhe, Stammdurchmesser oder Standort ergänzt werden. Hierzu werden drei Ansätze verfolgt: Zum Ersten können vorhandene Deep-Learning-Modelle auf verfügbare Daten angewendet werden und wiederum durch eine Feedback-Schleife optimiert werden (vgl. Abb.2). Zum Zweiten können automatisierte Anwendungen (auch ohne Nutzung von KI) bestimmte Merkmale großflächig ergänzen. Zum Dritten gibt es die Option, ein eigenes Modell zu

64

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

trainieren. Hierfür werden ausreichend Trainingsdaten benötigt, die in einem Crowdsourcing-Ansatz gesammelt werden sollen. Interessierte Bürgerinnen und Bürger erfassen mit Unterstützung von Fachkundigen und unter Benutzung einer anwenderfreundlichen und intuitiven Software neue Merkmale von einigen Bäumen. So soll der Datensatz im Ganzen um die jeweiligen Attribute ergänzt werden.

4.1 Einordnung der Datengrundlagen

Es gibt einige Datenquellen, die Informationen zu den städtischen Bäumen in Kaiserslautern bereithalten. Diese müssen zunächst auf ihre Qualität geprüft werden. Dabei werden die verschiedenen Kriterien je nach Anwendungsfall unterschiedlich gewichtet und bewertet. In diesem Fall spielen insbesondere die Fehlerfreiheit, die Zugänglichkeit und die Verfügbarkeit der Daten eine übergerodnete Rolle. Unvollständige, aber verlässliche Daten können genutzt werden, um den Datensatz mithilfe von automatisierten Anwendungen zu vervollständigen.

Um Datenquellen als Trainingsdaten für KI-Methoden nutzen zu können, sollten diese möglichst fehlerfrei sein, da das Modell sonst eventuell diese Fehler reproduziert. Des Weiteren ist es sinnvoll, Datensätze zu nutzen, die den Kommunen ohnehin vorliegen oder ohne großen Aufwand zu beschaffen oder erzeugen sind, um ein Modell perspektivisch auch auf andere Kommunen anwenden zu können.

Die Aktualität der Daten ist in diesem Use-Case zunächst untergeordnet, da im Verhältnis zur Gesamtanzahl der Bäume nur ein kleiner Anteil gefällt bzw. neu gepflanzt wird. Andere Merkmale, wie die Höhe, ändern sich kontinuierlich. Hier muss generell mit Ungenauigkeiten gerechnet werden und diese mit angemessenen Methoden quantifiziert werden. Dies ist insbesondere in Use-Cases, die ebenjene Merkmale verwenden, zu berücksichtigen.

4.1.1 Das Baumkataster der Stadt Kaiserslautern

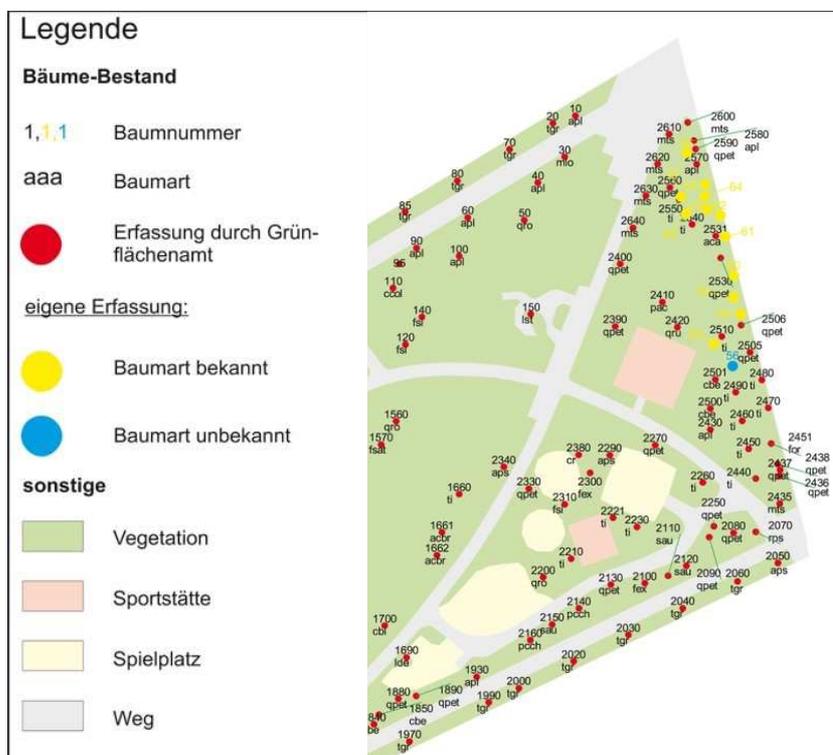
Das Baumkataster der Stadt Kaiserslautern enthält sehr präzise GPS-Koordinaten von ca. 16.600 Bäumen und der jeweiligen Bezeichnung der Gattung bzw. Art. Eine stichprobenartige Überprüfung der Daten durch Ortsbegehungen hat jedoch ergeben, dass viele Bäume hier noch nicht erfasst sind (s. Abb. 3). Es ist zudem entweder die Gattung oder die Art angegeben, wobei erstere aus letzterer hergeleitet werden könnte, umgekehrt aber nicht. Für die meisten Anwendungsfälle ist die Gattung als Information allerdings ausreichend.


Abb. 3: Karte mit vorhandenen und fehlenden Bäumen im Stadtpark von Kaiserslautern (rot=durch Grünflächenamt erfasst, gelb & blau = eigene Erfassung) [Henninger 2014]

4.1.2 OpenStreetMap

In der OpenStreetMap-Community gibt es das Bestreben, auch Bäume und Baumflächen mit diversen Merkmalen zu kartieren. Allerdings sind zumindest in der Stadt Kaiserslautern bisher wenige Eintragungen (nur rund 1000) vorhanden. Dazu kommt, dass mit dem Smartphone erfasste GPS-Standorte für bestimmte Anwendungsfälle zu ungenau sein können. Es ist darüber hinaus unklar, wie gut die Daten sind, die bisher erfasst wurden. In OpenStreetMap (OSM) sind einige Attribute vorgesehen, an denen man sich orientieren kann, um perspektivisch die neu generierten Daten in die Plattform zu integrieren. Erwähnenswert ist darüber hinaus jedoch, dass Merkmale enthalten sind, die ein anderes implizieren. Beispielsweise kann man durch Angabe der Gattung herleiten, ob es sich um einen Laub- oder Nadelbaum handelt. Umgekehrt ist das nicht möglich. Allerdings ist dieses Merkmal leicht von Personen zu erfassen, die weder Wissen über Baumarten noch technische Hilfsmittel zu deren Bestimmung haben. Es gibt auch eine Unterscheidung der Attribute height (Höhe) und est_height (geschätzte Höhe), die verhindern kann, dass falsch oder zu grob geschätzte Angaben als korrekt interpretiert werden [OSM Contributors 2023].

4.1.3 Luftbilder

Der Stadtverwaltung Kaiserslautern liegen Luftbilder aus Befliegungen zu unterschiedlichen Jahreszeiten und mit verschiedenen Auflösungen vor. Hier wird zunächst mit den Bildern der Frühjahrsbefliegung aus dem Jahr 2018 gearbeitet. Diese sind in einer Auflösung von 40cm frei über das Geoportal RLP [GDI-RP] verfügbar. Höher aufgelöste Luftbilder mit einer Bodenauflösung von 8cm sind aus Gründen des Datenschutzes nicht frei verfügbar, werden aber von der Stadtverwaltung zu Forschungszwecken zur Verfügung gestellt. Es soll überprüft werden, ob eine bessere Auflösung zwangsläufig auch eine bessere Kategorisierung nach sich zieht. Falls die Vorteile einer höheren Auflösung nicht signifikant sind, kann man die datenschutzrechtlich unbedenklichen und frei verfügbaren Daten nutzen. Dies macht eine Übertragung der Ergebnisse auf andere Kommunen und die Anwendung der Modelle auf neuere Luftbilder wesentlich unkomplizierter.

Des Weiteren wird auch ein Abgleich zu Befliegungen aus anderen Jahreszeiten und daher mit anderer Belaubung stattfinden. Es ist zu erwarten, dass je nach Use-Case unterschiedliche Jahreszeiten zu bevorzugen sind. Soll der Standort (Baumscheibe, Baumreihe oder Grünfläche) bestimmt werden, liefern die Luftbilder aus Jahreszeiten ohne Belaubung mutmaßlich bessere Ergebnisse.

4.1.4 Daten aus Straßenbefahrungen

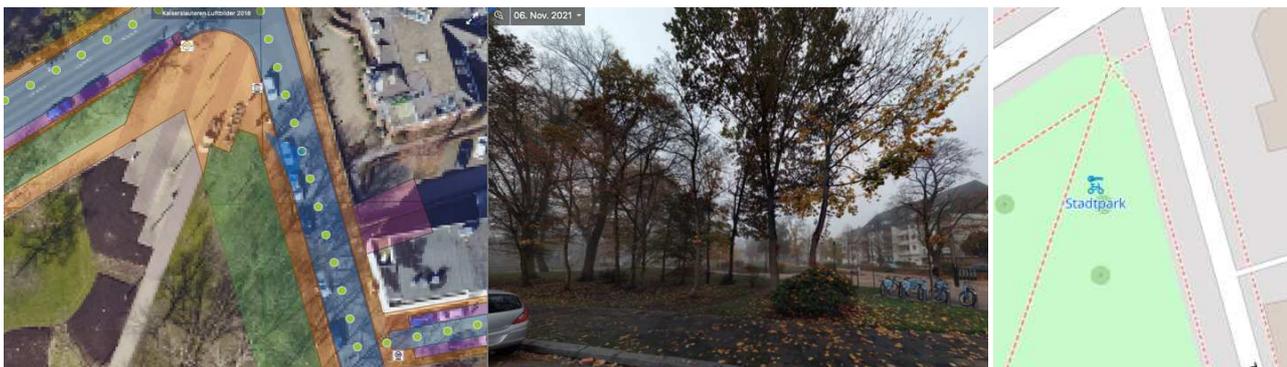
Im Herbst 2021 hat die Stadt Kaiserslautern Befahrungen im gesamten Stadtgebiet ausführen lassen, bei der Panoramabilder und LiDaR-Daten erfasst wurden. Unter deren Nutzung können präzise Messungen (Höhe, Kronendurchmesser und Stammdurchmesser) am PC durchgeführt werden.


Abb. 4: Screenshots aus Cyclomedia (links) und OSM (rechts) auf denselben Bereich des Stadtparks von Kaiserslautern in Abb. 3

Ein direkter Vergleich der Bäume, die in OSM dargestellt werden, mit dem Bildausschnitt der Straßenbefahrung auf den entsprechenden Teil des Stadtparks, zeigt sofort, dass in OSM bisher nur ein Bruchteil der Bäume verzeichnet ist (vgl. Abb. 4).

4.2 Auswahl, Anwendung und Anpassung von KI-Methoden zur Bestimmung von Position und Spezies

Es gibt bereits einige Ansätze, die sich mit dem Kategorisieren von Bäumen beschäftigen. Es ist also nahe liegend, diese zu nutzen und darauf aufzubauen. Die Übertragbarkeit auf Kaiserslautern hängt unter anderem davon ab, mit welchen Daten die bestehenden Modelle trainiert wurden. Wurden Traningsdaten aus Erdteilen mit einer im Vergleich sehr abweichenden Vegetation genutzt, ist es fraglich, ob das entsprechende Modell mit den hiesigen Bildern sinnvolle Ergebnisse liefert. Zudem muss die Jahreszeit berücksichtigt werden.

4.2.1   Vorhandene Modelle zur Positionsbestimmung von Bäumen

Es gibt bereits Modelle, die Bäume detektieren. Erste Anwendungen auf Kaiserslautern haben ergeben, dass die Ergebnisse noch nicht zufrieden stellend bzw. nutzbar sind. Im Rahmen eines Masterprojekts mit dem Titel „Improving the Tree Cadastre of KL using Object Classification (Python)" wird eines der Modelle angepasst und verbessert.

Ein Convolutional Neural Network (CNN) wurde auf Luftbildern aus Kalifornien trainiert und liefert so genannte Bounding Boxes, in denen Bäume stehen. Es detektierte in den Testdaten 73,3% der vorhandenen Bäume und 73,6% der detektierten Bäume waren tatsächlich existent [Ventura et al. 2022]. Diese Genauigkeit ist jedoch nicht ausreichend. Hinzu kommt, dass dem Modell vier Kanäle (RGBN) zur Verfügung standen, bei den Luftbildern in Kaiserslautern aber nur drei (RGB) vorliegen.

Ein weiteres vielversprechendes Modell wurde auf Bäume außerhalb von Städten trainiert [Weinstein et al. 2019] und dann mit Stadtbäumen in München feintrainiert.

Abb. 5: Ergebnisse der Modelle von Ventura et al. [2022] und Weinstein et al. [2019] angewendet auf die Luftbilder aus Kaiserslautern

4.2.2   Herausforderungen bei der Positionsbestimmung

Das Ziel der KI-Methoden besteht darin, eine hohe Präzision und Abdeckung zu erreichen. Das bedeutet, dass eine möglichst große Anzahl von Bäumen korrekt erkannt werden soll und dabei gleichzeitig möglichst wenige Fehler gemacht werden sollten. Es sollten also keine Bäume an Stellen gefunden werden, an denen tatsächlich keine stehen (False Positives, FP). Dies kann durch fehlerhafte Klassifizierung eines anderen Objekts oder durch ein Rauschen in den Daten verursacht werden. Umgekehrt sollten keine Bäume übersehen werden. Solche False Negatives (FN) treten auf, wenn die Bildqualität schlecht ist oder ungünstige Umgebungsbedingungen herrschen.

Da im städtischen Baumkataster schon viele Bäume fehlen, ist der Fokus auf einen hohe Abdeckung wünschenswert. Fälschlicherweise erkannte Bäume lassen sich schnell aus dem Datensatz entfernen, wohingegen nicht erkannte Bäume in Anbetracht der Angabe präziser GPS-Koordinaten etwas aufwändiger hinzuzufügen sind.

Da die vorhandenen Modelle Schwierigkeiten mit Baumflächen haben und es bereits Ansätze gibt, für Wälder auf Grundlage von Luftbildern das Verhältnis unterschiedlicher Baumarten zu bestimmen, wird diese Thematik zunächst hintenangestellt. Dennoch werden bei einigen Use-Cases die Baumgruppen und deren

Arten eine zentrale Rolle spielen. Daher muss langfristig auch für Baumgruppen eine Lösung gefunden werden.

In städtischen Baumkatastern sind häufig aus pragmatischen Gründen nur Bäume auf öffentlichem Grund verzeichnet, für die die Kommune auch eine Sicherungspflicht inne hat. Unter Anwendung von KI werden jedoch alle Bäume auf den gegebenen Bildern erkannt, also auch die auf halböffentlichem und privatem Grund. Diese sind insbesondere relevant für Anwendungsfälle, die sich mit Lufthygiene beschäftigen [vgl. Albert et al. 2022].

4.2.3 Artbestimmung von Städtbäumen mit KI

Wesentlich komplexer ist die Bestimmung der Spezies der Bäume, die neu im Kataster ergänzt wurden. Hierfür werden zwei Ansätze verfolgt, die auf Grundlage des usprünglichen Katasters fußen. Es soll erprobt werden, wie gut ein Modell mit hochaufgelösten Luftbildern die Gattung kategorisieren kann. Da hierfür erwartungsgemäß zu wenige Trainingsdaten vorliegen, wird ein zweiter Ansatz verfolgt, der die Panoramabilder nutzt. Diese und bereits existierende Modelle zur Baumbestimmung werden genutzt, um die fehlenden Angaben zur Spezies zu ergänzen.

4.3 Ergänzung weiterer Merkmale

Zusätzlich zu den Merkmalen Spezies und Position sind weitere Merkmale relevant, die soweit möglich, großflächig ergänzt werden sollen. Eine Priorisierung erfolgt in Abhängigkeit von den spezifischen Anwendungsfällen. Im Projektkontext haben Standort und Höhe eine hohe Priorität (vgl. Tabelle 1). Eine Orientierung geben unter anderen die in OSM verwendeten Merkmale.

Es ist unbedingt zu beachten, dass alle Attribute veränderlich sind. Die Höhe ändert sich stetig und es kommt bisweilen auch vor, dass ein Baum gefällt und an derselben Stelle ein Baum einer anderen Art gepflanzt wird. Das Baumkataster muss also regelmäßig aktualisiert oder mit entsprechenden Hinweisen versehen werden.

In OSM wird zusätzlich die Bedeutung eines Baumes erfasst. Diese umfasst zusätzliche Informationen z.B. ob ein Baum ein Naturdenkmal ist, eine besondere Landmarke darstellt oder historische Relevanz besitzt. Solche Attribute werden hier nicht berücksichtigt, da sie im lokalklimatischen Kontext keine Rolle spielen.

4.4 Automatisierte Ergänzungen

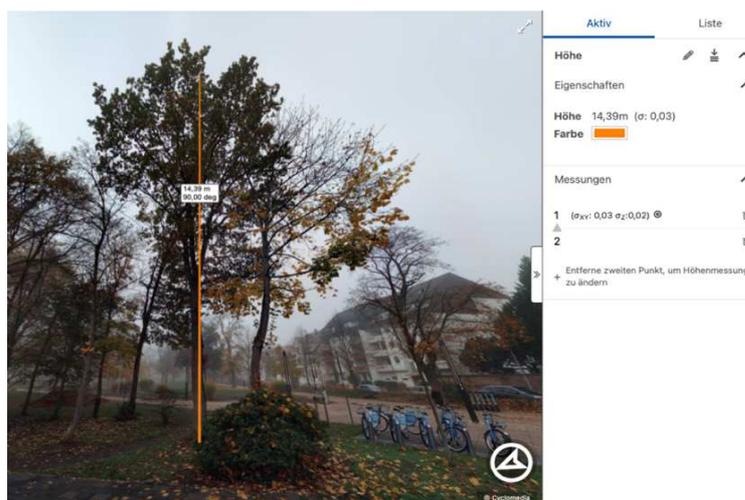
Messbare Merkmale wie Höhe, Stammdurchmesser und Kronendurchmesser können für Bäume, deren Position verfügbar ist, automatisiert aus den LiDaR-Daten errechnet werden (vgl. Abb. 6), die bei Straßenbefahrungen im Herbst 2021 erfasst wurden.


Abb. 6: Screenshot aus Cyclomedia mit der beispielhaften Messung der Höhe eines beliebigen Baumes

4.5 Bilden weiterer Deep-Learning-Modelle

Es sollen weitere Deep-Learning-Modelle gebildet werden, die eine Aussage über den Standort des Baumes treffen können: Steht dieser in einer Baumscheibe, einem Grünstreifen oder einer Grünanlage? Dies hat erheblichen Einfluss auf den Wasserbedarf des jeweiligen Baumes. In Baumscheiben sind arttypische

Wurzelausprägungen bis in die feuchteren Erdschichten hinein kaum möglich und werden durch Schutt im Untergrund sowie Medienträgern wie Rohre, Kabel und Leitungen zusätzlich erschwert.

		Merkmal	Beschreibung	Bemerkung	Priorität
In OSM	1	position	gegeben durch GPS-Koordinaten (Latitude, Longitude); in OSM auch Punkt oder Knoten	Die Präzision der Koordinaten ist für die Anwendung von KI relevant.	sehr hoch
	2	genus	Art; Sammelbegriff	kann aus (3) hergeleitet werden; in den meisten Use-Cases ausreichend	sehr hoch
	3	species	Gattung; Wissenschaftlicher Name	präziser, aber schwieriger zu bestimmen als (2)	mittel
	4	leaf_type	Laubbaum oder Nadelbaum	kann aus (2) hergeleitet werden	niedrig
	5	leaf_cycle	Beschreibt die Eigenschaft das Blattwerk abzuwerfen	kann aus (2) hergeleitet werden	niedrig
	6	est_height	geschätzte Höhe in Metern	falls keine genaue Angabe möglich	niedrig
	7	height	Höhe in Metern	relevant für Verschattung	hoch
	8	diameter_crown	Kronendurchmesser in Metern	relevant für Verschattung	mittel
	9	circumference	Stammumfang in Metern	kann aus (10) berechnet werden	niedrig
Weitere	10	diameter_trunk	Stammdurchmesser in Metern	kann aus (9) berechnet werden	niedrig
	11	standort	Umgebung des Baumes (Baumscheibe, Baumstreifen, Grünanlage)	relevant für Aussage über möglichen Trockenstress	hoch
	12	zustand	Gesundheitszustand des Baumes	kann nicht großflächig berechnet werden, da Trainingsdaten fehlen	keine
	13	sicherungsbedarf	Notwendigkeit Vorkehrungen zu treffen	kann nicht großflächig berechnet werden, da Trainingsdaten fehlen; unklare Rechtslage im Anwendungsfall	keine
	14	alter	Alter des Baumes	kann ggf. durch (2) und (7) geschätzt werden	niedrig
	15	standalter	Zeitpunkt der Pflanzung des Baumes am jetzigen Standort	zusätzliche Datenquellen sind nötig	keine
	16	besitz	Privatbesitz oder im Besitz der öffentlichen Hand	eine Verschneidung mit dem Liegenschaftskataster ist notwendig; relevant für die Sicherungspflicht	keine

Tabelle 1: Überblick Merkmale und ihre Priorisierung im Projektkontext

Die Erfassung dieses Merkmals kann also genutzt werden, um möglichen Trockenstress vorauszusagen und somit helfen, Priorisierungen beim Gießen von Stadtbäumen festzulegen.

Es gibt Merkmale, die in gut gepflegten Baumkatastern auftauchen und nicht leicht automatisiert auf Grundlage der bisher vorhandenen Datenquellen zu ergänzen sind. Dazu gehören Baumalter und Pflanzzeitpunkt. Ersteres könnte man anhand der Höhe und der Gattung grob abschätzen oder ein Intervall angeben. Zum Pflanzzeitpunkt könnten zusätzliche Datenquellen (z.B. Bebauungspläne) weitere Informationen bieten, wobei hierbei nur abgeschätzt werden kann, wann ein Baum frühestens gepflanzt wurde. Daher wird dieses Merkmal nicht berücksichtigt.

4.6 Einbezug der Zivilbevölkerung

Parallel zu den ersten Erprobungen und Verbesserungen der KI-Methoden wird eine nutzerfreundliche und intuitive Web-Anwendung entwickelt, die einen Einbeziehung interessierter Bürgerinnen und Bürger ermöglichen soll. Hierfür sollen diese unkompliziert weitere Merkmale ergänzen oder vorhandene editieren können. Das Nutzen weiterer Hilfsmittel wie Baumarten-Bestimmungsapps oder Messwerkzeuge bietet sich an. Fachkundige Personen sollen regelmäßig zur Einführung und Beratung zur Verfügung stehen.

In der Web-Anwendung werden ähnlich wie im Gieß-den-Kiez-Portal [Technologiestiftung Berlin] in einer Kartenansicht die vorhandenen Bäume angezeigt. Bei Auswahl einer dieser Punkte durch Anklicken öffnet sich ein Fenster mit zusätzlichen Informationen. Zudem soll es die Möglichkeit einer Registrierung geben, sodass nach einer Anmeldung die Möglichkeit besteht, Merkmale zu editieren oder zu ergänzen und Hinweise zu fehlenden oder gefällten Bäumen zu geben.

Initiiert und angeleitet von den Forschenden mit Unterstützung von Studierenden und Mitarbeitenden der Stadt, soll es regelmäßige Aktionstage geben, beispielsweise im Rahmen des bundesweiten Digitaltages, bei denen entweder vorhandene Merkmale kontrolliert oder neue Merkmale in der Web-Anwendung erfasst werden können. Jene könnten als Traininsggrundlage für weitere KI-Modelle dienen.

4.7 Übertragbarkeit, Evaluation und Pflege

Der Programmcode der Deep-Learning-Modelle und auch die trainierten Weights der Modelle sollen offen zur Verfügung gestellt werden, sodass andere Kommunen unter Nutzung der benötigten Datenquellen mit erheblich weniger Aufwand in der Lage sind, eigene digitale Baumkataster zu erstellen oder zu verbessern.

Des Weiteren kann durch Nutzung der Modelle mit zukünftig erfassten Daten ein Monitoring stattfinden, bei dem abgeglichen wird, welche Bäume ohne Vermerk im Baumkataster gefällt, gepflanzt oder ersetzt wurden.

Langfristig soll auch eine Evaluation der genutzten Methoden stattfinden: Wenn eine Aktualisierung der Baumhöhen anhand von Gattung, Ursprungshöhe und vergangener Zeit seit dem Erfassen der Höhe stattgefunden hat, soll ein Abgleich mit der tatsächlichen neuen Höhe stattfinden, so dass auch hier wiederum eine Verbesserung der Vorgehensweise vorgenommen werden kann.

5 ZUSAMMENFASSUNG UND AUSBLICK

Zusammenfassend ist festzustellen, dass sowohl die Erstellung als auch die Pflege eines qualitativ guten Baumkatasters eine aufwändige Arbeit ist, die jedoch vor allem im Angesicht des Klimawandels immer dringlicher und bedeutsamer wird. Ein digitales Baumkataster kann Mitarbeitenden von Kommunen helfen, Umwelt- und Klimaaspekte effektiver zu berücksichtigen und nachhaltigere Entscheidungen in der Stadtplanung zu treffen, indem z.B. geeignete Baumarten für entsprechende Standorte gewählt werden. Darüber hinaus bietet es Unterstützung bei der Voraussage von potentiellem Trockenstress, Verschattung und möglichen lufthygienischen Einflüssen bei bestimmten Wetterlagen. Durch die Einbeziehung von privaten Bäumen und die Ergänzung weiterer Merkmale wird das Baumkataster umfassender und nutzbarer für weiter reichende Anwendungsfälle aus der Wissenschaft.

Die (Weiter-)Entwicklung von Deep-Learning-Modellen erlaubt nicht nur eine Übertragung auf andere Kommunen, sondern auch eine regelmäßige Aktualisierung unter Anwendung von erneut erfassten Luft- und Panoramabildern. Dies ermöglicht überdies ein Monitoring der Datenpflege. Unter Verwendung geeigneter Schnittstellen, Portale und Web-Anwendungen sollen die Daten öffentlich zugänglich und editierbar sein.

Die Zusammenarbeit verschiedener Akteursgruppen aus der Forschung, der Verwaltung und der Bevölkerung ist zugleich herausfordernd und entscheidend für den Erfolg des Projekts. Eine transparente Kommunikation, die einfache Erklärungen und nachvollziehbare Gründe für eine Mitwirkung beinhaltet, ist hier unabdingbar.

Es ist überdies empfehlenswert, dass nach der Erprobung verschiedener KI-Modelle unter Anwendung auf unterschiedliche Datenbasen eine Evaluierung stattfindet, bei der Kriterien festgelegt werden, nach denen die zu verwendenden Daten und Modelle auszuwählen sind. Des Weiteren sollen einheitliche und vereinfachte Prozesse erstellt werden, wie eine Erfassung bzw. wiederkehrende Aktualisierung des Baumkatasters ablaufen kann und insbesondere wie mit fehlerhaften Ergebnissen aus den KI-Anwendungen umgegangen wird, die sich nie gänzlich vermeiden lassen. Eine weiterer großer Schritt, der noch umzusetzen und zu integrieren ist, wird der Umgang mit Baumgruppen sein.

1 ABSTRACT

Urban planning and design processes generally follow standardised procedures that have been tried and tested by generations of experts. However, due to the local context and changing framework conditions in each city and project site, processes always need to be adapted and result in unique planning histories that take into account the specific political, spatial, social, cultural and economic conditions of a place. Adverse circumstances might challenge ambitious process designs and lead to slimmed-down planning processes and unsatisfactory results, while an enabling environment can enrich the process and inspire the outcome. The reality, however, is not always black or white. There are multiple influential factors and it is the task of the planners not to lose sight of the goal and to use the circumstances in the best possible way to achieve high-quality design results. Urban design may be defined as "the process of providing quality contextual places for people" (Black & Sonbli 2019, 21). This indicates the contextuality of place and process and highlights the need to adapt to the local context in order to achieve an adequate result.

Within the framework of a consultancy for the European Bank for Reconstruction and Development (EBRD), an international and interdisciplinary planning team composed of architects, spatial planners, economists, and sustainable resource managers, made the effort to implement an integrated and participatory urban design process for two brownfield sites in Sarajevo. This paper explores the manifold challenges and obstacles that the team was confronted with and the creative approaches to overcome these hurdles. It takes a critical look at the adjustments in the process and the results, and gives an outlook and recommendations for the next steps towards implementation and development.

2 A CITY OF CONTRADICTIONS: SARAJEVO AND BEYOND

2.1 Political and administrative context and the lack of trust

The City of Sarajevo is the capital and largest city in Bosnia and Herzegovina (BiH) with a population estimated at 276,000 inhabitants, according to the latest census (Statistika, 2013). The area of the city is 141.5 km2 and it consists of four municipalities: Stari Grad, Centar Sarajevo, Novo Sarajevo, and Novi Grad. The city is represented by the Mayor of the City of Sarajevo and the City Assembly. Along with five other municipalities, it is part of Sarajevo Canton, which has its own legislative, executive and judiciary powers. It is governed by the Assembly of the Canton and the Prime Minister. Moreover, every municipality has its own Municipal Mayor and Municipal Assembly. The complex hierarchy of this governance system is reflected in all spatial processes and jurisdiction is often (mis)used in the planning of the city's development and urban growth.

The complex political-administrative structure of the Canton of Sarajevo, which is reflected in the management of the city itself, resonates at all levels of government, and complicates the management of the city, its territories and resources (Zupcevic & Causevic 2009). The frequent overlapping of responsibilities and the exclusion of certain levels from responsibilities, often supported by unclear or conflicting legal regulations, reduces public confidence in the abilities and intentions of those involved in management processes. The spatial planning authorities are particularly challenged, since private capital has been driving construction activities rapidly since the political system change, while strategic planning can hardly keep up with the definition of the necessary framework conditions.

Under these circumstances, and in view of the post-war reconstruction of the city, non-transparent developments of large spatial reserves were carried out, mostly at the sites of former industrial areas, but also in the central urban fabric, which shook trust in both political and professional goodwill of the actors involved (Tzifakis & Tsardanidis 2006). In many cases, planning documents were changed on investors' requests without the participation of the public. This was facilitated by the law on spatial planning at the time, which gave Municipal Mayors the opportunity to change existing planning documents through abbreviated procedures and for individual locations without holding a public hearing and presentation (Spatial Planning Act, Canton Sarajevo Gazette, 7/05, Article 46). Real estate developments without a legal basis or contrary to valid planning documents were not uncommon either.

Over the past two decades, the development of Sarajevo has led to the creation of large shopping centres and monofunctional residential areas. Unfortunately, many of these projects failed to comply with basic urban planning parameters, neglecting important factors such as fire safety standards, road width, and lighting. Private investments dominated the real estate sector, as public institutions lacked the capacity to actively participate in real estate development. Limited public budgets, the need to invest in socio-economic measures, and the absence of a resident-focused development strategy have profoundly influenced urban development in Sarajevo. Furthermore, the city's urban planning has been characterised by a lack of vision and strategy, driven by the imitation of global and regional trends, such as the separation of functions and a car-centric approach. Planning regulations often prioritised these trends rather than considering local potentials and the overall quality of life for Sarajevo's residents.

The wider public and planning professionals had limited influence on urban development in Sarajevo due to prevailing circumstances. Following the war, private ownership took precedence over public ownership, with land becoming a valuable asset for obtaining investment benefits. Consequently, private investors wield significant influence, sometimes overshadowing the concerns of the wider public and planning experts. This has led to a loss of faith in effective spatial planning, as responsible institutions often prioritise meeting the desires of investors over improving residents' quality of life (Botic 2013). Although current urban planning legislation recognizes public involvement, participation typically occurs towards the end of design processes, and public hearings often serve as justification for changes that have already been decided upon.

2.2 Environmental challenges and the new urban plan

At the same time, the Sarajevo urban area faces pressing challenges amidst multiple crises like climate change and social division. The quality of housing has declined and although the number of units its steadily growing, there is a lack of affordable housing for middle- and low-income groups. Public spaces and social infrastructure are lacking in existing and new settlements. Environmental problems, such as air pollution, worsen due to high private car usage and reliance on wood and coal for heating. Authorities' efforts to address these issues are slowly entering public discourse, but time and initiatives are needed for noticeable changes in daily life (Hewlett & Gallego-Lopez 2020).

Sarajevo's location in the valley allows only limited air flow, leading to frequent smog, particularly during winter months. Within the urban fabric, specific areas are more susceptible to pollution, causing significant impacts on the surrounding regions. Historical urban planning documents, spanning from the 1960s to the 1980s, acknowledged the importance of mitigating winter smog by implementing measures such as city gasification, promoting sustainable public transportation, and imposing height limitations in the central area where the valley is narrowest. However, as urban growth intensified in the 2000s, these policies proved insufficient to accommodate the pressures of urban growth. Irregular developments on vacant lots and abandoned industrial sites further exacerbated the environmental conditions in Sarajevo. Buildings of unfavourable height and position further impair the already problematic state of Sarajevo's air pollution.

The change in perspective and new understanding of social, economic and ecological urban needs are reflected in some important documents that have been developed over the last few years and are also used in preparation for the new Urban Plan. The Study on Ventilation Corridors was developed along with the Green Cantonal Action Plan for Sarajevo in 2020 (Hewlett & Gallego-Lopez 2020). The document proposes regulations for the positioning and height of the buildings along the main ventilation corridors in the city and has been adopted by the Government. The planning and construction needs of the Canton and the City of Sarajevo are subject of a new Urban Plan, which is currently being drafted. The last Urban Plan was created in 1986 and has long become inadequate and ineffective to address contemporary urban challenges. The lack

74

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

of a high-quality urban strategy was consequently reflected in the detailed planning documents (regulatory plans, urban projects), which were supposed to be based on the overall Urban Plan. However, the ongoing process of developing a new Urban Plan is leading to a number of problems as several major development projects in the city are halted awaiting its adoption. In such a stalemate, all efforts to activate and improve the urban space depend on the willingness of decision-makers to act and advocate for the incorporation of new solutions into the Urban Plan and their subsequent elaboration within the detailed planning documents. At this point of time, planning is a matter of building trust between the profession, the public, decision makers and investors, which requires a great deal of skill and time, as well as a change in the mindset of all stakeholders involved.

2.3 Brownfields as a potential for polycentric development

During the after-war period, large areas of former industrial complexes were abandoned. The regeneration of these brownfield sites holds great potential for future urban development and the emergence of new qualities in Sarajevo. In times of high land use and rapid soil sealing in the urban peripheries, brownfields represent an attractive opportunity to enable urban growth in a more sustainable way. Additionally, most brownfield sites already have access to basic infrastructure such as water, electricity and sewer connections. Due to the city's expansion over time, many brownfields in Sarajevo are located in high-density environments and in central positions within the city area today. The regeneration of these sites and a general focus of urban development activities on urban voids are significant in order to prevent urban sprawl and to generate a city of adequate density.

The development of brownfield sites in Sarajevo also offers the potential to create new mixed-use centralities in a largely monofunctional urban fabric that evolved along the valley and has its main administrative centre and business hub around the old town in the east. As a growing city, it is time for Sarajevo to develop new urban centres that fulfil multiple functions, offer job opportunities as well as recreational spaces, educational and cultural institutions. In a polycentric vision of the city, the numerous brownfield sites across the urban tissue are anchor points and incubators for such developments. The elaboration of a clear vision for Sarajevo's brownfield sites is crucial in order to induce the release of these high-potential land and encourage investments in their development.

The task of developing two brownfield sites in Sarajevo was at the beginning of the planning team's intense interaction with the city. Against the background of a complex political and administrative situation and a general lack of trust in urban planning processes, it was crucial to apply a professional approach, a transparent planning process and comprehensible, fact-based decision making.

3 CREATING TRUST THROUGH COMPREHENSIBLE PLANNING

3.1 Application of a good practice urban design process

Although each urban design process is unique in its procedure and outcomes, there is a broad consensus in scholarship and practice as to what basic stages should be followed (cf. Black & Sonbli 2019, Carmona 2013, Lloyd-Jones 2001). In order to create "quality contextual places for people", the design process should start with a multi-layer analysis that includes the urban context on different spatial scales as well as the policy framework and socio-demographic aspects. Based on the findings, a strategic design framework is developed. It informs the development of the design through concepts and scenarios before acting as an evaluation matrix for the outcomes. The design phase as such is circular rather than linear as it reverts to the concept through several evaluation loops and should be tested by local stakeholders. The stage of delivery and implementation adds another layer to the design that needs to remain flexible and adapt to the various demands that arise during realisation (Black & Sonbli 2019). The design process is rational and experimental, it works through a process of deduction, where a design solution is an early hypothesis to be tested, drawing on pre-existing models and exposing it to multiple realities (Lloyd-Jones 2001). It is important to stress that the designers do not act in isolation but are exposed to power relations that shape the process and its outcomes through agency and political structures. The history of place and the contemporary political situation influence the process along with numerous stakeholders ranging from policy makers, investors, space users, etc (Carmona 2013). Acknowledging the importance of all these actors is the first step towards enabling participatory design processes. The inclusion of local stakeholders in planning processes

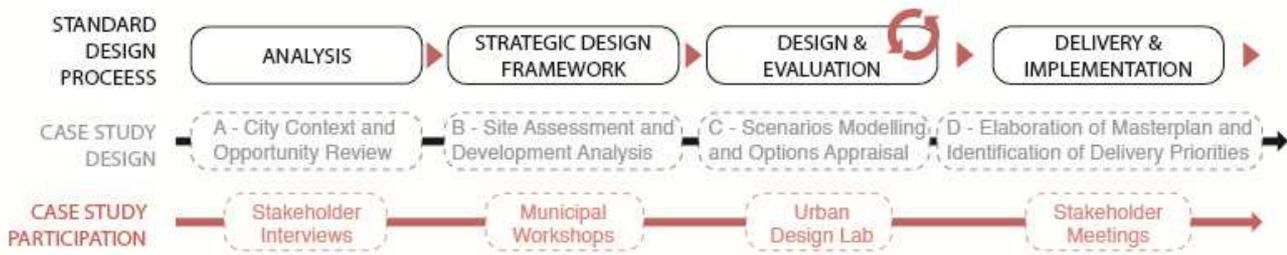
has steadily increased in recent decades and numerous tools for co-creation and participatory design have been developed that can be integrated into tried and tested processes (cf. Krebs & Mayr 2023, 550ff.).


Fig. 1: Stages of a standard urban design process as compared to the case study in Sarajevo. Source: Author's own figure based on Black & Sonbli 2019.

In Sarajevo, the work process was organised in four main phases. The first task was to understand the urban context of Sarajevo and review the many opportunities for brownfield development that the city had to offer. The result of a multi-criteria analysis of 24 brownfield sites was the selection of two target sites for further analysis and development: Kvadrant B in Marijn Dvor and the former Central Railway Workshop Vaso Miskin Crni (VMC) in Novo Sarajevo.

Kvadrant B is an eight hectare central location in the city of Sarajevo. The area is partially developed with new shopping malls, business buildings and services and is part of the city's new business and public centre, with old heritage buildings from the Austro-Hungarian period which are currently in private ownership. The rest of the site, near the Miljacka River, is used as a parking space, owned by the Canton of Sarajevo. The connection to the public transport system and the road network is excellent and high density surroundings are a good precondition for the implementation of mixed uses in the area. The redevelopment of the site has been subject of discussion for over 20 years and has evolved to a controversial topic.

The former Central Railway Workshop Vaso Miskin Crni was partially and poorly transformed into shopping malls after the 90s. The twelve hectare site is centrally located, with good connection to all the main traffic lines and the tram line in walking distance. It consists of both newly built facilities as well as old warehouses, which are currently abandoned. The central location and the high-density surrounding form an ideal condition for the implementation of a mixed-use neighbourhood. The high number of involved owners, among which there are both private and public entities, is a challenge to the development of the site.

The selected brownfield sites were assessed and a spatial analysis was carried out. In parallel, a Real Estate Demand Study was prepared to inform the planning process and decision-making. In order to test development opportunities, different spatial and mixed-use scenarios were drafted for both sites. They were discussed with the Working Group comprising representatives from all involved administrative levels to agree on the way forward. In parallel, the Sarajevo Urban Design Lab was conducted. The program included a series of academic workshops, public events, and stakeholder meetings that enabled a broader discussion about brownfield development in Sarajevo. At the same time, the different mixed-use scenarios for both project sites were evaluated, and their financial viability assessed against the backdrop of the previously conducted market analysis. A microclimate simulation analysed the impact of the design on the immediate environment in terms of heat and wind effects. Finally, clear design visions were developed for Vaso Miskin Crni and Kvadrant B, including a detailed design strategy, technical information, infrastructure plans, as well as environmental and social impact appraisals. The final design also made a strong case for the benefits of the proposed projects from the perspectives of urban regeneration and sustainable 'green' development.

The process was carried out by an interdisciplinary team of architects and urbanists, environmental and financial experts, as well as trained participation specialists. The clear process designed on the onset of the project increased transparency and provided a flexible and holistic approach where each stage informed the other. The clear structure was the basis for the involvement of public and private stakeholders throughout the process and promoted the trust and accountability needed in the Sarajevo context.

The following sections go into more detail on some of the components of the design process that were particularly important in order to respond to the diverse challenges we encountered in Sarajevo: public participation, market demand, sustainable urban design, microclimate simulations and land consolidation.

76

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3.2 Public participation in a complex environment

The concept of public participation is often explained along Sherry Arnstein's ladder of participation (1969). The model describes eight levels of participation ranging from manipulation to information and partnership all the way up to citizen control which is presented as the ultimate form of participation. This conception of citizen involvement, however, has also been criticised. Collins and Ison suggest that "[T]he linear conceptualization of participation does little to emphasise the importance of either the process or the existence of feedback loops, which shape understandings of the situation" (2009, 362). While a high level of public involvement is generally desirable, it is questioned to what extent power should be shifted from elected decision makers to small groups of people who have the capacity to engage. Moreover, the possibilities and range of participation vary according to the design question, scale of the problem, and local context. Therefore, the level, range and tools of public participation must be adapted to the specific parameters of each project.

In the case of Sarajevo, public participation in planning processes is usually limited to the legally required public hearings prior to adoption of a planning document. Involvement of local stakeholders throughout a design process is rare or virtually non-existent. There is, however, an emerging public interest in the spatial development of the city. Driven by the professional and academic community a public discourse on urban development is developing, which criticises the undesirable developments of the past and calls for a new style in urban planning. The focus is on issues such as quality of life, public space and social participation, while issues of sustainability and resilience are less present. Both selected brownfield sites have been in the focus of public attention for a while due to specific developments and expectations related to them. At the same time, there is limited experience with public participation processes and a lack of trust in the system of political decision making. This challenging situation is further complicated through the powerful position of private landowners and investors who try to influence the public discourse to their advantage.

In the midst of this complex situation, the planning team for the development of Kvadrant B and Vaso Miskin Crni endeavoured to involve decision makers, experts and the public in the planning process. In a first step, and in order to take account of the multilayered administrative and political situation, a Working Group was set up. Members of this group included representatives and decision makers of all administrative levels included in the planning process: Catnon, City and the Municipalities. Regular meetings with this group formed the basis for transparent communication across administrative boundaries and hierarchies and aimed to achieve broad political support for the developed design proposals.

In a stakeholder analysis, the planning team identified key players in the professional and academic field of planners and architects in Sarajevo who should be involved in the process in order to contribute their expertise and act as multipliers to make the discussion accessible to a broader public. The Stakeholder Core Group comprised experts and academics, representatives of the Association of Architects in BiH (AABH), and local practitioners. They were invited to planning workshops to discuss ideas for urban design, functions and possibilities for implementation. Additionally, interviews were conducted with selected stakeholders from different fields of expertise related to the economic, spatial, and socio-cultural development of the city.

The centre piece of participation and exchange was the four-day Urban Design Lab (UDL), which was carried out in cooperation with the University of Sarajevo. It included an urban design workshop with local students on both project sites, professional workshops with municipal staff and the Stakeholder Core Group, as well as public events like a movie night, panel discussion, and final presentation of the academic workshop. Since the urban design process was on a mere conceptual stage, the idea was to reach out to a wider public while staying in a professional context. The events were advertised through the networks of the University, AABH and Days of Architecture, a local architecture festival. The professional exchange during the UDL was very valuable for the design process and supported the development of robust masterplans that would respond to the urban context and local needs. The participation process also revealed broad support for the work of an 'external' planning team that would bring in new ideas and possible solutions to the development of two sites that have been much discussed and disputed in the past.

The entire planning process was thoroughly documented and the results were submitted for the National Architecture Award (Collegium Artisticum). It was selected as winner in the category urbanism and presented in a public exhibition. Moreover, the project report was published by the University of Sarajevo with a clear presentation of the design process and full disclosure of all plans and development proposals

(Krebs & Pavlović 2023). The planning team has thus guaranteed a maximum degree of transparency on the process and its results. It is now up to the political decision makers to initiate implementation and involve the public in a continued discourse on the design and its realisation in the urban context.

3.3 Market demand study and financial analysis

The aim of the market demand study and financial analysis was to understand the current situation of the real estate market in Sarajevo in order to base the design proposal on actual needs and respond to adverse trends. The approach was chosen in response to the uncoordinated real estate development of the last decades that has led to monofunctional housing estates on the urban fringes and underused spaces across the urban fabric.

As a first step, a detailed market demand analysis was prepared to understand the investment and development activity and trends in each real estate segment (residential, office, hotel and retail market) in Sarajevo and BiH. One of the key findings was that due to the unavailability of large lands for development within the urban fabric, most new development is on the suburban, greenfield land. The migration of residents to the outskirts resulted in the need for expansion of the city's infrastructure (communal infrastructure such as roads, sewerage, pedestrian paths etc.). In addition, the remote location of the new suburban neighbourhoods leads to long commutes to the downtown business district every day, mostly by car. This has a negative impact on the quality of air due to high CO_2 emissions. Furthermore, the distance of the new residential neighbourhoods to main public facilities (e.g. hospitals, schools, elderly homes etc.) and lack of mixed uses exacerbates social exclusion. The market demand study supported the case for regeneration of central dormant brownfield sites such as Vaso Miskin Crni and Kvadrant B. The two selected sites have access to the communal infrastructure (roads, public transportation – tram and bus lines, access to sewerage, electricity, water, telecommunication etc.) and they are close to the central business district and public institutions. In case of a reuse of the brownfield sites the greenfields might remain undeveloped and pollution could be decreased and social inclusion ensured. Moreover, given the sites' central location and connectivity, the utilisation of the existing urban infrastructure would be improved (more users and direct and indirect financial benefits).

Based on a detailed market research and analysis of the location of the two selected sites and their characteristics, a highest and best use analysis was conducted. The key conclusions of the analysis supported the elaboration of mixed-use concepts and project phasing schemes. Due to the vast size of the Vaso Miskin Crni site, one of the key recommendations was to keep an element of flexibility in the future planning documents to create the opportunity for a sustainable economic development rather than prescribing the long-term redevelopment according to short-term market projections (Bacon et al. 2008).

Finally, a financial case using a discounted cash flow method was prepared based on the development ratios and vision from the proposed masterplan. The financial case assessed financial feasibility and viability of the proposed concept. The quantification went beyond the typical investment return ratios. An estimation of the favourable environmental implications for the proposed development was also conducted. Some of the analysed implications were obtained by assuming the surface of public greenery per inhabitant and employee, estimating the reduced commute time and quantity of fewer CO_2 emissions.

3.4 Sustainable urban design and smart city innovation

Based on the spatial analysis, inputs from participation, financial considerations and other relevant factors, a robust urban design was developed for both sites as a first proposal for further elaboration.

The site of Kvadrant B is envisioned to be developed as a new business centre that incorporates mixed uses to create a lively and attractive neighbourhood. Ground floor areas will host shops, services, cafes, and restaurants, reviving the streets and public spaces of the area. The inclusion of a variety of new central functions will further support the implementation of business and retail uses. The concert hall which has been anticipated for the past 20 years will be taken into account with a designated plot that is temporarily used as a public park. Moreover, a significant percentage of high-quality housing should be present on site to counteract the decreasing number of residents in the central area of the city. The new urban structure responds to the Austro-Hungarian urban pattern in the east of the site and continues the typical block perimeter system. Existing heritage buildings shall be preserved and restored while the structure of new buildings will gradually transition towards the modernist buildings in the west, organically filling the gap in the urban fabric. Building heights develop with the typology, rising from east to west with a high point next

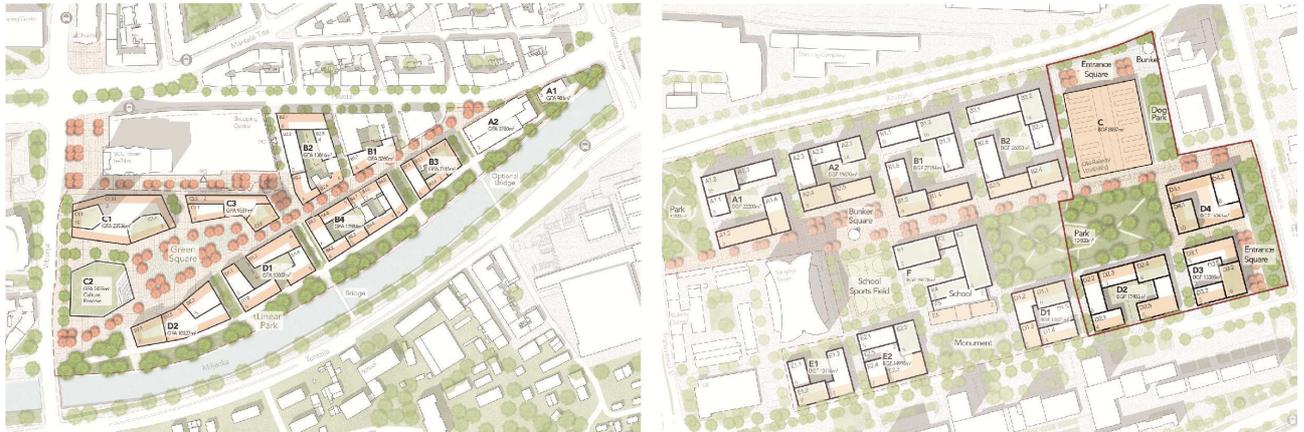
to the existing tower of the Sarajevo City Center. The area along the river will be transformed into a linear park providing a high-quality green space. The centre of the neighbourhood will be a new green square with multifunctional urban surfaces but many trees to provide shade and cool down the environment during hot summer months.


Fig. 2: Development propositions for Kvadrant B (left) and Vaso Miskin Crni (right). Author's own figure.

Vaso Miskin Crni could be redeveloped as a new centrality of Novo Sarajevo that integrates central functions which are currently missing. The development of a mixed-use neighbourhood will include offices, retail, housing, and social infrastructure in a balanced ratio that responds to market demands and establishes an urban business centre. Integrating active uses, like restaurants, cafes, and shops, in the ground floor zones of the buildings will be crucial in order to create a lively centrality that meets the demands of people working, living and seeking leisure in the area. The new urban fabric respects the industrial heritage of the site while responding to surrounding structures. It is recommended to keep two buildings of the old Railway Workshop as valuable assets that preserve the identity of the site. The form of the old production hall was picked up and replicated to shape the urban grid along the east-west axis. The predominant typology is a modern block development with green courtyards. The denser blocks in the southeast of the site have continuous plinths that provide larger spaces for retail and urban workshops. The general building height is five floors with selected high points of up to 16 floors. The main public space is the one-hectare park in the centre of the neighbourhood. It will be designed to fulfil the diverse needs of the new inhabitants and people working or studying in the area. The main east-west axis will be another important public space. Designed as a pedestrian boulevard with shops, cafés, and restaurants along the building fronts, it will be the vibrant spine of the neighbourhood.

With the development of the two brownfields, Sarajevo has the opportunity to implement flagship projects for smart and environmentally friendly urban development. However, sustainable urban development is a long-term transformation process that adds an extra layer of complexity to already complex urban design processes (Thompson 2016). In order to establish an innovative ecosystem in a smart city, numerous stakeholders need to be coordinated. Sophisticated governance with a long-term planning horizon is required, where tasks include management, decision-making and implementation, but also communication and creating transparency and opportunities for participation (Appio et al. 2019). In 2018, the City of Sarajevo launched a Smart City Initiative, developing a vision for Smart Sarajevo 2030. Initial projects have been implemented since, however, a legally binding and comprehensive Smart City Strategy has not been established yet. Measures against air pollution are a top priority in Sarajevo. Hence, reducing road traffic and promoting renewable energy provision and green spaces are the fields to be tackled in any urban development project. Considering the local challenges, the lack of a holistic strategy, insufficient sustainability standards in the building sector and limited public budgets, the recommended Smart City measures for the two brownfield developments focus on affordable innovations in the fields of renewable energy and energy efficiency, sustainable mobility solutions and green city.

The introduction of sustainable building standards in both development areas could be a lever to reduce the high energy demand for heating and cooling and is a prerequisite for shifting energy supply to local renewable energy sources such as district heating, geothermal and photovoltaic energy. Since green building certifications are not yet standard in BiH, the brownfields could be presented as lighthouse projects to be

scaled up in the future. The use of state-of-the-art building rating systems could also become mandatory in quality assurance and create transparency, which in turn supports the trustmaking process. Regarding the costs, which are an obstacle in the implementation of sustainable building standards, investors have to expect an additional 100 euros per square metre of net floor area or a total additional investment cost of 7 percent (Schöfmann et al. 2020; Hu & Skibniewski 2021) . On the other hand, the operating costs over the life cycle of a building can be reduced by up to 85 percent (Architektur Online 2020).

Sarajevo's path towards becoming a pedestrian and bicycle-friendly city requires the reduction of motorised vehicles and the promotion of active mobility with attractive public transport and supplementary micro-mobility offers (Appio et al. 2019). The establishment of car-free neighbourhoods with neighbourhood garages at the edge of the area with e-charging infrastructure and a general reduction of parking obligations for project developers have been recommended. Adequate bicycle infrastructure inside and outside the buildings (lockable bicycle parking, etc.) should be implemented. Sharing systems (bicycles, e-cars) can be a valuable complement to the use of public transport, but should be implemented on a city-wide level. Public transport remains by far the most energy-efficient mode of transport for daily use.

Air quality is a top priority in Sarajevo, so developers should prioritise green city solutions and create resilient urban spaces. Landscape planning should be integrated early and throughout the development process to be cost-effective. Greening and shading of public spaces are the most effective measures to avoid urban heat islands in the long term. Intensive planting (trees, façade greening) also has positive effects on the microclimate. Trees with a high crown density can reduce the perceived temperature by up to 18°C during the summertime (Stangl et al. 2019). In addition to heat, heavy rainfall is also one of the noticeable effects of climate change, so the implementation of comprehensive rainwater management is strongly recommended.

3.5 Microclimate analysis

The impact of wind and its relationship to temperature is crucial in a topographical valley like Sarajevo due to the high probability of the Inversion Weather Phenomenon (Walczak 2023). In order to understand and quantify the current urban situation and potential future projects, different simulation frameworks can be applied. "Rhinoceros 3D" with the algorithmic modelling extension of "Grasshopper 3D" allows a real-time bridge between qualitative 3D modelling (architecture and urban design) and quantitative simulation frameworks.

On the one hand, these tools were used to simulate temperature during a period representing the hottest week of the typical meteorological year. As input, historic weather files from the years 2007 to 2021 were used from the location of the International Airport in Sarajevo (Climate OneBuilding 2023). On the other hand Computational Fluid Dynamics (CFD) wind simulations were run through "OpenFOAM" cases. "OpenFOAM" is an open-source CFD software and has an extensive range of features to solve, among others, complex fluid flows and turbulences, which has been made accessible through the "blueCFD-Core" project (Walczak 2023). The simulation results have been calibrated and validated in Sarajevo through on-site 3D wind measurements using a mobile Galion LIDAR system "windRoverII" (Walczak 2023), as part of the 4D Digital Twin for Sarajevo developed within the "Urban Transformation Project Sarajevo - UTPS" (Walczak & Pagani 2022). Additionally, both frameworks required information on building volumes, facade materials, roofs and public spaces, as well as the location of vegetation.

Through an iterative process and fast visual feedback mechanisms, multiple scenarios were gradually tested and translated into the architecture and urban design of both brownfield sites. Challenges and opportunities included strategies in larger open spaces regarding urban heat islands and their mitigation through vegetation and non-sealed surfaces. Related specifically to wind, urban design features such as porosity in building volumes, the linear orientation following the wind direction and heterogenous building heights support urban ventilation and natural cooling. Also, the incorporation of water bodies and river streams is benefitting cold air streams.

As an outlook, conclusion and policy recommendation, for resilient planning and implementation, each regulatory plan would require such an analysis since the climatic boundary conditions are changing with every intervention (Pelja-Tabori 2021) .

80

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3.6 Towards implementation: ideas for land consolidation

Early phases of analysis have revealed complex ownership structures at both sites. Plot sizes range from very small to very large parcels with a diverse mix of more than twenty different landowners on each site. The largest shares are owned by private companies, followed by different public institutions and individual private landowners. In both cases, the complex ownership situation has been the main reason why a coordinated overall development has not taken place in the past. While large private owners have shown their interest and were willing to buy the parcels of smaller owners, the latter are hoping for higher returns and better opportunities at a later point. Public owners and the local administrations have not yet developed the necessary tools to facilitate and lead the development either.

The study of good practice cases from Vienna, however, offered solutions that could also be feasible for Sarajevo. The central tool for land consolidation would be a cooperation agreement in the form of an Urban Development Contract between all private and public owners that is based on a consensus about the masterplan for development and future cadastre plan of the area. The new cadastre plan redistributes the land according to their value after development. Landowners would own the same share of net gross floor area compared to the percentage of land that they own now. This ensures an equal distribution of the profit that arises from development. At the same time, selected land parcels would be transferred to public ownership to provide access roads, public parks, social infrastructures, etc. These assets are an added value to other landowners who can sell their properties for higher prices due to enhanced amenities in the surroundings. At the same time, they guarantee basic services and improve quality of life also for the people living around the site. The cooperation agreement also includes the founding of a joint Development Corporation that leads the development process from this point on, coordinating all stakeholders and implementing the masterplan as agreed.

The Vienna model of land consolidation has been presented to the local public authorities who showed interest in the approach. Major landowners were contacted to assess their willingness to cooperate in such a process. Overall there have been positive reactions but there were also concerns in relation to the transparency of such processes. The need to create and maintain public trust and to include the wider public in decision making processes related to both brownfield sites that represent key locations in the urban fabric was emphasised. However, the coordination of such a process through international and independent experts was seen as a potential to overcome such obstacles and to move towards implementation of sustainable, mixed-use neighbourhoods in Vaso Miskin Crni and Kvadrant B.

4 CONCLUSION

The elaboration of development proposals for Kvadrant B and Vaso Miskin Crni took place in the field of tension between the interests of different political and administrative levels, landowners and the public, as well as the contemporary demands on modern urban planning, which result from the climate and biodiversity crisis, social inequality and economic development requirements. The textbook approach to urban design was adapted and enhanced to meet the specific challenges that the City of Sarajevo presented to the planning team.

The complex political and administrative system and the lack of trust in public authorities were addressed through a transparent and comprehensible planning process where each step was a logical consequence of previous analysis and which was fully disclosed through a publication that covers the entire design process and final results. Local experts, academia and the professional public were included through the Stakeholder Core Group and open event formats reached out to a wider public for the discussion of concepts and design principles. The many layers of administration were involved in the process through the Working Group that was regularly informed and invited to participate in the design process through co-creative workshops.

The predominant role of developers in urban development in Sarajevo and complex ownership structures on the selected brownfield sites were tackled through the empowerment of the local administration in the Working Group that enhanced their internal cooperation and influence on the design process. At the same time, a comprehensive real estate demand study ensured that the recommended mix of uses was based on empirical facts rather than on personal financial interests or public misconceptions of the situation. The proposed land consolidation approach represents a possible solution for the problem of implementation and the possibility of further independent consultation by the international team has been offered.

Environmental and social challenges can be met through innovative design ideas and smart city approaches that were adopted to the local circumstances and potentials. The microclimate analysis is a new tool to refine urban design that has been used for the first time in Sarajevo and has proven the compatibility of the urban design proposal with the demands of the ventilation corridors. Some suggestions from this work could also find their way into the new urban plan currently being developed.

Overall, the aim of the design process was to elaborate sustainable, resilient and climate-fit development proposals for brownfield sites in Sarajevo and to showcase a design and possible implementation process that could be replicated in other urban voids throughout the city in order to create a polycentric city of short distances. Of course, the team's efforts cannot cease at this point and it will take much more work with a specific focus on stakeholder engagement, public consultation and transparent cooperation with landowners to move these projects towards implementation and "quality contextual places for people".

1 ABSTRACT

Urban heat islands are a frequent phenomenon that significantly impacts liveability and human well-being. The ongoing research aims to provide an updated map of Tessin Canton's critical spatial and thematic areas in Switzerland. Furthermore, the objective is to investigate the level of performance of the current guidelines and provide indications to ensure a greater level of sustainability in the urban planning of cities.

In adapting to climate change, the Swiss Confederation established an action plan for 2020-2025 comprising 75 measures. This intersectoral coordination document provides the cantons and municipalities with practical actions for tackling climate change.

The research stems from a holistic view of the south of the Alps heat island phenomenon through an interdisciplinary and multiscalar approach. Therefore, the attention is on the trend of summer temperatures, particularly on days of heatwave. Furthermore, the study verifies the effects of the nature-based solutions adopted in the territory. In this way, it evaluates the impact of the measures in the action plan and the variables that most affect human well-being.

The study is developed in three consecutive phases based on the literature and the work carried out by the Federal Office for the Environment (UFAM). First, the available satellite images calculated the Land Surface Temperature (LST) and the perceived temperature (PET). Integrating these results with geospatial, demographic and settlement data has made it possible to identify the most sensitive areas of Tessin Canton.

In the next phase, the liveability in the heat islands was investigated. Various instruments (sensors, Climametro and thermal imaging camera) were used to analyse the climatic data and the data on the built environment in the urban area of Mendrisio, a city in the south.

In the third phase, the main aim was to verify the urban microclimate and provide valuable indications for the definition of a sustainable city. Therefore, the relationships between land use, urban typologies and abiotic nature were investigated.

The results of the ongoing research concern extending the heat islands of the Tessin Canton and evaluating the effects of the measures promoted by the UFAM. The next phase will allow for an in-depth study of the role of surface and groundwater in urban areas and valley floors. The aim is to provide further indications for implementing the sponge-city concept.

The ongoing study is possible thanks to the synergies between the University of Applied Sciences and Arts of Southern Switzerland and the Republic of Tessin Canton. The results obtained greatly help provide guidelines for sustainable territorial planning that is attentive to human well-being.

Keywords: climate change, abiotic natures, urban microclimate, heat islands, Tessin canton

2 ADAPTATION TO CLIMATE CHANGE IN SWITZERLAND

In Switzerland, the Confederation has a coordinated role in climate change adaptation. The action plan for 2020-2025[1] currently in force consists of 75 interdisciplinary measures, which are in continuity with the 2012 strategy and the 2014-2019 action plan. The goal is to coordinate the actions put in place and prepare the necessary to face the challenges of climate change.

Based on the work carried out by the UFAM[2] and the literature on heat islands, the ongoing project started in 2020. The objectives were defined by an interdisciplinary team of SUPSI and the Department of the Territory of Tessin Canton.

---

[1] "Adattamento ai cambiamenti climatici in Svizzera. Piano d'azione 2020–2025".
[2] Federal Office for the Environment.

The project aims to map heat islands in Tessin Canton. In 2022, IPCC[3] defined the UHI[4] as "The relative warmth of a city compared with surrounding rural areas, associated with heat-trapping due to land use, the configuration and design of the built environment, including street layout and building size, the heat-absorbing properties of urban building materials, reduced ventilation, reduced greenery and water features, and domestic and industrial heat emissions generated directly from human activities".

The second objective is to investigate the perception of temperature within urban typologies. This aim allowed the study to obtain two other results. First, analyze the abiotic measures of the federal action plan in terms of performance. Furthermore, the study provided indications to improve the urban microclimate and gain greater sustainability in the urban planning of cities.

3 IDENTIFY HEAT ISLANDS

The research stems from a holistic view of heat island phenomenon through an interdisciplinary and multiscalar approach. Therefore, the attention is on the trend of summer temperatures, particularly on days of the heatwave.

The study is developed in three consecutive phases. During the first phase, the most problematic areas of the Tessin Canton were identified through the analysis of satellite data of the surface temperature. In addition to the impact of heat on the cantonal territory, it was essential to have information on the territory. Therefore, the study required information about the conformation of the territory to understand how it can absorb, reflect or reduce heat. At last, Canton's available territorial and demographic variables were needed to choose the relevant ones to identify the areas where the heat can produce the most significant impact on the territory and among the population.

3.1 The surface temperature and the perceived temperature

The first data analyzed were satellite data of the earth's surface temperature. The LST[5] is the temperature measured at the level of the earth's surface. According to Anderson et al., the LST is one of the most important parameters in the physical processes of surface energy and water balance at local through global scales.[6] Simplifying, it is not equivalent to the air temperature but to the temperature perceptible by touching a given surface.

The first step used an indicator that associates other variables with temperature to understand how environmental conditions affect people's well-being. It is the Physiologically Equivalent Temperature. According to Höppe, PET[7] is defined as the air temperature at which, in a typical indoor setting (without wind and solar radiation), the heat budget of the human body is balanced with the same core and skin temperature as under the complex outdoor conditions to be assessed.[8]

From a human bioclimatological point of view, it indicates the feeling of aphasia. The point was that people's thermal perception changes more rapidly than changes in air temperature. Matzarakis et al.[9] confirmed that the PET, expressed in °C, is a suitable indicator for the human-biometeorological evaluation of the thermal component of different climates.

After acquiring the LST values from satellite measurements[10], the maps of the perceived temperature were drawn up using a mathematical model based on the formula developed for the city of Dresden.[11] An initial check was carried out to validate the calculated PET. The case study was the Mendrisiotto Region, with the temperatures measured and the data acquired using the Climameter (see chapter 4.3).

[11] "Risiken beherrschen, Chancen nutzen. Die Region Dresden stellt sich dem Klimawandel".

Based on the available data, it was possible to produce three representations of the heat islands extension in Tessin Canton. The first map concerns the average extension of the heat islands on heat days with an average temperature above 25°. The second map identified the extent of heat islands during extreme weather events, such as in the summer of 2022, when the temperature exceeded 25° for two weeks. The maps underline that in addition to the more inhabited areas, there is an increase in temperature also on the valley sides.

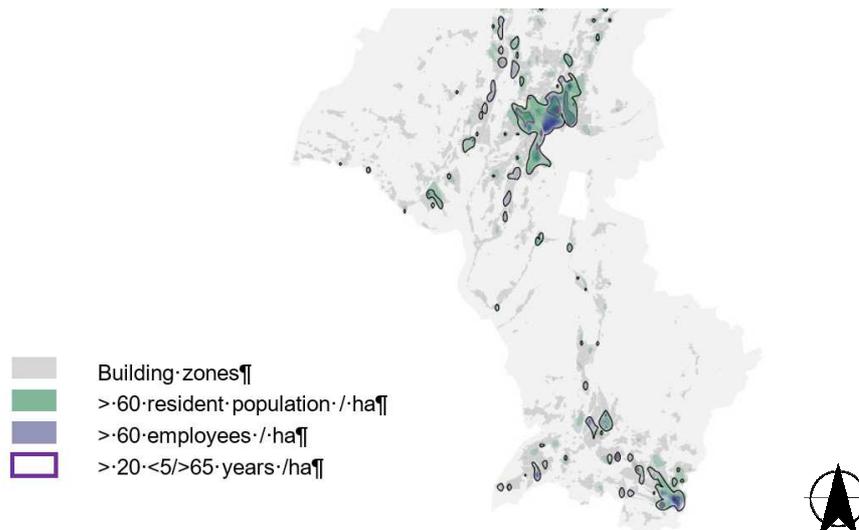

Fig. 3: example of the sensitive and vulnerable areas of Tessin Canton. Elaborations by the authors (2023).

3.2 The sensitive and vulnerable areas

In addition to the maps already introduced, a further study was made to understand where high temperatures are a problem for the population of Tessin Canton. Sensitive areas are areas where the density of the resident

population and workers exceeds 60 units/ha. This value is approximately equivalent to a utilization index[12] 0.5 that separates the typology of single-family houses with gardens from denser typologies. In addition, the study identified vulnerable areas where the density of children under five or people over 65 exceeds 20 inhabitants/ha. The analysis showed that heat islands often coincide with a high resident population density or employees.

4 LIVING IN URBAN HEAT ISLANDS

The elaborations in the first phase provided essential maps for understanding the urban heat island extension. Despite this, it took much work to indicate the abiotic nature measures to make urban microclimate more livable.

Therefore, three measurements examined the urban typologies and climatic elements determining well-being. The measurements concerned:

- the trend of the temperature and humidity of the air during 24h;
- the measurement of the surface temperatures with the thermal imaging camera;
- the evaluation of all the relevant data of the user in the space thanks to the Climameter.

The analyses were conducted in the Mendrisiotto region (focusing on Mendrisio, Stabio and Chiasso) during the summer of 2021.

4.1 Check the air temperature throughout the day

The first campaign verified different types of urban spaces on air temperature. The work aimed to compare spaces with similar characteristics in terms of construction and use but with different architectural and abiotic nature elements.

Bluetooth Data Loggers were installed in Mendrisio to record temperature and humidity trends. The loggers (Temperature range: -20° - +60°; Temperature accuracy: ± 0.5 ℃; Humidity range: 0-99% RH; Humidity accuracy: ± 5% RH) were capable of registering data every 10 minutes and of archiving data for 100 days. The data were exported in CSV format via Bluetooth from up to 50m. A total of 24 sensors have been installed.

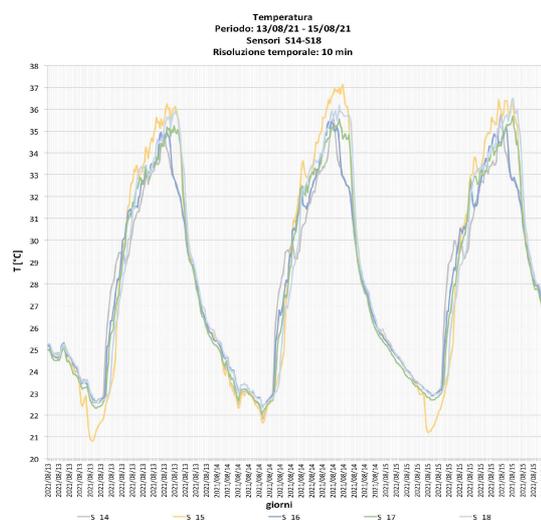
The comparison between measurements in the urban and rural areas was easy. The interpretation of the differences within the different urban typologies took more work. The analysis identifies that an irrigation system lowers the temperature by approx. 1° and that the shade lowers the area's temperatures by approx. 2°. However, these variations cannot describe the differences in terms of perception. The air temperature shows an average value that does not quantify the thermal stress a person is exposed to. Therefore, different measurement methods must be used to analyze other factors relevant to well-being within urban spaces.


Fig. 4: the measurement campaign in Mendriso (CH) with Data Logger Bluetooth. Elaborations by the authors (2023).

---

[12] Relationship between the gross useful area built on a land and the area of the land.

4.2 Measure and display surface temperatures

A thermal imaging camera was used during the second survey. "In a limited sense thermal imiging is basically concerned wih converting images produced by the longer-wavelength thermal radiation emitte by these cooler bodies to visual wavelength images that we can see. In a broader sense the term thermal imaging can also apply to systems where no visual image is generated, but a thermal image is captured and processed entirely electronically to measure some specified parameter or detect the presence of some object."[13]

The survey used the FLIR Lepton® camera with radiometric-capable solution that is smaller than a dime, fits inside a smartphone, and is one tenth the cost of traditional IR cameras. Using focal plane arrays of 80x60 active pixels, Lepton easily integrates into native mobile-devices and other electronics as an IR sensor or thermal imager. The radiometric Lepton captures accurate, calibrated, and noncontact temperature data in every image pixel.[14]

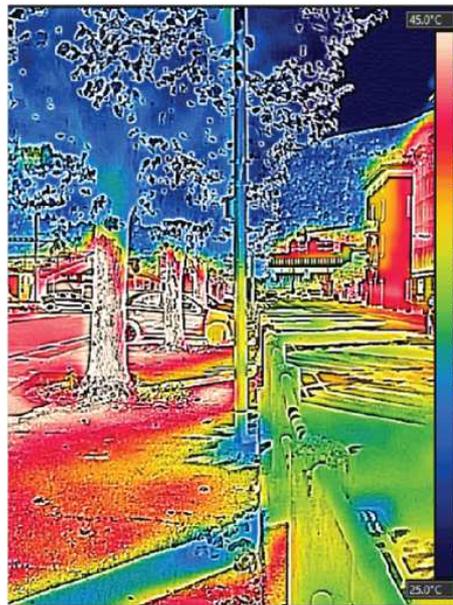
The following figure is an example of photos taken in the summer of 2021 in Mendrisio (CH).


Fig. 5: the measurement campaign in Mendriso (CH) with FLIR Lepton® camera. Elaborations by the authors (2023).

4.3 Detecting and calculating perceived temperature

For the third campaign, the study applied the CityFeel method. It is developed by HEPIA[15] and includes a measurement protocol and the Climameter instrument. CityFeel measures the human perception of the immediate environment in terms of response to hygrothermics and air quality.[16]

The Climameter is a light and compact backpack that can be used on climatic trips anywhere in the city. It is composed of several sensors for ambient and radiant temperature in vertical and lateral directions, humidity and air movement (wind), solar radiation, and hemispherical visual environment (sight) from which some urban indicators are extracted (view of the sky). It records other parameters related to the composition of the air (CO_2, NO_x, Ozone, PM 2.5-10) and the acoustic situation. It also includes a platform, a GPS and a data logging system.

The data collected by the sensors feed a model of the thermal equilibrium of the human body to evaluate PET. Other common indicators of comfort or stress are also calculated, such as PMV - Predicted Mean Vote, UTCI – Universal Thermal Climate Index, HUMIDEX - Humidity Index, and WBGT – Wet Bulb Globe Temperature.

[14] https://www.flir.com/products/lepton/

[15] Haute École du Paysage, d'ingénierie et D'architecture De Genève.

[16] "CityFeel – micro climate monitoring for climate mitigation and urban design".

The μCM-Viewer facilitates the observation and interpretation of the collected data using a graphical interface, making it possible to reproduce and analyze ex post the climatic paths performed in an almost immersive way.

The instrument was used for surveys in Mendrisio, Stabio and Chiasso during the summer of 2021. Around 20 routes were carried out at different times (morning, afternoon, and evening), each relief from one to two and a half hours. The planned routes were close to the 24 Bluetooth Data Loggers, close to the Meteoswiss measuring stations[17] in Stabio and close to the OASI[18] measuring stations in Mendrisio to compare the data. Furthermore, the main points of interest for the population were considered, such as hospitals, retirement homes, universities, railway stations, historical centres, industrial areas and open squares.

This campaign combined the factors mentioned in the first two campaigns and was crucial to represent the human experience.

Fig. 6: the measurement campaign in Mendrisio (CH) with the HEPIA Climameter. Elaborations by the authors (2023).

5 RECOGNIZING THE POTENTIAL OF URBAN TYPOLOGIES

The third phase aimed to verify the effects of the natural solutions adopted in the territory according to the analyses developed by Kleerekoper[19] about urban design and the indications in "Reducing Urban Heat Islands: Compendium of Strategies"[20] regarding the importance of trees on streets and parking lots. Specifically, the present study evaluated the impact of measures, including the federal action plan and the variables that most impact human well-being. Therefore, the relationships between land use, urban typologies and abiotic nature were investigated.

5.1 The retention and reflection of materials

Construction materials with different heat retention or heat reflection were considered. Analyzes have underlined that the most pleasant place in Mendrisio in the summer is still the historic centre. Even on hot summer afternoons, temperatures remain below the stress limit. The combination of shade with surface materials that balance the temperature throughout the day allows the cool of the night to be transported into the day.

Regarding the colours of the facades, light colours reflect the light better and heat up less. Therefore, making surfaces lighter usually reduces heat build-up. Nevertheless, light colours can increase PET if the reflective effect of white makes the situation in front of the facades less pleasant.

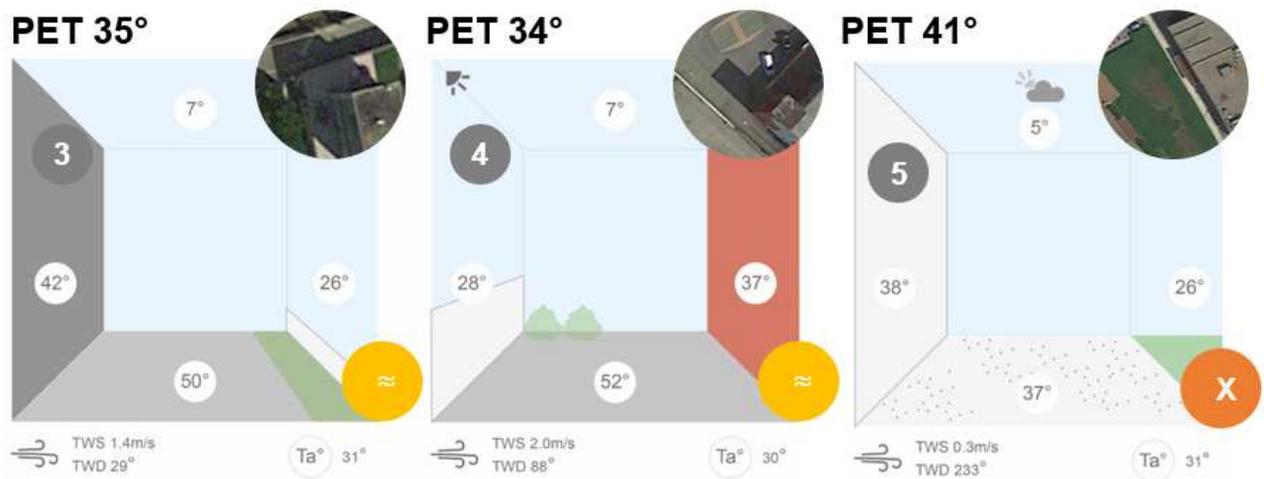
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Fig. 7: elaborations to investigate the effect of the materials and colors of the facades. Elaborations by the authors (2023).

5.2 The waterproof or vegetable flooring

Different ground, such as asphalt, gravel, grass or reinforced grass for parking, are typical of the study area.

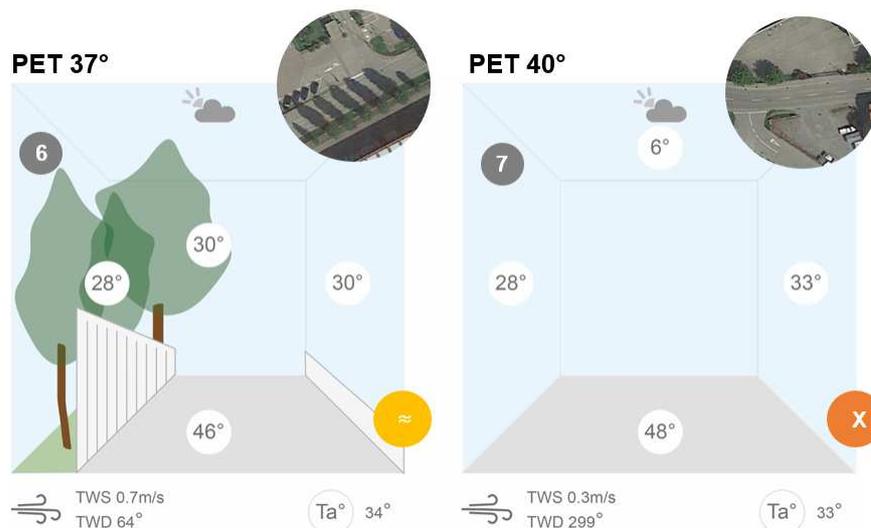
In the industrial area of Stabio, the difference between partially impermeable surfaces with tree-lined streets and asphalted streets or an impermeable street situation without elements giving shade was analyzed. The comparison of the collected data underlines that the introduction of single green elements contributes little to urban microclimate for people's well-being.


Fig. 8: elaborations to investigate the introduction of individual green elements. Elaborations by the authors (2023).

Combining the measures improves the situation for the user. Mendrisio's case study, for example, compared two car parks. The first combines trees with a permeable floor. The second case is entirely paved without mitigation measures. Data analysis of a summer heat day PET differs by almost 10 degrees between these two situations.

At last, a combination of elements is needed to improve the situation. Furthermore, the attention should certainly be paid to water retention. Vegetated soil conserves humidity and contributes to a pleasant climate, so ideally, the city becomes a Sponge City. According to the World Future Council, Sponge City indicates a particular type of city that does not act like an impermeable system not allowing any water to filter through the ground, but, more like a sponge, actually absorbs the rain water, which is then naturally filtered by the soil and allowed to reach into the urban aquifers. This allows for the extraction of water from the ground through urban or peri-urban wells. This water can be easily treated and used for the city water supply.[21]

---

[21] "Sponge Cities: What is it all about?"

5.3 The shade or exposure to solar and reflected radiation

The sky is usually pleasantly cool, and its surface temperature is between 5-7 degrees, higher with cloud cover. Thus, even in summer, people feel the cooling effect of the sky when they are outside. The sun's radiation compensates for this effect wherever shade is not.

Exposure to high temperatures is also influenced by the buildings' shade. For example, the situation between the sun and shade of the new SUPSI building in Mendrisio is lowered by over 10° PET despite the same external arrangement. This means it is comfortable during sunny days in the winter but becomes almost unlivable in the summer.

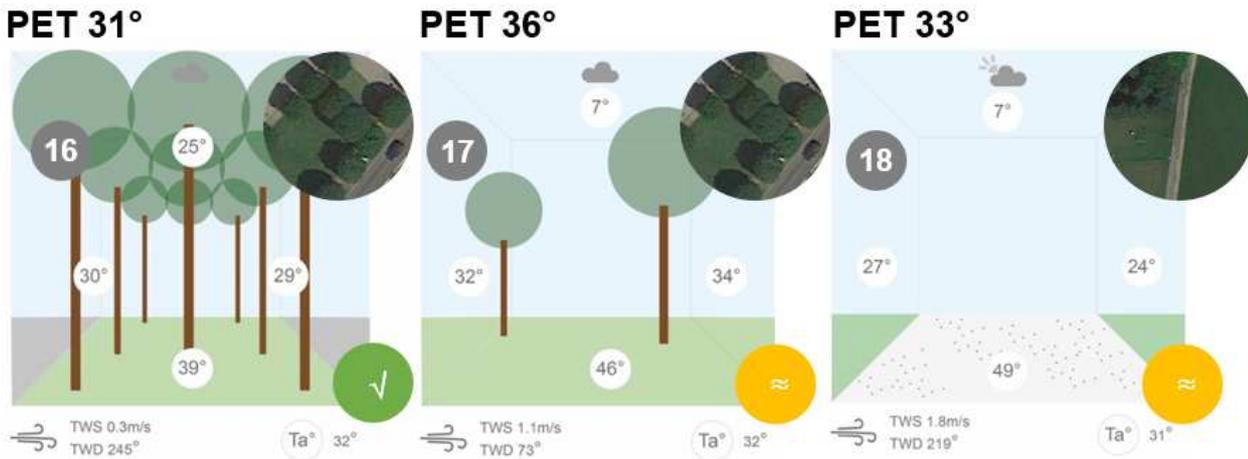
Finally, the data has shown that the temperature of gravel squares or dry green areas does not differ much from asphalted squares. The introduction of trees brings PET closer to air temperature. Therefore, the data is below the heat stress limit.


Fig. 9: elaborations to investigate the effect of shadow in public spaces. Elaborations by the authors (2023).

5.4 The design or not of the vegetation on the walls

Greening roofs and walls can mitigate the overheating effect. Plants cool the air by evaporating water and radiating less heat. A green facade or an intensive green roof thus also contributes to an acceptable climate in the public space.

Fig. 10: elaborations to investigate the effect of the greening of the walls. Elaborations by the authors (2023).

From these considerations, three situations in Mendrisio were analyzed during an August day with a clear sky and 31-32° degrees. The first case is a 20th-century street with buildings alternating with tree-lined gardens in front of a large park with centenary trees. Along the same road, the gardens are either converted to waterproof outdoor parking or occupied by a semi-underground garage bordering the road. The third case considered green walls. The analyzed data showed that greening private gardens without measures in the

road space lowers the temperature, but not below the necessary value. The green roof does not bring significant benefits to the public space. A similar effect is the case of green walls: the data analyzed do not show a significant contribution to well-being. Therefore, single greening interventions in a predominantly impermeable and built space exposed to the sun do not significantly contribute.

6   A NEW ATTENTION TO THE QUALITY OF PUBLIC SPACES

The ongoing study shows that in many localities in Tessin when an air temperature of 30° is reached or exceeded, people are already exposed to severe heat stress of over 38° PET. Therefore, reductions in the perceived temperature of approximately 10° are necessary to bring the situation back within tolerable limits. As described in the paper, applying single measures has limited effectiveness. In the best cases, they reduce a few degrees to a maximum of 5°. Only public spaces that combine several measures to reduce heat islands manage to achieve the goal. These reflections will be fundamental for envisaging measures and interventions in the cities of the valley floor but also for small or medium-sized urban centres, located in the valleys or in the mountains. Planners need to pay more attention to thermal comfort conditions in urban typologies, and interventions are also needed to limit overheating phenomena through ventilation or natural cooling measures of the external spaces. Therefore, more than a cosmetic greening of the existing city is required. A new approach to the design of urban spaces will be necessary so that they are also pleasant to live in as a function of climate change.

The research is still in progress. The deadline is expected in 2025. During 2023 the focus is on identifying the contribution of night cooling, on the open-source dissemination of the maps created and on the involvement of the municipalities to introduce the study results. At the moment, the phenomenon of heat islands must be addressed according to a holistic vision that includes the processing and interpretation of different types of data at different scales of intervention.

The importance of involving the population and local authorities is undeniable for the future. The focus of reflection must be the well-being of citizens in adapting to climate change.

1 ABSTRACT

The PeriSponge project is a three-year research project with an implemented prototype in Feldbach, a small town in the south of Austria. PeriSponge aims to improve potential hydrological retention areas and flood capacities along transport areas through well-designed, multifunctional and multicoded open spaces, while providing water management and quality of life solutions to improve climatic, ecological and social functions for quality sustainable peri-urban areas. The analytically applied research is being evaluated and will be made transferable to other cities. At this point, the project is at the end of the first project year.

Keywords: toolbox, blue-green measures, mobility open space, peri-urban, spatial planning

2 STATE OF KNOWLEDGE

Resilient urban areas need integrated planning and an frugal use of resources and land, while at the same time being liveable and of high urban quality (Degros & Bendiks, 2021). The idea of using resources and land as efficiently as possible is reflected in the context of urban sustainability, especially in the approach of multifunctionality (Jabareen, 2006). This applies even more to open spaces, which have to fulfil a multitude of requirements, from leisure and biodiversity to mobility and infrastructure, and which have to accommodate an ever-greater diversity of user groups (Becker, 2020) as well as climate change adaption measures. In order for such efficient use to succeed, urban planning and the design of open spaces must take on an important moderating role between the different sectoral plans in order to turn monofunctional and/or sealed infrastructure buildings, traffic areas, residual spaces, etc. into green-blue infrastructures for more quality of life and to be able to meet the overall demand for more green and open spaces (cf. Umweltbundesamt, 2021).

The impacts of already increased water-related events such as floods, droughts, water pollution, scarcity of biodiversity and pressure on high-quality open spaces in urban settlements, among others (Zandonella et al, 2013)are intensified by the steady growth of cities (Trenberth, 2011; O'Donnel and Thorne, 2020). Beyond the general focus on central places of the Urban, the 2005 UN Habitat report shows not only that 61% of the world's 5 billion population will live in urban areas by 2025, but more importantly that about 85% of this development process will take place in the urban hinterland, widely referred to as "peri-urban", "suburban", "outskirt" or "urban sprawl" (Prakash et al., 2011).

These peri-urban areas, which are largely car-dependent and lack urban infrastructure, are areas that have been created by economic, social and legal frameworks in recent decades. With the growth of sealed areas - especially on the periphery - a decoupling of spatial, hydrological, ecological and social needs and an increasing socio-ecological fragmentation of open space can be observed (Hecke, 2020).

This shows that these areas deserve more attention than they currently receive in general discourses on resilience, sustainability in urban planning and design.

3 TOOLBOXES FOR THE REDESIGN OF PUBLIC SPACE

In order to facilitate a systematic redesign of public space, a number of toolboxes, i.e. application-oriented planning aids focusing on the redesign of existing urban streets, have been developed (cf. BlueGreenStreets, 2022). The spatial focus of these planning aids is mainly concentrated on central urban areas such as inBerlin, Vienna, Hamburg, Zurich, Kassel, etc. (Stadtentwicklung Wien, 2011; Stadt Zürich, 2019; Umweltbundesamt, 2019).

These toolboxes were developed for the conditions of wide urban street spaces. The parameters of wide street spaces, such as historical, spatial local characteristics, allow a systematisation of redesign concepts. Above all, military, hygienic and representational purposes as well as the number of inhabitants were important factors why streetscapes were significantly widened. From the mid-19th century onwards, entire

districts and neighbourhoods were altered to create wide streets and boulevards in the urban structure, which are now subject of redesign measures to blue-green streets (cf. Degros et al., 2021). A second round of widening urban streets started with car-oriented urban planning schemes in the mid-20th century. In the search for space to implement blue-green elements for climate adaption, the research project Bluegreenstreets found that many streets in the urban study areas in different German cities had wider profiles than the nationally recommended minimum width. This additional space offers room for action in the transformation process to integrate blue-green infrastructure and recreational spaces, once the traffic shift is implemented.

Our study in small to medium sized towns in Austria, and there, on the outskirts of the cities, display on the contrary that many road widths mapped are even narrower than nationally suggested guidelines (ÖsterreichischeForschungsgesellschaftStraße-Schiene-Verkehr 2020) for sufficient dimensioning of road lanes and sidewalks. The historic road network were connections for agricultural and trading purposes and served as a national network for military operations in case of war. For these transport only uses, such roads were implemented with minimum widths. From the industrial age onwards, different functions and trades have settled along the historic road network. In the second half of the 20th century, these small trade and agriculturally driven cities saw more housing developments and commercial areas growing along the existing road networks while the narrow road widths remained. Agricultural or green areas were converted into sealed surfaces or parcelled out for single-family housing developments. With all the infrastructure created in parallel for this purpose, such as car parks, small garden settlements, agricultural land, cemeteries, etc., a mix of sealed, private and public and partly fallow land was created. Urban sprawl as well as such peri-urban sprawl puts high pressure on environmental resources, the developments "eat up" valuable natural habitats in the surrounding landscape (OECD 1990). However, this phenomenon affects not only ecological networks, but also publicly usable space. As the pressure for open space may not be comparable to dense centres, the heterogeneous character includes industries and commercial uses with workers and employees as well as units with apartment buildings and single family houses which all have a certain need for public space, may it be for recreation or socializing. On the other hand, urban and peri-urban sprawl also leads to interstitial and leftover spaces that are often private and socially underused (Mariani& Barron, 2014), This is particularly the case along the circulation areas of peri-urban spaces (Bendiks & Degros, 2019). Urban sprawl also reinforces the current dominant use of motorised transport of roads (cf. Umweltbundesamt).

Therefore, peri-urban spaces are particularly affected by a lack of quality publicly usable open spaces and a lack of valorisation of the few publicly usable spaces. They are also affected by heat stress caused by large sealed surfaces such as shopping centres and car parks (ÖROK, 2019).

These structural differences and challenges between urban and peri-urban space can only be addressed to a limited extent with the existing planning recommendations focused on inner urban streets and make the need for a toolbox for the peri-urban space all the more obvious. Literature is largely lacking, although peri-urban spaces are growing four times faster than inner-city spaces (cf. Piorr et al., 2011) and thus can and must make a significant contribution to climate change adaptation and mitigation.

4 THE PERISPONGE PROJECT – WATER, CITY, PEOPLE

The research project PeriSponge explores which potential streetscapes may have to contribute to a blue-green transformation of peri-urban areas. As public spaces are rather sparse outside central areas, infrastructures of mobility represent an important spatial resource for the implementation of blue-green elements. A blue-green transformation comes along with multifunctional benefits when aiming to make settlement areas more resilient for future challenges. Blue-green transformation means in the first place to introduce design principles for a decentralised local water management oriented towards sustainable local water cycles. Well-designed, multifunctional and multicoded (Becker, 2020) elements for water management in streets can contribute to provide rainwater retention for flood prevention, to keep rainwater for irrigation and vital urban greenery, to refill groundwater levels and last but not least to secure climate comfort for those using urban space by shading and cooling effects of trees and other vegetation (evapotranspiration) also in times of intensifying heat waves. The applicability and practicability of blue-green multifunctional designs for peri-urban streets will be tested and evaluated by means of a "prototype" implemented in Feldbach, Austria.

94

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

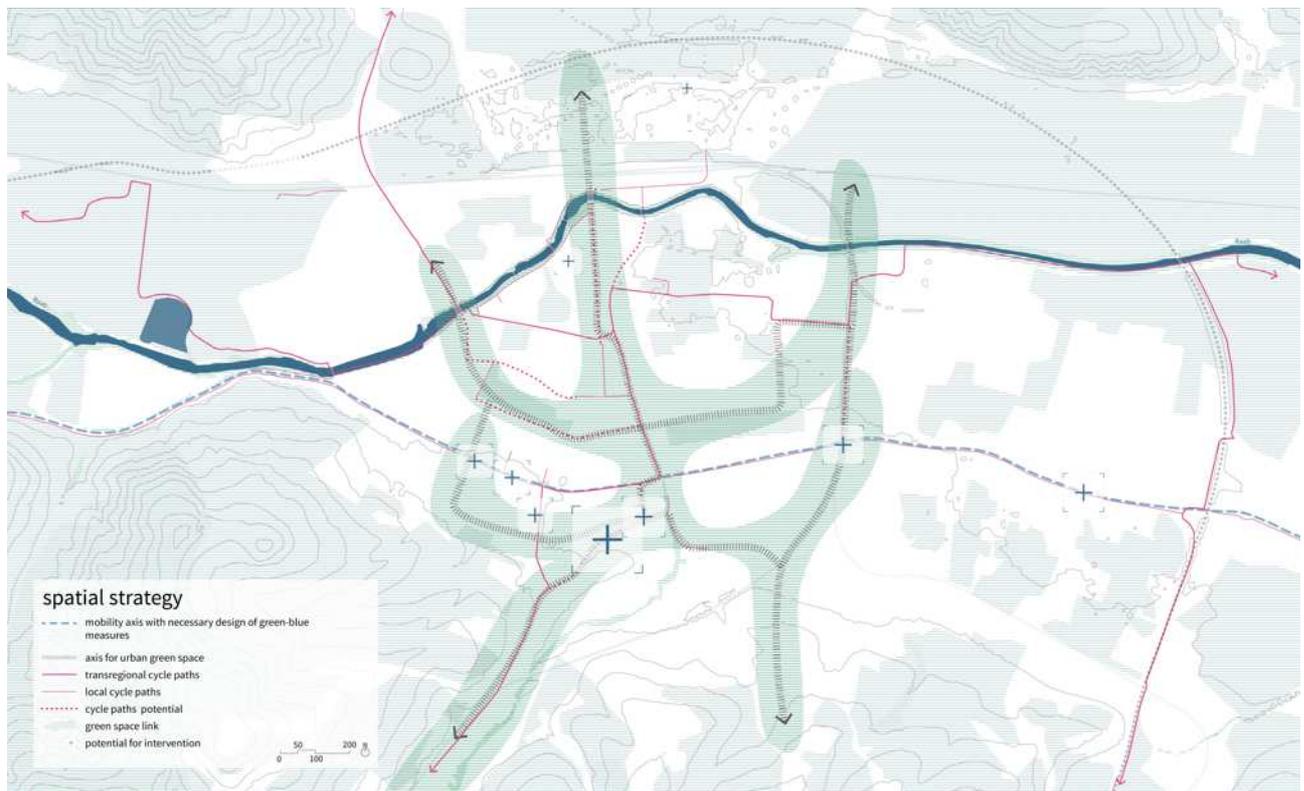
The choice of the implementation site of the prototype is derived from an analysis in three thematic levels: Water, City and People. The hydrological analysis defines danger spots where flood events and floods have occurred in the past and may occur in the future. Among other aspects, flow paths and slope waters are taken into account and possible areas for retention volumes are identified in order to store or retain rainwater. At the urban planning level, mobility, urban activities, green and open spaces, amenity qualities and sealed surfaces are analyzed. Gaps and missing spatial and ecological connections in the urban structure locate future areas for action. The hydrological and urban planning analysis are overlaid in the next step with local knowledge and show results for combined action needs in possible locations to integrate multicodedstreetscapes.


Fig. 1: Spatial Strategy Feldbach - overlaps for needs for action: potential project locations

The third level consists of the people, residents and interested parties, who are involved in the entire process. This serves to create awareness, a transparent design process in which wishes and suggestions are taken into account, and a resulting increase in acceptance among the population. Multicodedstreetscapes create additional spaces for people to stay. The scarce public space in the peri-urban area can thus be integrated along the streetscape. Naturally cooled and shaded areas can thus contribute not only to staying but also to pleasant movement with active mobility. This type of implementation supports the needs of adjacent residents and people moving in the peri-urban space.

In the design and implementation process, several events are offered in the project phases for further participation in order to communicate different design approaches and legal contents. After implementation, the prototype and its effectiveness will be analysed and evaluated.

From a hydrological perspective, the retention volume, the effectiveness of retardation/storage and the before/after effect of the microclimate will be evaluated, among other things. In addition, the degree to which rainfall events can be mitigated will be determined. From an urban planning perspective, the appropriation and acceptance of the new public spaces and their design will be evaluated. (Fig.2)

The project results will be used to develop transferable and scalable instruments, such as a practice-oriented toolbox and action guidelines for other peri-urban areas.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

5 IMPLEMENTATION SITE FELDBACH, AUSTRIA

Feldbach is the fifth largest city in Styria with 13,371 inhabitants and is growing, especially on the outskirts (LandesstatisitkSteiermark, 2019). Pressure can be observed especially on the outskirts of the city, which is mainly due to the expansion of infrastructure and led to demographic change and increased immigration

Situated in a valley, Feldbach is located on an axis between south-eastern Styria and Graz and embodies a medium-sized and regional centre. Topographically, Feldbach is bordered by elevations from the north and south. The main river runs north of the old town. The geographical valley location of Feldbachfavours floods during heavy rainfall events, especially slope water from the elevations in the south enters the urban area along flow paths from the. south. The heavy rainfall events in the summers of 2017 and 2021 in particular caused major damage to settlement areas along the streams.

The long-established and the newly built streets in Feldbachhave different characteristics, but can be described as peri-urban. Long-established peri-urban streets have heterogeneous use and declining density, while new peri-urban streets have strong monofunctional commercial or residential use. Both types are seen as peripheral streetscapes that are subject to faster transformation than urban streetscapes.

In direct comparison, the streets around the old town of Feldbach can be described with urban parameters. This is mainly reflected in the denser development, closed building lines and heterogeneous adjacent functions. Likewise, some integrated cycle paths indicate a more urban structure. If Feldbach is considered as a whole, the peripheral streets cancategorised as peri-urban. However, if Feldbach is put in relation to large cities and urban centres, the majority of streets in Feldbachcan be seen as peri-urban.

Fig. 4: Implementation site Oedter Straße, long-established street on the outskirts of the city

In the rapid development of the predominant development type single-family house over the urban fringe areas in Feldbach, the creation of inner-city, multifunctional green spaces was neglected. The development of blue-green infrastructures and green spaces was mostly limited to aesthetic elements (as the design of the main square shows) or not pursued at all, as in the redesign of the roadside greenery on the main streets. As a result, progressive soil sealing, the decline of open spaces and extreme precipitation events repeatedly lead to hydrological problems such as flooding, but also to a drastic increase in temperatures and changes in the city's microclimate (Gangl, 2020). The streets in Feldbach fulfil the already mentioned characteristics of

peri-urban streets, such as the too small or minimal street width, the high degree of sealing and too little green and public spaces.

6 INITIAL FINDINGS FOR A PERI-URBAN TOOLBOX

For the development of a peri-urban toolbox and a systematic redesign of existing streets, the first step was to categorize and analyse existing street network to show characteristics, usage patterns and spatial potential for transformation The findings are looked at from a systemic thinking to generate transferable knowledge and solutions.

The documented streets are analysed for the implementation of multicoded measures. Accordingly, not only potentials against flooding but also for natural cooling and quality of public space measures are examined. The latter are most likely to be integrated where most people flows take place. Schillerstraße functions as a transition between the old town and the peri-urban space of Feldbach. The total of 78 documented streets is located north and south of it. Peri-urban space per se has different functions, monofunctional residential streets are thus excluded from the documentation.

The 78 streets were photo-documented and categorised according to FRC (Functional Road Class). The number of lanes and directions of travel, number of adjacent pavements, bicycle lanes, vehicle parking areas and adjacent ground and upper floor uses were documented. Most of the streets are classified in the sixth category, that of collector streets. Most of these streets have only one lane, which can be used in both directions. Some of these streets have parking areas for motor vehicles, and rarely have pavements on both sides.

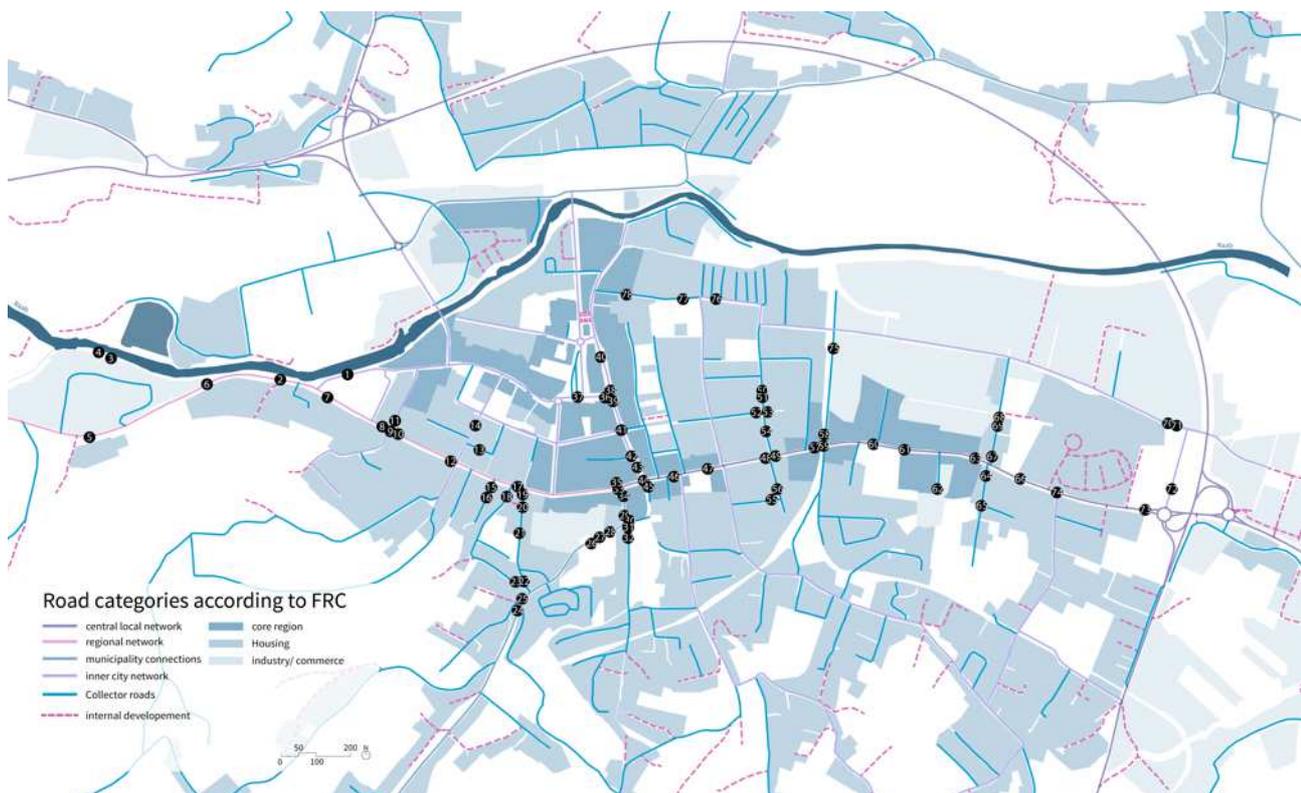
This category has the most roads and therefore has the largest surface area. Most collector roads have very small cross-sections and therefore a correspondingly low spatial potential for redesign, if traffic change is not considered.


Fig. 5: Road documentation in Feldbach
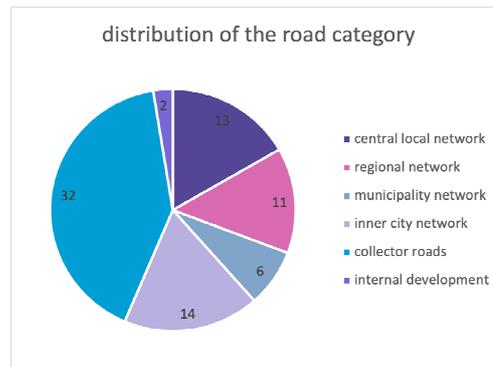

Fig. 6: distribution of the road categories in Feldbach according to FRC

(1) Central local network: Supraregional connections between district capitals or from district capitals to the provincial capital. Connections from district capitals to other employment, supply and tourism centres (13 documented streets)

(2) Regional network: Regional connections of municipalities or parts of municipalities to district capitals. Regional connections of municipalities or parts of municipalities to other centres of employment, supply and tourism (11 documented streets)

(3) Municipality connections: Small-scale and local connections between municipalities or parts of municipalities.(6 documentedstreets)

(4) Inner city network: Other local connection functions (14 documented streets)

(5) Collector roads: Connects service roads in residential or commercial areas to a main road (32 documented streets)

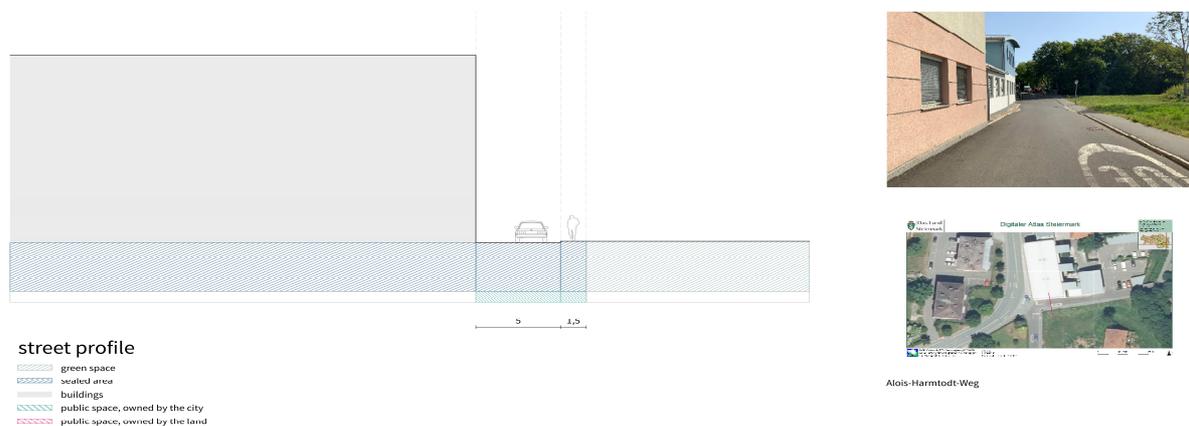
(6) Internal development: Connection to a building plot (2 documented streets)


Fig. 7: Example of collector street: nr30 – Alois-Harmtodt-Weg
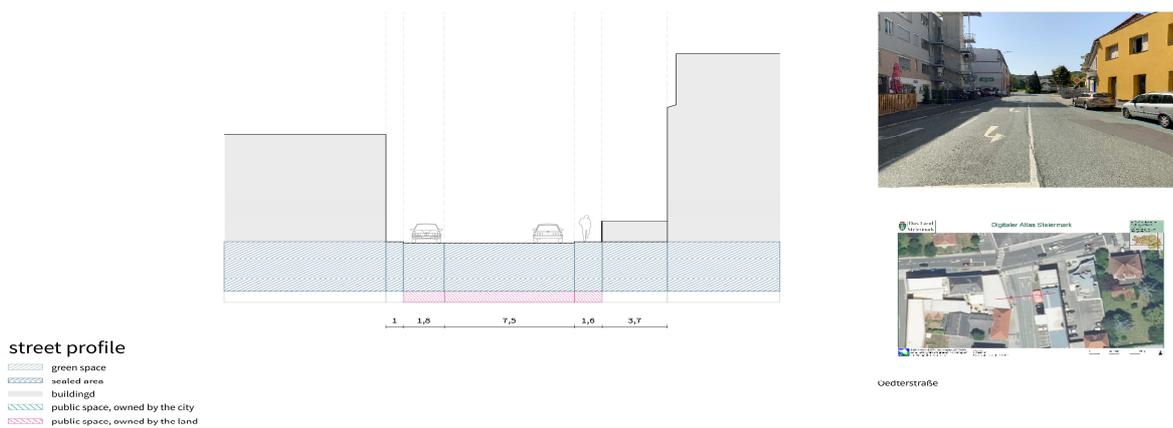

Fig. 8: Example of municipality connection: nr34 – Oedter Straße

6.1 Need for changes in mobility policy

The prioritisation of motorised traffic on the narrow cross-sections results in a monofunctional design of the street space. A spatial separation between active mobility, such as walking and cycling, and passive mobility, motorised traffic such as public and individual transport, for example, often only find space in current practice where the cross-section allows for implementation. In order to achieve an implementation of the design of multicoded mobility open spaces, the transformation process has to be linked with the mobility turnaround. This is the only way to defuse the prioritisation of motorised traffic and activate sufficient areas for the implementation of blue-green infrastructures.

6.2 Planning beyond property borders

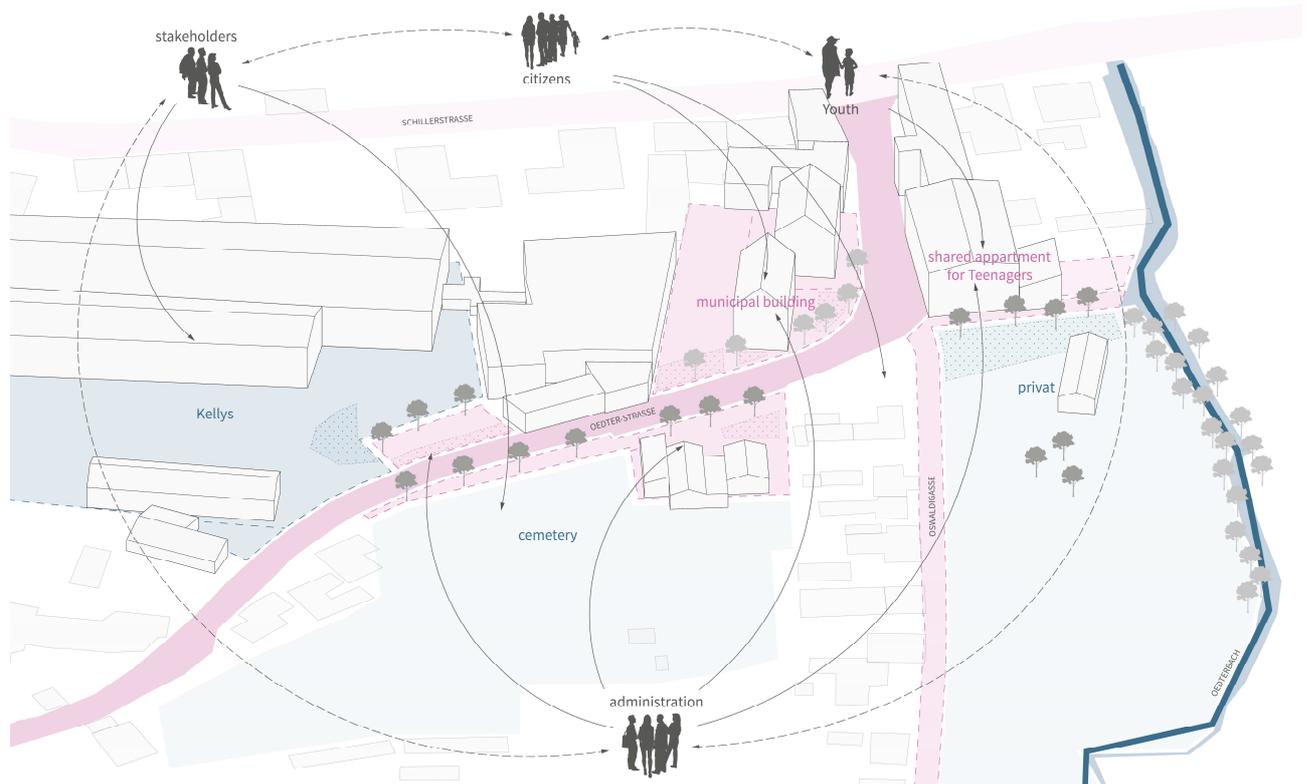
In the development process of the demonstration project in Feldbach it became apparent that the limited public street space at the implementation site of a peri-urban street cannot fulfil sufficient retention tasks in terms of area. In order to solve the existing heavy rain problems and to achieve a large retention effect, planning beyond the street boundary is inevitable. The limited public street space alone cannot bear the demands of rainwater management. For the greatest possible positive effect, you need cooperation and coordination with the adjacent neighbours. As in the demonstration project, this implies cooperation with many private actors, like a large commercial enterprise with large sealed areas, the cemetery, a large area with little green space quality, a municipal housing development, a social facility for young people and private property owners. In the coordination process, current projects or wishes of different agents must be included in order to be able to implement a project beyond property boarders. For the communication process with and between the agents, the local knowledge, which in small towns is bundled directly in the administration, must be used. From previous experience, it can be assumed that it is similar in comparably sized municipalities, as the administrative structures are the same. Our role as scientists and planners is mainly to guide which actors need to be brought to the table in order to implement blue green infrastructures. In this specific case, an attempt is being made to transform a road, which is administered by the province of Styria, but is located in the municipal area of Feldbach, which adds another administrative level that requires additional effort in terms of financial coordination, responsibility and approval.


Fig. 9: planning beyond property boarders at the Feldbach implementation site

6.3 Administrative challenges

The administration in small and medium-sized towns is often limited in terms of staff and faces additional challenges due to the complex, multidisciplinary tasks and the large number of actors. Another issue is that specific data is often not captured or older data is not yet digitised, which can slow down the work process if not planned for. Administrative tasks are often handled by only a few people in small towns. When important decisions hangon a single person, they can quickly be put off by more urgent tasks, for example when heavy rainfall events and consequent flooding occur. In the disaster phase, the importance of new projects thus quickly recedes into the background. The quality of the implemented projects is thereforenot only dependent on the way the administration works, but also on the local implementing companies. The novelty of the topic of creating multicoded spaces in the peri-urban space and the interdisciplinary work in the scientific context of a research project result in new ways of working for the municipality and local companies, which are to a large extent outside their previous practice and can thus cause uncertainties about the results.

Nevertheless, an advantage of municipalities is that the administrations know the local conditions well, can process orders quickly and react more flexibly than in the administratively complicated apparatus of big cities.

6.4 Thinking in strategies

In case of the pilot onOedterStraße, the research project defined five climate adaptation strategies. These strategies were derived from the local conditions. Nonetheless, due to the representative peri-urban mix of functions and road typologies in the project area, the strategies hint towards transferable solutions for peri-urban streets in general:

- Road repartition to gain space for blue-green climate-adaptive elements: through traffic calming, reduction of roadway widths according to goals for transformation of mibility patterns, to gain green and retention space determine

- Decoupling of public and or private parking lots along the street from the storm water channnels: through decentralized infiltration measures on side to relieve the pressure on the canal networks

- Decoupling of buildings or ensembles along the street from the storm water channnels: through decentralized infiltration measures on side to relieve the pressure on the canal networks

- Adjustment of road slopes for emergency waterways targeted drainage of slope water: through modification of road profiles

- Wetlands and/or rainwater retention areas: through identification of suitable propably underused adjacent spaces along the streets such as brownfields, underused parking lots, undeveloped land, gaps or other, preferably in public property or in chance for purchase

These strategies highlight the need to plan beyond property borders in often narrow peri-urban streets. This first strategies developed within the pilot project will be extend through a set of micro strategies for more central urban streets, that already have got some green elements like road trees. In many cases, such existing elements can be transformed into small elements for a climate-adaptive road network through relatively small interventions. These interventions could be to remove edgings of tree beds and create flat depressions in order to uptake rainwater. These two approaches for small scale and easy interventions together with bigger transformative measures hint towards a comprehensive goal for the blue-green adjustment of the wholeperi-urban road network on the long run, starting now.

6.5 Multifunctionalityand urban quality

The technical rain water solutions always need to be thought and planned along integrative goals for usable and comfortable public space. Streets and their ancillary spaces make up a significant part of the public realm especially in peri-urban areas. The major challenge of climate-adapted transformation of streetscapes therefore goes beyond purely functional tasks. Even though retention and infiltration areas are engineering facilities for water management objectives, it is necessary to consider them in the context of the public space in terms of design and to integrate social and aesthetic aspects. They should contribute to the spatial quality of the place. This means applying multifunctional planning principles. A retention basin can be designed as a park at the same time, a planted infiltration bed can enhance the green and open space, a row of trees the streetscape.

7   CONCLUSION

These points are of decisive importance for a transformation of mobility spaces in the peri-urban space. At the same time, the turnaround in mobility policy and the transformation of the public space in which it takes place must be thought about and developed together. The transformation must be integrated in the holistic system and cannot be part of an individual single solution.

With the prototype in Feldbach, we are testing how such a transformation can be implemented. The project already shows that new constellations of actors are needed. The approach of thinking beyond the plots creates an extremely local solution. Is it at all possible to make these approaches transferable to other cities or transferable at all?

How can the approaches developed be made scalable? What would a project look like that envisages transforming Feldbach's 10 most important gateways, also in terms of coordination with the province of Styria, budget, personnel, etc.?

The current issues and requirements for the project and the planned implementation show that it is essential to work together on approaches to solutions that are becoming increasingly relevant in the current challenges of spatial transformations (cf. Armengaud, Degros et al. 2023).

(Lecturer Amira A. Fathi, Alexandria University, Egypt, arch.amira.aboelnasr@alexu.edu.eg)

1 ABSTRACT

Climate change is expected to impact the habitability of many places around the world which will displace millions of individuals. According to the IPCC Fourth Assessment Report, the Nile Delta is one of the world's most vulnerable areas when it comes to sea-level rise, extreme weather conditions, and other factors worsened by climate change, which will lead to a significant population shift. Despite the evidence of this population shift in Egypt there is no obvious framework or strategies for dealing with such migration trends. Little research has been done to assess the number of people that may actually be displaced and where they will choose to go.

So, in this paper the effect of Sea Level Rise (SLR) on migration as an extreme weather event will be examined among governorates of Egypt especially the Nile Delta zone, predicting migration pathways between them. Secondly, the paper analyses and aggregate destination governorates of the Nile Delta zone to spot climate havens. Finally, a map will be concluded for vulnerable areas to SLR and probable destination areas in Nile Delta of Egypt which can help -in addition to the other climate factor- to navigate the challenges of planning for future climate-migration to plan for more sustainable, inclusive, and equitable cities for all.

Keywords: Sea Level Rise, climate migration, climate change, Egypt, Climate havens

2 INTRODUCTION

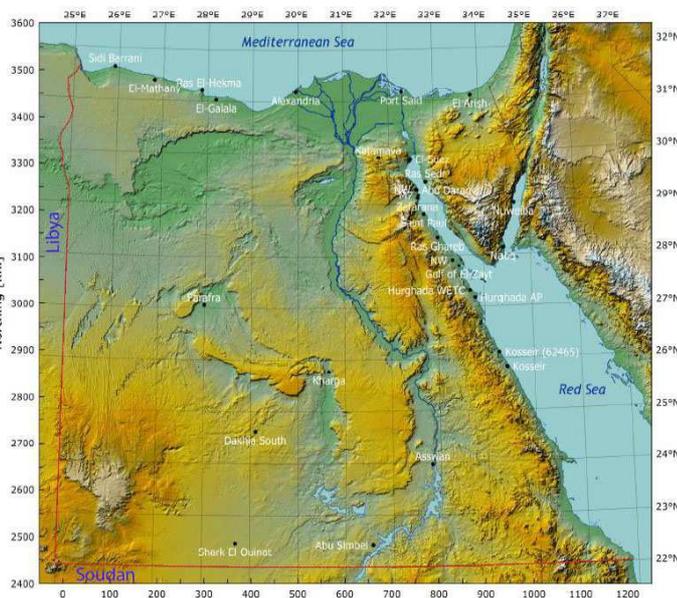
2.1 Climate vulnerability of Egypt


Figure 1: Egypt, its border with Libya from west and Soudan from south is highlighted (EGYPT THIRD NATIONAL COMMUNICATION: Under the United Nations Framework Convention on Climate Change, March 2016)

Egypt is located in northern Africa surrounded by Libya from the west, Gaza from the east and Soudan from the south, with a coastal strip extending for about 3,500 kilometers, overlooking the Mediterranean Sea in the north, and the Red Sea in the east. The River Nile extends from the south to the north forming the low laying Delta of the river with large cities and agriculture. The delta and its narrow valley are about 5.5% of Egypt's area and accommodates more than 95% of its population and agriculture (EGYPT THIRD NATIONAL COMMUNICATION: Under the United Nations Framework Convention on Climate Change, March 2016). As mentioned by the climate change knowledge portal, Egypt's climate is dry, hot, and dominated by desert.

It has a mild winter season with rain falling along coastal areas, and a hot and dry summer season. Egypt is a highly arid country and receives very little annual precipitation (Climate change knowledge portal , 2021).

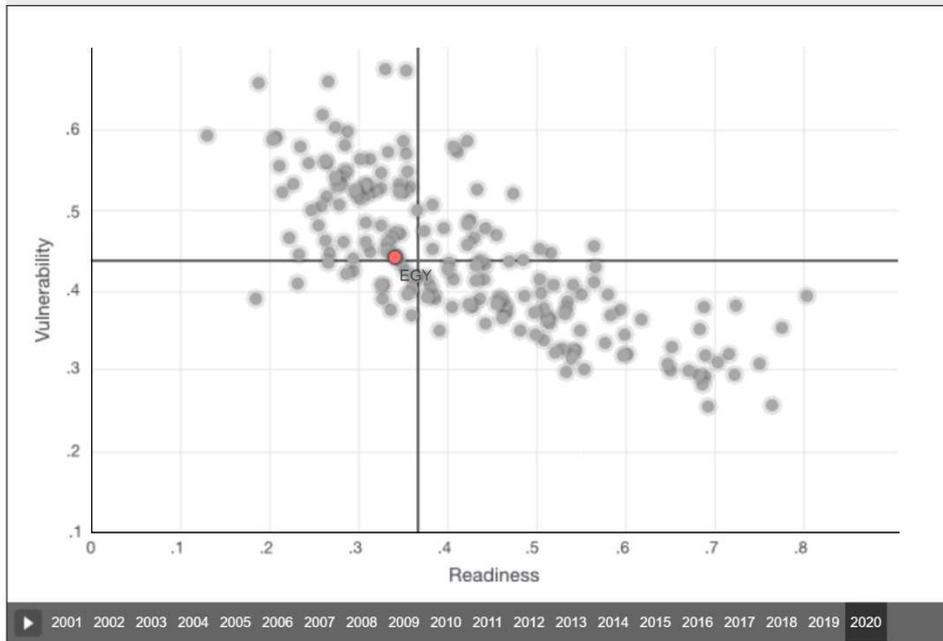
According to the ND-GAIN matrix which illustrates the comparative resilience of countries (Dame, n.d.), Egypt is in the upper left quadrant which indicates a high vulnerability to climate change with a low level of readiness to face it. That make Egypt in need of an adaptation plan for climate change, as well as investments and innovation to improve readiness Figure 2.


Figure 2: The ND-GAIN Matrix illustrates the comparative resilience of Egypt, in which the vertical axis shows the score of vulnerability to climate change and the horizontal axis shows the readiness score, source: Notre Dame global university (Dame, n.d.).

2.2 What is expected for Egypt?

A number of climate change studies considering Egypt (EGYPT THIRD NATIONAL COMMUNICATION: Under the United Nations Framework Convention on Climate Change, March 2016) (Perez, et al., 2021) (Mohamed Arouri, may 2017) stated that mean annual temperatures are increasing and expected to increase by 1.64°C and 2.33°C degree by the next 50 years (Figure 4). Precipitation, flooding and rainfall projections are uncertain, but they indicate slight reductions in precipitation for most months by mid-century (Figure 3). This increase in temperature and reduction of precipitation besides urban encroachment, pollution, depletion of soil fertility, water and soil salinity, sand dunes, soil erosion, and other indirect reasons leading to land degradation formed the desertification phenomenon in Egypt.

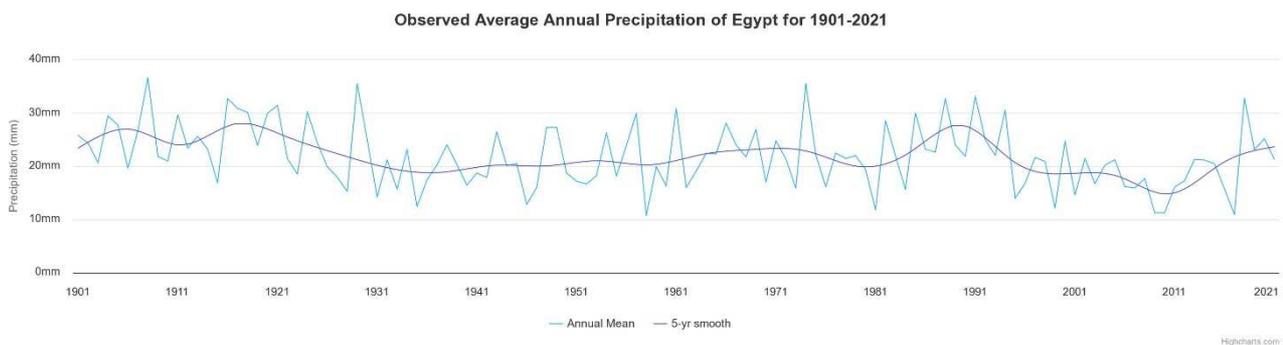
Moreover, there is uncertainty regarding the magnitude to which flood season discharge into the Nile River could be affected by climate change, but according to climate change knowledge portal south, Cairo may experience flash flooding due to sudden extreme rains. Variability in Nile flows is moderated by the High Aswan Dam. The dam has one year's worth of storage capacity, to help in handling periodic droughts, although Egypt remains vulnerable to multiyear droughts.


Figure 3: Average annual precipitation of Egypt for 1901-2021, source (Climate change knowledge portal , 2021)

106

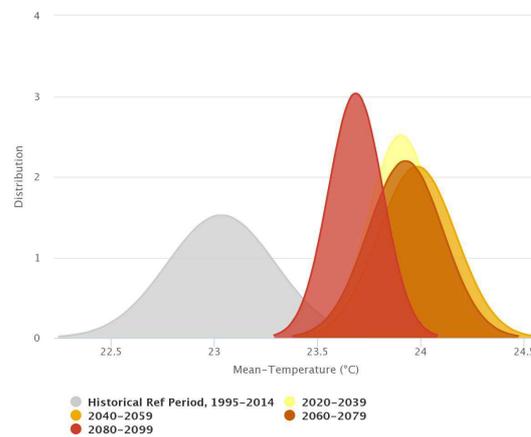
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Figure 4: Projected change in distribution, mean-temperature, Egypt. Source (Climate change knowledge portal , 2021).

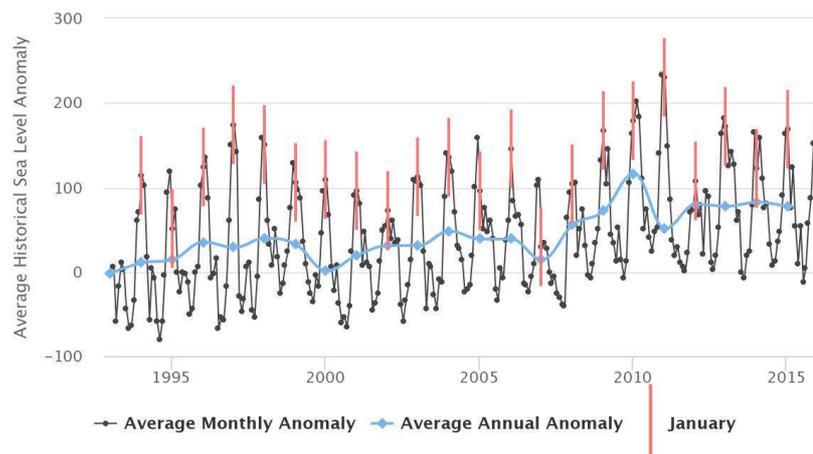
On the other hand, the sea level is continuously rising at a rate of 1.8 and 4.9 mm/year with an average of 3 mm/year, it is expected to rise between 3 and 61 cm this century, depending upon local heat and salinity levels of the Mediterranean (Figure 5). Risk areas in the Alexandria region are: Mandara and El Tarh (east of the city), and risk areas in the Nile Delta region are Al Manzala Lagoon barrier, east and west of the Rosetta City, Gamil, and the Tineh plain. Finally, Increased severity and frequency of sandstorms and haze have been documented (USAID, September 2015).


Figure 5: historical sea level for costal Egypt, source (Climate change knowledge portal , 2021).

2.3 Challenges

According to the climate change knowledge portal, the primary challenges are centred around water resource availability, changing precipitation patterns, and increasing population demands. Having high evaporation rate with the virtual absence of permanent surface water over large parts of the country results in water as a highly scarce resource. Moreover, the rising of the sea level which is not only threatening the physical coastline but also the costal ecosystem, can contaminate freshwater aquifers affecting agriculture and natural ecosystems, especially the densely populated Nile delta. Dr. Khaled Kazem in his report states that if the sea level rose by 0.5 m only, 67% of residents, 65.9% of the industrial sector, and 75.9% of the services sector would be submerged. Therefore, 1.5 million persons would better be displaced, which will result in social and economic repercussions in addition to security threats (Kazem, 2021).

The UNDP added that the most vulnerable areas in Egypt to climate change are: agriculture, coastal zones, aqua-culture and fisheries, water resources, human habitat and settlements, and human health. More than 95% of fresh water consumed in Egypt is generated outside its territory from the Nile River flowing through nine countries and its use is controlled by international agreement. Although the impact of climate change on the Nile basin is not clear yet, there are indications that we will witness a significant impact (EGYPT THIRD NATIONAL COMMUNICATION: Under the United Nations Framework Convention on Climate Change,

March 2016), especially the sea level rise due to its low elevation like all world deltas (Marzouk & Abo-ElHassan, May 2014). Egypt depends mainly on the agriculture and the Nile is the main source of water which will be greatly affected by climate change, and accordingly people who work in the agricultural field. The Nile Delta is already receding by 3-5 mm per year. This will lead to internal migration. On the other hand, East Africa and South Desert are one of the threatened areas in Africa, and because of Egypt's location it will be a desirable land for international refugees (Mohamed Arouri, may 2017).

So, among all the challenges the sea level rise phenomena will have a direct impact on the vulnerable spots in Egypt; from agriculture to coastal zones, water resources, and specially human habitats. In addition to the lack of accurate data to other consequences of climate change on Egypt this research will focus on the SLR phenomena from the climate change consequences, not only because of direct inundation, but also because of the potential impact on saltwater intrusion, extreme events, loss of biodiversity, socioeconomic and health implications (El Raey, El-Askary, El-Hattab, & Kafatos, December 2009). In particular, this research will focus on the Nile Delta area from the coastal zone as it is the lowest in elevation and most vulnerable to inundation due to SLR (EGYPT THIRD NATIONAL COMMUNICATION: Under the United Nations Framework Convention on Climate Change, March 2016). Besides it is the main agricultural land of Egypt and hosts over one-third of the population and nearly half of all crops, also hosts most of the industrial activities and commercial centers, and is highly vulnerable to various impacts of climate change (El Raey, El-Askary, El-Hattab, & Kafatos, December 2009).

3 DATA SETS AND DESCRIPTIVE ANALYSIS

To achieve the research goals, three main data sets are used to fulfil a three parts methodology to create the final results:

First, mapping and examining the sea level rise scenarios of the Nile delta Coastline, using SLR scenarios from different sources: The Intergovernmental panel on climate change IPCC, the scenario of the costal research institute CORI, the World Bank reports, and different researches and publications.

Second, examining the push and pull effects of the sea level rise phenomena on migration internally in the Nile Delta region to determine the movement of migrants. Data sets for migration variables is the Population and Housing Census of Egypt held by the Central Agency for Mobilization and Statistics (CAPMAS) in 1996 and 2006.

Finally, generating the finale results of the vulnerable and proposed destination zones.

4 CASE STUDY

4.1 Study area

The study area includes the Nile Delta region in Egypt and its coastline extending from Alexandria in the west to Port Said in the east with a total length of about 240 km. It extends from the seacoast in the north to the borders of Greater Cairo in the south, it is bordered on the east by the Suez Canal region and the eastern desert extends westward to Alexandria and the Western Sahara.

The coastline has two promontories, Rosetta and Damietta. There are three lakes connected to the sea: Idku, Al-Burullus, and Al- Manzalla. In addition, there are five harbors located on the coast: Idku fishing harbor, New Burullus fishing harbor, Damietta commercial harbor, El Gamil fishing harbor, and Port Said commercial harbor.

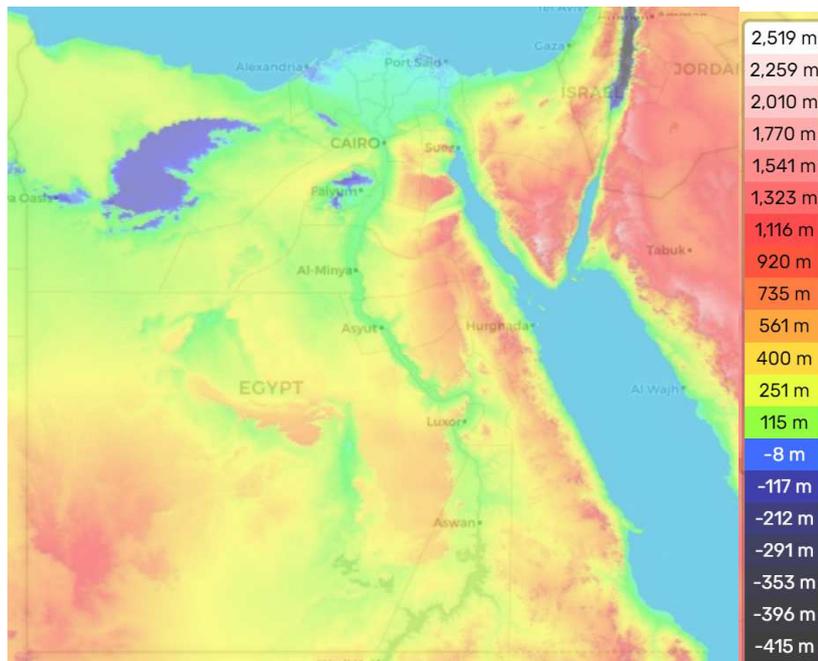
It is the most fertile land of the country and hosts most of the agricultural productivity with high density of population. Agricultural land use accounting for 75% of the total area of the region, followed by the urban uses by 17.9%, then the fallow land by 6.3% of the total area of the region. It is highly vulnerable to potential impacts of climate change due to its relatively low elevation (El Raey, El-Askary, El-Hattab, & Kafatos, December 2009) (Marzouk & Abo-ElHassan, May 2014) (Figure 6).


Figure 6: Egypt's elevations map, The Nile Delta with low elevation is highlighted, source: topographic maps (map, n.d.).

4.2 Vulnerability Assessment

By analysing the different expected scenarios of sea level rise, they can be summarised in two common scenarios: first, the scenario of the Intergovernmental panel on climate change IPCC which assumes that sea level will rise by only 0.5m in coming by 2050 (Figure 7). Second, the scenario of the costal research institute CORI which depended on areal surveying maps to develop the digital elevation model (DEM) for the Nile Delta coastal zones if sea level rises by one meter (Figure 8).

Figure 7:Inundation according to the Intergovernmental Panel on climate change IPCC (SLR 0.5m) (Dawod & Mohamed, October 2015) (Marzouk & Abo-ElHassan, May 2014), source: author.

Figure 8: Inundation according to the Intergovernmental Panel on climate change IPCC (SLR 1m) (Dawod & Mohamed, October 2015) (Marzouk & Abo-ElHassan, May 2014), source: author.

SLR	Affected population	Affected cropland km2
0.5m	3800000	1800
1m	6100000	4500

Table 1: estimated population and cropland affected by SLR (Marzouk & Abo-ElHassan, May 2014).

From examining the different Sea level Rise scenarios, the total number of affected population and cropland is estimated in Table 1 (Marzouk & Abo-ElHassan, May 2014) (EGYPT THIRD NATIONAL COMMUNICATION: Under the United Nations Framework Convention on Climate Change, March 2016).

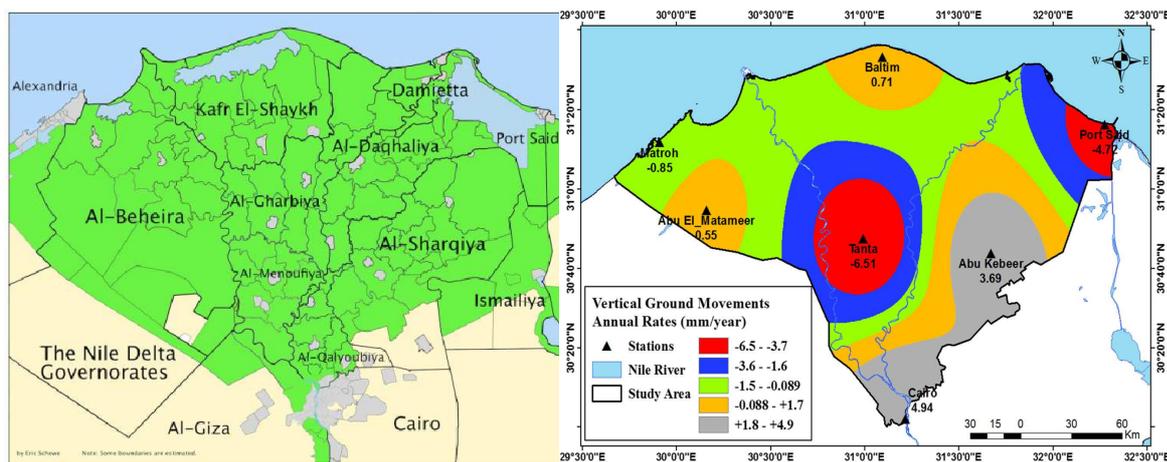
The Nile Delta consists of 11 governorates: Qalyobia, Gharbia, Monofiya, Sharkia, Port Said, Ismailia, Dakahliea, Damietta, Kafr El-Sheikh, El-Bohaira and Alexandria (Figure 9). According to FAO organization Nile Delta governorates comprise about 60% of the land cultivated with cereals, and 50% of sugar crops and many other products, besides its high population. According to the Central Agency for Public Mobilization and Statistics, Egypt's population the Nile delta region is nearly half Egypt's population (Table 2). In addition, as shown in Figure 6, the lower region of Egypt which make it highly vulnerable to inundation due to sea level rise and its other consequences.


Figure 9: Nile Delta governorates (Al-Agha, Closas, & Molle, 2015). Figure 10: Vertical Ground Movements Annual Rates in mm/year (El-Quilish, El-Ashquer, Dawod, El feki , 2022).

Governorates	%	Total population	
Total Egypt	100	102 878 749	
Cairo	9.8	10 100 166	
Giza	9.1	9 323 196	
Nile Delta governorates			
Total	48.9	50318343	
Sharkia	7.5	7 744 815	
Dakahliea	6.7	6 930 797	Costal governorates
El-Bohaira	6.5	6 723 269	
Qalyobia	5.9	6 024 438	
Alexandria	5.3	5 469 480	
Gharbia	5.2	5 343 756	
Monofiya	4.5	4 640 003	
Kafr El-Sheikh	3.5	3 645 111	
Ismailia	1.5	1 419 631	
Damietta	1.5	1 593 610	
Port Said	0.8	783 433	

Table 2: estimated population and their percentage, source: CAPMAS Egypt.

Taking into consideration land subsidence (Figure 10) according to (Dawod & Mohamed, October 2015) (El-Quilish, El-Ashquer, Dawod, & El feki , 2022) the subsidence is maximum in Port Said and Tanta followed by Damietta and Matrouh. By comparing the map of land subsidence and the SLR map it is concluded that the coastal zone will be affected by the Sea Level Rise in different time stages. By applying the worst scenario (SLR by 1m) and land subsidence it is found that about 19 urban agglomerations will be affected with approximate six million residents (Marzouk & Abo-ElHassan, May 2014).

4.3 Migration in Egypt

There are a lot of studies related to migration in Egypt but few are examining how it is linked to climate change. One of them is a working paper which found that temperature and precipitation does not affect migration among governorates but the weather of the destination areas (Mohamed Arouri, may 2017). But according to the expected climate changes in Egypt there will be a significant impact that may cause

migration between Egypt's governorates, especially coastal and delta governorates which is the study area of this research.

Illustrating internal migration rates in Egypt, the 2017 census found that the Red Sea and the Sinai governorates have the highest in-migration rates because of the touristic project, thus job opportunities. The Giza and Qaliobia governorates follow for being near to the Cairo governorates, while Suez has the highest out-migration followed by Port Said and Cairo (sector, September 2019). According to Table 4 the cause of migration is mainly work, followed by study and marriage. However, by time when Egypt's governorates witness a significant climate change consequence specially sea level raise those statistics should be affected and the motivations of the migrants and their choices for their future location will be affected.

Governorate	In-migration rate	Out-migration rate	Net migration rate
Cairo	1.8	4.5	-2.7
Alexandria	1.2	1.5	-0.3
Port Said	1.1	5.8	-4.7
Suez	1.2	7.8	-6.6
Damietta	0.5	3.3	-2.8
Daqahlia	0.4	0.4	0.0
Sharqia	0.6	0.8	-0.2
Qalioubia	3.5	0.4	3.1
Kafr Sheikh	0.4	0.8	-0.4
Gharbia	0.4	0.4	0.0
Menoufia	0.5	0.6	-0.1
Behaira	0.4	0.5	-0.1
Ismailia	1.9	0.7	+1.2
Giza	4.0	0.3	+3.7
Bany Swaif	0.3	0.7	-0.4
Fayoum	0.3	0.8	-0.5
Menya	0.2	0.6	-0.4

4.4 Migration due to Sea Level Rise

By illustrating the worst scenario of sea level rise in the Nile delta and the land subsidence of the study area, it is predicted that costal zones of Port Said, Damietta, Kafr El-Sheykh, and Alexandria will witness an obvious out-migration movement due to the sea level raise. Among these, Alexandria and Kafr el-Sheykh have a higher population density, while Damietta and Port Said have a lower density. On the other hand, Al Daqahliya, Al Gharbiya, Al Menoufiya, Al Sharqya, and Al Qalyoubiya are expected to witness in-migration due to the sea level rise to be a destination governorate.

In a previous study Mohamed Arouri (2017) examined the effect of extreme weather events on migration among governorates of Egypt. He used the gravity model in order to draw the flow of migration between governorates of Egypt. The Gravity model is inspired by Newton's law of universal gravity. It states that any two objects attract each other with a force that is proportional to their masses and inversely proportional to the squared distance between them. In other words, the migration flow between two distinct geographic locations is positively associated with their population size, geographic area, or GDP, and negatively associated with the distance between them. On the other hand, Davis, Bhattachan, PaoloD'Odorico, & Suweis (2018) used a radiation model to simulate migrations among districts of Bangladesh that were affected differently by SLR. Both agreed that - regardless of the climate factor- firstly, the distance between governorates negatively affects the migration flows. If the distance between two governorates increases by 1 percent, the probability of migration happening between them decreases by 0.2 percent. Secondly, people move from governorates with low population to those with high population. Finally, highly educated people tend to have better information and employment opportunities and they are more likely to migrate than low educated people.

According to Figure 9 Al Menoufiya, and Al Qalyoubiya are the remotest in distance from the costal governorates while Al Gharbiya, Al Sharqya, and Al Daqhaliya are less in distance; and according to Table 2, Al Sharqya and Al Daqhaliya are the most populated, followed by Al Qalyoubiya, Al Gharbiya, then Al Menoufiya. Applying the findings of the models described above, the five expected destination governorates Al Sharqya, and Al Daqhaliya may witness the biggest share of migrants.

5   RESULTS AND DISCUSSION

In order to determine which of the previous governorates are the most liable for the expected migration due to the predicted consequences of sea level rise in the Nile Delta of Egypt, we need first to define the climate havens. According to (Marandi & Main, 2021) climate havens are countries or governorates or any regions which are ready to welcome climate migrants, they are characterized by: climate resilience, not prone to sea level rise or wildfires and prolonged heat waves, with ready access to fresh water supply, high vacancy rates or abundance of affordable housing, high infrastructural capacity designed to support more residents than currently live there, an expressed desire to grow, history of or interest in improving adaptive capacity through sustainability or resilience efforts. There are several sources that provide information on climate havens. One such source is a website named Lucid Home which provides a list of cities that are considered climate havens in the United States (Lucidhome, n.d.). Another website is Climate Refugees which provides a map of potential climate havens in North America and some parts of Africa (Refugia Research Coalition, n.d.). Unfortunately, there are no similar applications or websites that can detect or help find climate havens in Egypt.

By illustrating the use of buildings in the previous possible destination governorates (Table 5), it is found that Al Sharqia has the highest number of buildings, including unoccupied buildings and under construction buildings, followed by Al Dakahlia and Al Qalyubia, with Al Gharbia and Al Minoufia having fewer buildings .

Governorate	No. of buildings	Housing	Work	Housing & work	Unoccupied	Closed	Under construction
Al Sharqia	1304132	862288	76333	66420	192140	30312	44605
Al Dakahlia	1094653	763740	53502	84142	98466	11931	38455
Al Qalyubia	843226	507149	44198	87465	133690	10404	37267
Al Gharbia	806850	572927	41736	61291	71103	10680	29466
Al Minoufia	746272	507091	30432	48483	107964	15053	25119

Table 5: Current use of regular buildings, source: CAPMAS Egypt.

The water supplies in those governorates were also analyzed (Figure 11) and it was found that Al Minoufia and Al Gharbia have the highest number of water stations for pure water. followed by Al Sharqia and Al Dakahlia, and then Al Qalyubia.

Figure 11: purified water stations, source: CAPMAS Egypt.

Based on the land subsidence data of Nile Delta governorates shown in Figure 10 and the definition of climate havens, the research concluded that the east of the Nile delta, especially Al Sharqia is considered a climate havens and is the most reliable governorate which is ready to host migrants due to its demographic and geographic characteristics.

On the other hand, this conclusion differs from the findings of the previous study (Marzouk & Abo-ElHassan, May 2014) which proposed that the direction of the expansions and mitigation in the Nile Delta have to be towards the west as shown in Figure 12. However, this research proposes that the expansion and mitigation is better directed towards the east of the Nile Delta, as shown in Figure 13.

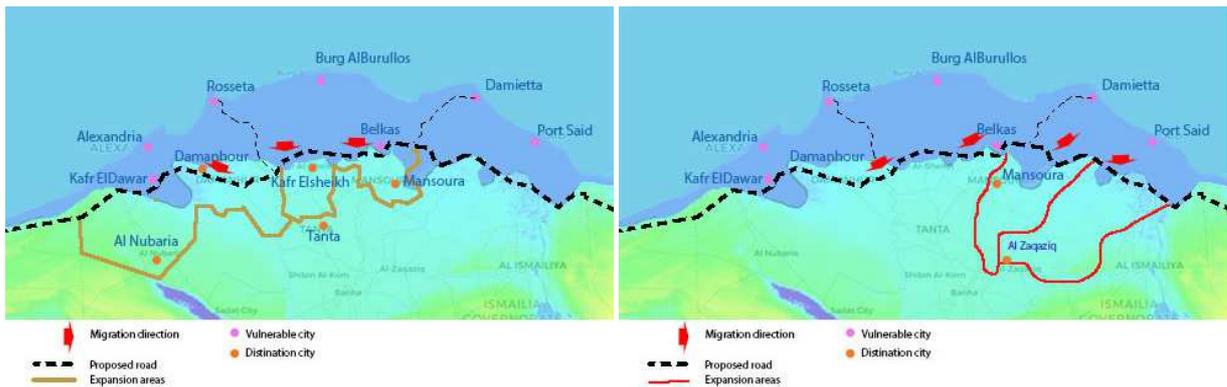
In order to have the most accurate conclusion more factors must be taken in the consideration. Factors considering more consequences of climate change besides the sea level raise, in addition to taking in the consideration more factors that lead migrants other than the climate change.


Figure 12: migration direction and mitigation areas, inspired by (Marzouk & Abo-ElHassan, May 2014). Figure 13: proposed migration direction and mitigation areas, source: author

6 CONCLUSION

This research focuses on assessing the vulnerability of the Nile Delta coast to sea level rise SLR caused by climate change, and the subsequent migration flow. Understanding these factors is crucial for adapting to the effects of a changing climate, especially sea level rise. Yet many aspects of human migration in response to climate change remain poorly understood. The Nile Delta region of Egypt with its highly populated governorates and vulnerability to the potential impacts of SLR and inundation was examined.

The research projects that by 2050, under various scenarios of sea level rise and its impacts, as many as six million people in the coastal area of the Nile Delta may be forced to migrate due to direct inundation. To assess the relocation of these migrants and where the best destinations are, models from existing literature have been applied to determine migration flow, and the destination of the migrants have been predicted accordingly. In addition to evaluating those destinations it is found that the most reliable destination is the east of the Nile Delta, especially the Al Sharqia governorate. The study also highlights the need for further research in understanding the complexities of human migration in response to climate change.

7 RECOMMENDATION

Further studies on the coastal zones of the Nile Delta and other Deltas worldwide should cover aspects such as groundwater salinity, infrastructure, and the natural resources of the coastal zone, in addition to the emphasis on coastal flooding due to expected sea-level rise. It is also recommended that vulnerable areas prone to inundation in the coastal zone of the Nile Delta should have additional protective construction to prevent inundation and subsequent migration.

To be fully aware of the migration flow due to climate change more data about climate change consequences other than the sea level rise must be studied and to be available for researchers so that climate havens can be spotted properly.

To prepare for the expected migration trend due to climate change, the government must develop policies and regulations that prioritise safety and equity. In addition, further research could come up with applications or sources that would help migrants to find the perfect spot.

Co-Creating Inclusive Public Spaces: Engaging Underrepresented and Marginalized Communities in the Planning Process

Marina Lovrić

(Marina Lovrić, Geodetic Institute of Slovenia, Ljubljana, Slovenia; marina.lovric@gis.si)

1 ABSTRACT

Demographic data show that life expectancy is increasing, due to medical developments, higher living standards, healthier diets, etc. But longer life expectancy also means a higher proportion of the elderly population with various functional handicaps. The concept of functionally disabled people is broad and can include persons with disabilities, the elderly, pregnant women, young children and anyone who is permanently or temporarily handicapped in some way. This paper reviews the academic research in the field of architecture in relation to the accessibility of public spaces for persons with disabilities, with a focus on co-creation and community engagement.

For all people, independent movement and mobility are essential. A requirement for ensuring the independent movement of persons with disabilities and their integration into society is the physical accessibility of urban areas and buildings. The technical foundations for accessibility design have been established by universal design's principles and guidelines, but they still require aesthetic value to be added. Allowing disabled people access to public spaces increases their visibility, which strengthens their sense of independence and autonomy and promotes a more positive perception of society. Persons with disabilities are less stigmatized as a result of their inclusion in society, and the general public and professionals are more aware of the need to modify environments and services so that everyone can use them. Inclusion of persons with disabilities in society leads to destigmatization and increased awareness among professionals and the general public about the importance of adapting the environment and services so that all users can use them on equal terms.

However, more than technical solutions are required to achieve accessibility and inclusion. Co-creation and community involvement are essential components of creating accessible and inclusive public places. Co-creation is a design approach that involves end users and designers working together to jointly develop solutions that are tailored to their needs (Prahalad & Ramaswamy, 2004). Community participation means actively integrating people of the community in the design and planning processes, particularly those who are underrepresented or marginalized, to ensure that their viewpoints are taken into consideration.

Architects frequently associate disability with accessibility and compliance with spatial legislation, but they overlook the social aspect of disability and the added value it can bring. Individuals with sensory and physical limitations view spaces differently, giving them a distinct perspective on and experience with the built world. By incorporating underrepresented and marginalized people in the design process, architects can acquire a more diversified perspective on accessibility and inclusivity, leading to more effective and meaningful design solutions.

This paper proceeds by saying that community involvement and co-creation are critical for developing inclusive and accessible public spaces. To accomplish accessibility and inclusion, more than simply technological improvements are required; a societal and cultural shift in favour of respecting diversity and strengthening underrepresented and marginalised people is also required. Involving persons with disabilities in the design and planning process may result in a more inclusive and equitable society.

Keywords: built environment, inclusion, urban space, disabled people, accessibility

2 INTRODUCTION

According to statistics provided by the World Health Organization (WHO, 2022), approximately 1.3 billion individuals, constituting 16% of the global population, are estimated to experience some form of disability. Furthermore, demographic data indicate noticeable growth within the ageing segment of the population, consequently leading to an increase in the number of individuals with disabilities. It is important to acknowledge that the definition of functionally disabled people encompasses a wide range of individuals, including those with disabilities, the elderly, pregnant women, young children, and anyone facing permanent or temporary limitations owing to various impairments.

The Convention on the Rights of Persons with Disabilities, the first international human rights treaty of the United Nations (UN) concerning the protection of the rights of persons with disabilities and the prevention of discrimination against them, introduces a social perspective into its definition. In contrast to the past, when individuals with disabilities were often perceived as recipients of medical treatment, the Convention recognized them as bearers of human rights. As per the Convention's definition, a person with a disability is „a person who has long-term physical, mental, intellectual or sensory impairments which in interaction with various barriers may hinder their full and effective participation in society on an equal basis with others" (UN General Assembly, 2007). Disability is defined as „an evolving concept, and results from the interaction between persons with impairments and attitudinal and environmental barriers that hinder their full and effective participation in society on an equal basis with others" (UN General Assembly, 2007).

The European Union (EU) recognizes and respects the right of persons with disabilities to measures ensuring their independence, social and occupational integration, and participation in community life, as stated in Article 26 of the Charter of Fundamental Rights of the European Union. In the European Action Plan 2006-2007 on the situation of disabled persons, the EU sets one of its three goals: „removal of barriers in the environment that prevent disabled persons from using their abilities" based on the principle of 'design for all' (European Commission, 2005).

In Slovenia, the rights of persons with disabilities are guaranteed by Article 14 of the Constitution of the Republic of Slovenia, which guarantees equality before the law and „equal human rights and fundamental freedoms for all, irrespective of nationality, race, sex, language, religion, political or other opinion, property, birth, education, social status, disability or any other personal circumstance". The field of social inclusion and equal opportunities for persons with disabilities and ensuring unhindered access is regulated in Slovenia by legal acts, such as the Equalization of Opportunities for Persons with Disabilities Act (ZIMI), Social Inclusion of Disabled Persons Act (ZSVI), Building Act (GZ-1), and Rules on Universal Construction and the Use of Construction Works.

For all people, independent movement and mobility are essential. A requirement for ensuring the independent movement of persons with disabilities and their integration into society is the physical accessibility of urban areas and buildings. If space is adapted to the needs of persons with disabilities, it becomes suitable for all users. This paper aims to provide a systematic literature review in the field of architecture and urbanism related to the paradigms of universal design and the relationship of architecture and architects with persons with disabilities. Additionally, the article will shed light on examples of good practices regarding the involvement of disabled individuals in the planning process, mutual collaboration, and learning.

3 CONCEPTS OF ACCESSIBILITY

The concept of accessibility design and planning is called differently depending on its occurrence in different periods and geographical areas, e.g. 'universal design', 'inclusive design', 'design for all', 'barrier-free design', 'accessible design', etc. All of the mentioned concepts have the same common principle, which advocates the design of the environment and products in such a way that, to the greatest extent possible, all people can use it. However, different terms describing the same design concept can lead to poorer awareness, slower implementation of established concepts in practice, and deliberate omission of suitable solutions (Albreht et. al, 2017, Persson et. al, 2104, Iwarsson & Ståhl, 2003).

The concept of 'barrier-free design' first emerged in the United States of America (USA) in the 1960s when the American National Standard for Accessible and Usable Buildings and Facilities was issued. The impetus for the development of the standard was the return of persons with disabilities from the Vietnam War to the USA. The aim was to provide an alternative to institutional healthcare and to support independent living (Persson et al., 2014).

The concept of 'universal design' has its roots in the concept of 'barrier-free design'. The American architect Ronald L. Mace, in the 1970s, defined the concept of universal design as "design that is usable by all people to the greatest extent possible, without the need for adaptation or specialised design" (Mace et al, 1991). Mace, had been a wheelchair user since childhood, said that the removal of the 'special needs' label was the most significant change brought about by the use of universal design (Null, 2014).

116

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Architect Selwyn Goldsmith explored the field of 'universal design' in the United Kingdom (UK). Goldsmith placed the disabled at the top of the universal design pyramid, demonstrating a participatory approach to design 'from the bottom up' (Goldsmith, 2000). He was the first architect to introduce a system of sloping access over kerbs or ramps on the pavement to facilitate the passage of wheelchair users (Goldsmith, 1997:214).

The term 'design for all' was defined in the 'Stockholm Declaration' by the European Institute of Design and Disability (EIDD) as „design for human diversity, social inclusion and equality". The Declaration was adopted by EIDD members at the Annual General Meeting in Stockholm on May 9, 2004.

The term 'inclusive design' is the most commonly used term in the UK. The British Standards Institute has defined 'inclusive design' as: „the design of mainstream products and/or services that are accessible to, and usable by, as many people as reasonably possible on a global basis, in a wide variety of situations and to the greatest extent possible without the need for special adaptation or specialized design" (BSI TBSI, Vol. BS 7000-6; 2005). The definition is similar to the purposes of 'universal design' and 'design for all', but includes the phrase 'as reasonably possible'. This means that adaptations to achieve accessibility do not have to be made if they are too expensive or difficult to achieve. This phrase allows accessibility solutions not to be implemented, which is unacceptable as it excludes vulnerable groups and denies them equal use of services and facilities.

The ISO standard defines the concept of 'accessible design' as a „design focused on principles of extending the standard design to persons with some type of performance limitation to maximize the number of potential customers who can readily use a product, building or service" (ISO/IEC Guide 71:2014).

In Slovenia, architect Marija Vovk worked on the topic of accessibility. With her handbook "Designing and adapting the built environment for the benefit of persons with disabilities"[1] (Vovk, 2000), she has made an outstanding contribution to the initiation of the process of removing architectural barriers and to raising awareness among professionals about the problem of the inaccessibility of the built environment. The research group, led by landscape architect Albreht Andreja, published a design manual 'Space for All', supplemented the guidelines for designing a space free of built and communication barriers, suitable for all users, with guidelines and examples of good practice also for members of the blind and partially sighted group (Albreht et al., 2010: 27-31).

The essence of universal design is to design and plan the built environment, products, and systems without creating barriers and, consequently, to enable the inclusion of different groups of people in social life. Vovkova stated that "the problems of the functionally handicapped or people with various disabilities in integrating into the living environment are mainly manifested in the inaccessibility and uselessness of the built environment; in other words, integration into everyday life, into society, is very difficult or even impossible for these people" (Vovk, 2000). By creating spaces that are adapted to different groups and the needs of people, social integration and inclusion are supported (Rodi, 2020). Therefore, designing spaces for different groups of people is a key element in the design process. An accessible physical environment has a significant impact on the accessibility of public spaces for persons with disabilities, and enables a change in the social environment, particularly in terms of society's behaviour and attitudes towards persons with disabilities (Butler & Bowlby, 1997). If persons with disabilities are given access to public spaces, their presence increases, thus strengthening their sense of independence and autonomy, while also fostering a more positive understanding of society. The inclusion of persons with disabilities in society also leads to destigmatization and awareness among professionals and the general public of the need to adapt the environment and services so that they can be used by all users on equal terms.

4 ENHANCING ACCESSIBILITY AND INCLUSIVE DESIGN IN ARCHITECTURE

Architects, planners and designers need to be aware of the needs and difficulties faced by persons with disabilities to plan and design a barrier-free built environment (Vovk, 2000), and this statement is often unfortunately not the case. In contemporary architectural practice, it has been repeatedly shown that architects do not consider the needs of persons with disabilities when designing architecture. Research shows that architects often stereotype disabled individuals as wheelchair users only, without considering the needs of persons with cognitive or sensory impairments (Imrie & Hall, 2001; 97). Furthermore, universal design

---

[1] Načrtovanje in prilagajanje grajenega okolja v korist funkcionalno oviranim ljudem, Vovk, M., 2000.

guidelines and examples are based on standardized criteria and narrowly linked to legislation and regulations (Ahmer, 2014; Boys, 2014; Vermeersch & Heylighen, 2015; Kajita, 2020), which leads to a sense of creative limitation and an inability for designers to develop inventive solutions. The challenge for contemporary architecture in designing spaces for persons with disabilities lies in designing buildings and built environments that do not simply meet the requirements of regulations. Such a design requires creative thinking and a change in perspective, which will ultimately offer progressive and thoughtful solutions (Ahmer, 2021; Steinfeld & Maisel, 2012).

4.1 Embracing Inclusivity: The Impact of Inclusive Architecture

Inclusive design, which aims to make objects and spaces accessible to a wide range of people, including those with physical, visual, or cognitive impairments, is a direct response to the problems of inadequate design practices and marginalization. While some individuals might raise doubts about the importance of considering the needs of perceived 'minority' groups, such as persons with disabilities, in architecture, it is crucial to recognize and address potential challenges and concerns that might hinder the adoption of inclusive design solutions. One of the common concerns is that designing for accessibility might compromise the aesthetics or architectural integrity of a building or space. Some architects may fear that accommodating accessibility features could lead to a perceived loss of creativity or will impair their artistic vision. Concerns about the cost and viability of including inclusive design components, particularly in pre-existing structures, may also arise. It may appear that retrofitting older buildings to meet accessibility standards is a difficult and costly task.

Furthermore, resistance may result from a lack of understanding or awareness of the diverse needs of persons with disabilities and other marginalised groups. Architects and designers may not fully comprehend the variety of challenges encountered by various users, resulting in the inadvertent omission of certain accessibility requirements (Imrie & Hall, 2001). Outdated attitudes and stereotypes about disability may also contribute to a lack of willingness to embrace inclusive design principles.

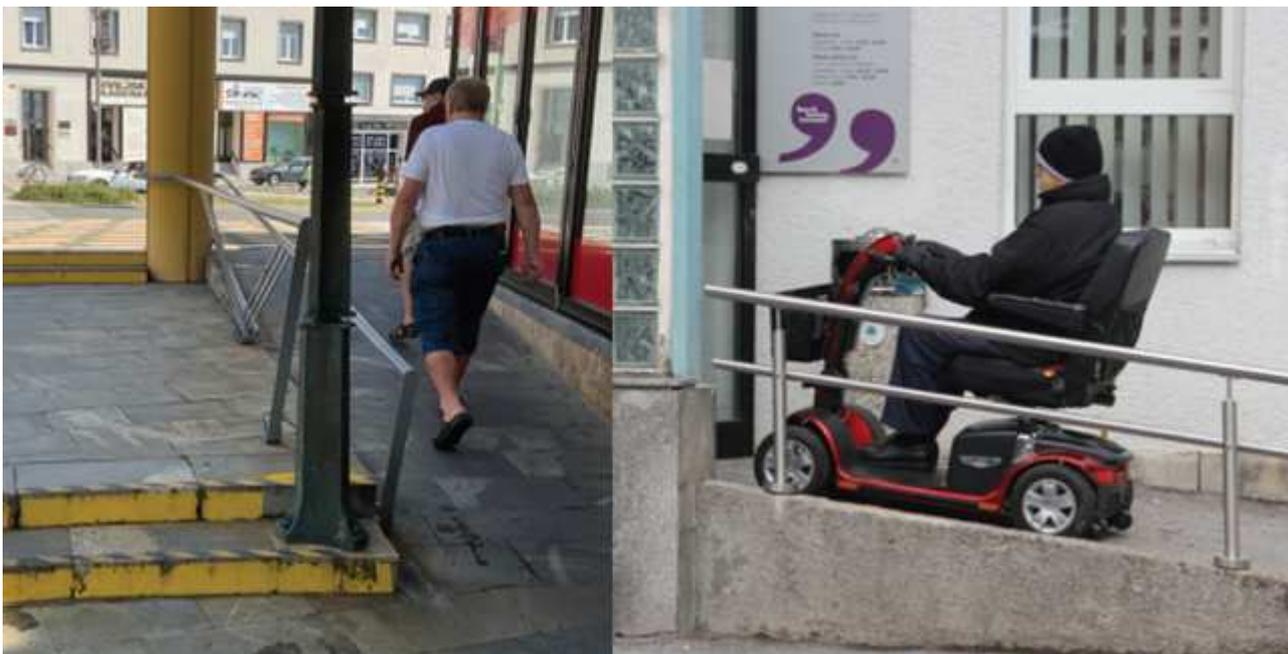
Nevertheless, it is critical to recognise that inclusive solutions benefit a much larger community than just those believed to be 'minority'. Designing accessible ramps and entrances not only improves mobility for people with impairments, but also helps the elderly, parents with strollers, and anybody with temporary ailments or mobility issues. Similarly, features such as tactile walking surface markers at crossroads, which were originally designed to assist visually impaired individuals, now serve as useful cues for everyone, signalling changes in the surface and improving general pedestrian safety and direction.


Figure 1: The ramps are also used by elderly people and elderly people on mobility scooters to make it easier to overcome the height difference. Source: Geodetic Institute of Slovenia

4.2 Shifting Perspectives: Designing for Inclusion

A good example of forward thinking in contemporary architecture is the Guggenheim Museum designed by Frank Lloyd Wright. The museum represents one of the first examples of the use of universal design. In this context, a ramp that runs through an entire building represents a space that is more than just a place for movement, an element to overcome the height difference. The ramp's meaning goes beyond its primary function of communication and becomes a space that allows equal and unobstructed use by all people regardless of their physical abilities.

Maison Bordeaux, designed by Rem Koolhaas for a person in a wheelchair, confirms the thesis that it is possible to design facilities that are accessible to functionally disabled people and at the same time offer technologically advanced and aesthetically perfect solutions. Koolhaas designed the concept of a house according to the needs of the user and outside the framework of the regulations' guidelines, which prescribe only the minimum technical requirements for the dimensions of doors, widths of corridors, ramps, etc. The house consists of three volumes with different programs connected vertically by a lifting platform. The lifting platform creates a spatial dynamic that always changes and redefines the space in which it stops (Ahmer, 2021). The house represents an innovative approach and an architectural achievement that manifests Le Corbusier's concept of the house as a 'machine for living'.

4.3 User participation and collaboration between architects and persons with disabilities

Accessibility should not be a constraint on quality architectural design. As Davis and Lifchez state, architects must actively seek out persons with disabilities to help them understand their needs. However, when designing, they should be careful not to stigmatize the client concerning possible functional impairments (David & Lifchez, 1987). In architectural practice, the embodied experiences of disabled people are rarely used as an important source for planning because they appreciate different spatial qualities than architects from different perspectives in their daily interaction with the built environment. (Vermeersch & Heylighen, 2015, Heylighen & Nijs, 2011).

Studies (Vermeersch & Heylighen, 2015; Heylighen et al., 2013; Heylighen et al., 2016; Heylighen & Nijs, 2011; Schijlen et al. 2015) conducted by architect Heylighen and colleagues show that collaboration between architects and persons with disabilities has been a positive experience for both parties. This study aimed to explore the potential of employing a disabled consultant who would experience their own space to advise architectural designers on how to improve architectural solutions. The findings of these studies suggest that such a service could add value to architectural design. However, additional efforts should be made to convince stakeholders of this added value, and alternatives for initiating innovative ideas should be further explored (Schijlen et al. 2015). This study also considered the social aspects and social value of employing a disabled person can bring. The presence of persons with disabilities in the workplace promotes awareness and acceptance of differences within the organization, which can have an impact on wider society. Employing a person with disability also has a positive impact on the disabled person, as they are affirmed as full members of society through employment.

Luck's study followed the work of designers who worked with persons with disabilities to create bespoke and tailored solutions to enable them to live more independently. An important conclusion that emerges from the results of this study is that people will respond positively to designer's products (this can also include architectural objects) if they are offered the opportunity to actively participate in the design process (Luck, 2018).

A notable example of collaboration with disabled persons is a project „Enabling multimodal mobility of persons with various disabilities" which is led by the Geodetic Institute of Slovenia and financed by the Ministry of Infrastructure of the Republic of Slovenia. The project's main goal is to improve the mobility of blind and partially sighted people, people with limited mobility, older people, and schoolchildren who may be at greater risk while navigating traffic. This can be achieved through innovative technologies, quality spatial data, useful information, and education for more independent and safer mobility of target groups. The project follows the principle of "Nothing about us without us" which is the motto of the European Disability Forum (EDF). Persons with disabilities were involved in all phases of the project, from the development of the data model to fieldwork and the promotion and transfer of knowledge. Engaging with representatives of different vulnerable groups is essential, as it provides insight into their needs and experiences of moving in space. (Rener et al., 2021).

Figure 2: Figure 2 shows the field capture training and the sharing of previous experiences among the capturers. Source: Geodetic Institut of Slovenia.

However, architects Davis and Lifchez warn that "participation will be unsuccessful if the architect is not genuinely committed to the idea of consultation by lay people in general or by lay persons with disabilities in particular, or if the architect considers such participation to be a waste of time that diminishes professionalism or compromises the aesthetic integrity of the project" (Lifchez & Davis, 1987). The negative stance against the participation of this kind can only stem from ignorance or fear of something that is not close to us or is completely unknown (Butler & Bowlby, 1997; 420). Furthermore, Boys (2014; 34) argues that user participation in architectural practice is often treated as an add-on, similar to how disability is considered an add-on to "normal" architecture.

In the process of architectural planning, considerations regarding accessibility in a building are typically addressed towards the end of the process. Accessibility and disability are equated solely to adherence to technical and functional requirements. Consequently, architects tend to neglect the consideration of disability as an integral part of their design activities, except in specific cases. Instead, they tend to rely on pre-existing off-the-shelf solutions that lack creative engagement. (Boys, 2014). Imrie suggested that universal design principles should be included to achieve high aesthetic requirements. Accessibility elements thus become part of the whole, not just an addition to architecture (Imrie, 2012). Elements, such as ramps and lifts are often seen as a functional addition to the architecture, which must be built to meet regulations and are devoid of any aesthetic considerations. They are most often placed where they will do the least harm to the aesthetic perfection of a building's architecture, hidden from the eyes of the majority.

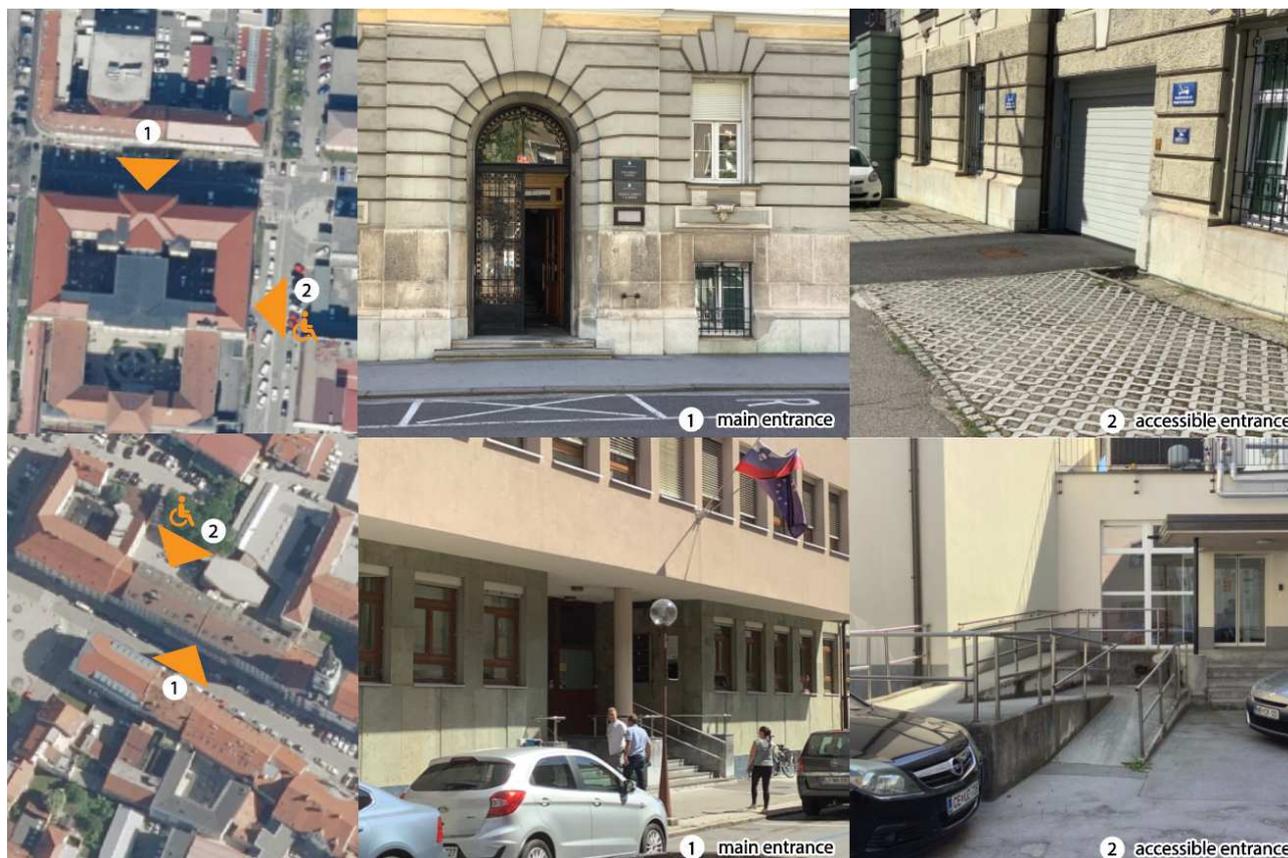
Such practices are most often observed in historically protected existing buildings, where a solution must be found to allow access to persons with disabilities. In such cases, various half-solutions are used, such as a separate entrance for persons with disabilities, through the technical areas of the building away from the main entrance. In this way, we deny the non-discriminatory principle of inclusive design, as we marginalize a group of people, hide them, and thus promote stigmatization.


Figure 3: Figure 3 shows the location of the accessible entrance for people with reduced mobility away from the main entrance to the building. Source: Geodetic Institute of Slovenia.

4.4 Inadequate solutions and Marginalization

As an example of contemporary architecture that does not consider accessibility in its design process, we can mention the work of architect Peter Eisenman, specifically the Memorial to the Holocaust in Berlin. The memorial is situated in a city block and consists of stone volumes. These volumes are placed on an orthogonal grid intersected by pathways running in north–south and east–west directions. The varying heights of the volumes created an undulating relief that was also reflected in the ground, forming a dynamic topography of alternating valleys and hillocks. During the design process, the minimum technical requirements regarding pathway widths and slopes that would enable independent wheelchair access were not considered. Consequently, individuals using wheelchairs were deprived of the experiential aspect of the memorial. Following criticism from the Swiss Center for the Disabled, 13 out of 130 pathways were subsequently modified to comply with the accessibility regulations. The justification for not considering technical requirements during design was that it was an artistic work not bound by accessibility legislation (Fitzsimons, 2012). This raises the question of whether persons with disabilities are not allowed to appreciate art?

4.5 The Multisensory Experience of Space

The relationship between people and space and how people use and experience them is fundamental to architectural practice. Davis and Lifchez, in their 'Open Letter to Architects', point out that "accessibility is more than a question of access or logistics, it is also about the quality of the experience. How one feels in a space, how one interprets it, or even whether one can interpret it adequately - these are all less quantifiable but crucially important aspects of accessibility" (Davis & Lifchez, 1987). We experience space with all of our senses. "The senses, touch and taste as well as sight and hearing, have aesthetic qualities. They do not have them alone, but rather in connection; as interactive rather than as simple and separate entities." (Dewey in Pallasmaa, 2005). When addressing architectural quality, encompassing functional characteristics, appeal, suitability, and aesthetic worth, we frequently utilise an unimpeded user with fully functional senses as the primary metric of success. If we take away the sight of our user, we can no longer evaluate a certain

architectural quality. The criteria for evaluating architectural qualities change if the user is a wheelchair user (Fitzsimons, 2012).

If a person loses any of their senses, they start to rely more on the remaining senses. The experience of space, their use, and spatial orientation varies between different disability groups. People without disabilities first perceive the space as a whole and then individual elements; for blind people, the process of perceiving space is the opposite - they first perceive individual elements and then form an overall picture from the interconnected individual elements (Ahmer, 2021).

As part of their study at the University of Leuven, researchers not only investigated physical obstacles but also examined the sensory characteristics of objects. The results of this research highlight the key role played by sensory perception in the evaluation and experience of a space. Functionally impaired individuals rely on their senses of smell, sight, hearing, and touch to assist them in understanding and navigating the object more easily, and their senses also influence the way they experience space. Examples from this study illustrate that the extent to which a building was experienced as accessible depended not only on its physical accessibility but also on how the space was felt and experienced by these individuals, who may have a unique perspective differing from most architects. Persons in wheelchairs are more attentive to visual quality from a lower perspective. Individuals with visual impairments possess both acoustic and tactile qualities. Persons with low vision are able to pinpoint poor lighting conditions. Individuals with autism are strong at identifying the general atmosphere of spaces, providing insight into the legibility of a building; for example, whether a public passageway is also experienced as public (Vermeersch & Heylighen, 2015).

5 CONCLUSION

Co-creation and community involvement are essential components in establishing accessible and inclusive public spaces for individuals with disabilities. Creating an accessible and useful environment for a diverse group of people, such as those with impairments, is a huge challenge. Various approaches and concepts have arisen around the world in response to the accessibility challenge, with the common goal of improving accessibility and ensuring inclusion for all individuals. The concept of universal design, the most well-known concept of accessibility, is a relatively new concept, first appearing 60 years ago. As our understanding of diverse abilities and user needs continues to evolve, there is plenty of room to upgrade and enhance the principles and practices of universal design. Based on the research examples provided, it becomes evident that the experience of space for persons with disabilities is desirable but often undervalued. Despite its importance, it is not fully acknowledged as an essential and valuable aspect of the architectural design process.

Architecture, as a direct and unavoidable medium, carries the responsibility for social relevance and plays a vital role in creating an inclusive society. Contemporary architecture has, to some extent, lost touch with the holistic dimensions and emotional proportions of individuals, irrespective of their physical abilities or limitations. Pallasmaa also concluded that „the inhumanity of contemporary architecture and modern cities can result in the neglect of the body and senses and the imbalance of our sensory system" (Pallasmaa, 2005). However, it is critical to consider architecture not in isolation, but rather as part of a larger interdisciplinary framework.

With interdisciplinary cooperation, we could bring out the potential for more inclusive and successful design solutions by implementing the principles of co-creation and community involvement. By combining the expertise and viewpoints of various fields, such as sociology, psychology, and urban planning, architects are able to move beyond the constraints of a purely architectural approach and develop a deeper understanding of the holistic dimensions and emotional proportions of people. Understanding societal dynamics and the social effects of built environments requires sociological insights. Psychological perspectives on design serve to clarify the complex relationship between individuals and the built environment around them by focusing on the emotional and sensory components of design. Urban planning expertise ensures that accessibility and inclusivity are integrated into the planning of the wider built environment. Using this interdisciplinary approach, architects may create environments that promote emotional and sensory stimulation for all persons, going beyond simply physical accessibility. Recognising the significance of inclusive design and actively including specialists and persons with disabilities in the design process can lead to places that are not just physically accessible but also emotionally and sensory stimulating.

Regardless, when it comes to applying inclusive design practises, there may be certain restrictions and problems. To overcome these obstacles, a proactive strategy is required. Cooperation among specialists, stakeholders, and the community is vital for overcoming potential difficulties. It entails cultivating an inclusive mindset, raising awareness, and removing barriers to the construction of truly inclusive places on physical, social, and psychological levels. We may go closer to building a more inclusive society by acknowledging and actively trying to address these problems.

As society continues to evolve, the importance of designing for diverse needs has become increasingly evident. Architects can leverage knowledge from multiple disciplines to develop environments that reflect society's aspirations for a more inclusive environment by embracing multidisciplinary collaboration. The thought of architects Davis and Lifchez in a meaningful way summarizes the important role of architecture in the inclusive society we are striving for, as architecture must be socially responsible given its direct and inevitable nature.

"The architect as visionary must remind others that architecture reflects society's relationship to itself, that creating an environment is a dynamic process, and that architecture must express society's highest aspirations and ideals." (Davis and Lifchez, 1987)

Co-Creating Development in Mining Towns: the Nexus between Social Labour Plans and Integrated Development Plans for Urban Development Planning in Rustenburg, South Africa

Samson Olaoluwa Faboye, Trynos Gumbo, Kgomotso Jackson Phillip Sebola-Samanyanga

(Samson Olaoluwa Faboye, University of Johannesburg, Department of Urban and Regional Planning, South Africa, sfaboye@gmail.com)

(Prof. Trynos Gumbo, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, tgumbo@uj.ac.za)

(Dr. Kgomotso Jackson Phillip Sebola-Samanyanga, University of Pretoria, Department of Town and Regional Planning, Pretoria, South Africa, jackson.sebola@up.ac.za)

1 ABSTRACT

Integrated Development Plans (IDPs) and Social Labor Plans (SLPs) are two crucial short and medium-term development strategy documents guiding the development of mining towns in South Africa. Besides socioeconomic growth that mining brings to the 'host communities', mining towns experience mining-related socioeconomic problems, specifically dereliction upon the closure of mines. To ensure sustainable development guarantees for mining communities, SLPs are requirements from mining companies as part of licensing obligations in South Africa. On the other hand, IDPs are five-year strategic action plans that South African municipalities must produce at the onset of a political tenure to guide municipal development over the set period. IDPs and SLPs are mutually connected to advance municipal development planning. However, with multiple agencies involved in monitoring and implementing both development plans, there are developmental questions about integrating both plans to achieve a unity of purpose. In this article, we examine the case of Rustenburg Local Municipality, noted for its vast Platinum reserves and mining globally. The study evaluates the challenges of cocreating development through SLPs and IDPs, beginning with conceptualising, implementing and monitoring these plans. Findings were sourced from primary qualitative sources (key informant interviews) and secondary sources, including desktop reviews. The research's findings reveal that while broader stakeholder consultations exist in creating IDPs, the same is not assured for SLPs. This creates gaps in integrating and implementing both action plans. Notwithstanding this obstacle, there is substantial potential for SLPs and IDPs to collaborate on inclusive municipal development in South Africa. A synergised co-creation of SLPs and IDPs at the stages of conceptualisation and implementation by all stakeholders is vital to assuring transparency, accountability and effective implementation of both strategic action plans.

Keywords: Strategic Plans, IDPs, SLPs, Co-creation, Development Planning

2 INTRODUCTION

South Africa's Municipalities are tasked with development planning by the constitutional and policy frameworks (RSA, 1996; RSA, 2000). This developmental mandate revolves around providing basic service delivery and socioeconomic empowerment. Within this mandate, municipalities must produce IDPs, a medium termed development document projected to span the five years of municipalities' elected political leadership. IDPs elaborate the municipality's developmental blueprint "with emphasis on the municipality's most critical development and internal transformation needs" (RSA, 2000: 38). In the same vein, iterated Municipal IDPs are to align with sectoral, provincial and national development plans – these being longterm development plans while IDPs are medium termed. Development plans iterated by all the government tiers in South Africa include a Spatial Development Framework (SDF) blueprint for land use management (RSA, 2013). In essence, the developmental plans prescribe the socioeconomic future while the SDF component addresses the issue of land use management. Making these developmental plans requires a participation process for significant inputs and vetting from the stakeholders these plans serve.

SLPs can be likened to Local Economic Development strategies for mining towns, albeit prepared by mining companies as part of mining licencing requirements set by the Department of Mineral Resources and Energy (DMRE) (RSA, 2002; CALS, 2016). It is aimed at a regeneration initiative of mining towns to ensure they do not slide into dereliction resulting from mining activities. The Mineral and Petroleum Resources Development Act 28 of 2002 (MPRDA) defines the legal framework for SLPs (RSA, 2002). SLPs come under the mandate of addressing the mine host community needs (inclusive of labour-sending areas and adjourning locations around mining communities affected by mining activities); therefore, the application for mining rights must be accompanied by one. This is addressed in Human Resource Development programmes

(inclusive of skills development plan, career progression plan and its implementation, mentorship and its implementation and internship and bursary plan and its implementation), Local Economic Development (LED) Programme, labour downscaling and retrenchment plan, financial implementation for the SLP. As stipulated in Regulation 42 of the MPDRA, SLPs, upon approval by the DMRE, must undergo a consultation process with the host communities and be aligned with the Municipality's IDPs (ibid).

According to Regulation 43 of the MPDRA, SLPs are subject to periodic 5-year reviews, a continuous process until a closure certificate has been issued to close up mining activities in the area (RSA, 2002). SLPs and IDPs are strategic planning instruments charting the development course of mining towns in South Africa. This article begins with the methodology utilised for data collection and a literature review on development planning. An overview of the study area, presentation of findings, recommendations, and conclusion follows this.

3 OBJECTIVES

- To explore the linkage between SLPs and IDPs in municipal development planning in Rustenburg Local Municipality.

- To investigate the problems associated with implementing SLPs in Rustenburg Local Municipality.

4 METHODOLOGY

The study adopts a qualitative approach incorporating documentary reviews and key informant interviews. Documentary reviews comprised literature reviews approached with keyword searches on "strategic planning", "governance", "development planning", and "participatory planning" sourced from the Web of Science and Google Scholar. Other sources of documentary reviews were South African government policy documents guiding the legal framework for municipal development planning in South Africa. These documents include the 1996 Republic of South Africa Constitution, MPDRA and Municipal Systems Act of 2000. Information was also sourced from the Municipal Infrastructure Support Agent (MISA) archives, which provided details on the alignment and implementation of SLPs in Rustenburg Local Municipality. A total of ten key informant interviews were conducted between October 2022 and April 2023. Key informants were drawn from the Rustenburg Local Municipality staff, South Africa development stakeholders, municipal officials, DMRE officials, and residents of Rustenburg Local Municipality. Key informants were selected through the snowball sampling technique.

5 INTERPLAY BETWEEN DEVELOPMENT PLANNING AND GOVERNANCE

Governance and development planning are closely intertwined, and their interplay manifests in producing IDPs and SLPs. Development is a multidimensional process to improve the overall quality of life, encompassing economic, social, and environmental aspects (UN, 2023). Rabie (2016) defines development as an economic and technological procedure deployed to make the best use of the resources at hand to spur economic growth and elevate the quality of life of community residents. Governance, on the other hand, is, according to Fukuyama (2016), an established framework for societal cooperation and administration between sovereign and non-sovereign entities. It is a framework for interaction between private and public actors to ensure the stability of society and political entities (Kjaer, 2011; Cashore et al., 2021).

The relationship between governance and development planning comes under the nuances of 'the good governance campaign'- a definition coined by the UN-Habitat. This is defined as the quality and "access to the necessities of urban life, including adequate shelter, security of tenure, safe water, sanitation, a clean environment, health, education and nutrition, employment and public safety and mobility" (UN-HABITAT, 2002: 14).

Governance and development planning involves the imposition of subtle coercive influence over people (Rode, Terrefe and da Cruz, 2020). Although the government oversees governance, it is demonstrated that several governance players are in the urban sociopolitical sphere. Governments are charged with providing services like housing, power, education, and development control, among other duties, yet these commitments are typically not fully met (Alford and O'Flynn, 2012). Okunlola (2001) highlights the local government as critical to implementing governance and development planning. Asserted herein (ibid) as

complementary to this are poverty reduction, government accountability, participatory budgeting and planning.

From the mid-twentieth century, urban planning underwent a paradigm shift with advancements for participatory community planning rather than professional-led master planning. This is viewed as a bottom-up developmental approach and more entrusted to entrench sustainable development. According to (Clark 2013), controlling fast urban expansion is not a task the master planning idea can handle. On the global scale, frameworks for human settlement planning favoured the shift from "master planning" to "strategic planning" (Watson 2009). Its inclusion of citizen engagement was one of the justifications for adopting strategic planning. In support of strategic planning, it has been said that democracy is now more deeply ingrained in society, particularly with the rise and growing importance of civil societies and community-based groups (Friedman, 1998; Amin, 2002).

Advocacy planning, closely associated with this novel planning movement, encourages widespread community involvement to develop plans that meet the needs of underrepresented groups and give them more power (Grooms and Boamah 2018). This kind of planning encouraged chaos to bring about justice and forced public authorities to consider neglected interests (Berke 2002). Developmental Strategies are thus prepared with stated goals intending to improve local communities' quality of life and contribute to the realisation of sustainable development (Williams 2002). Essentially, development planning is devolved to the local government level, which, according to (Madzivhandila and Asha, 2012), creates favourable conditions for mobilising material, financial, and human resources. This intends to improve the delivery of services to local communities and permits the utilisation of locally accessible resources. In post-apartheid South Africa, long-term strategic city planning was embedded in the 5-year tenured Integrated Development Plans (IDPs), reviewed annually and came with 'neo-liberal' policies (Todes 2014). The allusion to neoliberal policies in planning points to private sector participation in initiating and implementing development action plans (Jessop, 2002; Brenner and Theodore, 2005). SLPs, as applicable herein, as local economic action plans prepared and implemented by mining companies can be attributed to evidential neoliberalism in South Africa's mining town development.

Monitoring and evaluation is a veritable tool for ensuring the implementation of development plans and urban growth management. According to the UN-HABITAT (2009), most urban planning frameworks fail to integrate monitoring and evaluation in their implementation processes. This trend makes it difficult to evaluate the impact of development plans. In developed countries, "monitoring and evaluation of the implementation of urban plans have become part of practice in the more progressive planning departments of cities and regions" and vice versa in "transitional and developing countries" (ibid, 2009: xvi). Development planning as a core function of local government enables crucial choices regarding the distribution of limited resources to maximise the provision of health, education, and other services. It better understands local priorities and enables accountability on resource allocation decisions. However, monitoring the implementation of local action plans will ensure good governance at the level of local government governance.

6 PRESENTING RUSTENBURG LOCAL MUNICIPALITY

Rustenburg Local Municipality (RLM) is located in the Northwest Province of South Africa, covering 3,423 square kilometers (RLM, 2022). The Gauteng City Region, which includes the metropolitan regions of Johannesburg, Tshwane, and Ekhuruleni, is within a 120km radius of the municipality regarding accessibility. The municipality is one of five municipalities comprising Bojanala District Municipality, the others being Kgetleng River Local Municipality, Moses Kotane Local Municipality, Madibeng Local Municipality and Moretele Local Municipality. RLM is a part of the Bushveld Complex. Merensky, Upper Group, Middle Group, Lower Group, and Upper Zone, rich in vanadium, are the economically significant reefs of the western limb of the Bushveld Igneous Complex (DMRE, 2022). More than half of the world's platinum-group metals (the six platinum-group metals are ruthenium, rhodium, palladium, osmium, and platinum), gold, silver, and other related minerals like vanadium, chromium, and base metals (copper, lead, tin, aluminium, nickel, and zinc) are found in this igneous body (ibid).

7 CO-CREATING DEVELOPMENT WITH THE IDP AND SLP AT RLM

The White Paper on Local Government defines IDPs as one of the tools to achieve developmental outcomes: budgeting, performance management, stakeholder collaboration and participatory planning (RSA, 1998). Typically, a municipality's IDP assesses the socio-economic and environmental realities, determines the community needs from the participatory planning and lists a developmental vision for the municipality. It is anticipated that with IDPs, municipalities would be able to align their financial priorities and conciliate with provincial, national and international strategic plans. The IDP is a tool for local development planning that assists local municipalities in creating a thorough and long-term plan to promote services and development under their purview. For IDPs to be legitimate, the conceptualisation process must entail meaningful engagement reflecting the needs and objectives of local communities. Additionally, there must be interdepartmental cooperation and horizontal governance coordination to deliver adequate service. Thirdly, the successful implementation of IDPs relies on institutionalism inclusive of professionalism and competence, especially in finance management.

The SLP is a documentary requirement by the DMRE for granting mining rights to prospective firms. Section 23 of the MPRDA (Act 28 of 2002) mandates the preparation of an SLP as one of the mining licencing and mining permit renewal requirements. Under the 2020 amendments of the Act, it became mandatory for mining firms to publish approved SLPs. Regulation, 41 of the MPRDA, gives the objectives of the SLP as set to ensure mining firms with mining rights contribute to the socioeconomic development of mining communities and labour-sending areas (RSA, 2002). The participation process is also included in the making of the MPRDA, which according to Regulation 42 of the Act, mining firms, upon notification of acceptance of mining licence application, must within 180 days consult with affected persons about the contents of the SLPs and align to the targets of the municipal IDP. The participation process must be conducted by the terms of the Environmental Impact Assessment Regulations of Sections 24 (5) of the National Environmental Management Act of 1998 (ibid). This involves an advertisement for the participation call via written notice, among others. SLPs, once approved by the DMRE, are lodged with the DMRE's Regional Manager and subject to five-year periodic reviews, which are perpetual till a mining closure certificate has been issued. Regulation 45 of the Act mandates a minimum of three annual meetings between the mining firm and stakeholders (mining communities and other affected persons) and which outcome should be included in annual reports submitted as compliance to the DMRE's Regional Manager. Regulation 46 of the Act specifies the content of SLPs and the publication mandate. Approved SLPs are to be published within 30 days of DMRE's approval in English and the dominant official local language of the mining community. This should feature on the mining companies' website, libraries, municipal and traditional council offices and mass media advertisements/publications.

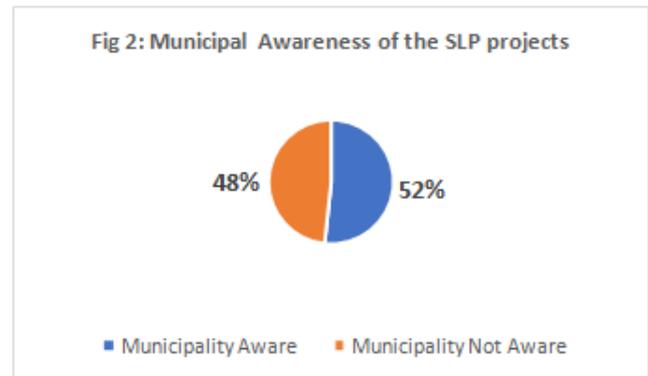
8 CO-CREATING DEVELOPMENT WITH THE IDP AND SLP AT RLM

The IDP and SLP are strategic planning documents towards enhancing local economic development at RLM. The creation process of the IDP mandates participation from ward committee sessions to wider community participation sessions. Mining firms as stakeholders ought to be one of the participants of the IDP consultation sessions. This would enable knowledge of community needs and familiarisation with the IDP preparation process, thereby assisting the preparation of SLPs. Conversely, mining firms are not mandated to initiate the SLP participation process until the notification of acceptance of application documents by the DMRE. The mandatory participation process in making IDPs establishes the co-creative development protocol. However, the municipality leads the local economic development process with the support and participation of the community, civil society and other stakeholders.

9 FINDINGS

RLM, as a mining community, is listed among the Distressed Mining Communities Programme launched in 2012 (MISA, 2022). In line with this programme, MISA undertook a programme to evaluate the alignment of SLPs with IDPs. The project was carried out between May 2019 and May 2022. The evaluation procedure involved the review of Mine SLPs, IDP legal framework, meetings and discussions with municipal representatives, project site visits, compilation, and the review of status quo reports for RLM. Thirteen companies were operating in the RLM, and a total of twenty-four SLPs were noted to be operational between the period from 2004 and 2024. Only five SLPs are still in tenure; sixteen of the SLPs already expired, while

three SLPs are within two years of expiration.

A total of sixty projects were listed for implementation in the examined SLPs. Findings from the evaluation of the projects are illustrated in charts in categories of SLP-IDP alignment, Municipal awareness, and implementation status.


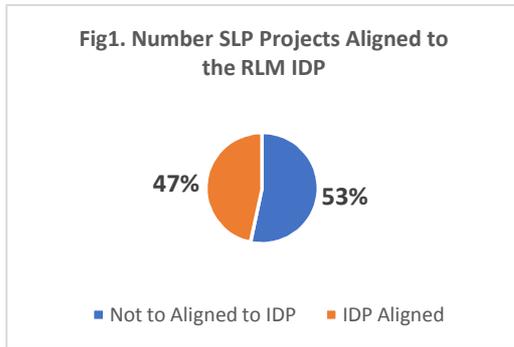


Fig. 1: Number of SLP projects aligend to the RLM IDP. Fig. 2: Municipal awareness of the SLP projects. Source: MISA, 2022.
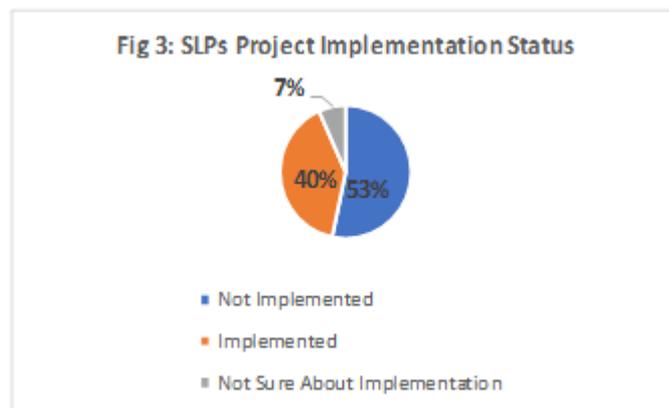

Fig. 3: SLP project implementation status. Source: MISA, 2022.

It was noted that all SLP projects not aligned with the RLM IDP(s) were not implemented. In contrast, most SLP-IDP-aligned projects were implemented except in 7% (4) cases where the implementation status is unconfirmed. Also, for the non-implemented projects, in most cases, RLM was not aware of the existence of such projects. However, ten such projects are listed in SLPs with a terminal implementation date of 2024. In summary, we find a strong correlation between SLP-IDP alignment and the successful execution of SLPs.

9.1 Discussion

The public participation process was identified as not adequately addressed by mining firms. An established engagement and communication channel between mining firms and core stakeholders (particularly the municipality and community) is critical to aligning and implementing SLPs. Though challenging, some mining companies participated through community meetings and communication (email exchanges) from the mines to the municipality. In cases where public participation was observed not to be held, this was noted in the lack of letters or proof of engagement (attendance register) between the mines and the municipality across the three generations of iterated SLPs.

SLPs are a means to assert relevance for service delivery by traditional leaders. Traditional councils hosting mining forms put together their infrastructure and socioeconomic needs for mines to input in the SLP. This asserted as a partnership between the community and the mining industry. The DMRE is noted to be ineffective in following up with the implementation of SLPs. According to a municipal official, requests by the municipality to resolve the adverse effects of mining activities are largely ignored. She elucidates the predicament by saying, "when you communicate with the mine as the municipality, the mine would say

DMRE says..".[1] The DMRE, operational within the national government's framework, cannot follow up with effectively monitoring SLP implementation at the municipal level.

The RLM has, however, sought ways to mitigate the misunderstanding with mines through the institution of the Mayoral Stakeholder Engagement Committee (MASECO). This committee consists of the executive mayor (as chairperson), Members of the Mayoral Committees (MMCs) and the directors. This committee monitors the implementation of SLPs to implemented within RLM. Though not entirely effective, this committee can coordinate the alignment and manage issues arising from the interaction of mining firms with the community. One issue of note is fiscal opacity by some mining companies. While some mining companies will not state the amount committed to listed projects, in other instances, fiscal discrepancies are observed between the declared budgeted funds and the actual amount committed. "For instance, the budget will state 5km of road to be constructed at the cost of 10 million Rands, and then you will discover only 5 million of the budgeted sum is spent. Where does another 5 million Rands go? You don't know.. they don't disclose…that is a problem."[2] There are allusions that mining companies as private entities may be desisting from publishing their financial allotments for SLPs to protect unwarranted public access to their financial records.[3] [4] However, with the 2020 amendments to the MPRDA now mandating SLPs to be published and legal provisions for public information access to organisations whose activities have a public impact, Mining firms as private liability holdings must declare their SLP financial commitments. SLPs are mandated by mining companies as a corporate social responsibility. Within this, mining firms must commit one per cent of declared profits to Corporate Social Responsibility.

Inadequacies of the participation process during the making of SLPs breed public dissatisfaction with the corporate efforts of mining companies. A community resident cites the perceived preferential treatment of mining companies to site projects mainly in traditionally administered areas. In contrast, dwellers of these perceived preferential project areas believe the labour-sending areas are better treated.[5] In another vein, there are cases in which mining companies do not carry out an effective project impact assessment. In the opinion of a resident respondent he acclaims mining companies offer training to his community on mining operations, which skills can only be used in the mines. However, most mining companies do not follow up the human resource training with employment offers, and as such, he sees such training as useless as the skill can only be deployed in the mines.

The poor participation process, fiscal opacity, and inefficient monitoring and evaluation process are co-creation challenges of integrating SLPs with IDPs and implementing SLPs in RLM. The nonstandardisation of the community consultation process and correspondence between the mining companies and municipalities is another conundrum. Examined SLPs were noted not to have implementation plans. "The format of this consultation and concurrence between the mines and municipalities and the contents of the SLP is currently not regulated. Most municipalities are requested to provide a letter with a list of projects to be included in the SLPs. The letter is not standardised and can be provided by either the Municipal manager, LED Manager, IDP Manager, or even a ward councillor."[6] This accounts for the awareness gap in the municipality of listed SLP projects. Similarly, approved SLP copies are not shared with municipalities. When published on the web pages of mining companies, it is well after the implementation tenure of the SLP. Associated with the fiscal opacity of SLPs is the nonstipulation of the procurement methodologies or strategies of the approved projects. The extant monitoring and evaluation process of SLP implementation requires mining companies to submit annual reports to the DMRE. However, municipalities are not involved in the monitoring and evaluation chain, which accounts for the implementation failings of many SLPs. The inadequacy of the IDP and SLP participation, monitoring and evaluation process of SLPs accounts for the ineffectual developmental co-creation the synergy of both plans was intended to achieve. This has bred mistrust among mining town residents, municipalities and mining companies. Associatedly, there are unrealistic expectations from the municipalities and communities towards mining companies to the extent of resentment towards the efforts of mining companies.

10 RECOMMENDATION AND CONCLUSION

SLPs, though the responsibility of mining companies, must be linked to the municipal IDP with attendant synergy in the implementation between both parties. The failure in some cases and non-appreciation of the successful impact of SLPs can be attributed to the co-creation inadequacies between the custodians of these two developmental plans. To mitigate the IDP-SLP co-creation shortcomings, the following recommendations are considered tangible to correct the inadequacies discovered from the findings of this study.

Mining companies must be compelled to attend IDP participation sessions and be included in the IDP steering committee in the wards of the jurisdiction of operations. SLPs, a Corporate Social Responsibility of mining companies, requires partnerships and collaborations among the stakeholders – the municipality, DMRE, mining companies, government departments and the community (inclusive of Community-Based Organisations, and formal and informal community leadership). The key to the success of a good partnership and working relationship between the municipality and the mining company is creating optimum institutional structures to ensure that projects decided on within and without the municipality are acted upon.

There is an observed gap in the chain of monitoring and implementation of SLPs. The reportage chain is directed solely to the DMRE, a national government department. This can be corrected by devoting monitoring and compliance checks to the municipalities (preferably the district municipality at the helm of local compliance checks). Such a tiered monitoring and evaluation arrangement devolving responsibility from the national to local government avails accountability and responsibility for coordination, handover, and delivery. The process of cocreating development through the synergy of the IDP and SLPs should be entrenched in partnerships intending to achieve a shared developmental goal. As medium strategic planning documents, coordinating the formulation and implementation of IDPs and SLPs is vital for efficiently allocating resources. So also, a devolved monitoring and evaluation framework incorporating inclusive participation of relevant stakeholders will ensure good governance delivery. This would be reinforced by institutional structures guaranteeing stakeholder collaboration with the essential character of cocreational planning.

1 ABSTRACT

Tourism is one of the most important sources of national & international income in the World. One type which has the potential to contribute to the sustainable development of local communities and alleviation of poverty levels is Ecotourism. Ecotourism implies responsibility to the environment, resident communities, and a duty to respect, invest, and develop local cultures. This definition not only suggests that there should be a recognition of and positive support for the conservation of natural resources, both by suppliers and consumers, but also that there is a necessary social dimension to ecotourism. The term 'community-based ecotourism' (CBET) takes this social dimension a stage further. This is a planning paradigm where the local community has substantial control over, and involvement in its development and management, and a major proportion of the benefits remain within the community. CBET is considered the logical link between the environment, the local community, and the tourism industry. It has become the newest planning process approach in tourism development, devised to support community involvement, improve their living standards and protect natural resources which is the main current problem resulting from the mass tourism industry in Egypt. Since 2002, also the year when eco-tourism was internationally promoted by the UN the Egyptian government began to seek new strategies and plans to actively support the participation of local communities in ecotourism development initiatives in Egypt's rich biodiversity and numerous protected areas. However, the actual implementation of involving communities in decision making is poorly achieved, which impacted negatively on the effectiveness and sustainability of these initiatives. This paper proposes an integrated community-based ecotourism framework. This was done through a theoretical study of the main principles and strartegies of community ecotourism that have been successfully applied in developing countries by using the Egyptian protected areas classifications which determine the applicable community participation types for effectively involving local communities in protected areas. Subsequently the framework can be applied to specific destinations and recommend action points for their development according to each area's needs and variable circumstances. Once developed, this integrated planning tool can be used to devise a local urban development plan by the local government and other organisations in protected areas to improve the physical and social environments and to create a better understanding of the relationship between tourism and community.

Keywords: protected areas, framework, community development, ecotourism, urban planning

2 TOURISM DEVELOPMENT

The ongoing influx of tourists, especially eco-tourists, intensifies the connection between protected areas (PAs) and ecotourism. There are two divergent and conflicting schools of thought among the academics regarding the expansion of ecotourism development in the PAs. On one hand, ecotourism is seen as being compatible with PAs and is therefore crucial to their creation and management (Foxlee, 2007). They are now recognised as one of the top ecotourism locations, offering visitors an exclusive experience. In this respect, ecotourism and PAs appear to be mutually reinforcing, with PAs needing ecotourists and the reverse (Ceballos-Lascurain, 1996). On the other hand, ecologists or conservationists typically resist the development of tourism-related activities in the PAs. Some contend that the historical compatibility of tourism and environmental preservation has been ambiguous (Lawton, 2001; Wall & Mathieson, 2006). Many PAs, for instance, were originally solely created with a non-profit environmental mission in mind; however, they are now increasingly dependent on tourism-based revenues, which could also degrade their resources (Lawton, 2001). This idea, however, seems dubious because certain tourist activity types, as well as their spatial and temporal dimensions, frequently influence resource degradation. Therefore, it would be irrational to consider tourism as a source of environmental degradation and to oppose its growth without considering the characteristics, form, and planning approach.

Therefore, governments, local communities, and non-governmental organisations have praised the promotion of ecotourism as a strategy to encourage environmental conservation in relation to the development of local communities in the PAs of developing nations (Butcher, 2007). In this regard, issues related to the evolution of community-based ecotourism development in a particular destination (like PAs), the ecotourism planning approaches, community-based ecotourism strategies, local attitudes towards ecotourism development, and the dynamics between local communities, (eco)tourism, and PAs have been discussed below to highlight the critical issues related to CBET development process.

3 ECOTOURISM

3.1 Ecotourism definitions

Ecotourism, as an alternative tourism, involves visiting natural areas in order to learn, study, or carry out environmentally friendly activities (Ruxandra-Irina Popescu, 2011). It's a tourism based on the nature experience, which enables the economic and social development of local communities as well as to ensure a meaningful experience to the tourists, increasing their awareness about sustainability issues and promoting sustainable tourism practices amongst them (UNEP, 2015). It focuses primarily on experiencing and learning about nature and their habitats, as well as about cultural artifacts from the locality. Ecotourism itself is meant to be a sustainable form of natural resource-based tourism. Even though ecotourism lacks a concrete definition, there are many well recognised definitions that have formed a clear picture of its core principles. Ecotourism, in its simplest form, is a responsible travel to relatively unaltered natural and cultural areas that, by building strong relationships and interactions between the place and its people as well as between the local community and ecotourists, fosters ecological and cultural awareness, by enhancing the natural and cultural heritage, and is based on social equity and leads to the long-term well-being of the local people. (World Tourism Organisation UNWTO, 2002).

3.2 Ecotourism planning and development approaches

Developing ecotourism and achieving its desired outcomes and goals requires strategy, careful planning, and ongoing evaluation (Denman, 2001). The unregulated tourism development is a market led view of tourism that basically provides attractions, facilities and services that the tourist market needs. The nature of this development lacks long term vision and usually results in environmental degradation and loss of socio-cultural integrity, even if it achieves short term economic benefits (Timothy, 2003). For successful ecotourism planning projects, the host countries have to recognise the importance and the urgent need for sustainable urban development. In recent decades, several tourism planning paradigms have emerged with a general aim to reduce the negative impacts of tourism and improve its positive impacts. These paradigms include: boosterism, the economic or industry-oriented approach, the physical/spatial approach, and the community-oriented approach. These the four recognised traditions of tourism planning.

3.2.1 Boosterism

It's a "growth-based strategy" that relies heavily on the marketing tactics for the expansion of tourism. This strategy predominated in the 1960s and the first few years of the 1970s (Wisansing, 2005), and it was reflected in the decision of the public and private tourism organisations to spend the full allocated budget to draw visitors. In accordance with this method, natural resources are viewed as assets to promote the market and boost the economic benefits, and tourism is seen as good to locations since it lowers development barriers (Getz 2008). However, this strategy disregards the consideration of the host community in the planning process and the carrying capacity of geographic areas. Boosterism continues to be supported by two kinds of people: politicians who think economic expansion is always advantageous and those who profit from tourism. (Farangiz Khaledi Koure, 2022)

3.2.2 Economic oriented

The second strategy is the economic tradition or industry-oriented strategy. Tourism is seen as an industry by which governments may achieve their growth goals, job creation, and regional development through financial incentives, research, and marketing. This custom is developed to bring in money and open employment prospects in particular regions, and it is centred on the economic advantages of tourism. This

strategy is a continuation of boosterism, emphasising commercial aims over social and environmental ones (Robinson, 2009).

3.2.3 Physical/Spatial

The environmental movement has been particularly critical of these two approaches since the 1980s, which helped give rise to the physical/spatial approach. Environmental issues were the main emphasis of the physical-spatial approach. Tourism should, in the opinion of proponents, be based on spatial patterns that minimise its detrimental effects on the environment. Additionally, they give the social, physical, and environmental carrying capacities particular consideration.

3.2.4 Community based

Critics only discovered the fundamental flaws in these three strategies throughout this decade. The main complaint was that contributions of local communities to tourism planning and decision-making were not given enough consideration (Hall, 2009). The community-based strategy was consequently proposed. It placed a strong emphasis on the equitable distribution of income and the bottom-up growth of tourism. The involvement of local organisations in the planning process was also emphasised. The dominant strategy was rejected in the 1980s due to its top-down methodology, which increased the importance of this approach. Participatory planning from the bottom up gained a lot more acceptance. According to this strategy, the planning and development process was facilitated and mobilised by the central government where locally defined goals and local development are an integral part of incremental tourism planning which allows for high levels of predictability, flexibility, and collaboration.

The beneficial function of local communities should not be disregarded in the development of ecotourism as a service-oriented and human-centred activity. Local communities should be seen as more than just consumers when it comes to ecotourism because their role goes beyond conceptions of production and supply. According to Nunkoo and Ramkissoon (2011), community participation gives locals the chance to express the significance of economic, social, cultural, and environmental repercussions from their point of view. He stressed the importance of contributions of local communities to sustainable development; as a result, it is advised to view community participation as the crucial piece lacking from the effective development of the ecotourism industry. Therefore, communities must be included and consulted in a way during the planning and policy-making phases to achieve a successful ecotourism development. It was cited that the lack of community interaction is the primary cause of the failed growth of ecotourism in their study regions.

3.3 Community based ecotourism

Community based ecotourism (CBET) is a type that improves the capacity of rural communities to manage tourism resources while ensuring the involvement of the local community. CBET can support the area local economy, maintain culture, protect the environment, and offer educational opportunities. It turns, it acts as a tool for reducing poverty because it might offer alternative sources of income to the neighbourhood. A long-term strategy for community-based ecotourism tries to enhance local community gains, and minimise the detrimental effects of tourism on the local population and its natural resources. It encourages the community to take part in connected initiatives and to be involved in observing and reducing negative effects. Below are a few general traits of CBET that UNEP and UNWTO have emphasised: (Bin Zheng, 2021)

- involving appreciation not only of nature, but also of indigenous cultures prevailing in natural areas, as part of the visitor experience
- containing education and interpretation as part of the tourist offer
- not exclusively, organised for small groups by small, specialised and locally owned businesses
- minimising negative impacts on the natural and socio-cultural environment
- supporting the protection of natural and cultural areas by generating economic benefits from it
- providing alternative income and employment for local communities; and
- increasing local and visitor awareness of conservation.

The development of community-based tourism must be done methodically, starting with an examination of the community's eligibility for participation in tourism and deciding which participation method is the most appropriate according to the local hosts and the destination circumstances.

The framework aim is to offer directions for tourist/rural planners, NGOs, industry participants, and CBET groups in determining which type could work for a certain community and, if it is practicable, how to participate in the tourism business and sustain it eventually. It's a flexible approach that suggests a step-by-step strategy with a list of actions to support each phase according to each participation type which will be discussed below.

3.3.1   Public consultation framework

The framework from the handbook is a result from the study of different case studies and best practices of government, NGO, industry, and community initiated CBETs in ten APEC member economies namely China, Viet Nam, the Philippines, Canada, Australia, New Zealand, Chinese Taipei, Indonesia, Korea and Malaysia. The framework offers two parts of nine procedures for establishing and maintaining CBET. The aim of this paper aim is to establish an appropriate similar framework for Egypt's protected areas, with deeper research when it comes to the first step "preparing the community for ecotourism", specifying the applicable community participation technique to each protectorate according to the different habitats, local communities, and protectorate type. The first four steps in Section A deal with launching and growing CBET efforts and are helpful for projects and sites that are starting CBET. The last five steps in Section B, which are more suitable for advanced CBET projects, are gradually advancing up the value chain, and are intended to address the sustainability of CBET initiatives. (Amran Hamzah, 2009) The development of CBET is advised in accordance with a set of action points that are presented in a tabular form below.

Fig. 1: Nine steps to develop and sustain CBET (Amran Hamzah, 2009)

3.4 Typology of community Participation

Starting with the consultation framework "assessing the community needs and preparing the community for tourism" highlights a very crucial issue which is the main question of this research: how and which technique to use when it comes to community participation. Although it has been referred to by many names and integrated into the development process in several ways, the participatory development concept has frequently surfaced in international development (Stone 1989). More specifically, there are differing viewpoints on the many forms of community involvement, and different experts have categorised the same idea under the same heading but with different titles. As a result, various categories under which to evaluate different forms of community participation exist. However, it has been suggested to categorise it under three broad sections in accordance with UN implications. (Farangiz Khaledi Koure, 2022)

3.4.1   Spontaneous participation

Spontaneous participation is voluntary, bottom-up without external support. It represents an ideal mode of participation, as it mirrors a voluntary and autonomous activity on the part of people to handle their problems without help from governments or other external agencies (UN 1981). This type is also referred to in the developmental literature as informal bottom-up. It may also represent a degree of community power in Arnstein's ladder of citizen participation. Although the above terms for spontaneous participation are used

interchangeably to a large extent, to explain some of them in further detail may help to identify some other dimensions of this kind of participation (Farangiz Khaledi Koure, 2022)

step 1

ACTION 1: ASKING THE RIGHT QUESTIONS
Why should the community be involved in tourism? Why tourism?

ACTION 2: DETERMINING THE ROLE OF TOURISM
a. Tourism as an alternative and lucrative source of livelihood and income
b. Tourism as a tool to justify the conservation efforts
c. Tourism as a "training ground" for future participation in other economic sectors

ACTION 3: CARRYING OUT A SITUATIONAL ANALYSIS
1. What does the community expect to gain from CBT?
a. Increase income
b. Employment opportunity
c. Upgrade the quality of life style
d. Complement the current physical development

2. Determine Community Values, Attitudes, Aspiration and Concerns
a. Pride in community
b. Conserve local culture
c. Sense of ownership

3. Identify the Labour Force Needs For Tourism
a. Level of education
b. Previous occupation
c. Current occupation
d. Special skills

step 2

ACTION 1: CONDUCT PRELIMINARY WORKSHOPS
WORKSHOP 1 : Identifying potential tourism activities to be developed and promoted
a. Discuss and identify the available resources and activities
b. Evaluate the existing resources and rank them
c. Select the top 5 – 10 attractions / activities to develop

WORKSHOP 2 : Developing linkages with surrounding tourism attractions
a. Identify the surrounding resources
b. Carry out an inventory of surrounding resources (location/distance/uniqueness/physical and etc.)
c. Develop corridors and packages

WORKSHOP 3 : Organising workshop on involvement of different sectors of community
a. Identify the types of contribution (e.g. services/ entrepreneurship and etc.)
b. Develop specific bureaus

WORKSHOP 4 : Identify training needs
a. Identify the gaps in term of the knowledge and skills
b. Determine the training needs for each section of community (e.g. women/ youth/guides and etc.)

WORKSHOP 5 : Developing and conducting training modules
c. Determine the training method (theory / hands on)
d. Determine the content of modules

ACTION 2: STUDY TRIPS AND "COMMUNITY TO COMMUNITY" TRAINING
a. To expose community to real life situation
b. To enhance the production, tourist experience and service quality

ACTION 3: FORMULATION OF TRAINING MANUAL
a. To ensure trainings carried out in a systematic and consistent manner
b. Documentation of the training modules and instructions
c. Formulate the training manual

step 3

ACTION 1: IDENTIFY LOCAL CHAMPION
a. Visionary
b. Good Communication
c. Disciplined
d. Proactive
e. Innovative
f. Sensible
g. Patient
h. Trustworthy
i. Courageous
j. Never say die attitude
k. Dedication
l. Commitment

step 4

TOURISM PRODUCT CYCLE
STAGE 1 : Community Organisation in Initial Phase of CBT
a. Drawing solely from the talents within the local community

STAGE 2 : Community Organisation As CBT Project Matures
a. Seeking professional help without sacrificing community structure

IDENTITY ROLES OF CBT ORGANISATION
1. Empowering women and youth
a. Creating specific bureau/association
b. Appointment of office bearers
c. Designation of roles and type of activities of each bureau

2. Formulating a common vision but realistic targets
a. Provide the direction to guide the community
b. Inform the locals about the impact of tourism
c. Formulated the common vision

Example of common vision
"to preserve the unique cultural heritage of the village by implementing the adaptive reuse of traditional buildings for the enjoyment of visitors without sacrificing the community structure, values and local way of life".

d. Set realistic targets (consider factors such as level of education, skills and training gaps)

3. Nurturing an anti handout mentality
a. Encourage self help sense of ownership

4. Establishing a community fund
a. Setup the community fund (to manage the income & expenditure)
b. Create revolving fund for community
c. Create microcredit facilities

step 5

1. Partnership with NGOs
a. To increase the community's capacity in undertaking of conservation project

2. Partnership with Universities
a. Educate the local community on the appropriate framework to develop CBT projects.
b. Equip the organisation with the tools and approaches to improve the quality of the tourist experience
c. Bring research expertise

3. Partnership with Government Agencies
a. Field officers stationed on site
b. Monitoring the project

4. Partnership with Tourism Industry
a. Focus on marketing and promotion
b. Establish network with specialist tour operators at the international level such as Intrepid Travel

step 6

1. Integration with conservation, sustainable development and responsible tourism projects
a. Spin offs in the form of conservation, sustainable development and responsible tourism
b. Provide employment opportunities for locals

2. Integration with other economic sectors
a. a "training ground" for the local community
b. prepare local community to undertake non-tourism projects
c. provide stable and better paying jobs for locals

step 7

ACTION 1: FORMULATING OF CBT MASTER PLAN
a. Detail inventory of tourism resources
b. Apply techniques (e.g. Product Inventory Matrix/ Product Competitiveness Index
c. Evaluate tourism products
d. Proposal (presented using plans, maps and illustrations
e. Approach expertise from universities or volunteers in preparing the Master Plan

CONTENTS OF CBT MATER PLAN
1. Product Development
a. Develop and showcase core product
b. Linkages with other attractions in the surrounding areas

2. Destination/Leisure Management
a. Adequate tourist infrastructure, facilities, good interpretation and high level service quality
b. Provide authentic experience
c. Provide educational experience
d. Provide entertaining experience
e. Enjoyable experience
f. Provide memorable experience

3. Interpretation and Communication
a. Visual presentation – interpretive trails/centre
b. Oral presentation – well-trained guides
c. Interactive relationship between host and tourists

step 8

ACTION 1: MATCHING THE PRODUCT WITH THE POTENTIAL MARKET SEGMENTS
a. Determine the potential market segments
b. Match product and market segments

ACTION 2: UNDERSTANDING THE CHANNELS OF DISTRIBUTION
a. Identify the channel of distribution
b. Network within "green tourism" and "responsible tourism operators

ACTION 3: EMBRACING ICT AS A PROMOTION TOOL
a. Carry out e-booking/online reservation
b. Carry out e-promotion
c. Build own website, blog, forum etc.
d. Invest in setting up hardware (computer and internet connection)
e. Invest in setting up software (training local youths)

ACTION 4: "PIGGY-BACK- RIDING" ON TOUR OPERATORS AND GROUND HANDLERS
a. Identify potential tour operators and ground handlers
b. Network with international counterparts such as Intrepid Travel

ACTION 5: SETTING UP AN IN HOUSE TRAVEL AGENCY
a. Set up in house travel agency
b. Nurture the spirit of entrepreneurship among youths

ACTION 6: LEVERAGING ON AWARDS CERTIFICATION TO SHAPE THE BRANDING

step 9

ACTION 1: CONSTRUCTION OF TOURIST FACILITIES GETTING THE COMMUNITY INVOLVED IN THE IMPLEMENTATION
a. Secured the funds to construct tourist facilities
b. Involved or empowered community in the construction of tourist facilities
c. Local community will enhance the existing skills and acquire the new skills

ACTION 2: REGULAR MONITORING OF PERFORMANCE
a. Create indicator to monitor the performance of CBT

Fig. 2: Nine steps action points (Amran Hamzah, 2009)

3.4.2 Induced participation.

On the other end of the spectrum, induced engagement is supported, required, and formally sanctioned. This type is the most prevalent method, present in 8 developing nations, as government plays a major role in institutionalising participatory action in several of these nations. Building self-management and cooperative organisations, encouraging local leaders to take on leadership positions, and assisting civic and community organisations are some of the techniques that have been used to achieve this (UN 1981).

Other names for induced involvement include formal top-down, passive. Understanding the terminology for induced participation in a broader sense may be aided by defining those terms, which are used interchangeably (Farangiz Khaledi Koure, 2022),

3.4.3 Coercive participation

Additionally, it is referred to as restricted participation and community oppressive. Eventually, forced community participation that lacks public support will prove to be counterproductive and erode community interest in participating in development activities, even though coercive forms of participation can sometimes be difficult to distinguish from the induced type in terms of form (UN 1981).

These three major types of community involvement in the development process undoubtedly represent a wide range of community involvement. Each of these categories includes several types of community participation, as shown in table 1. To draw a clear line between different forms of community participation in each broad category, nevertheless, appears to be quite challenging, as spontaneous, coercive, and induced involvement have similar scopes and meanings. Coercive participation involves more manipulation and tokenism than induced involvement. As a result, it is also known as non-participation. To engage in spontaneous participation, a community must take part in all phases of a development project, including

decision-making, implementation, benefit sharing, and assessment. In contrast, induced participation refers to community participation in the implementation and distribution of the benefits of development projects. Coercive participation, on the other hand, calls for a community to take part only in the implementation process of a development project, without necessarily sharing in its advantages. In the situation of coerced involvement, a community is left with no genuine alternatives (Farangiz Khaledi Koure, 2022).

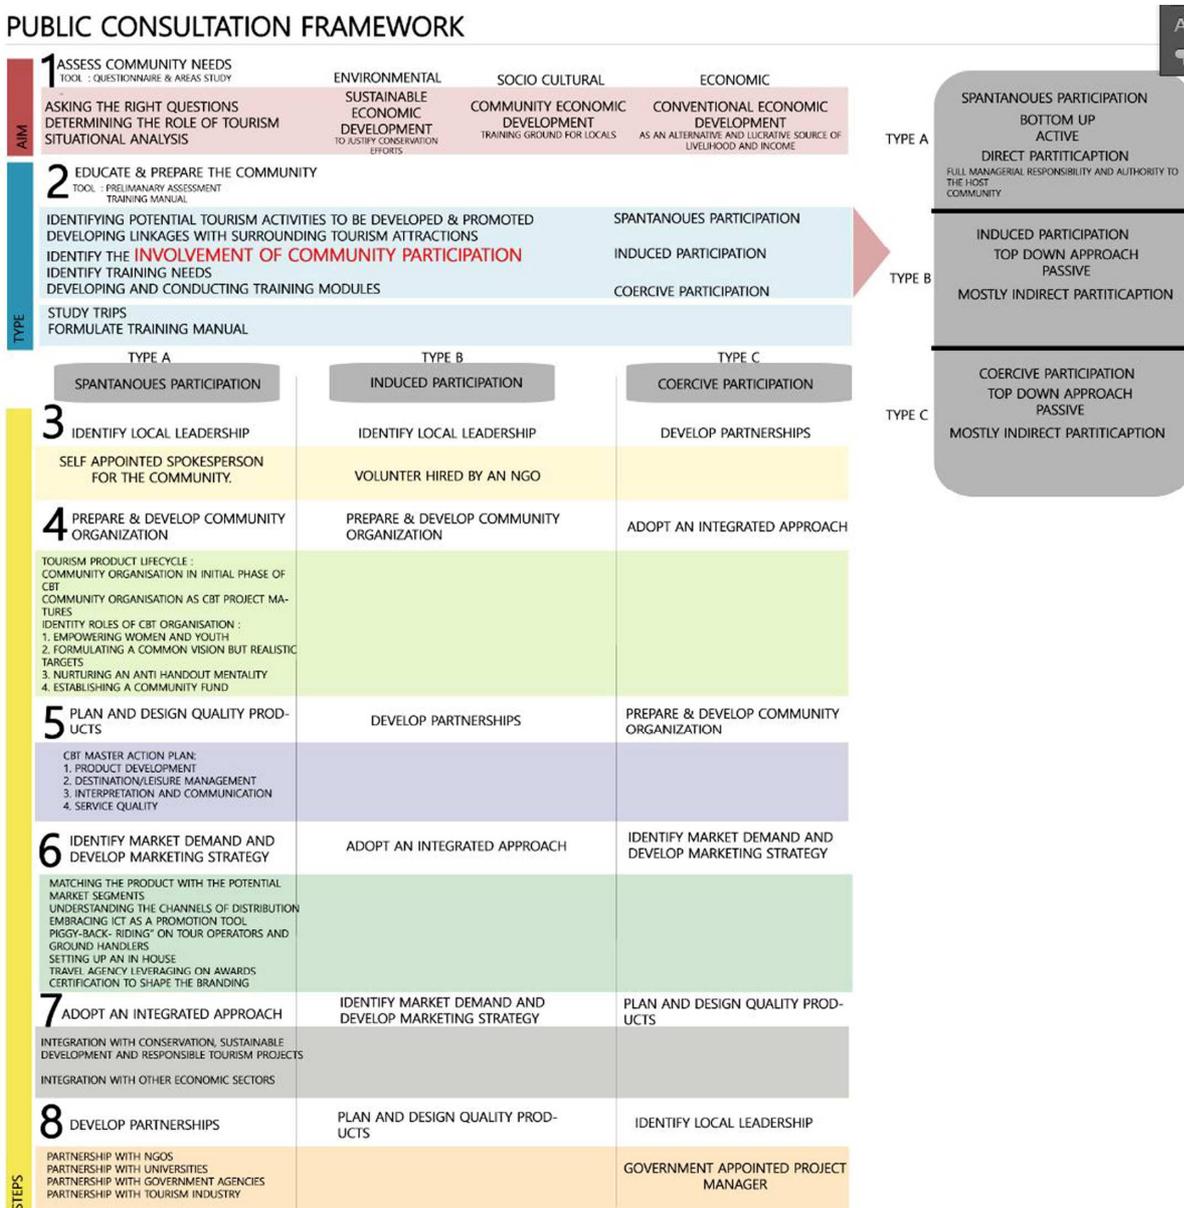
The categorazation of community participation may enable us to understand the participatory development activities in a better way in the real world by distinguishing various forms of community participation from each other. Hence, this typology seems to have contributed to conceptual clarity of the term 'community participation' in the tourism literature. After having a clear view of the framework to establish and develop CBET in a destination and according to the typology of community engagement that has been mentioned, several interpretations of community participation in the TDP are acceptable in various situations. In this sense, community engagement in the TDP should be seen as an adaptive and flexible paradigm that enables us to legitimise different forms of community participation in the TDP, depending on site-specific conditions. The public consultation framework above is by providing three different approaches to implement the processes by reordering the phases in accordance with each technique in the diagram below. The hierachy will vary from point 3 through to point 9 to allow a more focused and efficient development when step 2 is complete and which involvement technique works best for the destination and community has been determined.


Fig. 3: Community based framework tailored to participation types (author)

4 EGYPT'S PROTECTED AREAS

Egypt's overall land area is 92% dry desert and 8% fertile land, and it is located midway between Africa and Asia. 22 major habitat groups, including Mediterranean Wetlands, the Nile Valley and Delta, Central and North Sinai, Numerous kinds of vegetation and 324 different types of desert animals are thought to be ecologically significant, particularly in Sinai. With 80 plants, 100 animals, and 82 fish, wetlands particularly those near the Nile constitute a significant ecosystem in addition to the deserts. Along with 26 bird species and 26 reptile species, there are 51 species of mammals that are endangered.

Egypt has made the creation, proper administration, and expansion of protected areas a top goal ever since the country's first national biodiversity policy and action plan were introduced in 1997. The nation, one of the first in the region, declared over 15% of its total land area as protected land area, putting it remarkably close to the 17% global objective thanks to its substantial dedication to this priority. Egypt was able to declare 30 protected areas.Indications show that Egypt's biodiversity is being lost at an accelerated rate, with habitat destruction, over exploitation and pollution (WorldSummit, 2002). Based on existing trends, unless mitigation measures are taken, in the next ten to twenty years Egypt will stand to lose most of its biodiversity. A strategy for a national system of protected areas has been developed and the management of these areas were bearing in mind to make use of the technologies such as GIS and remote sensing. The local economic significance and value of these protected areas and their contribution to the national economy was being considered particularly through the development of ecotourism (WorldSummit, 2002).

4.1 Protected areas classification.

Understanding the location, culture and demographics of the area can help identify the potential community participation types that are applicable. Assessing the level of involvment of the locals and stakeholders, considering the objectives of the protceted area whether its conservation or sustainable development or recreation is also important. This study attempted to classify 30 protected sites in accordance with their various habitats, types, local cultures, geographic regions, conservation goals and tourism niches. In turn, this categorisation will help to determine the community's appropriate participation type in the protected area when applying the community-based ecotourism framework on the destination, leading to the application of more specified and suitable action points for a more sustainable successful development. (NCS, 2018)

Category	Description
Ia	Strict Nature Reserve: Protected area managed mainly for science.
Ib	Wilderness Area: Protected area managed mainly for wilderness protection
II	National Park: Protected area managed mainly for ecosystem protection and recreation
III	Natural Monument: Protected area managed mainly for conservation of specific natural features
IV	Habitat /Species Management Area: Protected area managed mainly for conservation through management intervention
V	Protected Landscape/Seascape: Protected area managed mainly for landscape/seascape conservation and recreation
VI	Managed Resource Protected Area: Protected area managed mainly for the sustainable use of natural ecosystems

Fig. 4: IUCN protected areas classifications.

According to the international IUCN categorisation of protected areas, No PA in the Egyptian network of PAs is categorised as a Strict Nature Reserve (Category Ia) or a Wilderness Area (Category Ib), However, 15 PAs are designated as protected areas with sustainable management. Within the PAs network, there is the use of natural resources (Category VI), which accounts for 50% of all IUCN management categories. (NCS, 2018)

4.1.1 Successful examples

This research looked at the CBE policies of four developing nations the Republic of Kenya, Tunisia, Jordan, and India achieving successful outputs and effectiveness of the development using the specific community-based ecotourism indicators and particularly the community participation types when it comes to each destination circumstances and local culture. (M. M. ELBARMELGY).

One prominent example of a successful community-based ecotourism project in Jordan is the "Dana Biosphere Reserve.". the community participation approach employed is a combination of different types,

focusing on collaborative and inclusive decision-making and sustainable development. Here are the key community participation types that were used:

Collaborative Decision-Making: Local communities, NGOs, and governmental agencies collaborate to make decisions about the management and development of the biosphere reserve. This ensures that diverse perspectives are considered, and decisions are collectively formulated.

Empowerment and Ownership: The project empowers local communities by involving them in the ownership and management of tourism-related enterprises, such as guesthouses and guides. This ownership gives communities a direct stake in the success of the ecotourism activities.

Participatory Planning: Local communities actively participate in the planning process of ecotourism initiatives. They share their ideas, aspirations, and concerns, which are incorporated into the design and implementation of tourism activities and conservation efforts.

Cultural Preservation and Sharing: Local communities play a central role in preserving and sharing their cultural heritage. Traditional practices, crafts, and local knowledge are incorporated into the ecotourism experiences, giving visitors an authentic cultural encounter.

Sustainable Resource Management: Community members are actively involved in the sustainable management of natural resources. They take part in monitoring and conserving wildlife and habitats, ensuring that tourism activities do not harm the delicate ecosystem.

Capacity Building: The project invests in capacity-building programs that empower local individuals to become guides, craftsmen, and service providers. This builds human capital within the community.

Education and Awareness: The project focuses on educating both visitors and local community members about the importance of conservation and sustainable tourism practices.

By combining these community participation types, the Dana Biosphere Reserve project in Jordan has managed to create a holistic approach to ecotourism development that not only benefits the local communities economically but also ensures their active involvement in conservation and cultural preservation. This inclusive approach has contributed to the project's success in both sustainable development and biodiversity conservation.

The selection of a suitable community participation type for a specific ecotourism project involves a combination of factors that consider the local context, goals of the project, and the needs and aspirations of the community. Here's how they have decided on the appropriate community participation type:

Community Assessment: The project likely started with an assessment of the local community's characteristics, including their social structures, cultural practices, economic conditions, and existing levels of engagement in conservation and tourism.

Stakeholder Engagement: The project organizers likely engaged with a diverse range of stakeholders, including community members, local leaders, NGOs, government representatives, and experts in various fields. This would help identify the needs, concerns, and aspirations of different groups.

Cultural Sensitivity: Considering the importance of cultural preservation in the Dana Biosphere Reserve, the project planners would have assessed the significance of local traditions and how they could be integrated into the ecotourism experience.

Environmental Considerations: The type of community participation would also be influenced by the level of interaction required with the natural environment. If the goal is strong conservation involvement, a more hands-on approach to resource management might be chosen.

Community Readiness: The readiness of the community to actively participate in various roles, whether in managing enterprises, preserving cultural heritage, or engaging in sustainable practices, would influence the choice of participation type.

Local Economic Conditions: The economic conditions of the community would play a significant role. If there's a need for alternative livelihoods due to declining traditional industries, a focus on community-owned enterprises might be more appropriate.

140

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Local Skills and Expertise: The existing skills and expertise within the community would be considered. For instance, if there are individuals with guiding skills or traditional crafts, these could form the basis for community involvement.

Alignment with Goals: The selected participation type should align with the overall goals of the project, which might include environmental conservation, cultural preservation, economic development, or a combination of these.

Flexibility: A flexible approach might be chosen that allows for multiple types of participation. For example, the Dana Biosphere Reserve project combines cultural preservation, sustainable resource management, and economic empowerment.

Ultimately, the selection of the community participation type would be a result of careful consideration of these factors, with the aim of creating a model that best suits the local context and ensures the project's success in both conservation and community development.

4.1.2   Egypt's protected areas classification

The following table was suggested after studying each Egyptian PA, classifying the 30 Egyptian protectorates according to their various habitat types, attractions, geographic location, tourism niche, IUCN classification, type, and the local communities. Formulating a deeper study of the PAs to be able to suggest an applicable community participation technique to start with the first steps of the public consultation framework to apply community-based ecotourism effectively in a destination. Egypt has a rich and diverse cultures with different local cultures varying from Nubians, Siwan culture, Bedouin cultures, Coptic culture, and fellahin cultures. Each of these cultures has their own unique traditions, customs, and way of life, which help to determine the applicability of the community tourism participation type. Also, according to their category in the IUCN classifications. Bedouins and Nubians are suited for spontaneous or induced type because they are more likely to be willing to engage and conscious of the development difficulties. Due to their rigorous adherence to their culture and traditions and lack of awareness about ecotourism, the nomad, fallhin, and saidii cultures should use either coercive or induced participation, depending on the other factors listed in the table below. Also, the PA category plays a big role in deciding the participation type, so different factors have to be taken into consideration when applying the selected technique found in the table below and in alliance with all the given factors, the participation type is suggested.

5   CONCLUSION

This study demonstrates that, depending on the destination characterstics and cirucmstances, community involvement in the development process can take many different forms. Different forms of community participation in the tourism development. however, are hardly ever mentioned in tourism research. Instead, it is suggested that one type of participation in the community must be accepted everywhere. This rigidity in tourism studies may be an indication that the field has debated the idea of a participatory approach to tourism development in isolation and with little connection to more general studies on community participation that might produce better insights and greater maturity for the formulation of community participation policies in the ecooturism development. For instance, participatory studies on rural development, housing, irrigation, Third World development programmes, etc. suggest that before beginning any participatory development activity, considerations like operational, structural, and cultural limitations to community participation should be made. Ignoring these restrictions could jeopardise the efficacy and efficiency of a participatory development strategy. This paper aims to start a much-needed conversation about community involvement in the CBET as an adaptive categorical word. This reasoning is based on the idea that different tourist destinations will present different opportunities and difficulties for host communities to participate in the TDP. These tourist destinations will also have various sociocultural, economic, and political conditions as well as different levels and types of tourism development. Naturally, community involvement should occur in these tourist sites on many levels and in various forms. The most important finding from the analyses that came before it is that community participation in the TDP should be viewed as a categorical term that allows host communities to participate in the TDP in a variety of ways and under a variety of conditions. Subsequently the framework can be applied on a destination and thus recommending action points for its development according to each area needs and variable circumstances. This integrated planning tool can be used to devise a local urban development plan by local governments and organisations in protected areas to

improve the physical and social environments and create a better understanding of the relationship betweeen tourism and communities.

1 ABSTRACT

Architecture design problems are known for their sequential steps that address a series of several interweaving, competing and/or aligning requirements. Describing them as open-ended, uncertain, solution searching processes makes them complex and ill-structured design problems. One of the methods to deal with nonlinear complex systems is that their components' properties and features must not be pre-determined and studied linearly in isolation. Instead, it is essential to consider the system as a whole, even if it means considering it generally and roughly, and then allow possible simplifications to occur from the dynamic interactions between components. Computational design methods that encounter distributed computation and artificial intelligence, such as Multi Agent System (MAS), showed promising abilities in addressing complexity and uncertainty faced with architecture design problems, as well as they proved positive effect on expanding architecture design exploration (ADE). This study has an interest in MAS capabilities in creating aesthetically innovative and performable architecture solutions.

Therefore, this research intends to investigate the use of MAS in Architecture in the years between 2010 to 2020. It contributes with a detailed examination of research papers to orient future research in the field of MAS. Hence, the applied literature review raises the question of what the proved capacities of MAS are and how future research can challenge it further to widen and develop the use of MAS in ADE and their possible capabilities when addressing building performances such as structural, functional, and environmental. The databases used for selecting these papers are Scopus, Web of Science, SAGE, Science Direct, Google Scholar, Connected Papers, CUMINCAD, IEEXplore, and ACM Digital Library. These studies are organized, analyzed, and compared to pinpoint key innovations in MAS's variable usage, study its applied methods, interesting results, important sources of data, implementation strategies, and shed the light on the gaps and shortcomings to draw a perspective of MAS in architecture. The examined studies are arranged chronographically. Then, each paper is analyzed and classified according to the aim of the methodology, domain, level, scale of application (experimentation level), model generation and optimization methods. Afterwards, a critical review is proposed.

Keywords: Computational Architecture, Design Optimization , Generative, Algorithmic & Evolutionary design, Agent based Modeling and Simulation, Multi-Agent Systems

2 INTRODUCTION

Architecture design problems are known for their sequential steps that address a series of several interweaving, competing and/or aligning objectives without a well-defined or specific design output (Terzidis, 2006). In all cases these objectives not only might align or conflict with one another, they are changed and uniquely defined in every single design problem based on the problem itself, the goal of the design, building program, constraints, client's requirements, surrounding context, etc. In addition, they are open-ended, uncertain, solution searching mechanism with no clear formulation of all required information and aspects any problem-solving processes would need. Therefore, they are identified as complex, wicked, and ill-structured problems (Rittel & Webber, 1973). To elaborate further; there are several clear aspects that complexifies such problems. For instance, the lack of the required definite and clear information for every attribute related to the problem, which challenges more the problem's tackling processes (Suh, 2005). Another aspect is related to creating innovative outcomes, which makes the expected product not specified and cannot be predicted. Another pivotal aspect that complexifies the architecture design problem further, is the nonlinear interrelationship, correlation and causation between whole system's pattern, properties, attributes and behvior observed on the global level and their inter-consequences and interactions of the constituent elements on the local level (Bar-Yam, 2002). It is a phenomenon described as micro-macro effect (Wolf & Holvoet, 2005).

One of the methods to deal with such nonlinear complex systems is that their components' properties and features must not be pre-determined and studied linearly in isolation. Instead, it is essential to take into

account the system as a whole, even if it means considering it generally and roughly, and then allow possible simplifications to occur from the dynamic interactions between components (Pantazis & Gerber, 2019). Computational design methods that encounter distributed computation and artificial intelligence, such as Agent based modeling and simulation (ABMS) and Multi Agent System (MAS), showed promising abilities in addressing complexity and uncertainty faced with architecture design problems (Macal & North, 2009), (Erdine & Kallegias, 2016a), (Gerber, Pantazis, & Wang, 2017), as well as they proved positive effect on expanding architecture design exploration (ADE) (Robertson & Radcliffe, 2009), (Liu, Li, Pan, & Li, 2011), (Zboinska , 2015), (Chang, Chien, Lin, Chen, & Hsieh, 2016), (Daemei & Safari, 2018), (Zboinska, 2019). Through the modeling of complex system in the level of their individual constituent, the whole system's pattern, structure and behvior can emerge without being explicitly programmed into the model (Heath & Hill, 2010), (Macal & North, 2010). Therefore, this research has an interest in the applications of MAS in architecture. It aims at developing a collective understanding of MAS capabilities between 2010 to 2020 and suggests future research.

3 MULTI AGENT SYSTEM DEFINITION AND NOTIONS

A Multi-Agent System is a computerized system composed of multiple interacting collaborating agents within an environment. These agents act autonomously and collaboratively to achieve more complex goals that any of the agents can do by itself (Pantazis & Gerber, 2018). Most research suggested that in order to deal with complexity and uncertainty faced in architectural design problems, non-conventional design methodology must be addressed. It is effectively proven that distributed computation and artificial intelligence can overcome such difficulties (Beetz, Leeuwen, & Vries, 2004) (Jennings & Wooldridge, 1999). Not only, but also the given nature of the design problem as "ill-structured" raises the necessity and ensure the provision of computational abstractions for design exploration and solutions optimization (Gerber, Pantazis, & Wang, 2017). The applicability of a distributed system provided by MAS described in abstractly fashioned agents with defined goals adapting to a local conditions, made MAS an appropriate for solving a large class of real world design problems, in several domains such as the work of (Davide , Pilosof, Hadas , Yahav, & Kalay, 2019) (Erdine & Kallegias, 2016a) (Davide, et al., 2016) and (Fernandes, 2013) (Viehweider & Chakraborty, 2015) to name a few.

4 LITERATURE REVIEW APPLIED METHODOLOGY

4.1 MAS in AEC Field, Collection and Selection

There is a significant interest in the field of MAS seen in the work of experimentalists in architecture in recent years. These include researchers, units, and practitioners such as David Jason Gerber, Achim Menges, as well as practices such as Zaha Hadid Architects and Morphosis Architects. Such approaches utilization is considered a paradigm shift in architecture thinking and exploration for more efficient solutions, challenging the complexity of a design problem. This section presents a brief representative of MAS in AEC, in the years between 2010-2020. The databases used for selecting these papers are Scopus, Web of Science, SAGE, Science Direct, Google Scholar, Connected Papers, CUMINCAD, IEEXplore, and ACM Digital Library. These studies are organized, discussed and compared to pinpoint key innovations in MAS's variable usage, study its applied methods, interesting results, important sources of data, and shed the light on the gaps and shortcomings to draw a perspective of MAS in AEC. Literature retrieval method is undertaken as follows: (Determine the time frame; (2010 – 2020) / Determined keywords: Agent based/ agent-based modeling (ABM)/ Agent based simulation (ABS)/ Agent based modeling and simulation (ABMS Multi agent system) / The targeted Language: English/ Search in Scientific Database Platforms: Scopus, Web of Science, SAGE, Science Direct, Google Scholar, Connected Papers./ Downsize them into papers concerned with architecture design phase./ Select a sample to show-case and represent MAS as a paradigmatic effect in the design process.)

4.2 Literature Review Analysis and Interpretation

The undertaken study went through several steps. First, they are arranged chronographically. Then, each paper is analyzed, classified and discussed according to aim of the methodology, domain, level, scale (application), model generation logic, optimization methods, refer to Figure 1, Table 1 and Section 6.

5   ANALYTICAL STUDY AND DISCUSSION OF MAS APPLICATION IN AEC

MAS is not just a system. MAS is a concept that can be seen in different areas and implemented on different scales to solve varies problems. There are several contributions made to the applicability of MAS in AEC they can be classified into three domains: knowledge capturing and recognition in drawings and sketches, simulation and performance of building designs, and collaborative environments (Beetz, Leeuwen, & Vries, 2004). The research will concentrate on the simulation and performance domain.

Levels of Design Problem Complexity: The usage of MAS can be seen in several precedents from conceptual design phase, seen in the work of (Erdine, 2016b) (Gerber, Pantazis, & Wang, 2017) (Guon & Li, 2017) (Yi & Kim, 2015) to name a few, to fabrication, found in the work of (Baharlou & Menges, 2013) (Gerber & Pantazis, 2016a) (Pantazis & Gerber, 2016) (Yazici & Gerber, 2016), (Smith, Danahy, & La Rotta, 2020). These contributions can be categorized into five different levels of process complexity. The first level is aesthetic-driven optimization. It was found that aesthetic is not usually a target or a measured target however it comes in form of interesting or exciting and novel outcomes and its suitability is measured in accordance to a targeted single performance or targeted multiple performances and/or fabrication feasibility, such the work of (Pantazis & Gerber, 2014) and (Smith, Danahy, & La Rotta, 2020). The second level is single-discipline optimization for instance; environmental performance (Sugihara, 2014), (López & Gerber, 2014), (Yi & Kim, 2015), (Pantazis, Gerber, & Wang, 2016), (Gerber, Pantazi, & Wang, 2017), (Pantazis & Gerber, 2018), (Agirbas, 2019), Material performance (Tsiliakos, 2012), Functional performance (Davide, et al., 2016), (Guon & Li, 2017), (Ghaffarian, Fallah, & Jacob, 2018), (Davide , Pilosof, Hadas , Yahav, & Kalay, 2019), (Fuchs & Neumayr, 2020). The third level is multi-discipline optimization, where more than one performance is targeted – such as. Environmental and Structural Performance, (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Gerber, Pantazis, & Marcolino, 2015), (Pantazis & Gerber, 2016), (Gerber, Pantazi, & Wang, 2017), (Pantazis, 2019). Environmental Performance and rationalization such as (Baharlou & Menges, 2013), (Gerber & Pantazis, 2016b). Aesthetic and structural performance and rationalization, seen in the work of (Smith, Danahy, & La Rotta, 2020) And the Fourth level is multi-discipline optimization and digital fabrication such as (Pantazis & Gerber, 2014), (Schwinn, Krieg, & Menges, 2014), (Gerber D. J., Pantazis, Marcolino, & Heydarian, 2015), (Erdine, 2016b), (Gerber & Pantazis, 2016a), (Yazici & Gerber, 2016), and as previously mentioned Building Systems (Wang, Yang, & Wang, 2010), (Lee, 2010), (Joumaa, Ploix, Abras, & Oliveira, 2011), (Ramchurn, Vytelingum, Rogers, & Jennings, 2011), (Klein, et al., 2012), (Zhao & Suryanarayanan, 2011).

Design Applications Scales: Multi-Agent systems have been applied to design problems of varying scales ranging from Urban design (López & Gerber, 2014). As well as building envelope design, (Sugihara, 2014), (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Yi & Kim, 2015), (Gerber D. J., Pantazis, Marcolino, & Heydarian, 2015), (Gerber D. J., Pantazis, Marcolino, & Heydarian, 2015), (Pantazis, Gerber, & Wang, 2016), (Pantazis & Gerber, 2018) (Agirbas, 2019) (Gerber, Pantazis, & Wang, 2017). In addition, structural element design like shading system or pavilion or a column, seen in the work of (Tsiliakos, 2012), (Baharlou & Menges, 2013), (Pantazis & Gerber, 2014), (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Schwinn, Krieg, & Menges, 2014), (Gerber, Pantazis, & Marcolino, 2015), (Pantazis & Gerber, 2016), (Erdine & Kallegias, 2016a), (Gerber & Pantazis, 2016a), (Yazici & Gerber, 2016), (Gerber, Pantazi, & Wang, 2017), (Pantazis, 2019), (Smith, Danahy, & La Rotta, 2020). Layout configuration driven by users' behavior simulation (Lee, 2010), (Klein, et al., 2012), (Davide, et al., 2016), (Guon & Li, 2017), (Ghaffarian, Fallah, & Jacob, 2018), (Davide , Pilosof, Hadas , Yahav, & Kalay, 2019) (Fuchs & Neumayr, 2020). Energy management demand such as (Wang, Yang, & Wang, 2010), (Lee, 2010), (Joumaa, Ploix, Abras, & Oliveira, 2011), (Ramchurn, Vytelingum, Rogers, & Jennings, 2011), (Klein, et al., 2012), and (Zhao & Suryanarayanan, 2011), to product design (Madhusudan, 2005) , (Sugihara, 2014).

MAS in terms of the Architecture Design Process: In order to comprehend more the strategy and technique of using MAS, it can be seen in terms of a design cycle stages. Any design cycle consists of synthesis (modeling, generation), analysis (simulation) and evaluation (examining and searching method for an optimal solution; optimization). In MAS, all these stages are represented as agencies, combined, and work autonomously and collaboratively to reach specific design goals assigned by the design team. MAS can be used in generation level (modeling) in terms of singular agency like the work of (Yi & Kim, 2015) (Guon & Li, 2017), and simulation (in simulating user behavior), seen in the research of (Dijkstra, Timmermans, & Jessurun, 2000), (Klein, et al., 2012), (Davide, et al., 2016), and (Davide , Pilosof, Hadas , Yahav, & Kalay,

2019), for evaluation and or optimization process (Madhusudan, 2005), (Tsiliakos, 2012), (Sugihara, 2014), (Pantazis & Gerber, 2014), (López & Gerber, 2014), (Schwinn, Krieg, & Menges, 2014), (Pantazis & Gerber, 2016), (Pantazis, Gerber, & Wang, 2016), (Erdine & Kallegias, 2016a), (Gerber & Pantazis, 2016a), and (Yazici & Gerber, 2016). Or Undertaken throughout the whole process, collaborating between agencies from generation to evaluation and optimization, where behavioral design methodologies do not only negotiate for geometry generation but also geometry generation in regard to local and global performance objectives that might align or compete with one another until reaching to the most optimal one (Wang, Yang, & Wang, 2010), (Joumaa, Ploix, Abras, & Oliveira, 2011), (Klein, et al., 2012), (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Yi & Kim, 2015), (Gerber, Pantazis, & Wang, 2017), (Gerber, Pantazi, & Wang, 2017), (Pantazis & Gerber, 2018), (Agirbas, 2019) and (Pantazis, 2019).

In synthesis (generation) stage, MAS has the ability to standalone through describing an agent-based modeling logic like the work of (Baharlou & Menges, 2013), (Sugihara, 2014) (Pantazis & Gerber, 2014), (Schwinn, Krieg, & Menges, 2014), (Pantazis & Gerber, 2016), (Davide, et al., 2016) (Pantazis, Gerber, & Wang, 2016), (Erdine & Kallegias, 2016a), (Gerber & Pantazis, 2016a), (Gerber & Pantazis, 2016b), (Yazici & Gerber, 2016), (Gerber, Pantazi, & Wang, 2017), (Guon & Li, 2017), and (Pantazis, 2019). OR it can be integrated with or governed by a generative approach (ex; Swarm Intelligence (SI), L-System (LS), Cellular Automata (CA), etc.) in several forms. To exemplify; all of (Tsiliakos, 2012) (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Agirbas, 2019) used the logic of SI in generation stage, while (López & Gerber, 2014) (Yi & Kim, 2015) (Gerber, Pantazis, & Marcolino, 2015) (Gerber D. J., Pantazis, Marcolino, & Heydarian, 2015) (Gerber, Pantazis, & Wang, 2017) (Pantazis & Gerber, 2018) used LS. In addition, (Dijkstra, Timmermans, & Jessurun, 2000) who used CA.

The efforts of optimization are enormous and can be enumerated in two areas; MAS can integrate an agent-based searching method (hypothetically speaking a linear form) or integrate heuristic searching method. Researchers who adopt MAS with an agent-based searching model always build a framework to reach to a better solution better than the base case, or embrace a concept, where reaching for a better solution is stimulated to find a better one than the previous one (a linear and in some cases exponential form), or tackling the area where when the searching method stops the resulted solutions are likely to be nearer to sub-optimal one than when the searching process started seen in the work of (Madhusudan, 2005), (Lee, 2010), (Ramchurn, Vytelingum, Rogers, & Jennings, 2011), (Tsiliakos, 2012), (Baharlou & Menges, 2013), (Sugihara, 2014), (Pantazis & Gerber, 2014), (López & Gerber, 2014), (Erdine, 2016b), (Erdine & Kallegias, 2016a), (Pantazis & Gerber, 2016), (Pantazis, Gerber, & Wang, 2016), (Gerber & Pantazis, 2016a), (Yazici & Gerber, 2016), (Ghaffarian, Fallah, & Jacob, 2018), and (Gerber & Pantazis, 2016b). In the area of optimization MAS uses as a rule-based searching methods written in agent's logic of thinking, where they use a linear searching system which always take a longer time than when using any other heuristic searching method.

MAS and Heuristic Searching Methods: In the area of integrating a heuristic searching method, the efforts are significant. To exemplify; (Klein, et al., 2012) used Markov Description Problems method, (Gerber, Shiordia, Veetil, & Mahesh, 2014)and (Gerber, Pantazi, & Wang, 2017) used Multi-objective optimization, (Yi & Kim, 2015) used Genetic algorithm, (Guon & Li, 2017) used Evolutionary Approach, (Wang, Yang, & Wang, 2010) used practical swarm intelligence, and (Gerber, Pantazis, & Wang, 2017), (Pantazis & Gerber, 2018), and (Pantazis, 2019) used hill climbing and simulated annealing. Despite these massive efforts in utilizing a heuristic approach, researchers did not clearly state how, or why they are using these approaches specifically. A more detailed explanation for the selection and how these heuristic approaches are integrated is strongly needed to be provided, which challenges and inspire the further research in this area. Solving multi objectives problems has been a challenge to researchers for a very long time until the first use of the evolutionary algorithms (EAs). It motivates them by its population-based nature of evolutionary algorithms - to solve such multi-objective problems (Coello, Lamont, & Van Veldhuizen, 2007). Evolutionary driven design targets the search for the optimum solution(s). It is applied after the initial level of conceptual design as a search engine, where applying evolutionary design supports the search of broader ranges of alternatives (Gerber & Lin, 2013).

Genetic Algorithm is one of the mostly used and successful investigative search methods for optimum solutions proved by several papers such as (Torres & Sakamoto, 2007) (El-Sheikh & Gerber, 2011) (Varendorff & Hansen, 2012) (El Daly, 2014) (Elghazi, Wagdy, Mohamed, & Hassan, 2014) and (El-

148

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Maghraby, 2016). Despite its promising capabilities limited number of papers utilized it in its search process for an optimal solution such as the work of (Yi & Kim, 2015). In this paper the researchers used a simplified design problem, where they used MAS in the modeling logic and did not appear further in the rest of the design process. Another attempt by (Smith, Danahy, & La Rotta, 2020) , where the researcher created three combined methods in one process. Each method tackle a part of the design process; topoform creates the column geometry using evolutionary-multi agent software, capable of generating diverse topological designs with structural and geometric performance governed and selected by GA integration - matform an agent based additive manufacturing tool-path able to produce gravitational material affects while adapting to local structural and geometrical data- and finally a matSim, a material physics simulation environment to simulate additive manufacturing material structurally and aesthetically in a high resolution. The proposed method showed a successful integration between GA with MAS, which inspire and challenge the research further in this area.

Human behvior in MAS: Research has proven that designing according to user needs, behavior and preferences has a great potential to reduce energy consumption. A usual applicability of user-related information is by informing the design process of user's possible interactions, comfort levels, preferences, and occupation schedules. In addition, research has proven that user-centered design could significantly increase the efficiency of any tested system. Despite these promising potentials and efforts applying them is usually harder as the designer does not necessarily have accurate information of possible occupants' behavior. In other words, people do not necessarily function according to these assumptions of occupancy pattern or such fixed schedules. Therefore, in the area of energy demand, (Klein, et al., 2012) presents, implements and integrates MAS encompassing Markov decision problems (MDPs) to model alternative management and control of building systems and occupants. Such strategies have a great potential in reducing energy through direct cooperation and coordination with building occupants in addition to improving control of building systems and energy resources. However, in the area of integrating MAS and ABMS researchers' attention were taken more towards behavior of human being, believing that instead of designing and constructing and then do post-occupancy assessment, they now design the other way around (bottom-up method). Through using anticipated behavior of people inside the space and accordingly the building will be created to most satisfy or provide these users with their needs and level of comfort inside the building, in terms of environmental, structural, or functional performance. A common approach of incorporating human-center design is by including user's behavioral model to simulate users' movements, interactions, and responses to examine a proposed design (Dijkstra, Timmermans, & Jessurun, 2000), (Davide, et al., 2016), (Davide , Pilosof, Hadas , Yahav, & Kalay, 2019) or to create a design like the work of (Ghaffarian, Fallah, & Jacob, 2018) in creating a spatial arrangement informed by the users' movements.

Another interesting attempt seen in the work of (Pantazis, Gerber, & Wang, 2016), when incorporating Immersive Virtual Environments (IVE) in the design process. Research has proven that participants perform similarly within IVE as they do in physical environments, and they also feel similar feelings of presence within such environments. To clarify the significance of such efforts, it is important first to define the word performance. Performance is a widely used word with different perceptions in architecture. Grobman and Neuman describe two different levels of performance (Grobman & Neuman, 2012). The first is a broad definition, which includes three dimensions: empirical, cognitive, and perceptual. The other level is the narrow definition, which is concerned with the empirical dimension disregarding the other two dimensions. The Empirical dimension can be translated into computer language; therefore, it is widely used. While the cognitive and perceptual ones mainly rely on questionnaires and statistical measurements, making them hard to achieve. In the work of (Pantazis, Gerber, & Wang, 2016) , they incorporate the use of IVE. This combination is very interesting where they could apply the broader definition of Performance by integrating IVE instance evaluation of a user. By doing this they can integrate designer's intuition into the design process to find an optimal solution technically, cognitively, and perceptually while considering user's experience with the proposed design.

Another research by Fuchs and Neumayr (2020) aims at developing a cross-disciplinary system that capable of generating spatial environments with higher social interactions. The intension is to design an office break out room governed by the occupants anticipated behvior and ensure increased human interaction. The researcher applies two layers of interactions; interactions between office spaces users which are governed by status, affiliation, position etc. and another between the users and the furniture elements such as tables,

reception desk, coffee machine etc. Despite this approach is valuable, it still has its limitations, here human behvior and interactions are still hard to be precisely mapped, which always comes at the expense of the whole system accuracy.

The Architecture Problem complication and using MAS: MAS made the integration of structural and environmental performance analysis to be possible, through decomposed design process into multiple agencies that work autonomously and collaboratively. This integration is seen in the work of (Pantazis & Gerber, 2014), (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Gerber, Pantazis, & Marcolino, 2015), (Gerber & Pantazis, 2016a), (Yazici & Gerber, 2016), (Gerber, Pantazi, & Wang, 2017), and (Pantazis, 2019). As well as the integration of material constrains and fabrication requirements in the early design stages, seen in the work of (Baharlou & Menges, 2013), (Pantazis & Gerber, 2014) (Gerber, Shiordia, Veetil, & Mahesh, 2014), (Schwinn, Krieg, & Menges, 2014), (Gerber, Pantazis, & Marcolino, 2015), (Erdine & Kallegias, 2016a), (Gerber, Pantazis, & Wang, 2017), and (Gerber, Pantazi, & Wang, 2017). Despite these essential studies paves the way to creating a system that is concerned with two different performable disciplines, an obvious gap seen in creating a MAS system that integrates environmental and functional performances all together, which challenges the research further to dig deeper in this area.

Spatial Planning, equivalent to word layout in this research; multiple researchers worked in this area from an evolutionary platform, refer to a review by (Calixto & Celani, 2015) concerning this issue. However, in the field of MAS spatial planning has been applied through three different methods: a proposed plan and testing its functional performance according to behavior of users and then adjust it accordingly, seen in the work of (Dijkstra, Timmermans, & Jessurun, 2000), (Davide, et al., 2016), and (Davide , Pilosof, Hadas , Yahav, & Kalay, 2019). A Users' behavioral model is used to create voids (circulation areas) and leftovers are defined as shape solid (functional spaces) like the work of (Ghaffarian, Fallah, & Jacob, 2018). Or MAS is used in achieving spatial relationship and functional requirements in two and three-dimensional, seen the work of (Guon & Li, 2017).

Tools of MAS: Concerning the tools to develop a MAS framework, most researchers develop their own tool or toolkit. In the work of (Sugihara, 2014), the researcher developed an open-source library on Processing called iGeo to help computational designers to explore design possibilities in agent-based algorithms. What is so distinctive about this paper is the detailed description of the code and its technical aspects. Therefore, it is considered a valuable source of inspiration in the realm. Though, other researchers use visual scripting platforms like grasshopper and then apply collaboration by wider platform that requires coding; external software that is concerned with the collaboration between different agents seen in the work of (Pantazis & Gerber, 2016) and (Gerber, Pantazis, & Wang, 2017). With their reliability on iGeo library, they provide detailed technical description, which is also considered valuable source for this research. In the area of human as agents the usage of Netlogo and unity is preferred, seen in the work of   (Fuchs & Neumayr, 2020). It has been noticed that utilizing MAS and ABMS requires the designers to create their own design toolkit to apply it, challenging the architects further to master several coding languages such as scripting coding, C# and Java script etc.

6 CONCLUSION AND FURTHER RESEARCH

There are various strategies in applying MAS. It can be used in any design stage, it can appears standing alone in the generation stage in terms of singular or multiple agent-based modeling, or simulation stage or optimization stage, or its agents can be distributed along the process where each agent act autonomously achieving its own local targets while collaborating with the other agents in the same stage or with other agents from a different stage to achieve the global targets, aiming for design exploration and/or optimization. It is obvious from the matrix seen in, Figure 1 , the selected sample fall in the area where agent-based is highly used in generation and/ or optimization level aiming to solve single/multi design problems that reflects system capabilities in addressing different level of design complexity. On the contrary, in the area of aesthetics the efforts are limited which raises the question towards the importance of aesthetics and how can they be measured and achieved so it can be tackled further by the use of MAS and ABMS. Finally using it in the building system and energy demand is noticeable specifically in the prime usability of the ABMS and MAS.

Architects are now capable of dealing with complex design issues targeting several performances at the same time, where MAS is capable of integrating several agents fall under different design stages and loaded with

its own set of behaviors and targets. Therefore, their vast capabilities are well-witnessed. To name a few: MAS ability in emergence which results in unexpected designs. Huge solutions spaces resulted when autonomous agents interact with one another while exploring design solutions. They can deal with huge and complex data set, computation and reasoning processes as they are conveniently distributed and modularized by using agents as the main module units. Different agents with varies roles for different practice aspects acting naturally. Dealing with different level of complexity, varies stages of design, different level of complexity and languages, different tasks (generating/ evaluating/ criticizing/ optimizing/ analyzing)., different parts of computational system.

It is also noticeable that agents can come in a form of mimicking human behavior, others acting like a building element and/or becoming as defined manipulators that when connected together they can form a building skin or column or a shading system. It can promote the achievement of several scenarios in the space; multiple users, multiple functions, using multiple sensors to control automation system etc.

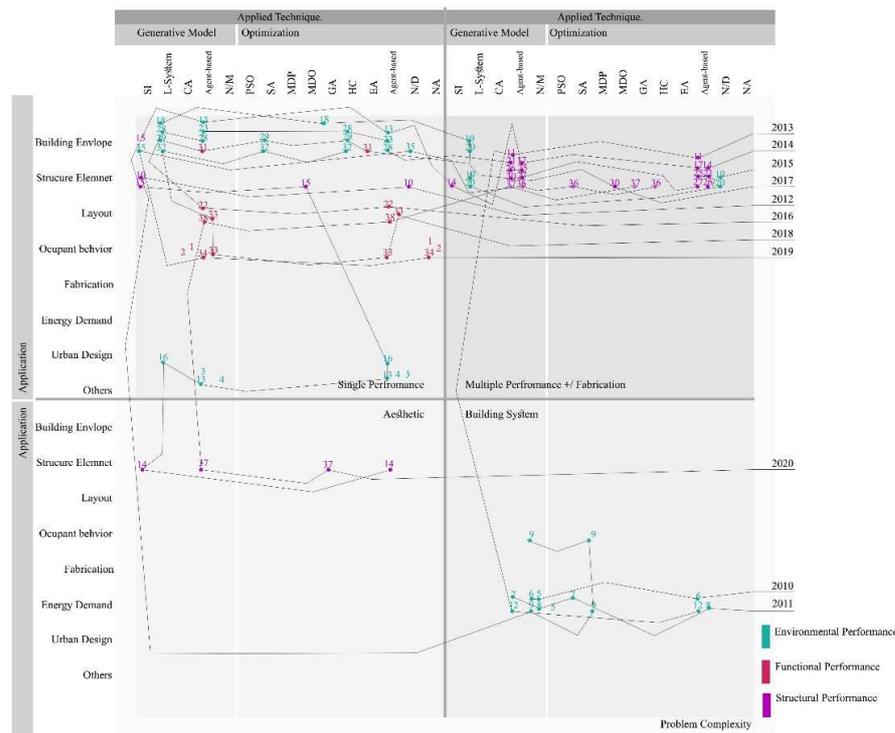
In addition, integration of Environmental and structural design problems can be solved in holistic fashion. In addition to merging fabrication constraints while designing and using fabrication constraints as designing drivers. This also reflected that MAS usage seems to have a global-related concern, which is climate change issue, where researcher's intent to design in regard to environmental performance and/or when the process integrates rationalization techniques to ensure material suitability and constructability and reduce expected waste in material. Going for complex design outcomes aesthetically with performable solutions proved the system vast capabilities in handling several design issues without simplifying the design outcome and taking it to a more holistic approach in terms of fabrication rendered the complex forms feasible for construction. However, the selected building types and design problems are still simplified, where most of papers tackle from two to three design objectives at maximum, which still does not reflect a highly complex design issue like designing for a huge shopping mall, hospitals etc., where the objectives with equal importance increase dramatically.


Figure 1: A Matrix Briefing the Applied Study (by author).

In the area of integrating heuristic searching method, relying only on agent-based searching method to find the optimal solution running to what this research called a linear searching process require extensive computation and time as handling that amount of rule-based parameter is endless. Therefore, incorporating a heuristic searching method is more promising to find the local-optimal or near optimal solutions in a reasonable time. Some insights on the optimization processes; Integrating two or more design objectives would complexify the design problem further making it a multi-objective optimization process. This was tackled differently by different researchers; Some would use multi objectives heuristic searching methods.

Others would combine all objectives in one formula where each objective is weighted differently in accordance with the researcher's criteria. And the process is turned into single objective optimization, where the system is trying to minimize or maximize the outcome. This formula would help to find the global optimal solution. However, this optimal solution is defined in terms of the designer/ creator weights to the formula's parameters which consequently affects the result greatly. This means the output is not necessarily the most optimal as for another weight factors the global optimal solution will result in a different one.

On the contrary, optimization based on pareto frontier in multi-objective optimization considered a more valuable technique, as it is seen to the user the different alternatives and where they fall on the pareto graph, how each solution out wins the other in each objective. This results in many alternatives and the designer can afterwards choose intuitionally and according to his/her own design targets which is the suitable or preferred solution. It can also give insights about the different objectives interrelation and correlation inside the system. Finally, the selected heuristic searching method is crucial in affecting the results outcome. They are another rule-based system with their own changing parameters added to the system, like the percentage of crossover to mutation in genetic algorithm. Therefore, defining the most suitable heuristic searching method is another research question. What is the most suitable searching method suitable for the problem at hand, especially with an ill-defined design problem like architecture design problems. Can one heuristic searching method outperform another? What are the internal parameters of the heuristic searching method and how they can drastically change the output? As they would. Should the designer use more than one to ensure the optimality of the output. Many questions can guide the research further in the area of integrating MAS with heuristic searching methods.

Some questions and notions were raised in response to this literature review to be investigated further in detail. Such as what is the possible validation processes a user can do to guarantee and validate the work of MAS, he/she created. Most researchers count on the end product; if the end product is valuable and falls under their criteria, the process can be considered valid. The question here is how can research validate further these processes what other possible ways of validation for such uncontrolled environments of exploration are witnessed on the level of ABMS usage in creation. In addition, the notion of constraints,

152

bias, and assumption. Can they offer a larger solution space or limit it, how the consequences of architects' bias and assumptions can be governed. With the intention to complexifies and yet produce exquisite forms the researchers adopt the concept of agent-based modeling and simulation in several levels such as manipulative level of agents that results into a form. The question here is how the design can be deliberate encompassing the architect's assumptions if ABMS gives and adapts an uncontrolled emergent phenomenon of exploration.

1 ABSTRACT

Urban public spaces play a central role in the regeneration of cities: their inclusive and sustainable design is crucial for creating equitable and climate-resilient urban environments. This paper presents the results of an applied research project that involved case studies in three cities on three continents - Dhaka, Maputo, and Santo Domingo – where the team of superwien, in partnership with local academic partners, developed designs for public spaces using an integrated approach. The participatory design process was implemented during the worldwide COVID-19 pandemic in 2021 and 2022 through academic urban living labs in our partner cities. Urban strategies and design solutions for the regeneration of public space were co-created with local communities through a moderated, innovative planning and design process. Additionally, accompanying research was conducted to explore the need for integrated planning approaches in urban regeneration that address multi-sectoral challenges. This approach aimed to ensure that the resulting proposals were holistic and responsive to the specific needs and aspirations of the local communities and urban environments in which they were implemented.

The case studies encompassed a range of sites reflecting diverse urban contexts: the urban lake of Shahjahanpur Jheel in Dhaka that had deteriorated into a dump site, central public spaces in informal neighbourhoods surrounding the historic centre of Maputo, and a central expressway in Santo Domingo. In intensive dialogue with the local populations, their needs and aspirations for these places were identified. Co-creation opportunities and place-making events empowered residents and local entrepreneurs to take an active role in the transformation of their neighbourhoods. Established participation tools were adapted to each local context and new techniques were developed for specific user groups. Additionally, young professionals were included in the design process through cooperation with local universities. Academic partnerships and the cooperation with local city administrations also supported capacity building and knowledge exchange. The results of the process included integrated urban strategies, urban designs, and architectural solutions, completed by cost estimates for implementation.

During the transnational work process, we identified seven overarching challenges that need to be addressed to transform public spaces with an integrated approach: inclusive mobility, housing, climate change adaptation, local economy, governance, as well as gender-sensitive and participatory planning. Considering these aspects in their specific local contexts supports the creation of lively public spaces for the development of inclusive, resilient, and sustainable cities. This paper presents how the challenges were identified and addressed through the applied research approach for the design of public spaces in Dhaka, Maputo and Santo Domingo.

Keywords: Co-Creation, Resilient Public Spaces, Participatory Urban Design, Academic Partnerships, Urban Design Lab

2 THE PANDEMIC AND OTHER JOINT CHALLENGES

In 2020 the COVID-19 pandemic spread across the world and left its mark in all aspects of human life. Urban life was hit particularly hard: high population densities, smaller housing units, and limited access to open space made life during the pandemic a serious struggle for many. In many cities, public parks and green spaces were closed or access restricted, people had to stay inside for days. Suddenly, the immense value of accessible public space became clearer than ever. This is the time when we started our research project in three cities around the world: Dhaka in Bangladesh, Maputo in Mozambique and Santo Domingo in the

Dominican Republic. All three cities are united in a notorious lack of public spaces. Especially poor or less developed areas face massive challenges when it comes to the provision of recreational outdoor spaces. Land prices are high and informal urban development swallows the remaining open spaces. However, the local municipalities are well aware of the need for quality open spaces for their inhabitants, especially after experiencing a global health crisis. Our task was to create and improve local public spaces in each city. Howeder, in order to approach the design in an integrated manner, several other challenges had to be addressed too.

2.1 Participatory design for inclusive public spaces

The main focus of the research and design challenge was to create inclusive public spaces for and with the local communities. The call for public participation in urban design processes is based on a paradigm shift in the planning world that started to recognize the place-based knowledge of local stakeholders. For most of the nineteenth century, positivism strongly influenced the social sciences and planning. There was a distinct division of roles and responsibilities among various actors, with architects and planners primarily serving as advocates for municipal government (König et al. 2023a). This separation has resulted in issues of injustice, marginalisation, and exclusion when higher authorities are solely responsible for designing public spaces (Rocco 2014). Other forms of planning started to emerge with the communicative turn in the 1960s and 1970s. In this approach, the city is made by the people who experience it in their daily lives. Contemporary planning approaches draw on the immense potential of local day-to-day practitioners and the expert knowledge of architects, urbanists, and other professionals. This approach is linked to the planner's position as an intermediary who has the task to reconcile interests, enable communication, and actively create a discourse about the production of space (Dangschat 2006). Participatory planning and design became the new tool for the creation of inclusive cities and public spaces.

2.2 Gender-sensitive planning

The discourse on participative and inclusive design also revealed a stark imbalance in the inclusion of girls, women and marginalised groups in planning processes. Urban design has long been a male-dominated discipline and this biased perspective on space has resulted in exclusive urban forms that make life more difficult for care-givers, disabled people, children, and other vulnerable groups (Falú 2020; Kern 2020). Feminist geographers have helped us understand how the unbalanced relationship between women and men is expressed spatially (Hurtig et al. 2023, 84). The feminist perspective on urban design therefore places the everyday life conditions of the neighbourhood at the centre of decision-making. It is necessary to understand the everyday activities and routines of different population groups, including the most vulnerable, to plan and build a city that is inclusive and offers the same opportunities for all. A participatory approach to urban design therefore must aim to include the diverse user groups of urban space with a particular focus on women, children, elderly, and disabled people.

2.3 Inclusive and sustainable mobility

The matter of inclusion is also an important topic in relation to urban mobility. Cities in the Global South are prone to particularly unjust mobility opportunities. Rapid urbanisation, uncontrolled urban sprawl in combination with a lack of road infrastructures and adequate public transportation lead to half of the inhabitants in this region suffering from restricted mobility (Venter et al. 2019). Especially inhabitants of urban peripheries and informal settlements, and thus the most disadvantaged members of society, face inequality in accessing urban opportunities such as employment, public institutions, and recreational facilities, which are primarily concentrated in the formal city centres (ibid.). For the working population in these areas, the everyday commute is a huge monetary and timely constraint, while the non-working population (often women, children, elderly) is entirely cut off from these urban amenities (Berger et al. 2014; König et al. 2023b). At the same time, mobility is still one of the biggest sources of CO_2 emissions and the transition towards sustainable modes of transportation is mandatory in order to respond to the ongoing climate crisis. The challenges of unjust and unsustainable mobility in cities of the Global South should therefore be addressed together and with a particular focus on the central role of public space. After all, streets make up for a large share of urban public spaces and the distribution of road space must be shifted towards a more just equilibrium that favours active mobility over individual motorised transportation (Nello-Deakin 2019).

2.4 Fostering local economies

Another activity that often takes place in public space, particularly in cities of the Global South, is trade and commerce. Small informal businesses provide the main income of many families and public spaces are often transformed into temporary or permanent workplaces. Informal economies are set apart from formal markets due the marginal nature of their activities that serve to sustain livelihoods. It is the result of insufficient demand for labour in underdeveloped countries (Young 2019). Up to 80% of urban dwellers rely on informal economic activities (Alison Brown 2018). Economic offerings greatly influence the overall atmosphere of a location. It's not surprising that areas with numerous shops and restaurants often become bustling urban hubs. With these places becoming more lively, they also have a greater impetus for new entrepreneurial endeavours. In this sense, economic activity can play an important role in reviving public spaces on the one hand, but can also foster unjust distribution of public space on the other (Gisinger 2023). City administrations play a vital role in managing public spaces and creating a balance between the stimulation of local economies and the provision of public spaces for other uses of general public interest (e.g. mobility, recreation, etc.).

2.5 Climate change adaptation

The local effects of climate change are becoming increasingly evident. The rise in sea levels is leading to a surge in natural disasters like floods, droughts, and heavy rainfall. Bangladesh, renowned for its severe floods, accounts for 50% of global cyclone-related deaths (Khan et al., 2011). Between 2011 and 2020, the Earth was 1.09ºC hotter compared to temperature records from the period between 1850 and 1900 when the first data on global surface warming became available (IPCC, 2021). Urban areas are facing mounting challenges due to the lack of green spaces, unplanned development, and inadequate soil permeability. Given the impact of climate change, it is crucial to transform cities in order to tackle these issues and implement eco-friendly urban development initiatives. Public spaces can play a significant role in urban adaptation efforts by harnessing their physical and social value to address weather phenomena (Silva & Costa, 2008). Incorporating large green areas and adopting sustainable practices are essential in densely populated cities to mitigate natural disasters and improve overall livability for all residents (WWF, 2020). Embracing nature-based solutions in urban planning is a vital approach to climate change adaptation, offering benefits like managing surface runoff and providing access to public green spaces (Abuje, 2022).

2.6 Providing affordable housing

Ensuring access to secure living environments is crucial for achieving inclusivity, resilience, and sustainability in all human settlements. However, in our project cities, there are significant gaps in accessing affordable housing. The inadequate supply of housing has resulted in the proliferation of informal settlements, currently housing approximately 880 million people (UN-Habitat, 2016). Furthermore, the commodification of housing has contributed to a global crisis of housing affordability. More than 330 million urban households are living in substandard housing or facing financial stress due to housing costs exceeding 30% of their incomes (McKinsey Global Institute, 2017). This housing crisis is particularly severe in the Global South, where rapid urbanisation is intensifying existing housing disparities. Spatial inequality within cities can lead to social segregation among communities (Martín, 2022). Our partner cities face formidable challenges due to accelerated urban growth. Moreover, the already precarious housing situation worsened during the Covid-19 pandemic, as strict curfews forced homes to become the primary spaces for work, study, and daily life.

2.7 Responsive city administration

In having to tackle all these challenges at once, municipalities often encounter significant governance challenges and limited resources for project implementation. They often adopt a reactive approach rather than proactive planning for the future. For example, prioritising investments in extensive road infrastructure like flyovers (as seen in Dhaka) or bridges (as observed in Maputo) over investments in health, safety, and well-being can perpetuate the struggle of communities to meet their basic needs and thrive. Moreover, insufficient resources hinder municipalities from fulfilling their responsibilities in urban development processes, and unclear roles and responsibilities can create power vacuums in project planning and implementation. Conversely, a responsive municipal administration takes action based on participatory urban development, whether at a small scale within an urban quarter or on a larger scale encompassing the entire

city (Reiter, 2021). In this context, addressing concerns related to public spaces becomes a crucial aspect of the responsive city discourse, as it directly influences the quality and accessibility of urban public areas. The following case studies in Dhaka, Maputo and Santo Domingo demonstrate how proactive city administrations can apply participatory design approaches to develop integrated projects that address multiple challenges at the same time.

3 CASE STUDY DHAKA – "DHAKA DREAMS"

In Dhaka, the World Bank is working with the Dhaka South City Corporation (DSCC), which administers the southern part of the metropolis, to implement the Dhaka Neighborhood Upgrading Project (DCNUP). The project focuses on the regeneration of public spaces, including the surroundings of Shahjahanpur Jheel, a small water body and green haven situated in one of Dhaka's most populated residential neighbourhoods. In order to address the many dimensions of this task, an interdisciplinary local team was set up for the work on the ground. The mixed team comprised young and experienced architects, urban designers, social anthropologists, and a geographer. The Department of Architecture at Daffodil International University was involved as local academic partner. The project sought to improve Shahjahanpur Jheel for and with the people. The community actively participated in this initiative from the beginning by taking part in various engagement activities.

3.1 Understanding the context of Shahjahanpur Jheel

The first project phase aimed to understand the local context, the challenges in public space, and aspirations of the community in relation to the development of the jheel. As a first step, the relevant stakeholders were identified. The local team was assisted by the Project Director of DSCC and the local ward councillor. They visited local communities, observed the area and compiled a comprehensive list of stakeholders which included members of the public administration, ward council members, a local police officer, land owners, residents, political figures, representatives of the local mosques, school teachers, and entrepreneurs.

Based on numerous stakeholder interviews and a detailed spatial analysis, the team identified eight Emerging Topics that are significant challenges and potentials related to the project development. These topics include poor water quality and pollution, insufficient waste management and maintenance, a lack of accessible public space, formal and informal economic activities, reduced public space due to construction, safety, and social conflict, as well as a strong sense of community and importance of human-scale mobility.

As a next step, residents were encouraged to express their ideas and opinions on the Shahjahanpur Jheel and its surrounding areas through anon-site spontaneous interaction. The goal was to involve groups like youngsters, the elderly, street vendors, mothers picking up their kids, guys spontaneously chatting, etc. who might not accept an offer to take part in a formal workshop or interview. The debate was centred around a big aerial map of Shahjahanpur Jheel and its surroundings. Men and women were asked about their favourite areas, places they did not like, and places that required improvement during the emotional mapping exercise. Blue, red, and yellow board pegs were used to indicate these locations. Another activity involved playing the Place Game with a group of invited stakeholders (PPS 2016). The game was modified to match the Shahjahanpur Jheel area, but the methodology remained the same.The participants included a variety of local decision makers, including representatives of mosques, business owners, landowners, educators, and political figures. Twenty people attended the workshop, seven of whom were women.

The results of the spatial analysis and community engagement activities were summarised to develop a common vision for the development of Shahjahanpur Jheel. This vision served as an overall guiding principle for the development of the conceptual design: clean recreational spaces for the community, lush greenery around the edge, a safe place for different groups, proper maintenance and an open public space for all.

3.2 Co-creation towards urban design

It was time to come up with specific concepts and design proposals for the Jheel area. Additionally, it was the consultant's duty to share the lessons learned from the first round of public engagement and provide seminars on developing capacity for students, faculty members, and DSCC associates. The Dhaka Urban Design Lab was organised with the academic partner, the Department of Architecture at Daffodil International University in Dhaka, as an online experience due to the pandemic situation at the time. It

Roland Krebs, Stefan Mayr, Sheikh Md. Rezwan, Katharina Höftberger, Theresa König, Victoria De Láncer Salas, Shaolin Saint Hilaire Jong, Anselmo Cani

included academic inputs on pertinent topics related to participatory urban design, training sessions on 24 participatory tools, and a student competition. A total of 120 participants joined the diverse program. The students who participated in the design competition for the area around Shahjahanpur Jheel received a competition brief, as well as all findings from the participation process, and data from the analysis. 92 students from five universities in Dhaka participated in the competitions. 24 teams completed their designs over the course of four days and sent them in for the jury's deliberation. All competition entries were of great quality and brought inspiration and new ideas to the project.

Based on this experience and valuable exchange, several co-creation workshops were held to include the opinions of local stakeholders into the design process. The first three workshops were aimed at specific groups, whose voices often go unheard: children, women, as well as street vendors and rickshaw pullers. The children sketched their ideas on tracing paper and pasted them over existing images around the jheel, women made detailed notes on specific locations and placed cut-outs of urban amenities on a map, local entrepreneurs provided input specific to particular locations that affect their businesses. Finally, local community representatives and officials participated in a workshop where they reviewed the top student projects from the Urban Design Lab and outlined and discussed their own ideas. It was innovative and new in the context of Dhaka, that a government project involved community members in the design of public space. The participants were carefully selected to represent diverse age, gender and occupations.

The second set of activities conducted in the co-creation phase were public events that took place directly at the Shahjahanpur Jheel site. The fundamental concept of the design-build workshop was to invite all neighbours and users of the public space to participate in the creation of their own environment, empower them to take care of the space, and create ownership. By promoting the event in advance on-site with banners and leaflets as well as by being present in the area when the event was taking place, many locals were reached. The workshop had an open structure, which allowed participants to drop in and out whenever they pleased, allowing for more flexible and impromptu involvement. A total of 50 to 60 members of the neighbourhood participated in the planning, design, and fabrication of temporary urban furniture as well as the painting of a wall in public space.

To close the series of co-creation activities, an interactive feedback exhibition was set up the day following the design-build workshop. The exhibition's goal was to present both the winning designs produced by the students during the Urban Design Lab and all the thoughts and suggestions that had been gathered from the neighbourhood during the co-creation workshops over the preceding weeks. The display also included a brief overview of the project and the opportunity to share further comments and suggestions.

3.3 Finalising the urban design

The vision and goals set the framework for the development of an urban design strategy that roughly outlines the main functions and features of the jheel development embedded into its urban context.The urban strategy is the initial step for changing the Shahjahanpur Jheel area. It is made up of various layers that describe the key characteristics, duties, and linkages of the site with respect to its surroundings. The plan focuses on the local requirements and potential for change while taking into account the urban layout, transportation patterns, and existing infrastructures in a larger area surrounding the jheel. The levels of the urban strategy deal with economic activity, green and blue networks, central locations, and accessibility.

Based on the vision, project goals and strategy, a conceptual design was developed for the regeneration of Shahjahanpur Jheel. The design incorporates most of the ideas and wishes formulated by the community and seeks to reconcile conflicting interests where possible. A continuous path around the jheel was recognised as the most crucial component mentioned by all stakeholder groups. More green space, public restrooms, a playground for children, an extra pedestrian bridge across the jheel, and seating areas are other design features that were requested and incorporated in the design. Some desired elements, like a large market area or a site for swimming and fishing, could not be included due to spatial or environmental limitations.Nonetheless, the implementation of the design will provide a climate-friendly and sustainable urban public space that accommodates the needs of diverse and vulnerable groups, offers opportunities for local entrepreneurs and fosters active mobility with a limitation for car traffic. It touches upon almost all challenges that have been identified in relation to the development of public spaces, and all of these topics emerged from a participatory process with the local community which is ready to take ownership and responsibility for their Jheel.

4 CASE STUDY MAPUTO – "MAPUTO URBAN LAB"

In Maputo, Mozambique, the World Bank has granted funding for the purpose of preparing and implementing the Maputo Urban Transformation Project (PTUM). This project aims to support the key priorities outlined in the Municipal Development Plan by undertaking impactful investments and reforms in urban infrastructure. It focuses on transforming specific areas into versatile community spaces and central hubs within neighbourhoods. Additionally, it involves the restoration of 20 km of pathways to facilitate pedestrian and cyclist connectivity across the city. The project's development has been guided by a collaborative urban design process and a place-oriented approach, actively involving local stakeholders throughout all phases. The engagement of various parties, such as local architects, urban planners, project residents, community leaders, and architecture students, has been instrumental in shaping the project from site selection to its final design.

4.1 Participatory analysis of neighbourhoods in the periphery

The project encompassed 20 neighbourhoods, covering an approximate area of 17.26 km2, and its benefits would extend to over 264,054 individuals (Instituto Nacional de Estatística 2019). To initiate the planning process, the neighbourhoods were prioritised based on various criteria, including vulnerability to climate conditions, poverty levels, and limited access to essential infrastructures. The areas exhibit high population density, with inadequate distribution of green and recreational spaces, and a lack of water supply, solid waste collection services, energy supply, and sewage services. Moreover, the neighbourhoods face recurring flood-related issues due to inadequate drainage systems (CMM, 2021).

To comprehensively analyse and evaluate the entire project area, a local team of architects and urban planners based in Maputo was assembled. They actively worked on-site, gathered essential information, and facilitated participatory activities. Furthermore, they served as a crucial link between local and international stakeholders. As part of an inclusive diagnostic process, the Municipality of Maputo identified 107 existing public spaces dispersed across the 20 project neighbourhoods, compiling a detailed dataset that analysed their condition and usage. The study revealed several deficiencies in these public spaces, including a lack of urban furniture and basic infrastructures such as public toilets and shaded areas. Additionally, many of these spaces were in a state of disrepair due to the absence of maintenance policies, exacerbating issues during rainy seasons when flooding occurs repeatedly.

The superwien team evaluated the data, focusing specifically on the accessibility of public spaces and the existing and future public transport systems. A "5 minutes walking distance" parameter was used to identify public transport stations, points of interest, and the road network close to public spaces. This analysis also incorporated the overlap between flooding areas and public spaces. All information was fed into a GIS-based multi-criteria analysis that considered all factors, and helped to select those public spaces with highest accessibility for as many residents as possible, distributed equitably throughout the entire project area.

Additionally, qualitative data was considered. Residents in each neighbourhood were interviewed about their mobility patterns. Participatory sessions were conducted in all 20 neighbourhoods, accompanied by the application of various engagement tools during interactions organised in collaboration with the neighbourhood secretaries. These participatory tools included emotional mappings, surveys, and interviews with key stakeholders to gather different perspectives on the public spaces. These methods provided an overview of the area, including the current state of the public spaces, maintenance challenges, characteristics of their current usage and the social groups that utilise them, as well as their development potential.

In order to involve even more local residents and future public space users, we sought out residents who held influential positions within the community, such as block chiefs, who could assist in reaching out to other interested residents and encouraging their participation in our workshops. The goal was to employ at least on of these multipliers in each of the twenty neighbourhoods within the project.

4.2 Expanding tested participation tools to all neighbourhoods

With the support of the multipliers, our team organised workshops with the local community in five pilot spaces. The aim was to test and determine the most effective participatory tools to be used in these irregular settlements of Maputo. The workshop concepts were tailor-made for the specific community groups that were engaged, and certain tools had to be adapted to suit the local context. Factors such as the participants'

160

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Roland Krebs, Stefan Mayr, Sheikh Md. Rezwan, Katharina Höftberger, Theresa König, Victoria De Láncer Salas, Shaolin Saint Hilaire Jong, Anselmo Cani

high illiteracy rate and the need to conduct activities in open spaces due to COVID-19 regulations were crucial considerations in tool adaptation.

In addition, supplementary activities were arranged for specific community groups, such as women, children, and community representatives. This approach enabled us to hear diverse perspectives and incorporate the viewpoints of vulnerable groups, fostering a more inclusive approach. The contrasting perspectives became evident during the workshops held for one particular public space. In the session with the general population (predominantly men), participants mentioned that the space was only used by women. However, in the workshop with women, they expressed that they indeed utilised the space frequently, particularly when men were absent. For engaging children, we found that creative and playful tools were most effective in keeping them interested and comfortable enough to share their opinions. For this purpose, we developed our own tools, such as an urban game called "Build-your-Square", which proved highly successful in engaging children and youth. Throughout the experimental pilot phase, dedicated to creating tailor-made co-creation tools for the design process in Maputo, lessons learned from each pilot were applied to subsequent ones. Based on these learnings, the tools were adjusted and gradually the most effective combination of co-creation tools for the local context in Maputo could be identified.

In order to implement these tools in the remaining 15 neighbourhoods, the team was supported by local architecture students from various universities who were interested in expanding their knowledge on participatory urban design. During the Maputo Urban Lab, we brought together representatives of the Municipality of Maputo, more than 35 local students, and 15 multipliers from the target neighbourhoods. The event, co-organised by the Municipality, superwien, Eduardo Mondlane University and the Ordem Dos Arquitectos de Moçambique, provided an opportunity to share the collective knowledge of all these parties and jointly envision the future of public spaces in Maputo. To prepare the students for their participatory workshops in the 15 neighbourhoods, the team offered training sessions for selected participatory tools. Under the guidance of the local multipliers, the students had the opportunity to put the tools into practice in the neighbourhoods. Through a dialog-oriented approach and with the support of the students and locals, we successfully gathered information, ideas, and visions for the public spaces to be transformed. The design process prioritised the co-creation of designs, involving residents from all locations.

4.3 A design concept based on seven essential elements

Collaborating with a diverse range of opinions provided valuable input for an inclusive design process, and the resulting design outcomes demonstrated the success of the approach. The development vision involved creating well-designed urban spaces that serve as central hubs for each of the 20 neighbourhoods and are accessible through an active mobility network. Seven essential design elements were identified that should be implemented in each of the 22 public spaces. The first element focused on maximising the size of public spaces, as well as increasing area densification. This addresses the current issue of limited and small public and open spaces. The second key design element is the inclusion of a community porch, which would act as the centrepiece for each neighbourhood's local community. This multifunctional community centre would serve various purposes, such as housing municipal offices, toilets, lecture and workshop spaces, and a library. The third element involved the economic revitalization of the area. Recognizing the importance of encouraging commercial activities in public spaces, we proposed incorporating specific marketplaces for both formal and informal commerce, as well as activating existing ground floor spaces. To promote inclusivity, the fourth key element focused on using diverse and inclusive urban furniture. This would ensure that public spaces can be utilised by people of all ages and genders. The fifth urban design element emphasised the significance of green infrastructure for sustainable future development. It involved planting trees and utilising sustainable materials in the design process. The sixth aspect was centred around local co-creation and maintenance. This approach would allow for some flexibility in each public space, enabling local adjustments while maintaining a cohesive design. It also encourages elements that foster a sense of local identity and can be developed and built by community members, strengthening their connection to the area. Lastly, security aspects and the integration of basic infrastructure are fundamental foundations for all designs, from the active mobility network to public spaces. These considerations ensure the safety and functionality of the overall design concept.

In accordance with the Dhaka case, the participatory process in Maputo revealed the multidimensional needs and functions of public spaces for the local community. The design concept builds on the identification of

multiple challenges and addresses them through an integrated design approach that incorporates elements of inclusive design.

5 CASE STUDY SANTO DOMINGO – "LABORATORIO SANTO DOMINGO"

Santo Domingo, capital of the Dominican Republic, is characterised by the dominance of car-traffic and the scarcity of public spaces. These aspects were the starting point of our research. A relevant example is the 'V Centenario' Expressway, built between 1992 and 1994, which connects Santo Domingo downtown with East Santo Domingo. This eight lane highway cuts through a homogeneous social and economic neighbourhood in District 3, a complex area characterised by a low-income population, high percentage of informal occupancy and lowest concentration of public space. Villa Juana and Villa Consuelo are two of the local neighbourhoods crossed by 'V Centenario' that were selected to be assessed and developed to improve the quality of life for residents through a new vision for the public space along the expressway.

5.1 A gender lens in public space diagnostics

As a first step of the participatory urban design process, the main stakeholders were identified. These included representatives of the public administration, community groups, street vendors, transport workers, national and international experts, and non-governmental organisations. The second phase included workshops in situ and collaboration with the Universidad Iberoamericana (UNIBE) to analyse the public spaces along V Centenario. Adapting superwien's experienced work methodology to the local context, resulted in a "Toolbox for Santo Domingo" with the followings tools: gender-sensitive responses, co-creation with the informal sector, co-creating inclusive public spaces: from ideas to sketches to conceptual designs, first-time bici (bycicle), build your daily route, digital collage, urban accessibility walk with people with disabilities, urban rally with athletes, cultural rally, and a case study discussion with vendors.

Based on the analysis, there were three specific topics that broadly structured the entire participatory process. Firstly, local economies through informal vendors, or street vendors, were generally considered a threat because they occupy sidewalks, obstruct public spaces, and generate garbage. There is competition for the use of public space and a sense of appropriation around it. Secondly, the V Centenario Expressway was designed at a point in history when the transportation model was very different from today's vision of inclusive mobility. This is reflected in the intervention strategies that focused on opening arteries to private cars, always prioritising the flow of traffic over the safety and comfort of pedestrians. And thirdly, a gendered focus on activities related to care and life support reveals inequalities that emerge from the prevailing logic of economic profitability in urban space. It allowed us to analyse some of the problems that had been identified as emerging topics, such as the lack of public space, which is monopolised by roads and parking lots, basketball courts and street vendors. Women, children, the elderly, and people with disabilities are disadvantaged in the distribution of uses in public space. In this way, the participatory process developed to identify the needs of the communities in relation to the expressway incorporated a diversity of perspectives in order to arrive at sensitive and contextualised project conclusions.

5.2 Talking to people to understand social spaces

The Laboratorio Santo Domingo was developed in close cooperation with the School of Architecture at UNIBE. It began with a cycle of open virtual workshops, in the form of master classes in which architects and urban planners with international experience were invited to a hybrid space between theory and practice. These workshops generated the basic skills to understand the methodology for participatory design. They were followed by a full week of concentrated activities, such as lectures, workshops on participatory urbanism, tactical urban planning strategies and placemaking, together with professors and enrolled students. The main question during these masterclasses was the role of participation in the specific context of Santo Domingo. At the end of the Laboratorio Santo Domingo, the students concluded that participation is about giving people the space to decide the future of their neighbourhoods. Talking to the local people is the most sensible approach to understanding places and their complexities. During the Urban Lab, the students went out into the street, talked to people using a range of tools, starting with the Goals Grid Analysis, to identify needs and desires regarding public spaces. They played the Place Game, conducting surveys to understand how different types of residents perceived their neighbourhoods. They carried out Exploratory Walks guided by residents, where they explored individual perspectives on space. We also carried out a Placemaking activity, where the students worked on preliminary ideas for the planning area on site and with the local

residents. This activity, using public space as the main stage and forum to gather people, was the highlight of the week. Neighbourhood leaders and local experts had the opportunity to give feedback on the students' ideas. The cycle was closed with an architecture and urbanism competition open to all students.

5.3 Design towards a green avenue

The participatory urban planning tools guided the design process, which resulted in three main approaches to public space intervention: a new urban avenue and inclusive green corridor; new centralities as game changers; and the transformation of residual public spaces into new parks. The overall concept was to take the subway stations as the main points of interest and focus the designs around that infrastructure.

The first essential aspect of the urban strategy was the transformation of the expressway back into an urban avenue. The second element of street transformation was the development of a green corridor, with trees along the avenue and in the neighbourhoods' service streets. The shade cast by the new trees would improve the conditions for active mobility like walking. In addition, specific public spaces would be transformed into new centralities characterised by urban or green functions. These parks were already there before, but nobody used them. Given that there would be more shade and thus more people walking, the project would also support the reactivation of ground floors, including commercial activities in public space, which could be better organised.

The resulting design reflects the lessons learned throughout the process, combining residents' views with technical requirements to create a proposal that responds to the environment, improves the urban quality of the two neighbourhoods it reconnects, and creates spaces for community gathering in new, inclusive, high-quality public spaces.

6   SEVEN TOPICS THAT LEAD TO INTEGRATED URBAN DEVELOPMENT

In conclusion, the applied research project highlighted the importance of inclusive, integrated, and locally rooted approaches in urban regeneration and how integrated designs could be implemented through participatory urban co-design processes. It showed that equitable cooperation across hierarchies is necessary and possible, icluding stakeholders on the global, national, local, and community level.The projects in Dhaka, Maputo, and Santo Domingo demonstrated the value of engaging local communities, considering gender perspectives, promoting sustainability, and fostering academic partnerships in creating equitable and sustainable urban public spaces. The study also demonstrated that successful implementation of public space projects depends on a multi-sectoral, integrated approach in the context of the given public space.

The seven overarching topics that were identified as crucial aspects in the transformation of public space were relevent in all three case studies. In each city, the specific context and potential of public space development was strongly characterized by the capacities of the local administration, the impacts of climate change and the lack of affordable housing. Informal settlements have encroached upon public spaces in Dhaka, Maputo and Santo Domingo, reducing public space and increasing the pressure on open spaces through high population densities. The housing crisis is therefore a main challenge, setting the framework for public space provision in the global south. Climate change increases the pressure on open spaces which are needed as retention spaces and habitats for biodiversity on the one hand, but also calls for the implementation of green infrastructured in the urban fabric to alleviate its immediate impacts like urban heat islands. This is particularly true for large urban conglomerations where the escape to natural areas around the city is reserved for high-income population groups. Local city administrations are confronted with numerous pressing issues and often fail to see the urgency of investments in public spaces. It is therefore even more important to highlight the integrated nature of public space interventions that bring along solutions for many other challenges.

The cases studies have also shown how two main activities are dominating and competing for public space: mobility and local economies. Both come along with great challenges and opportunities. Being considered more important than recreation and care work, car-dominated transportation infrastructures and economic activities often displace more vulnerable users like women, children, and elderly people who have different needs in relation to public space. However, economic activity is also vital for attractive public spaces that need activitiy and live in order to be interesting, enjoyable and safe. At the same time, the mobility transition towards sustainable transportation, that is mandatory in the face of climate change, has the potential to solve many challenges in relation to the unjust division of public space. As the design proposal for V Centenario in

Santo Domingo demonstrates, downsizing motorways can provide the space we need to enlargen public space and insert green areas into the city. Active modes of transportation are much more efficient in terms of space consumption, more compatible with nearby recreational uses, healthier and better for the environment.

Last but not least, these and other challenges as well as their potential solutions must be identified and developed with and through the local communities. Public participation with a gender-sensitive approach is key to an integrated urban design that is responsive to the local context. Adequate engagement tools must be adapted to the spatial context as well as to the culture and capabilities of the involved stakeholders. Moreover, co-creation should take place in situ to reach the actual space users. The findings of this project provided valuable insights and tools for practitioners and policymakers to adopt innovative approaches in their urban regeneration projects and promote inclusive and sustainable urban development in the Global South .

Crisis and Green Urban Development: Urban Agriculture and Post-Earthquake Urban Resilience in Christchurch, New Zealand

Andreas Wesener

(Dr Andreas Wesener, School of Landscape Architecture, Lincoln University, PO Box 85084, Lincoln 7647, New Zealand, andreas.wesener@lincoln.ac.nz)

1 ABSTRACT

The paper examines urban agriculture and local food initiatives in post-earthquake Christchurch, New Zealand and discusses their role for urban resilience. Like many other coastal cities in the world, Christchurch is prone to a range of natural and anthropogenic disasters including earthquakes, floods, extreme weather events, and sea-level rise. In 2010 and 2011, the Canterbury region was struck by two major earthquakes and a series of aftershocks. It was one of the most devastating natural disasters in the history of New Zealand killing 185 and injuring 7000 people. 90 per cent of residential properties were damaged, resulting in the demolition of around 8000 households and 80% of central Christchurch. In addition, recurrent flood events have been devastating large areas of the city on a regular basis.

Shortly after the experiences of the 2010/11 Canterbury earthquakes, various bottom-up urban agriculture initiatives sprung up and have led to the development of a network of organisations and spaces across the city. With the help of exemplary case studies, the paper discusses post-earthquake urban agriculture initiatives in Christchurch against notions of urban resilience. It critically reflects on knowledge gaps, potential areas for future research and related barriers and enablers for green urban development.

Keywords: green sustainable urban development, food networks, urban resilience, urban crisis, urban agriculture

2 INTRODUCTION

In the context of both natural and anthropogenic crises and disasters, urban gardens and farms can play an important role for community recovery (Fox-Kämper, 2016, p. 365). In disaster situations, urban gardens can help mitigate food shortages when supply chains are interrupted, for examples after earthquakes (Sioen, Sekiyama, Terada, & Yokohari, 2017). Urban agriculture can be "a survival strategy for displaced people to obtain food on a temporary basis, but also a valuable livelihood strategy for those who settle permanently, and for those who eventually return to their home cities" (Adam-Bradford & van Veenhuizen, 2015, p. 407). In the context of Hurricanes Katrina and Rita in Southern Louisiana, Sims-Muhammad (2012) demonstrated the role of urban community gardens in minimizing food insecurity when conventional food sources became unavailable. Following natural disaster, open spaces are often considered safer than built structures that may be damaged, unusable, unreliable, or unsafe. For example, when Hurricane Sandy devastated New York City in 2012, community gardens were considered as safe "multi-purpose community refuges which hosted meaningful and restorative greening practices" (Chan, DuBois, & Tidball, 2015, p. 625). Social activities in gardens help address physical and mental health issues in times of severe stress by increasing "psychosocial resilience after a disaster" (Heather A Okvat & Zautra, 2014, p. 85) and providing post-trauma therapy to "alleviate negative emotions and […] engage in experiences that enhance positive emotions" (p. 81).

Urban gardens encourage social interaction and help build networks between people through collaborative action (Firth, Maye, & Pearson, 2011, p. 565). Kato, Passidomo, and Harvey (2014) observed that community gardens empowered local communities in deprived urban areas to counteract socio-economic injustice in New Orleans following Hurricane Katrina. Disaster resilience depends on "the degree to which the social system is capable of organizing itself to increase its capacity for learning from past disasters for better future protection and to improve risk reduction measures" (UN/ISDR, 2004). Social interaction encourages social capital construction and thus disaster preparedness (Aldrich, 2012). With regard to disaster risk reduction and disaster preparedness, cities have been urged to include urban agriculture as part of their climate change strategies and plans (Dubbeling, van Veenhuizen, & Halliday, 2019). Urban gardens do not only provide benefits following a disaster, but can help prepare cities for future crises by increasing "the resilience of urban social–ecological systems" (Barthel & Isendahl, 2013; see also Barthel, Parker, & Ernstson, 2015; Bendt, Barthel, & Colding, 2013; Chan et al., 2015, p. 632; Colding & Barthel, 2013).

In this paper, urban agriculture is broadly defined as "the cultivation, processing and distribution of agricultural products in urban and suburban areas" (USDA, 2023). The paper presents a case-study informed discussion of urban agriculture projects in Christchurch since the 2010/11 Canterbury earthquakes against notions of urban resilience. It critically reflects on potential knowledge gaps, areas for future research, and barriers and enablers.

3 POST-EARTHQUAKE URBAN AGRICULTURE IN CHRISTCHURCH

Christchurch is historically known as the 'garden city' thanks to an abundance of public parks and private gardens in the context of low suburban residential densities. While the development of allotment and community gardens started in the early 1980s, the majority of gardens became established since the early 2000s with a clear upwards trend in recent years. In 2016, Christchurch City Council published community garden guidelines to "encourage community gardens throughout the city" (CCC, 2016, p. 1). In 2019, the Canterbury Community Gardens Association (CCGA) listed about 30 community gardens on their website within the Greater Christchurch metropolitan area (Shimpo, Wesener, & McWilliam, 2019). By January 2023, the number of gardens had grown to 52 (CCGA, 2023), an indication that community gardens in post-earthquake Christchurch have become increasingly popular.

Shimpo et al. (2019), who studied an urban community garden in New Brighton, a coastal suburb of Christchurch, argued that "community gardens may help secure food supplies and provide essential infrastructural support following a disaster. However, first and foremost, community gardens help strengthen social interactions, relieve stress and build the social capital that is needed when a disaster strikes" (p. 31). Wesener (2020), who studied eight urban community gardens in post-earthquake Christchurch, discussed three commonly experienced benefits against the backdrop of the 2010/11 earthquakes: First, community gardens became post-earthquake sanctuaries and places for social exchange. They were perceived as safe and accessible places to meet other people, work and talk together, participate in shared activities and events and "escape from the difficult situation – at least for a few hours" (p. 82). Second, community gardens provided food to those who needed it. Examples include transporting food supplies by helicopter from a community garden in Kaiapoi to a cut-off coastal suburb in Christchurch, participating in food donation schemes such as the delivery of food packages via local charity organisations, and contributing directly to the food supplies of people in need. And finally, local community gardens became post-disaster learning spaces where people could explore practical skills such as cooking, DIY repairs, or how to save water and install a composting toilet if regular infrastructure had become dysfunctional.

Following the Canterbury earthquakes, a variety of community groups developed projects for the temporary use of vacant urban spaces across the destroyed city with the idea to re-activate spaces until permanent urban redevelopment started (Wesener, 2015). One of these projects was 'Agropolis', a "scalable transitional urban farm" (LIVS, 2015) and collaborative community initiative that opened in 2013, conceptualised as a temporary urban space. Agropolis continued for about three years featuring regular working bees, workshops and community events. However, more importantly, it became an inspiration and incubator for other urban agriculture projects such as a vertical pop-up garden (LIVS, 2016) and 'Cultivate Christchurch', an urban farm that started on a vacant central city site in 2014 and extended to a network of urban farms combining urban food production with social work around youth development and community engagement. Cultivate merged with a larger commercial organic farm in 2021, realising "that our small scale model of urban farming is not robust enough for supporting our youth programme over the long term, nor a viable business in the competitive Canterbury organic veggie market" (Cultivate Christchurch, 2021). The Ōtākaro Orchard project is another example of a post-earthquake urban agriculture project with a distinct educational rationale. It combines a food forest and edible garden with a food information centre, a restaurant, office, event spaces and outdoor educational facilities (Ōtākaro Orchard, 2023). Other types of edible urban gardens in Christchurch include traditional indigenous Mahinga kai sites (Ngāi Tahu, 2023), community orchards and food forests, institutional and school gardens, and food foraging sites (CCC, 2016, p. 2).

Outside the central city, particularly in the Eastern suburbs, large areas were affected by earthquake-related soil liquefaction and lateral spreading causing widespread damage to land and properties. After the February 2011 earthquake, the decision was made to 'red-zone' these areas, and to demolish existing structures and prevent future rebuild (CERA, 2016). The largest residential red zone, the Crown-owned 'Ōtākaro Avon River Corridor', is a vast 602-hectare area in the East of Christchurch that has become home to various food

168

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

projects and edible gardens. The 2019 Ōtākaro Avon River Corridor Regeneration Plan lists as preferred land uses "farming and food-based opportunities" including commercial farming, horticulture, market and community gardens, food forests, and "plot to plate" facilities including cafes and restaurants (DPMC, 2023, p. 46). An example for urban agriculture in the Ōtākaro Avon River Corridor is the 2015 established Richmond Community Garden. The garden provides a range of community services and activities from a recycling drop station to community composting, olive oil production, spring fairs and dog-friendly 'day-outs' in the red zone. Another example, the 'Moon River Flower Farm', is the first commercial nursery in the residential red zone "selling cut flowers and bouquets to the public" (Harvie, 2021). Christchurch City Council (CCC) encourages food foraging in the Ōtākaro Avon River Corridor and publishes a web-based fruit tree map that allows people to find specific fruit tree species across Christchurch.

4 URBAN RESILIENCE

Urban resilience is a contested and politicized concept often involving different narratives (Amin, 2014; Leitner, Sheppard, Webber, & Colven, 2018; Wilson & Jonas, 2018). However, despite many conceptual differences, most urban resilience narratives involve a high and continuous level of preparedness: "The resilient city – depending on local affordance – is imagined as the city of active citizens, intelligent technologies, and vigilant governance, a body on full alert" (Amin, 2014, p. 310). Likewise, urban resilience narratives rely on "the many bureaucracies, supply chains and metabolic systems" that work "constantly in the silent background" (ibid: , p. 311). In the context of urban agriculture in post-earthquake Christchurch, there are at least two relevant sub-categories of urban resilience that require attention: food resilience and community resilience.

4.1 Food Resilience

The Canterbury earthquakes became a catalyst to reflect upon the production and distribution of food in Christchurch. The Food Resilience Network was born in 2013 "from a range of organisations who all had an interest in food resilience" (Edible Canterbury, 2023). The Food Resilience Network developed a 'Food Resilience Strategy', that was adopted by the City Council in November 2014 with the key objective to provide "healthy, affordable and locally grown food for all people" (CCC, 2014a). The related 'Food Resilience Network Action Plan' seeks to establish a "patchwork of food growing at local hotspots, linked together like a ribbon and woven into the fabric of our communities" by growing networks and partnerships across organisations, educating people, and supporting and strengthening the local food economy, for example by developing supportive policy frameworks (CCC, 2014b). In 2015, the 'Edible Canterbury Charter' was signed by a range of organisations including CCC and the Canterbury District Health Board setting out "guiding principles of our collective efforts to create a more food resilient region". The Edible Canterbury web-portal was developed "as a one-stop shop for information about growing and enjoying local food" (Edible Canterbury, 2023). CCC defines food resilience as "[p]hysical and economic access, by all people, at all times, to enough food to maintain an active and healthy life" based on a "local food production and distribution system based on ecological sustainability, able to withstand natural and man-made shocks" (CCC, 2014a). This definition makes a distinct connection to natural and anthropogenic disasters. This is echoed by local urban agriculture initiatives such as the Ōtākaro Orchard who reflect on their website that following the earthquakes "we realised that supermarkets carry only 3 days' worth of food and if our supply chains get disrupted, we go hungry" (Ōtākaro Orchard, 2023). Similarly, Edible Canterbury defines food resilience as "the ability to prepare for, withstand, and recover from disruptions in the food supply chain in order to make food accessible for all" (Edible Canterbury, 2023). The specific connection between food and disaster resilience prevalent in above definitions is contextually interwoven with the history of a city and region that went through a major earthquake in its recent history.

4.2 Community Resilience

Community resilience (CR) is a concept of collaborative action at various levels (Daly, Becker, Parkes, Johnston, & Paton, 2009) to obtain and utilise resources to cope with and thrive under unpredictable and continuously changing circumstances (Magis, 2010). At an institutional level, CR requires governance arrangements that enable community action, empower communities, and provide support from and collaboration with governmental and civic agencies (Daly et al., 2009). Urban gardens, in particular community garden, are places that encourage community action and empower communities. They can help

increase "the resilience of urban social–ecological systems" (Chan et al., 2015, p. 632) before a disaster "by providing the structure and practices to support social–ecological diversity, learning, and community support networks to better respond to future disturbances" (Chan et al., 2015, p. 633). After a disaster, they can provide "psychosocial resilience […], especially by enhancing cognitive capacity, positive emotions, and community engagement" (Heather A Okvat & Zautra, 2014, p. 85) and encouraging neighbourhood social interaction to help build social capital (Aldrich & Meyer, 2015). Community gardens are accessible open spaces with multiple opportunities for collaborative action that can strengthen the role of a community within the complexity of local and regional power relationships following a disaster: "By expanding their social network and deepening their extant social ties, community gardens were able to mobilize resources (ranging from grant money to volunteers) to support their garden, their members, and their neighbourhood" (Chan et al., 2015, p. 632).

5 DISCUSSION

Looking at post-earthquake urban agriculture initiatives in Christchurch through the lens of urban resilience shows that urban gardens are part of systems that operate "in the silent background" (Amin, 2014, p. 311) and only expand their full potentials in a disaster situation (Wesener, 2020). The above discussion of urban agriculture initiatives in Christchurch shows that urban gardens strengthened community resilience in the immediate aftermath of the earthquakes by providing multiple benefits with regard to coping strategies. However, and perhaps more importantly, many of these projects have become learning spaces and incubators for future action. Such findings support studies that have highlighted the important role of urban gardens as educational hubs (e.g., D'Abundo & Carden, 2008; Gregory, Leslie, & Drinkwater, 2016; Surls et al., 2014; Wesener, Fox-Kämper, Sondermann, & Münderlein, 2020) for developing community resilience beyond an immediate crisis situation.

The Canterbury Earthquakes created also new opportunities for green urban development in Christchurch. However, there are opportunities to rethink the role of urban gardens and further develop their potential contribution to urban resilience. For example, in the context of urban design, landscape architecture and planning, new spatial networks that link existing urban gardens could become green corridors connecting with the Ōtākaro Avon River Corridor. Such a network of green spaces could provide far-reaching sustainable urban development opportunities, e.g., with regard to integrated green-grey infrastructure systems (Wesener & McWilliam, 2021), urban transport, biodiversity, stormwater management, and recreation.

There are plenty of other opportunities for urban agriculture to increase urban resilience. Climate change is one of the most imminent global threats to human survival. Many countries – including New Zealand – have signed the UN Framework Convention on Climate Change and passed corresponding national acts to address related issues. Cities need to adapt to climate change related adversities such as extreme weather events, droughts, and higher temperatures. At the same time, certain urban structures, processes and lifestyles can contribute to reduce greenhouse gases as a mitigation measure. Urban gardens can help cities mitigate and adapt to climate change, e.g. by sequestering carbon emissions (Heather A. Okvat & Zautra, 2011; Richter, Haase, Thestorf, & Makki, 2020), and reducing carbon footprints through the local production of food (Edmondson et al., 2020). In addition, urban gardens strengthen urban socio-ecological systems that are vulnerable to the adverse effects of climate change (Demuzere et al., 2014; e.g., Gill, Handley, Ennos, & Pauleit, 2007). Gardens could, for example, play a more vital role with regard to stormwater storage and filtration (Pauleit & Duhme, 2000), urban temperature reduction (Rost et al., 2020), and environmental education (Bendt et al., 2013). However, the (potential) role of urban gardens within local urban climate change policy frameworks has rarely been studied and represents a significant research gap (Clarke, Davidson, Egerer, Anderson, & Fouch, 2019).

6 CONCLUSIONS

The paper discussed urban agriculture through the lens of urban resilience in the context of crisis and disaster. However, disasters can also be catalysts to learn, rethink sustainable urban development and explore new development options. The international literature provides many examples of how urban gardens have contributed to urban resilience. However, while beneficial links between urban agriculture, sustainable food production, social interaction, community empowerment, education and urban resilience have been

170

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

discussed, national and local government agencies remain often unaware of the full potentials of urban agriculture and its abilities to make cities more resilient to natural and anthropogenic disasters. This opens up various opportunities for research. For example, it would be valuable to find out how community gardeners perceive the potential contribution of their garden and their own role with regard to climate change mitigation and adaptation strategies (bottom-up perspective). This would produce valuable insights about how urban gardens could be better integrated as part of local urban climate change policy frameworks.

Urban gardens remain underestimated assets for urban development. Garden initiatives suffer from a lack of funding, struggle to find affordable land to set up new gardens, and do not receive adequate administrative and political support to keep them running for a longer period of time (Fox-Kämper et al., 2018; Wesener et al., 2020). There are rarely comprehensive urban planning and design strategies that include urban gardens as core components of resilient green urban development at city scale. It is time to reconsider such attitudes and treat urban gardens as valuable tools to strenghten urban resilience and prepare cities better for crisis.

Decoding Stress – ein interdisziplinärer Stressforschungsansatz zur Förderung qualitätsvoller öffentlicher Stadträume für den Rad- und Fußverkehr

Nina Haug, Peter Zeile, Markus Neppl

(MSc. Nina Haug, Karlsruher Institut für Technologie KIT, Professur Stadtquartiersplanung STQP, nina.haug@kit.edu)
(Dr.-Ing. Peter Zeile, Karlsruher Institut für Technologie KIT, STQP, peter.zeile@kit.edu)
(Prof. Markus Neppl, Karlsruher Institut für Technologie KIT, STQP, markus.neppl@kit.edu)

1 ABSTRACT

Wie nehmen wir Stadträume wahr, wenn wir mit dem Fahrrad oder zu Fuß unterwegs sind? An welchen Orten in der Stadt fühlen wir uns wohl, respektive unwohl und gestresst? Welche spezifischen Faktoren beeinflussen dabei unsere Emotionen? Und vor allem: Wie können diese Einflussfaktoren für die Planung entschlüsselt werden?

Ausgehend von den Emo-Cycling-Stressmessungen der Urban Emotions Initiative untersucht die Studie „Decoding Stress" auffallende Stress-Hotspots für Radfahrende im urbanen Kontext. Im Fokus steht dabei die Entwicklung eines interdisziplinären und multimodalen Analyseansatzes zur Erweiterung der Stressorenanalyse. In diesem Zusammenhang greift die Studie zum einen auf bereits vereinzelt in der Radverkehrsforschung zur Anwendung kommende, digitale Analysetools und Open-Data-Ansätze zurück. Darüber hinaus beschäftigt sich der vorgestellte Forschungsansatz intensiv mit der Erweiterung der Methodik um einen bislang vorwiegend im Bereich der Architektur- und Stadtplanung bekannten, analogen Werkzeugkasten. Innerhalb eines experimentellen Rahmens erprobt die Studie dabei die vielfältigen Einsatzmöglichkeiten von Mappings und fotografischen Annäherungen, sowie deren Kombination. Im Kontext der Ursachenforschung des Stressempfindens von Radfahrenden soll damit ein holistischer Analyseansatz erprobt werden, der quantifizierbare „harte" Faktoren und qualifizierbare „weiche" Faktoren gleichermaßen berücksichtigt. Die gewonnenen Erkenntnisse leisten einen Beitrag dazu, die interdisziplinäre Zusammenarbeit von Stadt- und Verkehrsplanung zu fördern und schließlich gemeinsame Lösungsansätze für qualitätsvolle und menschengerechte öffentliche Stadträume zu erarbeiten.

Im Rahmen dieses Beitrags werden erste Ergebnisse der experimentell im Untersuchungsgebiet der Karlsruher Innenstadt durchgeführten Stressorenanalyse vorgestellt. Der Beitrag evaluiert die durchgeführten Analysen sowohl inhaltlich, als auch methodisch und skizziert darüber hinaus erste Lösungsansätze.

Keywords: Emotion Sensing, Stadtplanung, Stressorenanalyse, öffentlicher Raum, Radverkehrsforschung

2 EINLEITUNG

Seit der Errungenschaft des Autos und dem damit verbundenen autogerechten Umbau unserer Städte in den 60er Jahren hat sich das Mobilitätsverhalten unserer Gesellschaft stark verändert. Trotz der unveränderten Beliebtheit des Autos, das in Deutschland immer noch für rund 57 Prozent aller Wege genutzt wird (BMVI, 2018), gewinnen aktive Mobilitätsformen, wie zum Beispiel das Fahrrad, vor allem in den urbanen Ballungsgebieten zunehmend an Bedeutung. Aber auch erst kürzlich neu hinzugekommene Verkehrsmittel wie Pedelecs, E-Roller und Lastenräder stellen in den Städten nicht nur neue Mobilitätsangebote dar, sondern konfrontieren den öffentlichen Raum auch mit ganz neuen Herausforderungen. So beginnt sich die zunehmende Überlastung unserer öffentlichen Räume in Form von Staus, Luftverschmutzungen und steigenden Unfallzahlen allerdings auch immer negativer auf die Lebensqualität in den Städten auszuwirken.

Durch diese Entwicklung sehen sich sowohl die Politik, als auch die Verwaltung und Planung nunmehr dazu aufgefordert, sich diesem Problem zu stellen und nachhaltige, menschengerechte Lösungen für die Mobilität in unseren Städten zu entwickeln. Im Rahmen der Diskussion um die Reduktion des Autoverkehrs und die damit verbundene „Rückeroberung" öffentlicher Räume durch den Menschen ist es dabei vor allem der Langsamverkehr, also der Rad- und Fußverkehr, der im urbanen Raum als eine flächensparende, gesunde und vor allem klimafreundliche Form der Mobilität (BMDV, 2022), eine Schlüsselrolle einnimmt.

Dass der Faktor Urbanität diesbezüglich eine wichtige Rolle spielt, lässt sich an der aktuellen Aufteilung des bundesweiten Modal Splits nach Raumtypen (BMVI, 2018) gut erkennen. In Abbildung 1 werden die Langsamverkehrsanteile (Rad- und Fußverkehr) im Vergleich zu den restlichen Verkehrsmitteln (Auto und ÖPNV) dargestellt. Festzustellen ist dabei, dass der Anteil des Langsamverkehrs am Gesamtverkehrsaufkommen in Metropolen bei überdurchschnittlichen 42 Prozent liegt, wohingegen er in

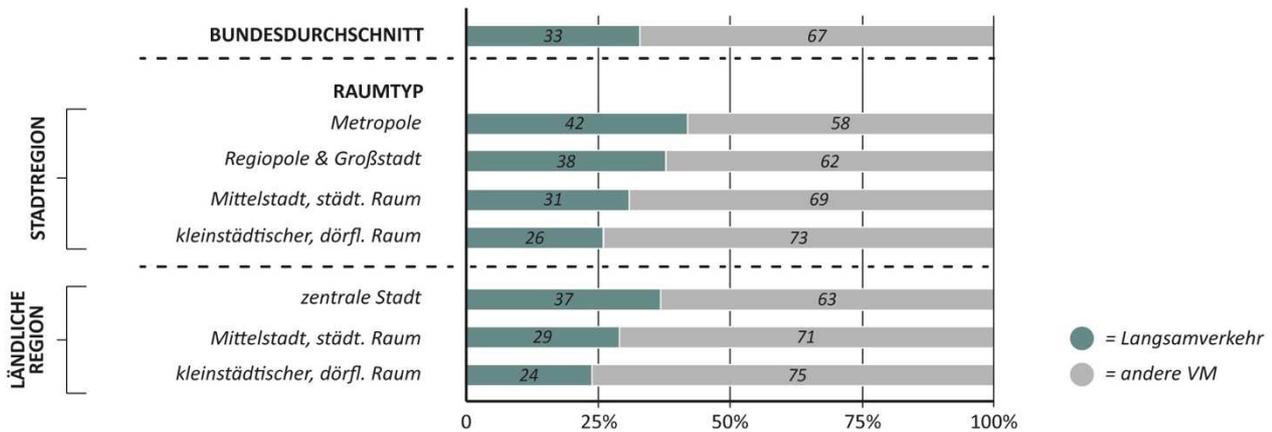
ländlichen Regionen im dörflichen Raum nur rund 24 Prozent beträgt. Dieser extreme Unterschied lässt sich zum einen durch das vielfältige und gut erreichbare Anbegot im urbanen Raum begründen. Denn ganz nach dem Leitbild der 15-Minuten-Stadt (Kurth, 2021) werden aktive Mobilitätsformen vorrangig innerhalb solcher Raumtypen genutzt, in denen die Wegstrecken nur wenige Kilometer betragen.


Abb. 1: Langsamverkehrsanteile im Modal Split nach Raumtypen. (Quelle: Eigene Darstellung nach Datenquelle BMVI, 2018)

Darüber hinaus wird die Entscheidung der Nutzerinnen und Nutzer für oder gegen das Fahrrad, beziehungsweise das Zufußgehen, jedoch maßgeblich auch von Aspekten des Wohlbefindens und Sicherheitsempfindens beeinflusst. In diesem Kontext konstatiert auch der Nationale Radverkehrsplan 3.0, dass sich eine Person nur dann für ein Verkehrsmittel entscheidet, wenn sie dieses subjektiv als sicher einstuft (BMDV, 2022). Hinsichtlich der Förderung aktiver Mobilitätsformen in der Stadt ist es daher essentiell, stressfreie Räume für den Rad- und Fußverkehr zu gestalten. Es erscheint daher evident, dass der Identifikation und Untersuchung von neuralgischen Stresspunkten für den Rad- und Fußverkehr eine Schlüsselrolle zugeschrieben werden muss. In diesem Kontext stellt die Methode des Emotion Sensings, beziehungsweise auf das Fahrradfahren bezogen die EmoCycling-Methode, seit einigen Jahren eine echte Innovation in der Stadtplanung (Polis Magazin, 2022) dar. Mithilfe dieser innovativen Stressmessungen ist es schließlich gelungen, das subjektive Empfinden von Probanden während ihrer Bewegung durch die Stadt anhand biostatistischer Marker objektiv messen zu können (Höffken et al., 2014; Zeile et al., 2014). Die Ergebnisse der Messungen werden als Heatmaps visualisiert und geben standortgenau Auskunft darüber, an welchen Punkten die Probanden Stress, respektive keinen Stress empfunden haben. Über die Ursachen, die die physiologisch messbare Stressreaktion bei den Probandinnen und Probanden ausgelöst hat, kann nach diesem Verfahren jedoch keine Aussage getroffen werden.

Die notwendige und auf diesen Erkenntnissen aufbauende Ursachenforschung (Stressorenanalyse) befindet sich hingegen noch in den Anfängen. Die Mehrheit der in diesem Kontext angeführten Studien fokussieren sich dabei jedoch auf eine reine Analyse der Verkehrssituation, wie beispielsweise der Untersuchung von Führungsformen und Spurbreiten. Vereinzelt wird auch auf „digitalen" Analysetools, meist in Form von Entwicklungen aus der Sensorik, zurückgegriffen. Diese berücksichtigen allerdings ausschließlich quantifizierbare „harte" Faktoren und können im Rahmen einer Ursachenforschung nur ein sehr fragmentarisches Bild der Situation liefern. Im Gegensatz dazu macht es sich der Ansatz der hier vorgestellten Studie zur Aufgabe, den Einfluss qualifizierbarer „weicher" Faktoren und die damit verbundenen Einsatzmöglichkeiten „analoger" Analysemethoden zu erforschen. Mithilfe eines multimodalen und interdisziplinären Ansatzes soll es dadurch ermöglicht werden, die spezifischen räumlichen Situationen der identifizierten Stress-Hotspots ganzheitlich zu betrachten und dabei nicht nur verkehrsplanerische, sondern auch stadträumliche Faktoren zu berücksichtigen.

3 STAND DER FORSCHUNG

3.1 Stressmessungen mithilfe der EmoCycling-Methode

Im Gegensatz zu Ansätzen, die mit rein qualitativen Befragungen arbeiten und die bewusst von den Probanden wahrgenommenen Gefühle abfragen, werden beim EmoCycling die menschlichen Emotionen

anhand ihrer nahezu unverfälschbaren körperlichen Reaktion gemessen (Polis Magazin, 2022). Damit leistet die EmoCycling-Methode einen Beitrag zur Operationalisierung von Emotionen in der Planung.

3.1.1 Physiologische Stressreaktion des menschlichen Körpers

Empfindet ein Mensch Stress, so schüttet der Körper Hormone aus, die bestimmte Teile des Nervensystems (HHN-Achse und autonomes Nervensystem) aktivieren. Damit versucht der Körper, den Stress auszugleichen und den Zustand der Homöostase, also einen „stabilen" Zustand, wiederherzustellen. Für diese Anpassung verändert der Körper mitunter die Herztätigkeit, Schweißdrüsenaktivität und die Hauttemperatur (Chrousos et al., 1988; Boucsein, 1988; Kreibig, 2010). Diese messbaren physiologischen Signale können eindeutig in Verbindung mit der Reaktion des menschlichen Körpers auf eine Stresssituation gebracht werden (Karthikeyan et al., 2013) und können als Indikatoren dienen. Heutige Messungen im Kontext des Emotion Sensings greifen hauptsächlich auf die Elektrodermale Aktivität (EA) zurück, die als empfindlichster und zuverlässigster Marker für eine emotionale Erregung (Kyriakou, Resch, et al., 2019) gilt.

3.1.2 Methodik, Setting und Auswertung

Die Ursprünge der EmoCycling-Methode gehen auf Christian Nold zurück, der für seine „emotionalen Kartografien" im Jahr 2009 ein eigenes „Bio-Mapping"-Gerät (Nold, 2009) entwickelte. Damit wurde es erstmals möglich, die messbaren Stress-, beziehungsweise Erregungszustände georeferenziert innerhalb eines situativ-räumlichen Kontexts aufzuzeichnen und visualisieren. In den späten 2000er Jahren wurden die Methode dann von der Urban Emotions Initiative an der TU Kaiserslautern und der Universität Heidelberg mit einem ähnlichen Aufbau erprobt und erste Stadtkartierungen vorgenommen (Zeile et al., 2010). Später wurde dieser Ansatz vor allem am Karlsruher Institut für Technologie (KIT) und der Paris Lodron Universität Salzburg (PLUS) weiterentwickelt. Schnell konnte im Rahmen dieser ersten Annäherungen festgestellt werden, dass sich die Methode mit der sekundengenauen Messung des emotionalen Zustands der Probanden auch bestens für die Anwendung im Kontext des Fahrradfahrens (Höffken et al., 2014) eignet.

Abb. 2: Heatmap als Ergebniskarte der EmoCycling-Messungen in Karlsruhe (links) und Setting mit Smartband Empatica E4 und Smartphone (rechts). (Quelle: Eigene Darstellung nach Datenquelle Cape Reviso)

Das Setting der seither als „EmoCycling" bekannten Methodik wurde daraufhin weiter optimiert und erzielte schnell einen Durchbruch in der Radverkehrsforschung. Die Messungen werden nunmehr lediglich mithilfe eines Sensorarmbandes (Empatica E4) und einem Smartphone durchgeführt (Zeile et al., 2021; Zeile et al, 2022; Werner et al., 2019). Das Sensorarmband misst dabei die Vitaldaten der Probanden (Hautleitfähigkeit und Hauttemperatur), synchonisiert diese mithilfe des Smartphones mit den dazugehörigen GPS-Daten und sammelt sie in einer App. Das Auswertungsmuster ist seit den Anfängen der Methodik unverändert: Eine Stressreaktion, auch Moment of Stress (MOS) genannt, wird dann identifiziert, wenn direkt nach einem Reiz ein temporärer Anstieg der Hautleitfähigkeit in Kombination mit einem Absinken der Hauttemperatur messbar ist.

Die ausgewerteten Datensätze werden daraufhin mithilfe eines Geoinformationssystems (GIS) georeferenziert dargestellt und in Form einer Heatmap visualisiert. Über die verwendete Farbcodierung der Heatmap kann dann ausgewertet werden, in welcher Intensität und an welcher geografischen Position die Probanden Stress, beziehungsweise keinen Stress empfunden haben. Die entsprechend der Farbcodierung rot

dargestellten Punkte, sogenannte „Hot-Spots", symbolisieren dabei eine Konzentration der gemessenen Stressmomente, wohingegen in den blau dargestellten Bereichen verhältnismäßig weniger Stressmomente gemessen wurden.

3.2 Stressorenanalyse

3.2.1 Ursachenforschung mithilfe „digitaler" Analysemethoden aus der Radverkehrsforschung

Die Disziplin der Verkehrsplanung gilt mit ihrem Feld der Radverkehrsforschung als Vorreiter der Stressorenanalyse. Vor allem was das sensorengestützte Messen verkehrsspezifischer Faktoren anbelangt, kann hier mittlerweile auf ein verhältnismäßig großes Methodenspektrum zurückgegriffen werden. Zu nennen sind hier beispielsweise Entwicklungen wie der OpenBikeSensor (OpenBikeSensor, 2023) zur Abstandsmessung bei Überholvorgängen, beziehungsweise sein Pate, der Radmesser (Tagesspiegel, 2018). Aber auch experimentelle Ansätze, wie der Einsatz von Eye-Tracking-Geräten zur Überprüfung der Blickerfassung von Beschilderungen (Walther et al., 2022) kommen in ersten Studien zum Einsatz. Im Rahmen der Radverkehrsforschung der BMDV-Stiftungsprofessur Radverkehr wurde an der Hochschule Karlsruhe in diesem Zusammenhang ein „SensorBike" (Temmen, 2020) als standardisiertes Messfahrrad entwickelt, das sowohl über fest verbaute Messinstrumente verfügt, als auch situationsspezifisch mit Sensoren ergänzt werden kann. Zu den fest verbauten Sensoren des SensorBikes zählen neben einem Leistungsmesser, Vitalsensoren, Beschleunigungs- und Erschütterungssensoren, einem Abstandsmesser und Kameras auch Sensoren zur Erhebung spezifischer Umweltfaktoren. Dabei gelingt es vor allem durch die Verknüpfung der verschiedenen Datensätze, neue Erkenntnisse für die Stressorenanalyse zu generieren.

3.2.2 Ursachenforschung mithilfe von Crowdsourcing-Ansätzen

Durch die zunehmend auch im Freizeit-Radsport ankommende Digitalisierung konnten in den letzten Jahren neue Möglichkeiten zur partizipativen Datenerfassung und -auswertung in der Radverkehrsforschung (Lißner et al., 2018) entwickelt werden. In diesem Kontext bietet primär das Smartphone, das mittlerweile nahezu flächendeckend in der Bevölkerung verbreitet ist, als ein ubiquitärer und multifunktionaler Sensor (Eckart et al., 2020) mannigfaltige Möglichkeiten, um spezifische Bewegungs- und Umweltdaten zu erheben. Verschiedene, meist frei verfügbare Applikationen bieten hier eine sehr niederschwellige Anwendungsmöglichkeit. Darüber hinaus konnten auch durch die wachsende Beliebtheit sozialer Sport-Netzwerke erste Erfolge in der Nutzung von Big Data in der Radverkehrsforschung erzielt werden. So untersuchte zum Beispiel ein Forschungsprojekt der Technischen Universität Dresden (Lißner et al., 2018) im Jahr 2017 die Anwendungsmöglichkeiten von Radverkehrsdatensätzen der Provider „Strava" und „BikeCitizens" in der Evaluation kommunaler Radverkehrsnetze. Mithilfe der Analysefunktionen der beiden Plattformen gelang es dem im Rahmen des Nationalen Radverkehrsplans geförderte Forschungsprojekt, wichtige Erkenntnisse für die Stressorenanalyse zu generieren. So konnten zum Beispiel die analysierten Fahrgeschwindigkeiten und die Wartezeiten an Ampeln direkt mit gemiedenen, beziehungsweise bevorzugten Streckenabschnitten in Beziehung gesetzt werden.

3.3 Analyseansätze aus der Stadtforschung

Wie die vorangegange Untersuchung zeigt, ist im Feld der Stressorenanalyse bislang eine starke Ausrichtung auf verkehrsspezifische Faktoren und deren Erhebung mithilfe von digitalen Analysemethoden zu beobachten. Die Einsatzmöglichkeiten von analogen, beziehungsweise grafisch und visuell arbeitenden, Analysemethoden, wie sie aus der Stadtforschung und -planung bekannt sind, bleiben in diesem Kontext noch weitestgehend unerforscht.

3.3.1 Umweltpsychologische Grundlagen zur Wahrnehmung von Stadträumen

Die Disziplinen der Umweltpsychologie und Raumwahrnehmung definieren die Stadt als eine äußerst komplexe Umwelt mit einem hohen Reizvolumen für den Menschen (Mehrabian, 1987). Bei seiner Bewegung durch die Stadt nimmt der Mensch in seinem Unterbewusstsein davon deutlich mehr wahr, als ihm bewusst ist. Er ist stetig damit beschäftigt, sich ein inneres Bild dieser komplexen Umwelt anzufertigen (Lynch, 1965). Zurückzuführen ist dieser Vorgang der inneren Verbildlichung auf sein natürliches Bedürfnis nach Orientierung, beziehungsweise der Notwendigkeit eines Bezugsystems, das für seine ursprüngliche Lebensweise überlebensnotwendig war. Wir Menschen beziehen unsere Wahrnehmung von Stadt, respektive

unser Bild der Stadt, deshalb noch heute auf uns bekannte, wiederkehrende und klar ablesbare Elemente und aktivieren zur Wahrnehmung unserer Umwelt unterbewusst all unsere Sinne. Je nachdem, ob dabei eine positive oder negative Wahrnehmung der Umgebungsreize überwiegt, empfinden wir Sicherheit und Wohlbefinden oder Unbehagen (Mehrabian, 1987). In unseren heutigen urbanen Stadträumen sind wir jedoch einer solch enormen Masse an Reizen ausgesetzt, dass sich die Auswirkungen von einzelnen Reizen auf unser Empfinden kaum noch herausfiltern lassen. Es wird daher in der Umweltpsychologie immer das Zusammenspiel unterschiedlicher Faktoren und dessen Auswirkungen auf das menschliche Empfinden betrachtet, beziehungsweise eine Art von „Rauschen" mitberücksichtigt.

3.3.2   Analysemethoden aus der Stadtforschung

Die Stadtforschung steht als ein interdisziplinäres Forschungsfeld im engen Zusammenhang sowohl mit der Geografie, der Anthropologie, der Soziologie und der Ethnologie, als auch mit einigen anderen raumbezogenen Forschungsfeldern (Pelger et al., 2021). Im Kontext ihres Forschungsgegenstandes ist diese Interdisziplinarität notwendig, um das komplexe Raumgefüge Stadt nicht nur beschreibend in ihrer Theorie, sondern auch in ihrer Dynamik als ein sich stetig verändernder Raum zu durchdringen. In der Erforschung von Stadt gibt es deshalb kein vordefiniertes Forschungsdesign, wie es in anderen wissenschaftlichen Disziplinen Usus ist, sondern es wird sich meist an einer Kombination unterschiedlicher Methoden bedient (Eckardt, 2014).

Innerhalb der Stadtforschung kann somit auf einen breiten Fächer an Analysemethoden und entsprechender Darstellungsmöglichkeiten zurückgegriffen werden, die je nach Umfang und Art der Aufgabe ganz unterschiedliche Analyseaspekte und Detailtiefen bearbeiten können. Mitunter sind dabei Interviews, Beobachtungen, Kartierungen, Mappings, Fotografien und künstlerische Annäherungen als gängige Methoden (Eckardt, 2014) zu nennen. Die mithilfe dieser visuellen und grafischen Methoden entstehenden Analysegrafiken können im Rahmen komplexer Aufgabenstellungen dabei helfen, die Grenzen des digital Erfassbaren, beziehungsweise quantitativ Messbaren zu überwinden.

In diesem Zusammenhang geht es bei der Erforschung von Stadträumen jedoch nicht nur um eine Erhebung und Analyse vorhandener raumbezogener Daten, sondern immer auch um ein In-Beziehung-Setzen der Daten (Pelger et al., 2021). Im Rahmen von Mixed-Methods-Ansätzen können so zum Beispiel durch die Kombination von räumlichen Darstellungen mit anderen Datensätzen, respektive Werkzeugen, wie zum Beispiel abstrahierten Illustrationen oder fotografischen Annäherungen, neue Erkenntnisse gewonnen werden.

Abb. 3: Schnittanalyse verschiedener Straßenräume im Vergleich zu Las Vegas in Bezug auf Raum, Maßstab, Symbol und Geschwindigkeit. (Eigene Darstellung nach Venturi et al., 1979; Beschriftung und Anordnung der Ursprungsgrafik verändert)

Abbildung 3 zeigt in diesem Kontext eine frühe analytische Annäherung Robert Venturis Ende der 70er Jahre (Venturi et al., 1979), die im Kontext der Analyse von Straßenräumen und Symbolik der Geschäftsstadt Las Vegas durchgeführt wurde. Dabei kombiniert Venturi nach dem Mixed-Methos-Ansatz eine Schnittanalyse mit der abstrahierten Darstellung der vor Ort beobachteten Symbolik und den Bewegungsgeschwindigkeiten. Durch die vergleichende Darstellung und die Kombination der analysierten

Inhalte wird in der Analysegrafik die Beziehung zwischen verschiedenen Bewegungs-, beziehungsweise Fahrgeschwindigkeiten und der daran angepassten Dimension von Stadträumen und Symbolen deutlich.

4 ANWENDUNG DES INTERDISZIPLINÄREN STRESSFORSCHUNGSANSATZES

4.1 Bezug zu den Projekten der Urban-Emotions-Initiative

Vor dem Hintergrund der Analyse von Stresspunkten im urbanen Kontext, gliedern sich die Forschungen der vorliegenden Studie im Kontext der Urban Emotions Initiative ein. Die Studie unterstützt dabei insbesondere das aktuelle NRVP-Projekt „Cyclist and Pedestrians on Real and Virtual Shared roads", kurz: „Cape Reviso" (Zeile et al., 2021), in der experimentellen Weiterentwicklung der Stressorenanalyse. Sowohl inhaltlich, als auch methodisch sollen mit der Studie Erkenntnisse gewonnen werden, wie die bislang rein auf infrastrukturelle Faktoren konzentrierte Ursachenforschung des Projekts in Richtung einer ganzheitlichen Stadtraumanalyse weiterentwickelt werden kann.

4.2 Aufbau und Ablauf der Studie in der Untersuchungsstadt Karlsruhe

Der interdisziplinäre Ansatz der Studie wird seit April 2023 im Rahmen erster experimenteller Untersuchungen zunächst in der Stadt Karlsruhe erprobt.

4.2.1 Datengrundlage der Untersuchungen: EmoCycling-Heatmap

Als eine wichtige Grundlage dient der Studie die Stress-Heatmap aus dem Urban Emotions Projekt „Cape Reviso" (Zeile et al., 2021), die als Ergebniskarte von zwei EmoCycling-Messungen im Winter 2021/22 entstanden ist. Dabei wurden die Stressreaktionen von insgesamt 17 Radfahrenden auf einer vorgegebenen Route gemessen. Nach Abzug einiger fehlerhafter Datensätze konnten bei dieser Erhebung 26 Tracks gesammelt werden und dabei 1121 Moments of Stress detektiert werden. Die entstandene Heatmap dient der Studie als ein erster Überblick über die neuralgischen Stress-Hotspots für Radfahrenden in Karlsruhe. Die auffallende Ballung der Stressmomente am Berliner Platz im Bereich des KIT-Campus ist der Start- und Endpunkt der Route und muss als Fehler in der Auswertung von den Betrachtungen ausgenommen werden.

4.2.2 Strukturanalyse der Untersuchungsstadt Karlsruhe

Im weiteren Verlauf setzt die Studie die Ergebniskarte der Stressmessungen in Beziehung mit den Strukturelementen der Stadt Karlsruhe (siehe Abbildung 4). Methodisch werden dabei frei verfügbare Datensätze der Plattform OpenStreetMap zu verschiedenen Themenbereichen, wie zum Beispiel zu Freiraumnetz, Baustruktur und Nutzungsverteilungen, in einem GIS-Programm inhaltlich und grafisch aufbereitet. Durch das Rückkoppeln der verschiedenen Strukturelemente mit dem Layer der EmoCycling-Heatmap sollen für das weitere Vorgehen der Studie Untersuchungsräume identifiziert werden, die nicht nur innerhalb der Stressmessungen auffallend waren, sondern denen auch stadtstrukturell und -räumlich eine besondere Bedeutung beizumessen ist.

Abb. 4: Überlagerung der EmoCycling-Heatmap mit prägenden Strukturelementen und Nutzungen der Stadt Karlsruhe. (Quelle: Eigene Darstellung nach Datenquelle OpenStreetMap, Heatmap nach Datenquelle Cape Reviso)

178

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

In diesem Zusammenhang werden neben den meist auch in anderen Städten häufig an großen Kreuzungspunkten auftretenden Stresspunkten in der „Fächerstadt" Karlsruhe insbesondere die räumlichen Schnittstellen zu den prägenden „Strahlen" als Hotspots identifiziert. Zu erwähnen sind in diesem Kontext der Bereich um den Ludwigsplatz im Westen, der ringförmig verlaufende Zirkel, der Rondellplatz im Zentrum, sowie das Gebiet um den Kronenplatz und das Durlacher Tor im Osten. Insbesondere in den belebten und hochfrequentierten Bereichen des Zentrums, in denen sich eine Vielzahl an Nutzungen ballen, konnten dabei vermehrt Stressmomente gemessen werden. Auch in diesem Kontext ist der Bereich um den Ludwigsplatz auffallend, an dem sich darüber hinaus nicht nur das Radwege- und Schienennetz kreuzt, sondern auch die wichtige Nord-Süd-Achse der Karlstraße verläuft.

4.2.3 Auswahl eines Untersuchungsgebiets als Experimentierfeld für die Stressorenanalyse

Aufgrund des besonderen Anspruchs der Studie, die Wahrnehmung von Stadträumen und die damit verbundenen „weichen" Faktoren in den Fokus der Stressorenanalyse zu rücken, fällt die Wahl des ersten Untersuchungsgebiets für die Studie auf den Bereich rund um den Karlsruher Ludwigsplatz. Die Route führt dabei von Westen über den Stephanplatz und die Karlstraße über den Ludwigsplatz weiter nach Osten. Die Abgrenzung des Untersuchungsraums und der Routenverlauf sind in Abbildung 5 zu sehen. Neben den stadtstrukturell prägenden Elementen, dem Verlauf wichtiger Fahrradrouten und der hohen Frequentierung können in diesem Gebiet verschiedene Raumansprüche und -konflikte beobachtet werden.

Abb. 5: Das Untersuchungsgebiet Karlsruhe Ludwigsplatz als Zoom-In der Strukturanalyse (links) und im Luftbild (rechts) mit Route. (Quelle: Eigene Darstellung nach Datenquelle OpenStreetMap und Google Satellite, Heatmap nach Datenquelle Cape Reviso)

4.2.4 Identifikation potentieller Einflussfaktoren

Im Rahmen der Studie „Decoding Stress" wurde beginnend im Mai 2023 auf dem Untersuchungsgebiet des Ludwigsplatzes dann zunächst mit der Identifikation und Analyse verschiedener Einflussfaktoren begonnen.

Abb. 6: Auswahl-Pool potentieller Stressfaktoren zur experimentellen Analyse im Untersuchungsgebiet Karlsruhe Ludwigsplatz.

In einer ersten Annäherung wurde in diesem Zusammenhang ein Pool (siehe Abbildung 6) aus verschiedenen Themengebieten und potentiellen Stressfaktoren definiert, bei denen von einer Einflussnahme auf das subjektive Empfinden von Radfahrenden bei der Bewegung durch den Untersuchungsraum ausgegangen werden kann, beziehungsweise vermutet wird. Dabei wurden neben beispielsweise baulichen, gestalterischen

und freiraumspezifischen Faktoren auch sensuelle Faktoren, wie zum Beispiel die Wahrnehmung von Gerüchen, Geräuschen und Lärm als zu untersuchende Faktoren identifiziert.

4.2.5 Experimentieren mit adäquaten „analogen" Analysemethoden

Aufbauend auf diesem Pool zu untersuchender Faktoren experimentiert der in der Studie erprobte Ansatz intensiv mit der Entwicklung adäquater „analoger" Analysemethoden und deren Übersetzungsmöglichkeiten. Neben den intensiven Vor-Ort-Untersuchungen mithilfe von Mappings, Skizzen und fotografischen Dokumentationen, die sehr spezifisch auf die Analyse der jeweiligen Stressfaktoren zugeschnitten sind, konnte dabei insbesondere mit der Übersetzung der Analyseerkenntnisse in schematische „Stressorenabwicklungen" erste Erkenntnisse generiert werden. Durch die anschließende Gegenüberstellung in der „Stressorenmatrix" (Abbildung 7) können die verschiedenen Einflüsse der analysierten Faktoren auf das Stressempfinden, beziehungsweise auch mögliche Korrelationen zwischen den einzelnen Faktoren auf diese Weise vergleichsweise einfach identifiziert werden.

4.3 Erste Ergebnisse der Studie

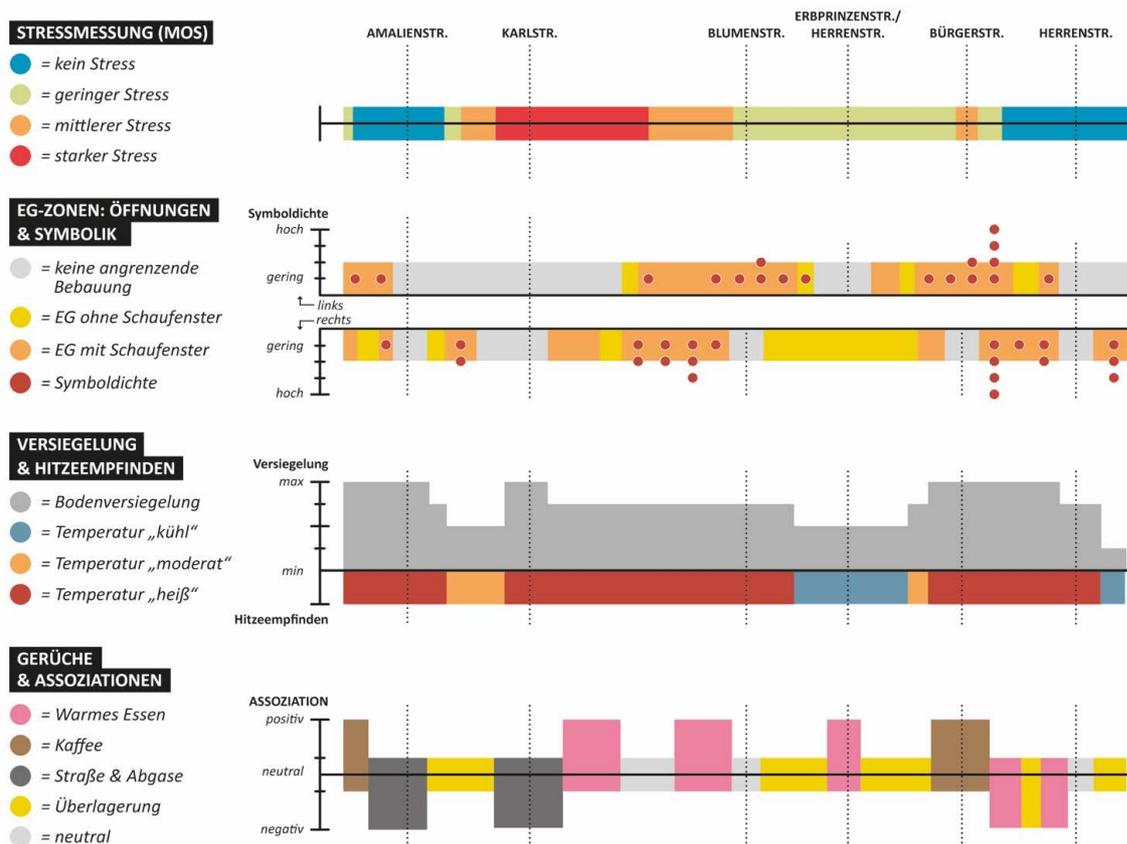
Im Juni 2023 konnten mit dem erarbeiteten Methodenbaukasten erste Ergebnisse präsentiert werden. Die Vor-Ort-Erhebungen fanden in einem Zeitraum von zwei Wochen im Untersuchungsgebiet Ludwigsplatz statt und behandelten insgesamt 23 potentielle Stressfaktoren. In Abbildung 7 wird die Stressorenmatrix exemplarisch mit den Stressorenabwicklungen von drei analysierten Faktoren gezeigt und mit den Ergebnissen der Stressmessungen verglichen. Für jeden Faktor wurden dabei unterschiedliche Farbcodierungen, Symoble und Bewertungsskalen angesetzt.


Abb. 7: Auszug aus der Stressorenmatrix: Vergleichende Darstellung der Stressmessungen mit den analysierten Faktoren Öffnungen & Symbolik, Versiegelung & Hitzeempfinden, Gerüche & Assoziationen.

Die Analyse der Erdgeschosszonen untersucht die angrenzende Bebauung des definierten Streckenabschnitts hinsichtlich ihrer Öffnungen und Schaufensterflächen. Darüber hinaus wurde auch die Symboldichte in den Erdgeschosszonen untersucht, die zum Beispiel in Form von Werbeplakaten, Leuchtreklamen und Aufstellern auf die Wahrnehmung Einfluss nehmen können. Bei der Darstellung in der Abwicklung wurde die linke und rechte Seite der Straße getrennt voneinander betrachtet.

180

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Als eine weitere Analyse wurde die Versiegelung der Bodenflächen in Kombination mit dem subjektiven Hitzeempfinden untersucht. Im Anfangsbereich der Route weist der Bodenbelag des Stadtraums dabei einen hohen Versiegelungsgrad auf und wird als sehr heiß wahrgenommen. Im Bereich des Stephanplatz wird die Versiegelung durch Baumscheiben und Beete punktuell aufgebrochen und das Temperaturempfinden deutlich abgesenkt. Nach der Überquerung der hochversiegelten Karlstraße wird die Waldstraße dann größtenteils mit Kopfsteinpflaster fortgeführt, das im Bereich des Ludwigsplatzes erneut punktuell aufgebrochen wird und für Abkühlung sorgt. Die Fortführung der Route auf der Erbprinzenstraße weist schließlich wieder einen höheren Versiegelungsgrad und äquivalent dazu ein stärkeres Hitzeempfinden auf.

Der letzte Stressfaktor, der in der dargestellten Matrix analysiert wurde, betrifft die olfaktorische Wahrnehmung des Stadtraums und analysiert die wahrnehmbaren Gerüche und ihre positive, beziehungsweise negative Assoziation. Hierbei ist auffallend, dass um die Kreuzungspunkte zur Amalienstraße und Karlstraße starke Abgasgerüche wahrnehmbar sind, die negativ assoziiert werden. Im Bereich des Ludwigsplatzes sind dann vorwiegend positiv konnotierte Essensgerüche der Gastronomie wahrnehmbar, die große Bereiche auf dem Platz einnimmt. An der Einmündung zur Bürgerstraße ist darauf folgend intensiver Kaffee-Geruch positiv wahrzunehmen. Im darauf folgenden Abschnitt vermischen sich die Essensgerüche verschiedener Imbisse und werden größtenteils negativ assoziiert.

Auch, wenn die Analysen noch zu einem sehr frühen Zeitpunkt der Studie vorgenommen wurden und in der Abbildung nur ausschnitthaft dargestellt sind, lassen sich in der Auswertung im direkten Vergleich zu den Ergebnissen der Stressmessungen erste vorläufige Thesen zu etwaigen Abhängigkeiten aufstellen. Faktoren wie negativ wahrgenommene Gerüche, ein hohes Hitzeempfinden durch starke Versiegelung der Bodenflächen, sowie auch ablenkend hohe Schaufenster- und Symboldichten zeigen sich zum aktuellen Stand der Untersuchung als potentielle Einflussfaktoren.

4.4 Ausblick

Die Studie „Decoding Stress" befindet sich aktuell noch in den Anfängen. In einem nächsten Schritt sollen die bis dato identifizierten Stressfaktoren und die exemplarisch im Untersuchungsgebiet Ludwigsplatz angewendeten Analysemethoden deshalb zunächst weiter erprobt und die Erhebungen systematisiert werden. In diesem Zusammenhang sollen die angeführten Analysen in einem zweiten Untersuchungsgebiet innerhalb der Stadt Karlsruhe wiederholt und entsprechend adaptiert werden. Es ist dabei zu klären, ob die im Rahmen der ersten Untersuchungsergebnisse getroffenen Annahmen über die Korrelationen zwischen den einzelnen Stressfaktoren dann auch in anderen Untersuchungsgebieten zu beobachten sind.

In einer nächsten Arbeitsphase soll der entwickelte Ansatz zur Stressorenanalyse dann auch in weiteren Untersuchungsstädten zur Anwendung kommen. Perspektivisch sollen mit dem entwickelten Ansatz nicht nur die Einfluss nehmenden Stressoren identifiziert werden, sondern dadurch auch zukünftige Stellschrauben für die Planung benannt werden können. Die gewonnenen Erkenntnisse sollen damit einen Beitrag dazu leisten, Lösungsansätze für die Gestaltung qualitätsvoller und menschengerechter öffentlicher Stadträume zu erarbeiten.

5   DISKUSSION

Mit den ersten Ansätzen der vorgestellten Studie „Decoding Stress" wurde eine Methodik entwickelt, die es ermöglicht, Aspekte der Stadt- und Raumwahrnehmung in die Stressorenanalyse miteinzubeziehen. Damit wird ein Beitrag dazu geleistet, das subjektive Empfinden des Menschen bei seiner Bewegung durch die Stadt zu erforschen und ihn erstmals auch in den Fokus der retrospektiven Stressorenanalyse zu rücken. Aus diesem Verständnis heraus bleibt das Subjekt, also der seine Umgebung wahrnehmende und verarbeitende Mensch, ein wichtiger Teil der Methodik. Es ist ihr Anspruch, unsere subjektive Raumwahrnehmung zu erfassen und zu objektivieren, ohne dabei jedoch die subjektive Komponente vollständig zu eliminieren. Die in den Stressorenabwicklungen analysierten Faktoren können deshalb zwar nicht als vollumfänglich objektiv angesehen werden, vielmehr soll mit der entwickelten Methodik jedoch das Zusammenspiel aus objektiven und subjektiven Komponenten systematisiert und vergleichbar gemacht werden.

In diesem Kontext bleibt schließlich auch die Frage nach der Anwendbarkeit des Methodenansatzes in der Praxis zu stellen. Bis dato gestalten sich die Erhebungen und Auswertungen der Studie noch sehr zeitintensiv. Im weiteren Verlauf bleibt deshalb zu klären, inwieweit sich die Erfassung der Stressfaktoren, sowie die Darstellung in der Stressorenabwicklung, beziehungsweise in der Stressorenmatrix, zukünftig

Decoding Stress – ein interdisziplinärer Stressforschungsansatz zur Förderung qualitätsvoller öffentlicher Stadträume für den Rad- und Fußverkehr

systematisiert werden könnte. Dabei könnten Crowdsourcing-Ansätze, beziehungsweise digitale Erfassungstools eine Schlüsselrolle spielen, um die Methodik schließlich für die Planung zu einem anwendbaren Tool zu transferieren.

1 ABSTRACT

In design education, the architectural design studio environment is one of the most significant environments that should be a stimulator of creativity. It's known for the amount of time students spend there, so it's considered their second home. Researchers aspire to create a unique and different design studio environment that motivates students' creativity. This study presents the biophilia theory as a technique that generates a creative design studio environment. The purpose is to determine the applicability of the biophilic design theory patterns to the design studio environment, which in turn has an impact on motivating the students' creativity. The research method will be conducted through a comprehensive analysis of several world-famous architectural schools, by understanding the application of the principles of nature and connecting them with biophilic patterns. As a result, the research has yielded applicable criteria for biophilic patterns in existing design studios.

Keywords: Architectural design studio, Creative learning environment, Biophilia, Biophilic design studio, Biophilic Patterns

2 INTRODUCTION

Creativity is described as the ability to create something unique. As a result, creative talents are required in many forms of education and jobs. Creative students are necessary for all sorts of education, including the arts, music, sciences, mathematics, and engineering, and architecture is one of them ("10 Jobs That Require Creative Thinking Skills", 2023; "Best Degrees for Creative People", 2022; Easton & Djumalieva, 2018; Rufener, McCaulley, & Sealey-Morris, 2023; Vilorio, 2015). The design studio has always been a rich material for investigation. Its impacts on interpersonal interactions, academic performance, and meeting students' psychological needs are crucial (Dhanapala, 2021). As a space, it extends beyond just being a box-shaped classroom to play a larger role. It has to be configured to encourage students to work and unwind when they encounter conceptual difficulties (shaqour, 2021); in addition, it has to be a source of inspiration and imagination (Davies et al., 2013; McCoy & Evans, 2002; Thoring, Desmet, & Badke-Schaub, 2018; Thoring, Gonçalves, Mueller, & Badke-Schaub, 2017; Vyas, van der Veer, & Nijholt, 2012). Actually, architecture students want spaces for chilling, places for socializing and conversing, suitable furniture, views rather than just walls, and a corner for laptops with the necessary equipment (Lewinski, 2015; Vyas et al., 2012). These needs are reflected in the studio's furnishings, which are usually divided up into smaller groupings to create a more intimate setting that supports the desired social interactions (Utaberta, Hassanpour, Handryant, & Che Ani, 2013). In addition, they prefer a panoramic view of the surrounding landscape, especially greenery elements in all the interior and exterior spaces, outside nature, green open spaces, green elements, indoor greenery, and indoor plants, as they feel comfy while working (shaqour, 2021). This is according to many references (Dhanapala, 2021; Ibrahim & Utaberta, 2012; Lewinski, 2015; Obeidat & Al-Share, 2012; shaqour, 2021). They have highlighted incorporating aspects of the natural environment as a prerequisite to its optimal performance as a catalyst for creativity.

Biophilia is a biological tendency to affiliate with nature (Stephen R. Kellert, 2012; WILSON, 1984). Biophilic design, as a reflection of the Biophilia principles in the design studio, presents a viable translation of "nature" to shape the design studio environment and accordingly affect its creativity potential (Stephen R. Kellert & Calabres, 2015). The challenge lies in the applicability of the biophilic patterns to the physical configurations of the design studio. It has to be addressed within a proper understanding of students' perceptions as related to incorporating elements of nature into the architectural design studio (WILSON, 1984).

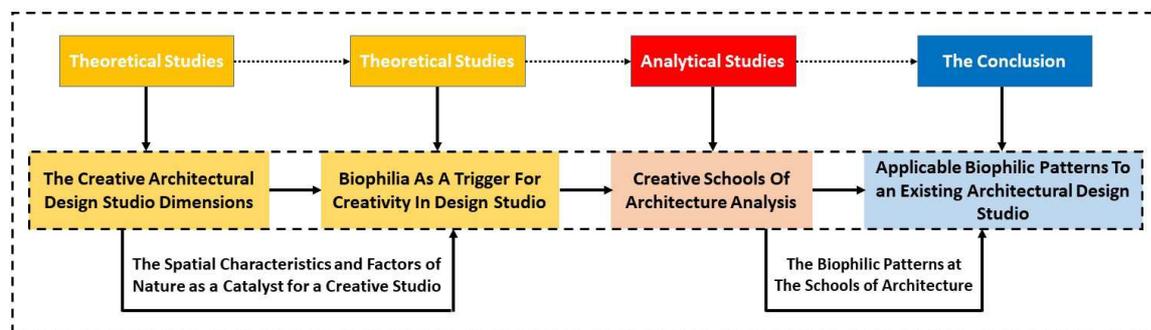
This paper raises questions about the creative potential of applying biophilic design patterns to the existing design studio. To answer these questions, it reviews related literature to come up with a solid understanding of the typology of the 'creative design studio' on one hand, and the relation between nature-based interventions that influence these creativity potentials. In addition, three featured examples (mentioned within the leading 10 existing schools of architecture worldwide) are analyzed. A correlation analysis between the natural features of these schools and the related biophilic patterns is used to conclude a framework for applying the biophilic patterns in design studios to enhance their creative potential, This methodology has been shown in Figure 1.


Fig. 1: The Reaserch Methodology. Source: Researchers.

3 THE CREATIVE DESIGN STUDIO

The design studios' physical environment should be a trigger for creativity and innovation (CANNON & UTRIAINEN, 2013). because It is not only important to improve students' performance but also to make them more inventive and increase their creativity potential to create innovative products (Thoring et al., 2018). To establish an educational environment that inspires students to be more creative, several guidelines can be followed. Several literature reviews have mentioned certain spatial principles, characteristics, or requirements that can be applied to the educational environment. Many sources discussing spaces as triggers for creativity within academic, practice, or other innovation environments were identified.

The spatial requirements that can be applied were pointed out. Through these references, it was discovered that there are several spatial guidelines that are constantly repeated in different references and which turned out to be related to the natural environment. Some of the literature reviews allude to various learning environments in general. (Bramble, 2017; McCoy & Evans, 2002; Thoring, Desmet, & Badke-Schaub, 2019; Thoring, Guerreiro Goncalves, Mueller, Badke-Schaub, & Desmet, 2017; Thoring, Mueller, Desmet, & Badke-Schaub, 2020; Williams, 2013). Additionally, some other literature reviews were cited specifically pertaining to the architectural design studio. (Muniandy, Khan, & Ahmad, 2015; Obeidat & Al-Share, 2012; shaqour, 2021; Thoring et al., 2018; THORING, LUIPPOLD, & MUELLER, 2012,). Practitioners, educators, and researchers can use the presented overview to investigate the possible impact of creative space design and to identify research gaps for conducting further research in the field. The spatial characteristics that are connected with nature as a trigger for creative space will be analyzed in Table 1.

3.1 The Spatial Characteristics and Factors of Spaces as Triggers for Creativity

The first factor is the visual connection with nature. That factor can be applied by using open views and making many openings, windows, or curtain walls, which give a wider perspective. Additionally, using greenery, which can be used in the space by using living indoor plants and flowers of various shapes, sizes, and types (CANNON & UTRIAINEN, 2013; Davies et al., 2013; De Paoli & Ropo, 2017; Dul & Ceylan, 2014; McCoy & Evans, 2002; Muniandy et al., 2015; Oksanen & Ståhle, 2013; shaqour, 2021; Thoring et al., 2018, 2019; Thoring, Gonçalves, et al., 2017; Thoring, Guerreiro Goncalves, et al., 2017; THORING et al., 2012,; Thoring et al., 2020; Williams, 2013).

The second factor is the components of the space, which focus on furniture arrangement and design as well as unusual and activating furniture, which can be applied by using different shapes of furniture that express nature. Also, using visual details in the interior design gives rich sensory information. Furthermore, the size and shape of internal object organization follow a spatial hierarchy similar to those found in nature. (CANNON & UTRIAINEN, 2013; Ceylan, Dul, & Aytac, 2008; De Paoli & Ropo, 2017; Dul & Ceylan,

184

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

2014; McCoy & Evans, 2002; Muniandy et al., 2015; Setola & Leurs, 2014; shaqour, 2021; Thoring et al., 2018, 2019; Thoring, Guerreiro Goncalves, et al., 2017; THORING et al., 2012,; Thoring et al., 2020; Williams, 2013).

Factor	Identification	Factor	Identification	Factor	Identification	Factor	Identification
Connection with nature	Open Views	components of the space	Interior Haptics and Finishing	Stimulating	Stimulation	Natural light	Light, Quantity of light
	view of natural environment		less use of manufactured materials.		Sensory stimulation		Use of Natural Daylight
	extended views		Complexity, Complex Shapes		Sound (positive sound)		Use of Ambient, Soft Light
	Use of Outdoor Spaces		Size, Shape Internal Organization of Objects		Smell (Positive Smell)	Natural colours	Pale Colors, Calming, Inspiring Colors
	Use of Open Space				Natural Textures		
	Use of Park Theme Inside		Visual Detail	Materials	Transparency, Semi-Transparency		Fewer Cool Colors
	Greenery		Furniture Design & Arrangement		Use Of Natural Materials		Warm Color
	Living Plants Indoor		Unusual Furniture	Ventilation	Micro-Climate		Energetic Colors, Bright Colors
	Vista				Indoor Climate		
			Activating Furniture		Fresh Air		

Table 1: Overview of The spatial characteristics that are connected with nature as a trigger for creative space. Source: Researchers.

Stimulation is the third factor. That factor can be applied by using furniture that imitates elements of nature and biomorphic forms and shapes. And any suggestions for simulating nature in space (Bramble, 2017; CANNON & UTRIAINEN, 2013; Davies et al., 2013; Jindal-Snape et al., 2013; McCoy & Evans, 2002; Muniandy et al., 2015; Oksanen & Ståhle, 2013; shaqour, 2021; Thoring et al., 2018, 2019; Thoring, Gonçalves, et al., 2017; Thoring, Guerreiro Goncalves, et al., 2017; THORING et al., 2012,; Thoring et al., 2020).

The fourth factor is the material connection with nature. This factor can be applied by using natural materials and textures in the space on furniture, walls, floors, ceilings, and any other elements in the space (CANNON & UTRIAINEN, 2013; Davies et al., 2013; De Paoli & Ropo, 2017; De Paoli, Sauer, & Ropo, 2018; McCoy & Evans, 2002; Muniandy et al., 2015; shaqour, 2021; Thoring et al., 2018, 2019; Thoring, Gonçalves, et al., 2017; Thoring, Guerreiro Goncalves, et al., 2017; THORING et al., 2012,; Thoring et al., 2020).

The fifth factor is natural ventilation and airflow. These factors affect the indoor microclimate that can be created by using many sources of natural ventilation, such as windows, courtyards, and atriums (CANNON & UTRIAINEN, 2013; Jindal-Snape et al., 2013; McCoy & Evans, 2002; Muniandy et al., 2015; shaqour, 2021; Thoring et al., 2018, 2019; Thoring, Guerreiro Goncalves, et al., 2017; THORING et al., 2012,; Thoring et al., 2020; Williams, 2013).

The sixth factor is natural light. The quantity of natural daylight and ambient, soft light affects students' mental and physical health. Therefore, using natural light enhances our wellbeing, which impacts students' creativity (Davies et al., 2013; De Paoli, Sauer, & Ropo, 2017; Dul, Ceylan, & Jaspers, 2011; Jindal-Snape et al., 2013; Makhmalbaf & Do, 2007; McCoy & Evans, 2002; Oksanen & Ståhle, 2013; Peschl, 2014; Thoring et al., 2018; Thoring et al., 2020; Williams, 2013).

The seventh factor is natural colors, which have a positive influence. Colors affect our feelings. Natural, pale, bright, calming, and inspiring colors create a connection with nature. Warm and energetic colors create a feeling of power. All this can create a creative space (Bramble, 2017; CANNON & UTRIAINEN, 2013; Davies et al., 2013; Eismann et al., 2021; Jindal-Snape et al., 2013; McCoy & Evans, 2002; Muniandy et al., 2015; shaqour, 2021; Thoring et al., 2018, 2019; Thoring, Guerreiro Goncalves, et al., 2017; THORING et al., 2012,; Thoring et al., 2020).

After recognizing the role of nature in stimulating creativity in the design studio, theories have been explored through which the experience of nature can be applied. The biophilia theory is one of these theories.

4 BIOPHLIC DESIGN

Biophilia, our biological connection to natural environments (Browning, Ryan, & Clancy, 2014; Stephen R. Kellert, 2012; WILSON, 1984) has been theoretically linked with creative output and performance. (Ulrich, 1993). The justifications for selecting the biophilia hypothesis as a foundational approach to applying the experiences of nature in design studio environments are:

- Biophilic design's fundamental objective is to handle these imperfections of contemporary or current building and landscape practice by setting up a new framework for the fulfilling experience of nature in the constructed and built environment (Browning et al., 2014; Stephen robert Kellert, 2008; Stephen R. Kellert & Finnegan, 2011).

- Biophilic design aims to create useful habitat for people as an organic and biological organism in the built environment that improves people's creativity, productivity, health, fitness and wellbeing (Browning et al., 2014; Calabrese, 2015; Stephen R. Kellert & Finnegan, 2011).

- The biophilic theory was chosen based on some research and literature reviews that carried out quantitative and computational experiments on some space users and measured their creativity in different environments (Chulvi, Agost, Royo, & García-García, 2020; McCoy & Evans, 2002; Ulrich, 1993), including: a) The first one is the neutral study space; b) The other one is the same educational space, but a simulation of the natural environment inside this space was made by relying on the biophilic theory; and c) The last environment is the natural environment itself (the outdoor natural environment), as shown in Figure 2. The results indicate that both types of environments – simulated (biophilic) and natural settings – have higher creative values than a neutral situation.

Fig. 2: Photos showing 1) Real nature: outdoor garden area. 2) Simulated nature by biophilic theory: artificial representation of the garden indoors. 3) Neutral environment: normal lecture room. adapted from: (Chulvi et al., 2020).

With the aforementioned justifications, it can be concluded that biophilic design can create a creative design studio. Therefore, it was necessary to know the components of biophilia theory, which consist of principles and patterns (Browning et al., 2014; Stephen R. Kellert & Calabres, 2015). Several fundamental principles must be followed in order for biophilic design to be successfully implemented, which are:

- Frequent and continuous contribution to nature;

- Focusing on human willingness to accept nature;

- Encouraging emotional linking to similar environments and places;

- Strengthening the interaction between people and nature, which helps to increase the sense of responsibility towards human and natural societies;

- Inspiring the existence of interconnected and integrated architectural solutions (Browning et al., 2014; Stephen R. Kellert & Calabres, 2015).

There are 14 patterns of biophilic design that can be used when applying biophilic design within any space, and the 14 patterns fall into three groups: nature in space, natural analogues, and nature of space (Browning et al., 2014; Stephen R. Kellert & Calabres, 2015; WILSON, 1984), as shown in Table 2.

Based on this, it was determined that the biophilic theory is concerned with interior environments that are surrounded by nature. It can also provide a sense of the natural context, even if this interior space is in the center of a city in a built environment. Through various treatments and the application of additional principles and patterns within the space, it is possible to convey a sense of the natural environment and

context even though that space is inside the built environment. This is possible thanks to biophilic theory (Browning et al., 2014; Stephen robert Kellert, 2008; Stephen R. Kellert & Finnegan, 2011).

5 CREATIVE SCHOOLS OF ARCHITECTURE'S ANALYSIS

Some examples from a number of the top architectural schools in the world will be singled out based on the Quacquarelli Symonds Rankings (QS) ("QS World University Rankings", 2022). The criteria for selection depend on the existence of the largest number of natural principles, creativity simulation, Their existence in a built or natural environment, and the availability of data. At the school, an analysis of the natural characteristics as a creative space trigger will be conducted in relation to the factors in Table 1. The main goal is to know the differences in the application of nature and natural elements in different locations, like a built environment, a tropical climate environment, and a mixed environment. As a result, the application of those natural characteristics will be connected through biophilic patterns. The three schools are: 1) TU Delft Faculty of Architecture and the Built Environment (rank 2), which is located in a mixed area (built-up and natural areas). 2) National University of Singapore School of Design and Environment (rank 6), which is located in a natural area. 3) Manchester School of Art (rank 7), which is located in a built-up area.

The following descriptions are analyzed based on some literature reviews, which contain journal articles, papers, reports, websites, and books that were utilized to describe the building designs and the aim, purposes, and values of the three architectural schools.

5.1 TU Delft Faculty of Architecture & the Built Environment

In terms of research and education, the faculty of architecture and the built environment is a global leader. The faculty's solid research reputation as well as the passion, enthusiasm, and creativity of its academic community and student body are what drive its success (Hoeven et al., 2022; Voordt, Jonge, & Hans; Wamelink, 2010). Academics and students have been working on enhancing the built environment to create a creative learning environment for students to become excellent, brilliant, and creative architectural engineers (Avermaete et al., 2014; "BK CITY, DELFT: a vibrant educational environment", 2022; Hoeven et al., 2022; ir-arch. T. (Tom) Coppens, Dipl.-Ing. Dr.techn. I. (Iva) Kovacic, G. (Gabriele) Lobaccaro, D.M. (Despina) Stratigakos, & Verbakel, 2023; Rooij, Klaassen, Cavallo, & Arts, 2019; "TU Delft Architecture and the Built Environment: About the faculty", 2022; Voordt et al., 2010).

5.1.1 Spatial Characteristics of Nature Principles as a Creative Space Trigger Related to Table 1

One of the factors at the TU Delft Faculty of Architecture and the Built Environment is the connection with nature. It's demonstrated inside the school through the presence of different plants, gardens, parks, and a backyard gathering area, as shown in Figures 3 and 4. The studio walls are mostly glass curtain walls, allowing views of nature. The second is components of the space, which are similarly characterized by complex geometries, internal haptics, and distinctive finishing. Then, as seen in Figure 5, there is a simulation of plants and other natural elements using their colors, shapes, and functions. The utilization of natural materials in multiple places is one of the distinctive characteristics. The studio at TU Delft is distinguished by its significant reliance on natural light, which enters through the ceiling's 17 skylights and curtain walls. As seen in Figure 6, the design studio is also defined by the presence of natural colors that provide many sources of inspiration. (Avermaete et al., 2014; "BK CITY, DELFT: a vibrant educational environment", 2022; Hoeven et al., 2022; ir-arch. T. (Tom) Coppens et al., 2023; Rooij et al., 2019; "TU Delft Faculty of Architecture & the Built Environment", 2022; Voordt et al., 2010).

5.2 National University of Singapore School of Design and Environment

The aim of the school is to become a top one that brings creative minds together to create a better future ((NUS), 2019 ; P, 2021; "School of Design and Environment", 2021). The design seeks to emphasize learning as a communicative, collaborative, and creative method. The design concept isn't just to create a creative learning environment for students but also to benefit the entire system by opening up the debate over design in general. So what distinguishes the building design is not only creating a learning environment that helps students communicate, be more creative, and collaborate ((NUS), 2019; Lasternas, 2018; "National University of Singapore School of Design & Environment", 2019; "NUS School of Design & Environment" " 2022; P, 2021; Poh et al., 2018; "SERIE ARCHITECTS", 2022).

5.2.1   Spatial Characteristics of Nature Principles as a Creative Space Trigger Related to Table 1

The building is widely connected with nature in many ways; it's extremely open. Nature and the landscape all around the building, as shown in Figure 7, As seen in Figure 8, there are various terraces and planted balconies. A huge overhanging roof protrudes along the south façade, integrating a tropical porch surrounded by mature trees. The building's architecture is adaptable and efficient. There are no formal distinctions between study, work, and social environments, as shown in Figure 9. The raw and natural features of the building materials have a major relationship with the biophilia notion. The ventilation at the school depends on natural sources. The building is called a "climate-responsive building." The majority of the rooms may be exposed to the prevailing winds, and more than half of the space is naturally ventilated. When necessary, only air conditioning is used. The school also depends on natural light. Parts of the façade can be taken apart and replaced with new methods and systems. a veil-like metal curtain that filters sunlight. There are also about 1,200 solar photovoltaic panels above the roof, as shown in Figures 10 and 11 ((NUS), 2019 ; Lasternas, 2018; "National University of Singapore School of Design & Environment", 2022; "NUS School of Design & Environment", 2022; P, 2021; Poh et al., 2018; "SERIE ARCHITECTS", 2022).

Fig. 10: Longitudinal Section components. Fig. 11: Cross Section components. Both adapted from: ("NUS School of Design & Environment","2022).

5.3 Manchester School of Art

The vision of the school is to be an inclusive art gallery for the people of Manchester and the wider world, opening minds to the essential role of creativity in making a healthy society and contributing to social change (Fallon, 2018; Jefferies, Stone, & Kwan, 2017; "Manchester Art Gallery", 2022; university, 2016). The Manchester School of Art's significant expansion by Feilden Clegg Bradley Studios has helped raise the prominence of the university and the art school by creating a creative, vibrant, interesting, and engaging environment for staff and students to work in (Fallon, 2018; Jefferies et al., 2017; "Manchester Art Gallery", 2022; "MANCHESTER SCHOOL OF ART", 2015; ofsted, 2013; University, 2013, 2016).

5.3.1   Spatial Characteristics of Nature Principles as a Creative Space Trigger related to Table 1

The school is characterized by a great connection with nature through the presence of living indoor plants and flowers of different types and shapes. A hybrid creative environment was created. There is also a green roof for the gathering, called the design garden, and a skylight. The size of the internal configurations is appropriate, and the visual details are simple. The arrangement of the interior furnishings of the studio, workshops, and cafes is active and unusual. There is a simulation of some elements in the school. There are some motifs on the column faces, including plants and small flowers, as shown in fig. 12. Most of the surfaces in the space and the furniture are made of natural materials, such as wood. There are no complex manufactured materials inside the space. The interior design of the space provides good ventilation and air renewal due to the presence of the atrium, which ends with a skylight. The building facades are curtain walls, so the whole building relies on natural light. Also, the colors inside the school are natural, calm, and motivating colors that generate a feeling of inspiration and creativity, as shown in fig. 13 (Fallon, 2018; Jefferies et al., 2017; "Mnchester school of art", 2015; "Manchester School of Art", 2022; ofsted, 2013; University, 2013, 2016).

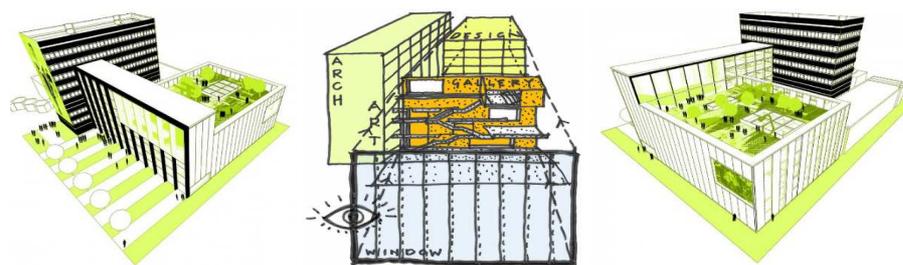

Fig. 12: Photos showing 3D shot showing the green roof and the outdoor green areas around and above the building. Adapted from: "Manchester School of Art", 2022.

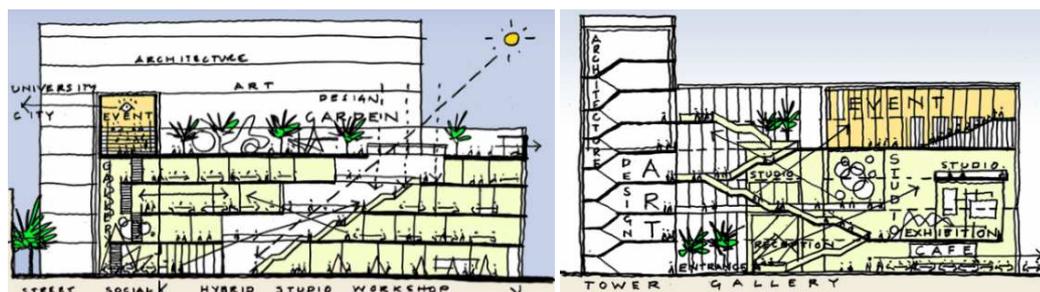

Fig. 13: Photos showing Two orthogonal sections of the building zoning showing the biophilic patterns in the different zone of the building. Adapted from: "Manchester School of Art", 2022.

5.4 Results: The Biophilic Patterns at The Previous Schools of Architecture

In order to create a creative architectural studio environment that depends on the application of biophilia theory as a translation of nature's principles, it was necessary to know how to connect the principles of nature and the biophilic patterns. The following paragraphs will explain how the aforementioned Spatial characteristics of nature principles have been applied to the biophilic pattern for each school.

The Visual Connection with Nature pattern was applied at the three schools in different ways. It mainly depends on green plants, which can be employed in any style of interior design, like residential, educational, and office settings. The focus here is on how it is employed within the architectural studios, and the following can be used to determine this: It was applied at the first school by creating views of nature from windows and curtain walls, the existence of parks with seasonal plants, pots, bushes, and trees, gathering gardens, and inner plants. But at the third school, it depends on the curtain wall on the north façade, windows on walls in the other façade called "windows on the arts," and a roof with green plants that is called a terraced hybrid environment. However, this pattern is stronger in the second school, by making terraces, planted balconies, and constructing a tropical portico, inner areas and exterior spaces can be in close proximity to the surrounding landscape. The non-visual connection with nature pattern was implemented at all three schools in a similar way, by relying on the indoor plants' smell and sounds from the outer gardens through birds, insects, and plants' movements and seasonal outdoor plants' changes.

At the first school, the non-rhythmic sensory stimuli pattern was performed by combining emerging with rich, layered ground and wall coverings, skylights, and tall trees. At the second school, it was applied by making outdoor and indoor seasonal plants. Then at the third one, they used various ground and wall coverings, a skylight, and tall grass. The thermal and airflow variability pattern was utilized at the first and third schools by creating curtain walls and operable skylights. In the second example, a majority of the rooms are exposed to the prevailing breezes, areas are created to capture natural light throughout the day, and more than 50% of the space is naturally ventilated. Only air conditioning is utilized when necessary, as the biophilic theory can deal with the spaces found in a natural setting to apply "climatic, or eco-design, using natural processes" due to its availability. However, if the spaces are located inside a built environment, mechanical or artificial methods (such as natural ventilation, direct sunlight, solar electricity production, etc.) may be used. In case of the inability to use the natural processes (Browning et al., 2014; Stephen robert Kellert, 2008; Stephen R. Kellert & Finnegan, 2011).

At the three schools, there is no presence of the Water pattern. The dynamic and diffuse light pattern is achieved in the first school by adding 3-sided curtain walls, 13 skylights, and dynamic artificial warm lighting. Then at the second school, there is a veil-like metal curtain that filters sunlight and emphasizes a link to the environment. The four facades are curtain walls with light filters. But the third school includes skylights, window units on the other facades, and an oblique court. The connection to natural systems was visible in the first and third schools through seasonal changes in vegetation in the gardens. However, the second school contains a landscape that improves water quality; nearly 50% of the plants selected are native species, and most are from the southern tropics; 1200 solar photovoltaic panels on its rooftop; and an innovative hybrid cooling system that supplies rooms with 100% fresh pre-cooled air.

The pattern of biomorphic forms and patterns at the first and second schools was applied by making one-colored spaces, motifs, and ornaments of natural elements; most of the colors and materials are from nature. At the third school, that pattern was implemented by using a curtain wall that allowed a view of the old buildings with ornaments and motifs that simulated elements from nature. The Material Connection with Nature pattern was implemented at the first and third schools by designing furniture and space elements from natural materials. At the second school, the building has a strong biophilic component, which is the deliberate use and celebration of the raw and natural characteristics of the materials. also the use of natural colors and materials for walls, floors, and columns, such as wood, stone, and glass.

The Complexity and Order pattern was applied at the first school by making patterned ceiling and wall tiles. On the second, there are patterned wall tiles; different sizes and textures of the stone are utilized; patterned ceiling tiles for lighting fixtures; and ordered facade panels. Patterned vertical ceiling tiles and orderly window units were used in the third one. The Prospect pattern was used at the first and second schools by creating a studio layout with views across for surveillance, an unobstructed view from the mezzanine floor, and an upper level elevated above street level. Besides that, the third school added open floor plans for

studios and galleries. The Refuge pattern appeared at the first school by relying on a landscaped courtyard to separate it from the city. Then, at the second one, there are many outdoor terraces and corridors. Finally, at the third school, there were enclosed conference and work rooms. The mystery pattern didn't appear in the first school. But at the second school, it was applied by creating a partially obscured view of plants from the studios and the hallway; an entry switchback creates visual intrigue. At the third school, there were glimpses of plants and greenery through openings in the walls. The risk/peril pattern wasn't significantly represented in the three examples.

After realizing the biophilic patterns that were applied to the previous three architectural schools, the common patterns that were applied in the schools were extracted at Table 3. as they are essential patterns that can be applied to any design studio.

The Biophilic Design Patterns			TU Delft Faculty	Singapore University	Manchester School	Common Biophilic Patterns between the school
NATURE IN THE SPACE	P1	Visual Connection with Nature	yes	yes	yes	Nature views; open views; extended views; large windows; curtain walls; exterior plants, park, and gardens; private gathering open spaces and gardens; inner Living indoor plants of different types, such as greenery, pots, trees; view of the natural environment.
	P2	Non-Visual Connection with Nature	yes	yes	yes	The plants' smells, sounds, and movements; Birds, insects, and bees exist; seasonal plants.
	P3	Non-Rhythmic Sensory Stimuli	yes	yes	yes	Native landscaping; tall trees; rich and various layered wall and floor cover; seasonal plants.
	P4	Thermal & Airflow Variability	yes	yes	yes	Operable Curtain wall, tall windows, skylight.
	P5	Presence of Water	x	x	x	Not significantly represented in the project.
	P6	Dynamic & Diffuse Light	yes	yes	yes	Curtain walls; tall windows; skylights.
	P7	Connection with Natural Systems	yes	yes	yes	seasonal changes in the plants, gardens, and parks outside and inside; possibilities to observe interactions between plants, bees, insects, and birds.
NATURAL ANALOGUES	P8	Biomorphic Forms & Patterns	yes	yes	yes	motifs and ornaments of natural elements; most of the colors and materials are from elements of nature.
	P9	Material Connection with Nature	yes	yes	yes	Natural colors and materials for most surfaces; pale colors for walls and floors; many wooden surfaces for furniture, walls and floors.
	P10	Complexity & Order	yes	yes	yes	patterned tiles for the ceiling, walls, and curtain walls; different sizes and textures of furniture and materials.
NATURE OF THE SPACE	P11	Prospect	yes	yes	yes	A clear view over a long distance for observation, surveillance and planning.
	P12	Refuge	yes	yes	yes	Outdoor terraces and passageways that can be used to create a secure area where one can withdraw from their surroundings or the main activity stream while yet being shielded from above and behind.
	P13	Mystery	x	yes	yes	partially obscured views and glimpses for the surroundings
	P14	Risk/Peril	x	x	x	Not significantly represented in the project.

6 CONCLUSION: APPLICABILITY OF THE BIOPHILIC PATTERNS TO THE ARCHITECTURAL DESIGN STUDIO

The educational environment affects students in several ways. It motivates students to provide their best performance, particularly for architecture students. Therefore, the design studio learning environment should

foster creativity. After research and analysis, it was discovered that connection with nature, such as using living plants, greenery, open views, and other guidelines that promote nature's connectedness, can help create a creative learning environment while also enhancing students' creative performance. As a result, theories were investigated to determine how nature could be applied within the space. The biophilia theory, which expresses the human proclivity for nature, consists of 14 patterns that can be used to create a connection with nature within a space. In order to find out how these patterns can be applied, a number of examples of different biophilic environments were analyzed. Through the examples' analysis, it has been concluded that these patterns can be applied through many of the methods that have been mentioned.

After discovering how to apply the biophilic pattern, it was found that some patterns could be applied to an existing design studio but others could not. The following will present an analysis of the biophilic patterns that can be applied to an existing design studio. The patterns: visual connection with nature; non-visual connection with nature; non-rhythmic sensory stimuli; thermal and airflow variability; dynamic and diffuse light; connection with natural systems; material connection with nature; Biomorphic Forms and Patterns; complexity and order, can be applied to an existing design studio as long as its application capabilities are available and affordable. The methods, additions, and treatments by which they can be applied are listed in Table 3. As for the "Presence of Water" pattern, that wasn't applied to any school due to the lack of application capabilities.

The prospect and refuge patterns were applied to the three schools; the mystery pattern was applied to only two of the three schools; and the risk/peril pattern also wasn't applied to any schools. However, those three patterns are difficult to implement in an existing architectural design studio. because mostly those patterns depend on the location in which the studio's building is sited and also the surrounding spaces around the studio. And with this, the aim of this paper was reached, which was to find out the possibility of applying the biophilic patterns to an existing architectural design studio and to determine the methods by which these patterns could be applied. In order to give all existing design studios, the opportunity to transform their usual design studio into a biophilic design studio, which helps improve their creative performance and enhances their efficiency.

1 ABSTRACT

The design of learning environments has a significant role in students' health and well-being, particularly in the light of the COVID-19 pandemic which has highlighted many challenges concerning the quality of learning environments in our schools, especially elementary schools. This emergency caused a massive closure of schools and around 1.2 billion students were unable to learn in their physical learning environments during this period. Before developing medications for the epidemic, one solution to limit the infection was transforming our learning environments and adding layers of protection to ensure healthy and safe spaces for students.

This paper aims at investigating the design principles of healthy learning environments according to AIA strategies for safe reopening schools which can be included in providing healthy indoor environmental quality, integrating nature with the learning environments, and providing safe contact in the learning environments. Then, a comparative analysis will be conducted on three existing schools which have succeeded to limit infection transmission and transform into healthy learning environments during COVID-19. Finally, the paper provides a framework and recommendations for the designing of future healthy learning environments to face any potential pandemic which may occur in the future.

2 INTRODUCTION

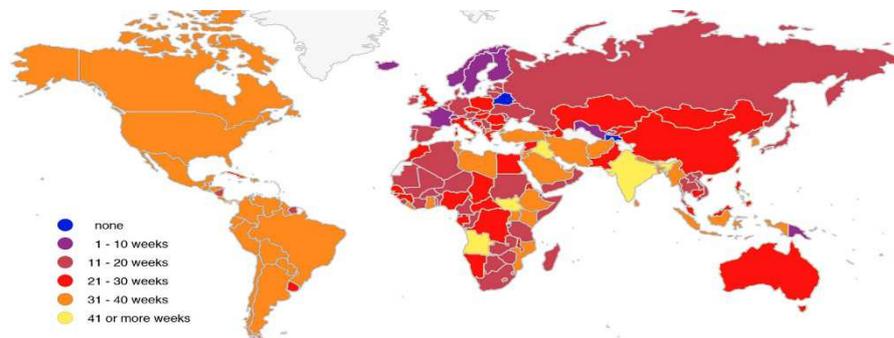
The COVID-19 pandemic has proven that a catastrophe does not always face a recognized enemy. The enemy might be hidden with disastrous impacts (Goniewicz et al., 2020). The most immediate effects of COVID-19 are on physical health, but it also has severe effects on social and emotional functioning. Globally, the COVID-19 pandemic has had a negative impact, particularly in the field of education, as the rapid spread of the virus has forced governments to take extreme actions, including the total or partial closure of existing schools in over 190 countries as shown in Fig. 1, in an effort to prevent the spread of the disease and limit its effects. By the middle of May 2020, more than 1.2 billion students were unable to learn in physical learning environments (Spitzer, 2021).


Fig. 1: Location and duration of school closures by country, (Spitzer, 2021).

School closure was the only solution to protect students from the COVID-19 pandemic because schools are not designed to adapt to any urgent crises or health pandemics for the following reasons:

- Current schools neglect social isolation; instead, schools have a large density of students and were designed to be a place where students can interact with each other (Van Doremalen et al., 2020), so keeping social distancing will lead to difficulty because the number of classrooms in existing schools is not sufficient to meet the whole number of students while maintaining social distancing.

- The surfaces and furnishings in existing schools were not designed for hygienic purposes; rather, they were only designed with sustainability and environmental concerns as priorities (Khanam et al., 2006). In addition, hygienic strategies in existing schools are not enough to face the pandemic; students must also physically push or touch surfaces to operate doors, windows, lights, etc., which increases the risk of COVID-19 spreading among students (Chin et al., 2020).

- The ventilation rates of existing schools are only 3.44 dm3/s/person, which is insufficient because the minimum needed ventilation rate for schools must be 8.5 dm3/s/person to be able to fight infection transmission according to the Dutch Building Code (Blocken et al., 2020).

Because of these problems, learning environments were not healthy enough to adapt to the COVID-19 pandemic and were obliged to be closed. During this period, education was provided through distance learning. Although distance learning offers a secure way to ensure learning continuity while protecting students, there is no substitute for physical classrooms because of the drawbacks of distance learning, like the difficulty of using distance learning for younger students. Also, distance learning can lead to social isolation by keeping students away from physical activities that are essential for learning, growth, and innovation. This will lead to issues related to mental health (Jiao et al., 2020). Consequently, AIA, CDC, and WHO started preparing strategies for the existing schools to reopen securely, and for future learning environments, the design principles won't be similar because health factors will be required to add safety layers to adapt to any pandemic that may happen in the future (CDC, 2021).

3 METHODOLOGY

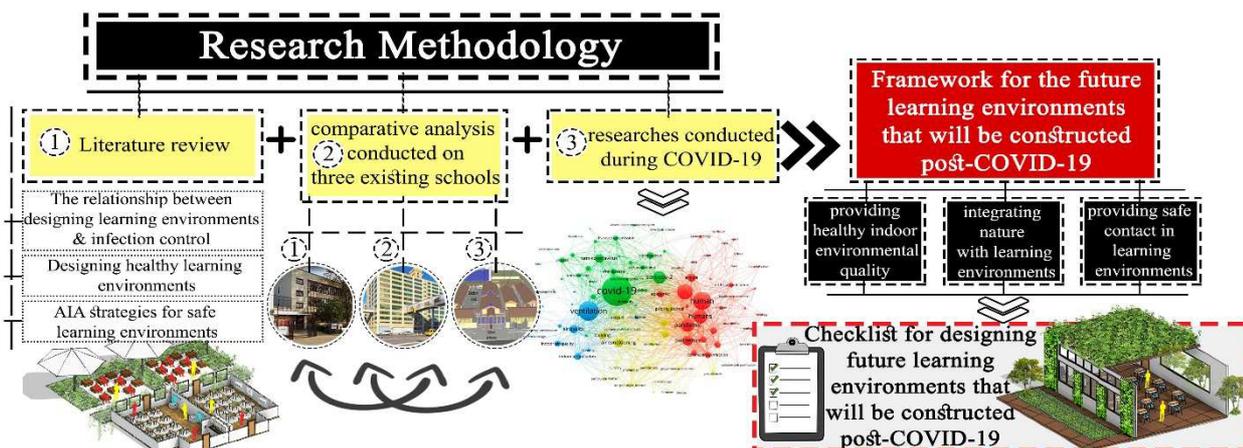
This study is an exploratory study that is based on three main sections, as shown in Fig. 2. The first is a literature review presenting the relationship between designing learning environments and infection transmission control, and the importance of being healthy future learning environments. The research then investigates the design principles of healthy learning environments according to AIA strategies for safe learning environments. The second section presents a comparative analysis conducted on three existing schools that have succeeded in applying AIA strategies to their schools to limit infection transmission and transform them into healthy learning environments during COVID-19. According to these findings, in addition to the researches conducted during COVID-19, we can finally devise a framework and a checklist of measures for designing future learning environments that will be constructed post-COVID-19 to be resistant to any potential pandemic that may occur in the future.


Fig. 2: Research methodology.

4 LITERATURE REVIEW

4.1 The relationship between designing learning environments and infection transmission control

Pandemics and intense catastrophes have always had a harmful impact on our built environment. In addition, they have transformed our built environment for many years. As a result, architects and urban planners acted as the treaters, helping stop pandemics by upgrading the design considerations of buildings throughout the years as a response to pandemics, as during pandemics, the form, like the function, has always followed the fear of infection (Ellin, 1999). As a consequence, the current health crisis demands upgrading the principles

196

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

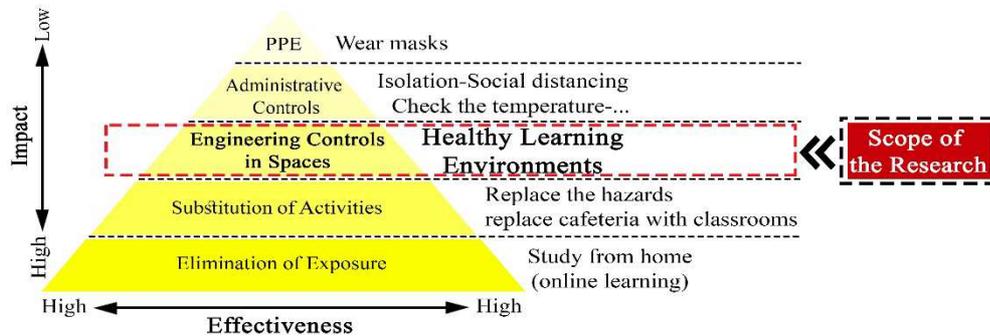
of designing future schools to be healthy and resistant to any pandemic that can occur in the future (Megahed & Ghoneim, 2020). According to the hierarchy of hazard control, there are numerous strategies to maximize our defense against the infection transmission of COVID-19 or any virus, which can be concluded in five layers of defense as shown in Fig. 3. All layers must always be applied together to limit infection transmission, and the measure at the bottom of the hierarchy is more effective than those at the top. This hierarchy of hazard control shows that to limit infection transmission among students in schools, designing healthy learning environments will be an essential aspect in the future (CDC, 2015).


Fig. 3: Applying the hierarchy of controls in schools for COVID-19, upgraded from (CDC, 2015).

4.2 Designing healthy learning environments

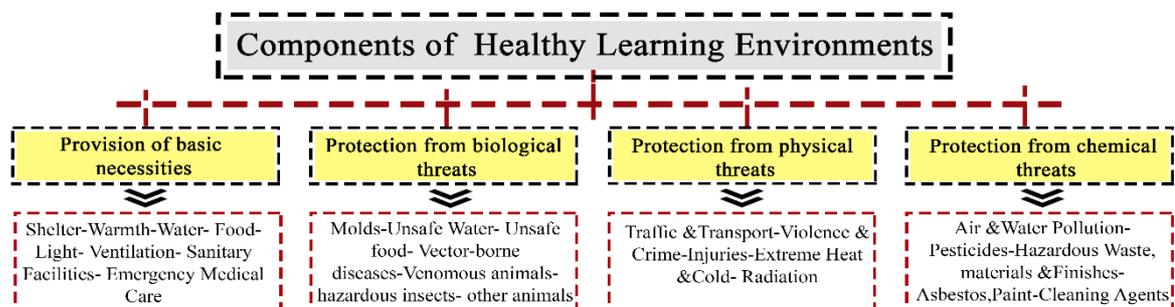
According to Zhen et al., (2019), a "healthy building" is a physical structure that improves an individual's well-being and promotes healthy spaces as well as promoting physical, mental, and social health. Post-COVID-19 pandemic, healthy learning environments became a concept that must be applied to both future and existing schools to create ergonomic and healthy indoor learning environments (Megahed & Ghoneim, 2020; Saeed et al., 2021). This is because healthy learning environments can protect students from sickness and harm and promote preventative methods versus risk factors that might result in disease in the future by promoting suitable essential environmental factors (such as relative humidity, ventilation, thermal, acoustic, and lighting comfort, etc). It also can protect students from physical threats as well as protection from chemical and biochemical threats (WHO, 2004) as shown in Fig. 4.


Fig. 4 : Components of healthy learning environments, upgraded from (WHO, 2004).

As previously mentioned, it will be crucial to design healthy learning environments in the future, not just to protect students from pandemics but also to protect them from any viruses or diseases that may harm their health. For instance, influenza is hazardous for young students due to their lack of immune systems, and this can harm their bodies to the extent of death (CDC, 2021). Healthy learning environments will enable students to learn and succeed in an atmosphere free from environmental risks or diseases, which will enhance their social, mental, and physical health (Saeed et al., 2021; WHO, 2004).

4.3 Strategies of AIA for the existing learning environments during the COVID-19 pandemic

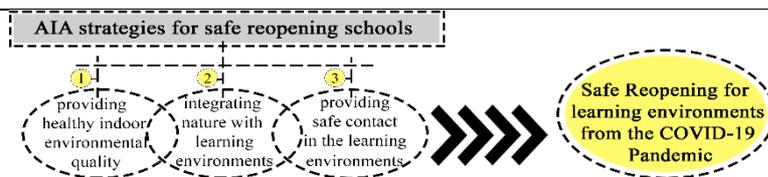
For some students, the ability to attend physical classrooms can mean the difference between life and death, and there is no alternative to physical classrooms (OECD, 2020). Thus, AIA provided strategies focused on developing existing schools' designs in accordance with CDC and WHO guidelines to provide safe reopening for learning environments (AIA, 2020). The strategies of AIA for safe reopening schools can be concluded in three parameters: providing healthy indoor environmental quality, integrating nature with learning environments, and providing safe contact in the learning environments, as shown in Fig. 5.


Fig. 5: AIA strategies for reopening schools safely.

4.3.1 Providing healthy indoor environmental quality

Indoor air quality (IAQ), thermal comfort, lighting and acoustic comfort are the four main indicators of indoor environmental quality. The quality of the indoor learning environment influences the built environment, affects students' health, and protects them from learning in a sick building syndrome (Megahed & Ghoneim, 2021). Fig. 6 shows The relationships between environmental health and its impact on health.

Fig. 6 : The relationships between environmental health and its impact on human health, (Megahed & Ghoneim, 2021).

The AIA has recommended the following strategies, as shown in Fig. 7, for ensuring indoor air quality:

- Relying on natural ventilation because it is very essential to control cross-infection by removing virus-laden aerosols exhaled by infected student by keeping windows and doors open, using ceiling exhausts to enhance the flow of air, and holding outdoor classrooms (CDC, 2019).

- Enhancing ventilation systems following ASHRAE recommendations, which include updated relative humidity (40–60 percent) and temperature (68–78 °F), as well as installing CO2 monitors, upgrading air filtration from MERV 8 to MERV 13 filters, and using UV light in HVAC and/or classrooms to purify the air from any pollutants and viruses(ASHRAE, 2023).

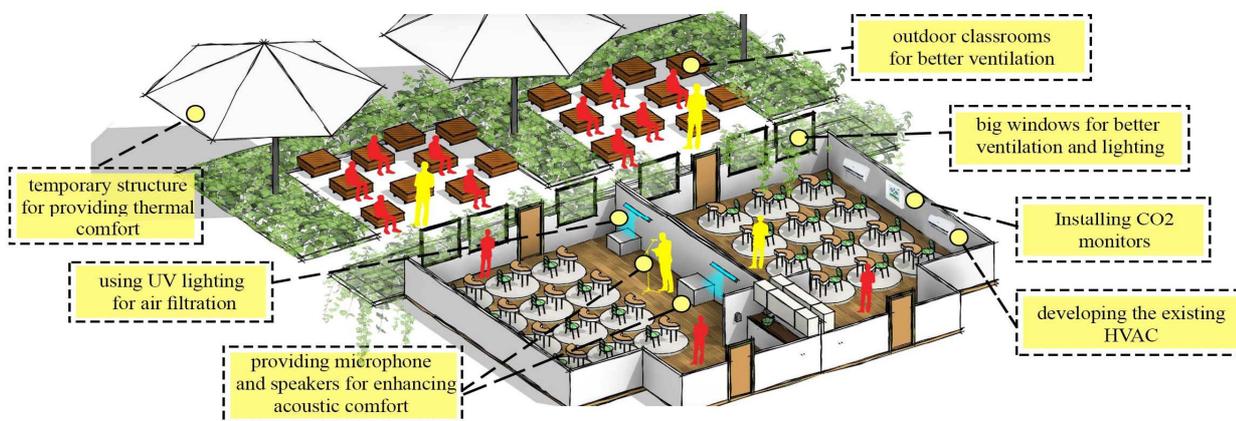
AIA recommended providing natural lighting whenever possible, Also AIA proposed using temporary shades to promote thermal comfort in outdoor spaces and outdoor classrooms during extreme weather; on the other hand, AIA suggested the use of microphones and speakers in the classrooms to provide acoustic comfort because masks can be considered as a sound barrier (AIA, 2020).


Fig. 7: AIA strategies for providing healthy indoor environmental quality in the learning environments.

4.3.2 Integrating nature with the learning environments

The COVID-19 pandemic has significantly changed learning environments, including increasing awareness that learning in outdoor areas can be safer than learning in indoor spaces when the infection is a a concern

198

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

(Jones et al., 2020). So AIA suggested holding classrooms and activities in outdoor spaces to promote natural ventilation and interactions between students and nature, as well as providing big windows and doors in each classroom to promote views to outdoor greenery and to provide access to outdoor spaces (AIA, 2020).

4.3.3 Providing safe contact in the learning environments

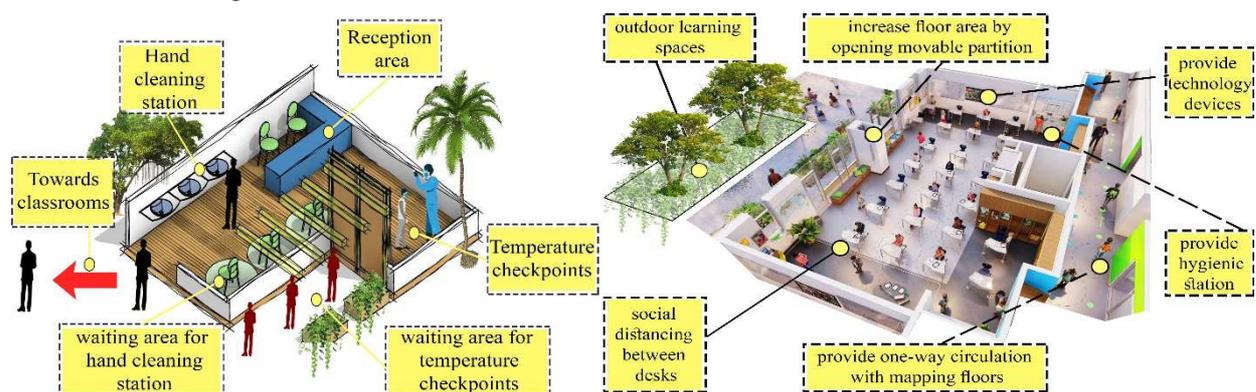
AIA proposed strategies that provide safe contact between students, which can be provided via hygienic control, using hygienic materials, providing touchless systems, and enhancing social distancing. AIA proposed measures to provide hygienic control by adding hygienic stations at schools' entrances, as shown in Fig. 8, as well as creating isolation rooms for infected students. AIA recommended using hygienic materials with short-term COVID-19 stability, such as copper and its alloy. As well as providing touchless systems by substituting flush valves and drinking water dispensers with touchless ones, controlling artificial lights and door openers is also recommended with touchless systems. AIA proposed several strategies to maintain social distancing between students in entrances, classrooms, circulation, and spatial organization. At entrances, social distancing was maintained by using ground markings indicating a minimum distance of 1.8 m between students. In addition to providing multiple points of entry, and applying staggered schedules to decrease traffic at entrances. In classrooms, AIA suggested keeping social distancing between students (with 1.8 m between each other) and, where social distancing is not feasible, placing transparent physical barriers. On the other hand, AIA promoted social distancing in circulation and spatial organization by creating one-way circulation in corridors and mapping the floors. Social distancing in schools caused a problem, which is that classroom areas are not large enough to accommodate all students at the same time while maintaining social distancing. Therefore, AIA proposed converting cafeterias and gyms into bigger classrooms and converting outside areas to outdoor classrooms and outdoor activities, also by using movable partitions. Another solution was providing distance and hybrid learning by providing classrooms with the essential tools, as shown in Fig. 9 (AIA, 2020).


Fig. 8 (left) : Providing hygienic stations at schools' entrances. Fig. 9 (right) : AIA strategies for maintaining social distancing in classrooms, upgraded from (AIA, 2020).

5 COMPARATIVE ANALYSIS

This comparative analysis includes three examples of schools worldwide that have succeeded (if they were compared with other schools) to apply AIA strategies in their schools and transformed them into healthy learning environments during COVID-19 to limit infection. This comparative analysis is conducted according to AIA strategies between these examples, which are public school 138 Samuel Randall in the Bronx, Brooklyn Laboratory Charter Schools in New York, and Projeto Espaço Educativo 12 Salas – PEE-12 in Brazil. This comparative analysis aims to investigate the parameters and strategies of healthy learning environments that will be essential to make future learning environments resistant to any potential pandemic.

5.1 Public school 138 Samuel Randall in the Bronx, NY (elementary school)

The Urbahn architects designed a transforming proposal for this school to enable it to adapt to the COVID-19 pandemic. The Urbahn strategy focused on promoting hygienic control, so Urbahn suggested establishing two prefabricated handwashing stations before each entrance of the school, as shown in Fig. 10, as well as installing prefabricated wash stations in the hallways and each classroom to be accessible to all students, and also reusing auditoriums as isolation spaces. The Urban additionally concentrated on maintaining social distancing in entrances by adding entry points, providing social distancing in the sidewalk queue area (1.8m)

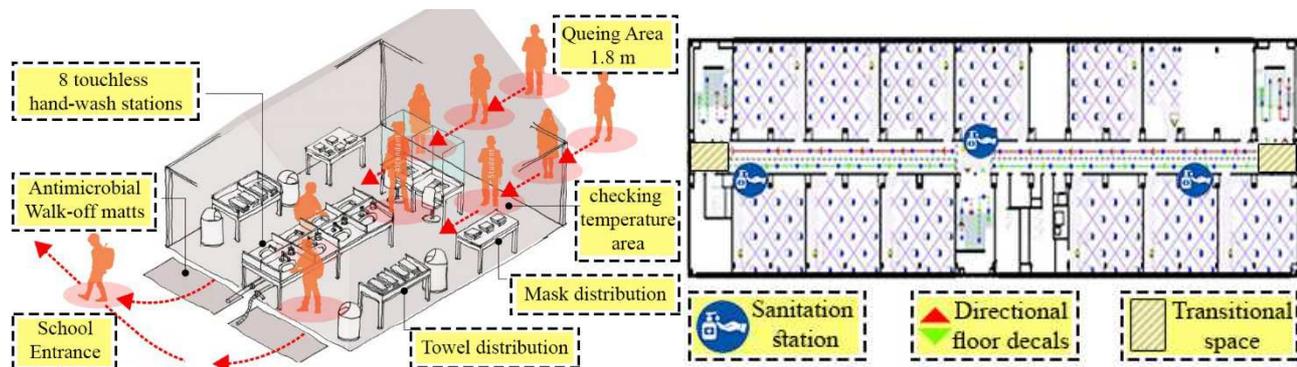
by mapping the floor, and using transparent barriers between washbasins. They additionally maintained social distancing in classrooms by rearranging the furniture in a diagonal pattern to keep a distance of 1.8 meters between students. Besides using one-way circulation in stairways and pathways by using coloured tape on the flooring as shown in Fig. 11 and Fig. 12. (Dubey, 2020).


Fig. 10 (left) : Prefabricated handwashing stations before each entrance of the school, upgraded from (Dubey, 2020). Fig. 11 (right) :Social distancing in classrooms and paths, upgraded from (Dubey, 2020).

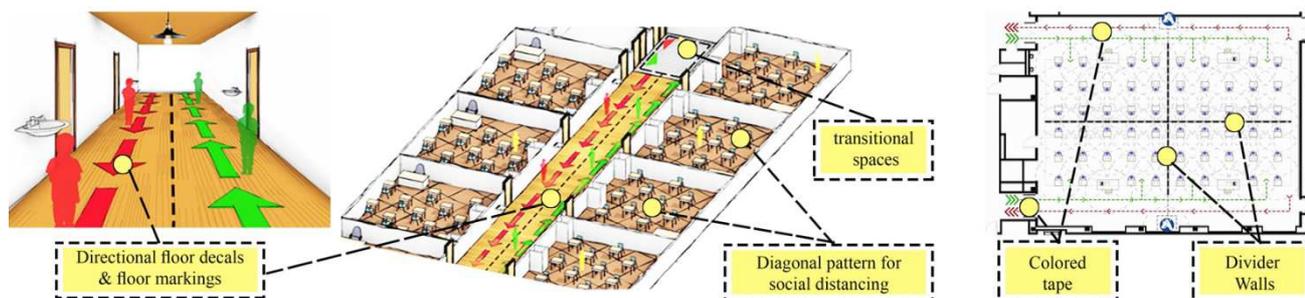
Because classroom sizes are insufficient to accommodate all the students with social distancing at once, one solution was to divide the cafeteria and gym into classrooms, as shown in Fig. 13. Other alternatives included offering an alternate schedule and encouraging hybrid learning to decrease densities. For long-term strategies, Urbahn architects proposed that future classrooms must be widened (AIA, 2020; Dubey, 2020).


Fig. 12 (left) :Social distancing in classrooms and paths. Fig. 13 (right): Dividing gym into four classrooms by using divider walls , upgraded from (Dubey, 2020).

Furthermore, Urbahn suggested improvement of ventilation systems, particularly natural ventilation by using exhaust vents on the roof to speed up airflow and shutting return dampers to avoid air recirculation to decrease infection transmission. As well as utilizing MERV 14, 15, or 16 filters instead of MERV 13 filters and adding UV lamps and portable filtration devices in classrooms (ASHRAE, 2023; Dubey, 2020).

5.2 Brooklyn Laboratory Charter Schools in NY (middle and high school)

This school applied adaptation strategies to face COVID-19 pandemic, so the school collaborated with five design companies, including Gensler, PBDW, PSF Projects, SITU, and WXY, to come up with the best solutions, which were executed in the school. SITU designed a sidewalk with a shed at entrances, as shown in Fig. 14, for sanitizing hands and checking the temperature of students while maintaining social distancing (a minimum 1.8 m distance between students) by mapping the floor. They also proposed increasing entry points and using an alternative schedule. Whereas SITU and PSF suggested adding exterior stairs to the school as an additional vertical circulation to promote social distance, PBDW and Gensler concentrated on promoting social distance inside the classrooms (1.8 m) between students and/or utilizing a transparent barrier between students, as shown in Fig. 15. They additionally enhanced social distancing in circulation by providing one-way circulation in the paths and stairways by using coloured tape, as shown in Fig. 16. Because the classroom area is not big enough to accommodate all students while maintaining social distancing WXY suggested that sidewalks before entrances can be used as outdoor classrooms, as shown in Fig. 17, whereas PBDW proposed designing flexible classrooms with movable acoustic and whiteboard walls to promote extension, in addition to applying staggered schedules for online and hybrid learning.

200

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Further, PBDW emphasized creating hygienic indoor learning environments by increasing airflow through window openings, upgrading HVAC air filters to MERV 13 filters, and keeping humidity levels 40%-60%

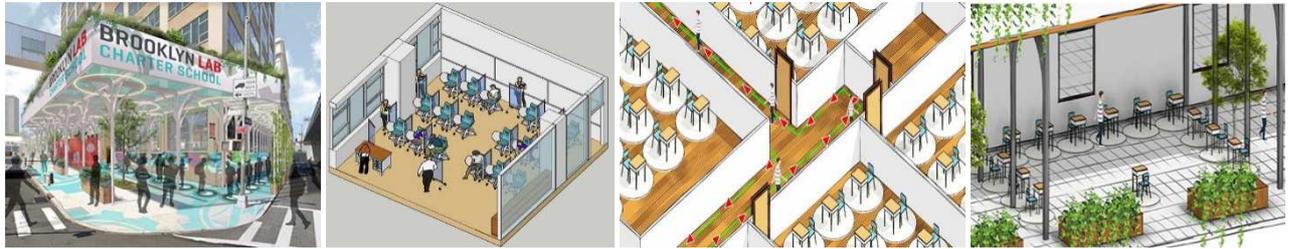
. Additionally, they provided touchless systems by adding foot controls for doors and sensor-operated hands-free technology for valves and flushometers in bathrooms (Brooklyn Lab Charter School, 2020).


Fig. 14 (left): SITU design for the shed before entrance, (Brooklyn Lab Charter School, 2020). Fig. 15: Transparent barrier between students in classroom. Fig. 16: One-way circulation in the paths. Fig. 17(right): The proposed outdoor classrooms.

5.3 Projeto Espaço Educativo 12 Salas –PEE-12 in Brazil (elementary school)

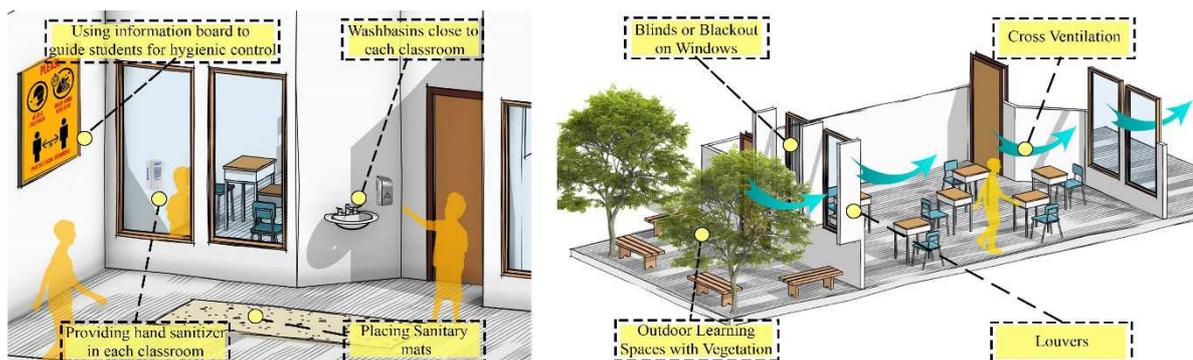
During the COVID-19 pandemic, Furlani and Cardoso architects presented several adaptation solutions for the return to face-to-face classrooms in this standard public school in Brazil. They suggested strategies for hygienic control in schools, including providing sanitizer for the hands in all classrooms, using furniture made of cleanable material, and placing sanitary mats outside the school as shown in Fig. 18 (Fantini et al., 2020). They also recommended improving natural ventilation by providing cross ventilation which is more effective towards infection control than single-sided ventilation. Improving visual comfort was achieved by covering windows with shades to reduce glare, as shown in Fig. 19 (Furlani & Cardoso, 2021).


Fig. 18 (left): Hygienic control techniques in school. Fig. 19 (right):Techniques for better ventilation and lighting in classroom.

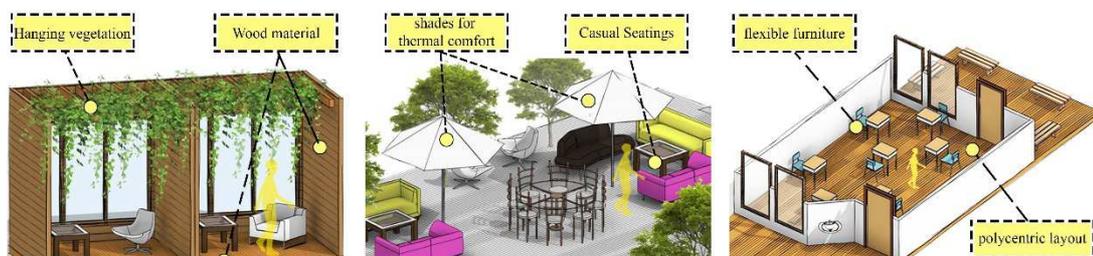
To connect students with nature, they encouraged creating areas in the outside yards that might serve as learning spaces and casual eating areas, as shown in Fig. 20 & Fig. 21. In order to maintain social distancing, they provided a polycentric layout in classrooms with a 2-metre space between student chairs, which can be movable as shown in Fig. 22. They also provided hybrid learning, so they supplied classrooms with technology devices like laptops, PCs, or tablets, projectors, printers, digital whiteboards, etc. Additionally, they provided alternative schedules to reduce traffic between students (Furlani & Cardoso, 2021).


Fig. 20 (left): Outdoor learning spaces. Fig. 21 (middle): Outdoor casual eating area. Fig. 22 (right): Social distancing in classrooms.

6   DISCUSSION AND RESULTS

The comparative analysis reveals three main parameters of healthy learning environments, as shown in Table 1, that made these schools partially able to cope with COVID-19 as much as possible. On the other hand, these schools could not apply all strategies of the three parameters because they were restricted by many

factors related to the existing schools' design, like site location and size, the condition of these schools, and the integration of the schools with surrounding areas. So applying strategies to existing schools will not fit or succeed completely in all the schools because of the restrictions in existing schools. On the other hand, these parameters and their strategies will be effective when considered in designing future learning environments.

| Parameters		public school 138 Samuel Randall in the Bronx	Brooklyn Laboratory Charter Schools in NY	Projeto Espaço Educativo 12 Salas – PEE-12 in Brazil
1. Providing healthy indoor environmental quality	Indoor Air Quality	- Promoting natural ventilation and using running exhaust vents on the roof -Using MERV 14, 15, or 16 filters and adding portable filtration units - Installing UV disinfection lamps -Closing return dampers	- Sanitizing ducts of HVAC - Keeping the humidity (40% - 60 %) -Opening windows to improve ventilation - Upgrading filters into MERV 13 filters -Providing outdoor classrooms and outdoor activity areas	-Promoting cross ventilation by opening the windows on the two sides. - Using the outside yards as outdoor classrooms and outdoor eating areas to increase natural airflow
	Acoustic comfort	....	- Installing speakers on sidewalks that were as outdoor learning spaces	....
	Lighting	....	-Providing natural lighting in outdoor learning spaces by designing the shed with transparent material, also installing artificial lighting to the sidewalk areas	- Using blinds and louvers on windows to avoid glare in classrooms -Providing artificial lighting in outdoor spaces
	Thermal comfort	....	- Designing outdoor sheds at sidewalks areas & outdoor learning spaces	-providing shades for outdoor space - using louvers on classrooms facade
2. Integrating nature with the learning environments		....	-Providing terraces and outdoor spaces to encourage outdoor learning & activities - Using vegetation elements in outdoor areas and terraces.	- Designing classrooms with big windows to provide views to outdoor green areas - Using outdoor areas as learning spaces - Using natural materials such as wood
3. Providing Safe contact in the learning environments	Hygienic Control	- Installing two prefabricated hygienic stations at each entrance - Adding prefabricated wash stations in the hallways and in each classroom - Reusing auditoriums to be isolation rooms	- Creating sidewalk sheds before entrances to be hygienic stations and to check temperature of students before entering schools -Setting up hygienic stations in each classroom.	-Installing information signages to guide students to avoid sharing items and wear masks - Putting washbasins near each classroom, and providing sanitizers in other spaces
	Hygienic Materials	- Adding antimicrobial walk-off mats before school entry	....	-Replacing coatings that are difficult to maintain and clean, in addition to using furniture made of cleanable material - Placing sanitary mats outside the school
	Touchless Systems	- Installing sensor control faucets and liquid soap dispensers in hygienic stations	- Adding foot controls for doors, and sensor-operated hands-free technology for valves and flushometers in bathrooms	....
	In physical learning environments — entrances	- Adding additional entry points in addition to maintaining social distancing in the sidewalk queuing area (1.8m) by mapping the floor	- Increasing entry points - Using an alternative schedule - Adding exterior stairs to the school as an additional vertical circulation	....
	classrooms	- Rearranging the furniture in a diagonal pattern to keep a distance of 1.8 meters between students - Dividing the cafeteria and gym with divider walls to be smaller classrooms -Providing an alternative schedule - In the long-term strategies, classrooms must be bigger in the future	-Promoting social distance (1.8 m) between students by mapping floors - Utilizing a transparent barrier - Holding outdoor classrooms to reduce the density of students - Applying staggered schedules - Designing flexible classrooms with movable walls to promote the extension	- Providing a polycentric layout in classrooms with a 2-meter space between student chairs which can be movable - Using an alternative schedule - Repurposing the outside yards into spaces for informal eating and classrooms
	circulation&spatial organization	-Using one-way circulation in stairways and pathways by using colored tape on the flooring to define circulation patterns	-Providing one-way circulation in the paths and stairways by using colored tape on the floors	....
	In online learning	- Promoting hybrid & Online learning	- Providing hybrid & Online learning	-Providing hybrid learning by supplying classrooms with technology devices like laptops, PCs, tablets, projectors, etc.

Table 1: Comparative analysis between the three examples.

7 FRAMEWORK FOR FUTURE HEALTHY LEARNING ENVIRONMENTS

According to AIA strategies, comparative analysis, and a lot of studies that have been recently done in light of the COVID-19 pandemic, a framework has been reached for designing future learning environments. This framework is generic and does not relate to specific countries (considering Brazil & New York) and provides a lot of detailed strategies to achieve the same parameters, while each future school can apply the appropriate strategies from the framework according to its factors like school location, climate, cost, etc. So the framework isn't prescriptive for schools, but it defines the priorities of strategies according to their importance to make schools healthy. On the other hand, it's very hard to apply this framework to existing schools because of their restrictions, like site planning, existing building conditions, etc. While it will be effective when applied to future schools. The framework provides three parameters that must be promoted in future learning environments: providing healthy indoor environmental quality, integrating nature with the learning environments, and providing safe contact in the learning environments (Table.2). The framework provides a scoring system; Each parameter gets a different percentage according to its importance to make the school healthy and able to cope with pandemics based on the literature review and the WELL rating system for healthy buildings. Each parameter can be prompted by a lot of strategies that have a percentage to achieve the main parameter. Parameter 1 strategies make schools healthy with 45%, Parameter 2 strategies

202

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

make schools healthy with 15%, and Parameter 3 strategies make schools healthy with 40%. The framework will help architects to identify (before construction) if the future school will be able to face pandemics or not by giving it a percentage for each strategy of the proposed design. If the percentage of the school is less than 50%, then additional strategies from the framework can be added to make schools resistant to pandemics.

parameters	Framework for designing healthy learning environments	Detailed Strategies	must be considered before construction	can be applied after construction	percentage to total	percent. to parameter	P1,P2,P3 Percentage
1. providing healthy indoor environmental quality — Indoor air quality — ventilation	Natural ventilation should be merged with mechanical ventilation to limit infection	There are a lot of factors affect on ventilation such as the school site, site planning, the school form, classrooms orientation, site climate,..etc (Hamed, 2021) **In hot climate (as known in Brazil in many regions at many times of the year):** - Depending on natural ventilation than mechanical ventilation by using cross ventilation and openings must be central and big as we can, the outer openings must be larger than the inners. Providing courtyards, atriums,&wind catchers (Zhen et al., 2022)			Natural Ventilation 10%		PAR(3) 40% of total
	1. Natural ventilation : Single sided ventilation will not be preferred **Cross ventilation and stacked ventilation** will be recommended in the future learning environments (Saeed et al., 2021)						
	2. Mechanical ventilation: Mixing Ventilation must be avoided in future schools because it recirculates the air, so it increases the infection transmission. It'll be recommended to depend on the **personalize, stratum, and displacement ventilation** with considering the grills to be linear slots and away from students (Fan et al., 2020)	**In cold climate (as known in New York in many regions at many times of the year):** In cold climates time, there is a challenge to get ventilation VS warmth. These strategies can help (Fan et al., 2020) -Using a combination of natural and mechanical ventilation to provide both warmth and fresh air -Opening windows partially or opening them for a short period of time according to co2 monitoring -Providing windows at different height, so in the extreme weather the upper level windows will provide natural ventilation with thermal comfort			mechanical Ventilation 6%	Total = 54 % of parameter 1	
Humidity & temperature	Humidity must be (40-60%) & the temperature is still 20-28 C (ASHRAE, 2023)	**To increase humidity levels:** Using vegetation and humidifier devices in classrooms, in addition to providing water surfaces and buried water pipes will be effective (Manzano-Agugliaro et al., 2015)			3%		PAR(2) 15% of total
	It can be controlled by controlling it in the HVAC in the mechanical ventilation case						
	It can be controlled by **using passive techniques** according to the climate site and location of school	**To decrease humidity levels (such in Brazil):** Installing double glazing and dehumidifiers devices in classrooms, also improving thermal insulation of building will be necessary (Manzano-Agugliaro et al., 2015)					
Air disinfection	Using filtration and purification technology in schools (Megahed & Ghoneim, 2021)	-Mechanical filtration: such as using MERV 13,14 which can be installed in HVAC, or using HEPA filters which can be installed in HVAC systems or can be a portable device (ASHRAE, 2023) Biofiltration technology: such as using green wall (Megahed & Ghoneim, 2021)			3%		PAR(1) 45% of total
	Filtration technology :by using mechanical filtration or biofiltration technology (ASHRAE, 2023) (Megahed & Ghoneim, 2021)						
	Purification technology can be provided by using Bipolar Ionization technology or UVC Technology (Megahed & Ghoneim, 2021)	-Bipolar Ionization needs a lot of studies in future -UVC Technology : such as UVC lamps which must be installed in the classrooms with high ceiling and it must be pointed upward, or Upper-room UVGI by suspending UCV lamps from a wall or ceiling with 2.6 m heigh (Megahed & Ghoneim, 2021)			2%		
Acoustic comfort	COVID-19 highlighted the necessity of acoustic comfort because masks is a sound barrier .Also social distancing weaken the sound. Also, online & hybrid learning will be essential after COVID-19 pandemic, so providing acoustic comfort will be essential during recording lessons (AIA, 2020)	Considering location of schools, the classroom layout and spatial organisation of spaces (James, 2002)			3%	13% of P1	
		-Using soft resilient floor finishes & absorbent materials such as resilient backed vinyl, resilient feet can be fitted to furniture (James, 2002)			2%		
		-Installing speakers and microphones in the classrooms to reinforce the sound (AIA, 2020)			1%		

parameters	Framework for designing healthy learning environments	Detailed Strategies	must be considered before construction	can be applied after construction	percentage to total	percent. to parameter	P1,P2,P3 Percentage
1. providing healthy indoor environmental quality — Lighting	Daylighting and electrical lighting should be integrated together due to the increased use of technological devices in classrooms (Ochs, 2022) / Sunlight was used to treat microbial infections, so the future classrooms must depend on daylighting to be antivirus places (Megahed & Ghoneim, 2020)	Considering the orientation and ratio of classrooms, shape and orientation of windows, and placement of shading devices by using simulation programs according to site climate. Also providing cut-outs in the school form, increasing the ceiling height for natural lighting, providing blackout shades, especially during the switch-on of projection, and providing light shelves if needed (Autodesk Education Community, 2018b)	●		5%	15% of P1	
	Artificial lighting doesn't limit infection transmission, but it'll be very essential with the increased technology devices after COVID-19 (Ochs, 2022)	Considering the type of lighting fixtures, their illumination, and the distribution of it. For added flexibility, using dimming and sensor controls will be effective, artificial lighting will be more important especially in cloudy weather (Pelet et al., 2015)	●	●	2%		
Thermal Comfort	Humidity became (40-60%) instead of (20-80%) and the temperature is still 20-28 C (ASHRAE, 2023)	Using flexible solutions such as thermal mass, providing movable façade with suitable shading devices, using suitable trees around classrooms, using BPS Simulations,..etc (Fan et al., 2020)	●	●	3%	18% of P1	PAR (3) 40% of total
	humidity control ways have been mentioned, to control temperature there are two ways: (ASHRAE, 2023) / Temperature can be controlled by controlling it in HVAC systems in the mechanical ventilation case / Temperature can be controlled by using passive techniques in the natural ventilation case / Considering orientation of classrooms, site climate, form of schools buildings and the surroundings (ASHRAE, 2023)	In hot climate (as known in Brazil in many regions at many times of the year): Providing big windows, courtyards, atriums, & wind catchers for ventilation. Also using double glazing, louvers, double skin, thicker walls, overhangs & shading of the glazed openings, providing green roofs, and using light reflective paint (Manzano-Agugliaro et al., 2015) / In cold climate (as known in New York in many regions at many times of the year): using thicker wall, atriums, suitable shading and overheads, designing windows with different levels and sizes to provide natural ventilation with warmth in cold climates (Manzano-Agugliaro et al., 2015)	●		5%		PAR (2) 15% of total
2. Integrating nature with the learning environments — Direct experience with nature	It must be provided in future schools if possible because it influences students' health and can also limit infection transmission (Jones et al., 2020)	-By providing planting elements in classrooms such as green walls, .etc or/& Enabling views to outdoor landscape by glass of windows as possible according to the climate in school (Almusaed et al., 2022)	●	●	4%	67 % of Parameter 2	
	Visual connection with nature which can be inside or outside classroom / Providing outdoor classrooms / Considering the location, orientation of it and environmental factors in the site - Considering the outdoor classroom relation with surroundings in site and the size of site - Considering providing infrastructure and being near to utilities like toilets and hand sanitizers,..etc. - Providing clear accessibility by clear paths and doors from each classroom -Considering alternative schedule and capacity of outdoor classrooms -Providing wind control devices source (NAAEE, 2020)	In extreme climates such as heavy winters or extreme heat, these strategies will be suitable : -Using rolling garage- style doors or movable facade in classrooms to enable the indoor and outdoor to be one space for thermal comfort -Providing shades, tree canopies, and shelters -Using movable shading to open in extreme weather for thermal comfort and close in nice weather - Physical& online classrooms will be more suitable / In hot climate (as known in Brazil in many regions at many times of the year): Providing cooling devices, Providing enclosed outdoor spaces like courtyards or recessed for shading for protection from heat / In a cold climate (as known in New York in many regions at many times of the year): Providing heater devices, Providing Artificial lighting in cloudy weather, and Providing semi-closed or semi-pened outdoor spaces for protection from rain source (NAAEE, 2020)	●		6%		PAR (1) 45% of total
In-Direct experience with nature	It has an effect on mental health, but it doesn't control infection transmission, so it must be merged with the direct experience it can be suitable more in schools which can't provide direct experience techniques according to the extreme climate there (Roös, 2021)	It'll be preferred to use natural colors to help students feel calm, for example, using blues, light browns, greens, and avoiding red and orange	●	●	1%	33% of P2	
	Natural color	It will be preferred to use wood in chairs, desks, flooring, and walls because not only it is a natural material, but it's also a hygienic material	●	●	2%		
	Natural material	Natural features such as plants, water, etc. through using paintings, photographs, sculptures, etc	●	●	1%		
	Image of nature / Natural shapes and forms	It should be inspired by nature, such as the shapes of plants, waves, mountains etc., as patterns on an exterior façade or a column, such as tree columns source (Roös, 2021)	●		1%

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Table 2: Framework for designing future learning environments.

8 CHECKLIST FOR DESIGNING FUTURE LEARNING ENVIRONMENTS THAT WILL BE CONSTRUCTED POST COVID-19

Table 3 provides checklist for designing future learning environments to make them resistant to pandemics.

Classrooms	
☐ Installing signs for prevention measures.	☐ Providing classrooms with technological devices such as laptops, projectors, cameras, speakers, etc. for hybrid and online learning.
☐ Mapping floors to delineate one-way walking paths and furniture locations.	
☐ Designing classrooms with flexible walls or partitions. ☐ Using movable furniture.	☐ Creating touchless handwashing hygiene stations in or adjacent to the classroom or sanitizing station(s).
☐ Considering the finishing materials to be a hygienic material like antibacterial paint, wooden and vinyl coverings, nanomaterial, etc.	☐ hexagon layout of the classroom If it's possible, this shape will be suitable based on the shape of the virus head biologically.
	☐ Expanding the size of classrooms than in current schools.
Acoustic comfort	
☐ Considering being away from sources of noise such as mechanical rooms, etc.	☐ Using touchless systems to open doors and windows as much as possible, if it isn't possible, using mechanical push by arm or foot to open them, or if it isn't possible, using copper in door and window handles and elevator buttons will be effective.
☐ Considering the layout and geometry of the classroom, and avoid using domes or barrel vaults in the classroom section, also avoid using a curved wall in opposition to a flat wall.	
☐ Enhancing acoustic treatment in classrooms by using absorbent materials if it's needed.	**Engaging classrooms with nature**
☐ Installing microphones and speakers.	☐ providing planting elements in classrooms.
	☐ Using natural and organic shapes in furniture if it's impossible according to learning styles.
Providing suitable ventilation	☐ Providing natural features and natural colors.
☐ Considering the site climate, location of classroom, and the wing walls placement by using simulation programs.	☐ Using natural materials that can be antibacterial ☐ Enabling views to outdoor landscape through as many windows as possible according to the climate in school.
☐ Installing CO2 monitoring.	
☐ Considering the form of the school, the height of the classrooms, and the roof shape of them.	☐ Each classroom should have a door for entry and another for accessibility to outdoor classrooms if the climate is suitable for outdoor classrooms, as we will mention in the checklist.
☐ Considering the orientation of the classroom according to the climate and the style of learning, it's generally recommended to have a northern orientation.	**Providing thermal comfort (20-28 C) & (40-60%) humidity**
☐ Providing windows at different heights, so in extreme weather, the upper-level windows will provide natural ventilation with thermal comfort.	☐ Considering the orientation of classrooms & site climate.
☐ Using suitable mechanical ventilation like POV, Stratum, PEV, Displacement ventilation, Mixing ventilation must be avoided.	☐ Using movable façade with suitable louvers
In hot climate, for example (**as known in Brazil in many regions at many times of the year**):	☐ Using suitable trees and considering thermal mass
☐ Using cross ventilation. Openings must be as central and big as possible .The outer openings must be larger than the inners.	☐ Using Building Performance Simulations (BPS)
☐ Providing courtyards, atriums, & wind catchers	☐ Using suitable HVAC systems
☐ Using single sided ventilation with improving by splitting the opening into two by using wings wall , using fans, and providing transom window above the door if the cross ventilation is impossible to be achieved.	In hot climate, for example (**as known in Brazil in many regions at many times of the year**): ☐ Providing big windows, courtyards, atriums, and wind catchers for providing cross ventilation. ☐ Using double glazing, louvers, double skin, thicker walls, overhangs, and shading of the glazed openings. ☐ Providing green roofs and light reflective paint. ☐ The humidity in Brazil is more than 60%,, so using a dehumidifier in classrooms will be effective.
In cold climate, for example (**as known in New York in many regions at many times of the year**):	In cold climate, for example (**as known in New York in many regions at many times of the year**): ☐ Using thicker walls, atriums, and suitable shading ☐ Designing windows with different levels and sizes to provide natural ventilation with warmth in cold climates.
☐ Using a combination of natural and mechanical ventilation to provide both warmth and fresh air.	
☐ One way is to partially open windows or to open them for a short period of time, according to CO2 monitoring.	
☐ Opening higher-up windows during heavy rain.	**Lighting comfort**
	☐ Considering the orientation and the classroom ratio, also the shape and orientation of windows and shading device placement by using simulation programs ☐ Providing cut-outs in the school form if it is possible.
Using filtration and purification technology in classrooms	☐ Providing blackout shades, especially during projection.
☐ Using green walls or planting filters.	☐ Increasing the ceiling height for natural lighting.
☐ Installing UVC lamps or UVGI at high levels.	☐ Considering artificial lighting using sensors
☐ Using MERV 13,14 or/ and HEBA.	

outdoor classrooms	Site

☐Considering the location of it to be in quiet spaces, well connected to classrooms to enable teachers to monitor students, and not in dark or corner places for student safety. ☐ Considering the climate in the schools and whether it's possible to provide outdoor classrooms or not in schools. ☐ Considering outdoor classrooms orientation and relation of them with the surroundings on site and the site size. ☐ Considering providing infrastructure and being near utilities like toilets and hand sanitizer. ☐Providing Clear accessibility by providing clear paths and doors from each classroom and making them well defined. ☐Providing wind control devices in outdoor classrooms. ☐Designing them with buffer space around them for movement. ☐Considering the alternative schedule and capacity of it. ☐Considering designing soft and hard landscape elements.	☐Considering the location of the school's site to be away from noisy. ☐Providing multiple points for entry and exits. ☐Having enough space before each entrance to have a waiting area before the entrance for checking the temperature of students and providing hygienic stations. ☐Considering the site size and site planning to enable it to extend to future needs and to provide outdoor classrooms, playgrounds, and classrooms in suitable spaces. ☐Considering providing separate parking circulation away from students. ☐Considering staggered times for entry if it is needed. ☐Considering spacing buildings' schools by a distance of at least 5 times the height of schools to provide natural ventilation ☐Considering the placement and types of vegetation and trees on the site.
In extreme climates, such as heavy winters or extreme heat	**Services and additional spaces**
☐**physical and online classrooms will be more suitable** ☐Using rolling garage- style doors or movable facade in classrooms to enable the indoor and outdoor spaces to be one space for thermal comfort. ☐Using movable shading to open in extreme weather for thermal comfort and close in nice weather. In hot climate, for example (**as known in Brazil in many regions at many times of the year**): ☐Providing cooling devices in hot regions. ☐considering drainage and protection from landslides. ☐Providing enclosed outdoor spaces like courtyards or recessed for shading for protection from heat. In cold climate, for example (**as known in New York in many regions at many times of the year**): ☐Providing heater devices in cold regions. ☐Providing Artificial lighting in cloudy weather. ☐Providing semi-closed or semi-open outdoor spaces for protection from rain.	**General notes** ☐Using touchless systems to open doors and windows as much as possible, if it isn't possible, providing mechanical push by arm or foot to open them, or if it isn't possible, using copper in door and window handles will be effective. ☐Considering the finishing material to be hygienic material like using antibacterial paint, nano coating materials, etc. ☐Using touch-free faucets, sinks, soap dispensers,etc. ☐Mapping the floor of the cafeteria, gym, and other service spaces to define the circulation path as one-way. **New additional spaces should be considered in schools** ☐Providing isolation rooms for infected students with negative pressure, separated entry and exit, and a separate toilet. Also, it should be located on an exterior wall. ☐Providing recording rooms with technological devices for recording lessons in hybrid and online learning. **Bathrooms** ☐Providing toilets with side exhaust fans. ☐providing enclosed bathroom stalls. ☐Cleaning automation in bathrooms will now be a priority. ☐Using cleaning robots and self-cleaning devices with touch-free faucets, sinks, soap dispensers,etc.
Circulation and Spatial organizations	**Cafeteria, gym, and other services spaces**
☐Breaking down the school into separate zones, and classrooms can be grouped around common services. ☐Avoiding pinch points. ☐Providing one-way circulation in corridors and stairs. ☐Mapping the floor to define the circulation paths. ☐Eexpanding the width of corridors than in current schools. ☐Providing single-loaded corridors if possible for ventilation if it'll be suitable according to the climate. ☐Considering cutouts in a building's form by classroom organization for daylighting if it will be suitable with climate.	☐Considering acoustics, lighting, thermal comfort, ventilation, air filtration, and engaging spaces with nature as mentioned in the checklist of classrooms. ☐Installing signs for prevention measures. ☐Providing entry and exit for the large service spaces. ☐Providing hygienic stations in each space. ☐Using flexible furniture in cafeterias, gyms, etc.

Table 3: Checklist for designing future learning environments, Author based on the previous framework sources.

9 CONCLUSION

COVID-19 has highlighted the lack of health in our learning environments, so the parameters for designing learning environments must be updated in the future to provide healthy learning environments. The parameters that must be provided in future learning environments to make them able to face any pandemic or crisis are: providing healthy indoor environmental quality (by promoting indoor air quality, acoustic, lighting, and thermal comfort); integrating nature with the learning environments (by providing natural views, outdoor classrooms, etc.); and providing safe contact in the learning environments(by providing hygienic stations, hygienic materials, touchless systems, and making the learning environment flexible to extend or be able to maintain social distancing in case there is any pandemic).

Diagnose Digital Skills Gap between Professional and Academic Sectors in Architecture Discipline – Jordan Case Study

Anwaar Banisalman, Ibrahim Marouf, Ali Abou Ghanimeh, Amira Fathi

(Arch. Anwaar Banisalman, Alexandria University, Faculty of Engineering, Alexandria, Egypt, anwar.salman@alexu.edu.eg)
(Prof. Dr. Ibrahim Marouf, Alexandria University, Alexandria, Egypt, ibrahim.maarouf@alexu.edu.eg)
(Prof. Dr. Ali Abou Ghanimeh, University of Jordan, ghanimeh@ju.edu.jo)
(Dr. Amira Fathi, Alexandria University, Alexandria, Egypt, arch.amira.aboelnasr@alexu.edu.eg)

1 ABSTRACT

There are many studies on digitization. The newly graduated engineer has a way of thinking, currency, and outlook on engineering work. Research on the ability of universities to graduate qualified architects for the professional market has become necessary to bring about changes in teaching methods and link them to digital programs. This paper looks at if there is a consensus between the opinion of professionals and academics about digital skills, trying to integrate urgent digital skills needed by the labor market in the Architecture education study plans.

Mixed between quantitative and qualitative research methods, researchers analyze the study plan of 12 universities, using the Curriculum Content Mapping)CMM(method, and conduct a questionnaire for academics and professionals. Accordingly, we prove the gap between the profession and the academic world in the discipline, and there is no agreement between them about the digital programs needed. Then researchers provide a matrix expressing the relationship between the digital courses and the AE courses in a way to connect the two.

Keywords: Study plan, Factor Analysis, Digital Architecture, Curriculum Mapping Method CMM, Architecture Engineering Education(AE)

2 INTRODUCTION

The study plans are linked to a set of competencies, transferring them to students to prepare competent engineers who can meet the needs of the labor market, and the most important of these competencies is the ability to work on digital programs, starting from thinking of the idea until preparing plans and then implementation. Researchers note that there is a gap between what architectural universities teach in Jordanian universities and the need for the labor market due to the tendency of many students to take reinforcement courses to improve their chances of obtaining a job.

2.1 Research Hypothesis:

There is a difference between the programs taught in universities and those needed by the professional market.

2.2 Methodology

This research used mixed techniques (quantitative and qualitative research methods). Firstly, to prove the gap quantitative method was used, depending on CMM; It is a technique used to explore how architectural knowledge is to be taught together with skills in curriculums, depending on the competency concept. (The Organisation for Economic Co-operation and Development, 2020)

(maart, Frantz, & Mphil, 2021) Use curriculum mapping to demonstrate the alignment of an undergraduate dental curriculum with a competency framework, and curriculum mapping revealed areas for improvement or gaps in the UWC dentistry curriculum's Afro MEDS competencies.

(Alshanqiti, Benaida, Alam, and Namoun, 2020) use the same method as a two-dimensional matrix expressing the relationship between the student's learning outcomes and the courses.

Secondly, to create the digital -course's network, researchers distributed questionnaire forms to professionals and academic architects and then analyzed the result using factor analysis and Cohen's weighted kappa in SPSS.

2.3 Goals and objectives

(1) The research aims to prove the existence of a difference between what architectural universities teach in the study plans in the field of architecture and the need of the labor market, especially technical programs.

(2) It also aims to provide a realistic touch of emergent programs in the era of digitization.

(3) Develop a network of relationships between teaching courses and digital programs that enhances the student's digital and architectural efficiency.

3 LITERATURE

3.1 Architecture Discipline in Jordan

According to JEA (Jordanian Engineers Association, 2021), unemployed engineers increased to 34% in 2021; Architects registered at JEA equal to 9% of the total engineers, while 38% of architects are unemployed, table 1.

Discipline	Total engineers that Able to work	A worker at offices and companies	Work outside the country	Un employee	Un employee percentage
Civil engineers	46265	21630	8750	15885	34 %
Architecture engineers	14436	6326	2559	5551	38 %
Mechanical engineers	31968	15952	6453	9563	30 %
Electrical engineers	57534	27540	11141	17955	31 %
Mining	1149	870	120	159	14 %
chemical	8284	4640	1877	1767	21 %
total	159636	76958	30900	50880	32%

Table 1: Unemployment rate in each engineering section. Source: JEA (Jordanian Engineers Association, 2021).

Graduated students mainly work in the following sectors: Private practices, large construction companies, the public sector, large industry organizations, or in the academic sector. The engineering sector was counting on job opportunities outside Jordan, but these opportunities seem to diminish over time (see Table 2). In the same manner, there is an increase in obtaining professional degrees between 2014-2020, as shown by Table 3.

YEAR	2012	2013	2014	2015	2016	2017	2018	2019	2020
Local Opportunities	1515	1809	1679	1888	1597	1320	685	1489	438
International Opportunities	1201	2399	4941	6209	2187	587	451	566	173
Total	2716	4208	6620	8097	3784	1907	1136	2055	611

Table 2: Job opportunities by JEA 2012-2020, 2020. Source: (Jordan Engineers Association, 2020).

	2014	2015	2016	2017	2018	2019	2020	TOTAL
Civil	1	22	61	59	64	90	64	361
Architecture	4	24	14	16	19	16	13	106
Mechanical	43	47	42	31	70	55	29	317
Electrical	24	50	37	30	85	61	42	329
Mining	----	---	10	1	3	6	1	21
Chimical	---	5	11	2	17	9	14	58
TOTAL	72	148	175	139	258	237	163	1192

Table 3: Engineers with professional degrees 2014-2020. Source: (Jordan Engineers Association, 2020).

The number of engineers working in engineering offices was (7971) in 2020, (5063) in design, (and 2908) in supervision. On the other hand, (8003) engineers worked in 2019, (5004) in design, and (2999) in site supervision, with a drop ratio were (0.4%).

3.2 Digital Skills in the Professional Market

(Khodeir & Nessim, 2020) evaluated the level of importance of the graduate skills, they found that responsibility, positive attitude, and researchers rate teamwork as the top. However, (Salleh, Md Yousof, & Momon, 2016) in their research highlighted that the quality of graduates evaluated through technical and non-technical skills. Employers in the professional world usually seek other skills apart from the technical skills gained during undergraduate studies in architecture schools. Correspondingly, there is a high demand for architects with the skills to manage real projects. Those skills are not limited to planning and designing but also include diverse employability skills, including critical thinking, teamwork, leadership, and

210

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

negotiation. Also, (Khodeir & Nessim, 2020) evaluated the importance of graduate skills; they found that responsibility, positive attitude, and teamwork skills were at the top.

Figure :1 advertisements examples for demand skills in Jordan professional market, source: architects of Amman-facebook group.

3.3 Digital Skills in Architecture Education

The standard architectural curriculum incorporated design studio as the center subject; the teaching happens within the studio, and the other basic abilities are design theory, history, visual communication, and representation, building innovation. The researchers divided the educational environment into two main titles: "distance education" and "formal education." Formal education environments are varied, such as classrooms, workstations (cluster, group), and one-by-one interactive and educational tools, such as traditional and digital tools. (Yıldırım, Yavuz, & Kırcı, Experience of traditional teaching methods in architectural design, 2012),researchers illustrate that teachers manage design studios in both a "teacher-oriented" and "student-oriented" manner in terms of the method.

Moving toward new teaching methods in the architectural design studio is a need as (Ciravoğlu, 2014) and (Walter & Rangaswamy, 2014) mentioned: "By bringing technology into the classroom and by doing complex and realistic problems, we can make our classes livelier and relevant." (Saghafi, Mozaffar, Moosavi, & Fathi, 2015)

Mention two techniques in architecture teaching which are the teaching method with the creation of the Design Studio and the free-Hand Drawing Teaching Method as insured by (Tepavčević, 2017), "rethinking of models for design-led research provides a new framework for design pedagogy that responds to technological shifts and new design thinking."

Rivka Oxman (2006), in her paper "Theory and Design in the first digital age," proposed a theory of digital design that tried to map the different levels of interaction of the user with digital media and integration of the computer into the design. Oxman identified four components of digital design - representation, generation, evaluation, and performance - specified performance (Oxman, 2006).

4 FINDING AND DISCUSSION

Digital technology changed the way we teach and learn architecture, even digital design courses or standalone courses. Digital technology, such as the virtual design studio, many architectural schools introduce a new method of teaching architectural design. Focusing on the fact that computerized design education plays a significant part in tomorrow's architectural education, the curriculum developer can create computerized substance into a platform in the modern architectural curriculum.

By Analyzing Jordan universities' study plans researcher aims to know the standing-alone computerized courses, and digital design courses in Jordanian education as shown in Table 4.

4.1 Curriculum Content Mapping (CCM) Results

	Name of Universities	Credit hours	Computerized courses		Digital design courses	
			CREDIT HOURS	PERCENTAGE	CREDIT HOURS	PERCENTAGE
1	University of Jordan	178	10	5.6%	3	0.01%
2	Hashemite University	172	10	5.8%	0	0 %
3	AlbalqaApplied University	166	10	6%	0	0 %

4	Philadelphia University at Jordan	165	10	6%	3	0.01%
5	AlAl-Bayt University	165	9	5.4%	0	0 %
6	Muta University	172	14	8%	0	0 %
7	Al Ahliyya Amman University	165	11	6.6%	0	0 %
8	Zarqa University	167	12	7.1%	0	0 %
9	Amman Arab University	169	7	4%	0	0%
10	Al Isra Private University Amman	169	10	5%	0	0 %
11	Al Ahliyya Amman University	165	11	6%	0	0%
12	Al Yarmouk university	167	6	3.5	0	0%

Table 4: Credit hours and computerized courses in the study plan at the sampling universities. Source: Researchers.

(5.4 -8 %) the study plan in AE are separate courses that teach computer science as stand-alone courses; (BIM,2DCAD,3D CAD, C++, GIS), and there are no digital courses except in two universities, the University of Jordan and Philadelphia University.

Those numbers do not mean that universities do not use several programs in the educational process. However, they use them in a non-programmed way that differs from one teacher to another according to the instructor's efficiency.

4.2 Questionnaire Results

The researchers sent the statistical survey digitally to 32 professional and 16 curriculum developers; the survey consisted of three items, and the value of Cronbach's alpha for the survey α= 0.9, as shown in Table 5.

Ratings	Weighted Kappa	Asymptotic Std. Error	z^c	Sig.	95% Asymptotic Confidence Interval Lower Bound	Upper Bound
academic - professional	-.061	.073	-.713	.476	-.205	.083

Table 5: Cohen's Weighted Kappa using SPSS.Source: Researchers.

In general, by asking professionals and academics to rank the programs, we found that:

To professionals, REVIT is the most important, then Sketch up, Photoshop, 3DMAX, GIS, GRASSHOPPER, and finally, the least important are BIM and RYNO, but in the academic sector CAD is the most important program, as is 3DMAX, and finally REVIT. By asking about essential programs according to job requirements, we found that: Private architects, Large construction companies, Public sector bodies, Academic sector differ in their needs, as Table 6 shows.

On average private architects prefer 3DMAX, BIM, GRASSHOPPER, AND RYNO. Large construction companies need GIS,3DMAX, GRASSHOPPER, and RYNO. Public sector-governmental: prefer GIS. The academic sector emphasizes CAD and REVIT.

Competence	Role	Private architect practices	Large construction companies	Public sector bodies	Academic sector
Media and Visualization skills	BIM	3	4	4	1
	CAD	4	3	4	4
	GIS	2	2	3	3
	3DMAX	3	2	2	2
	REVIT	4	4	4	4
	GRASSHOPPER	3	2	2	2
	RYNO	2	2	2	3
	PHOTOSHOP	3	3	4	3
	Average rank	3	2	3	4

Table 6 categorizes the digital program by job role. Source: Researchers.

The researchers found no consensus between the academic and professional points of view about the digital programs needed; this ensures the gap between the professional and academic sectors.

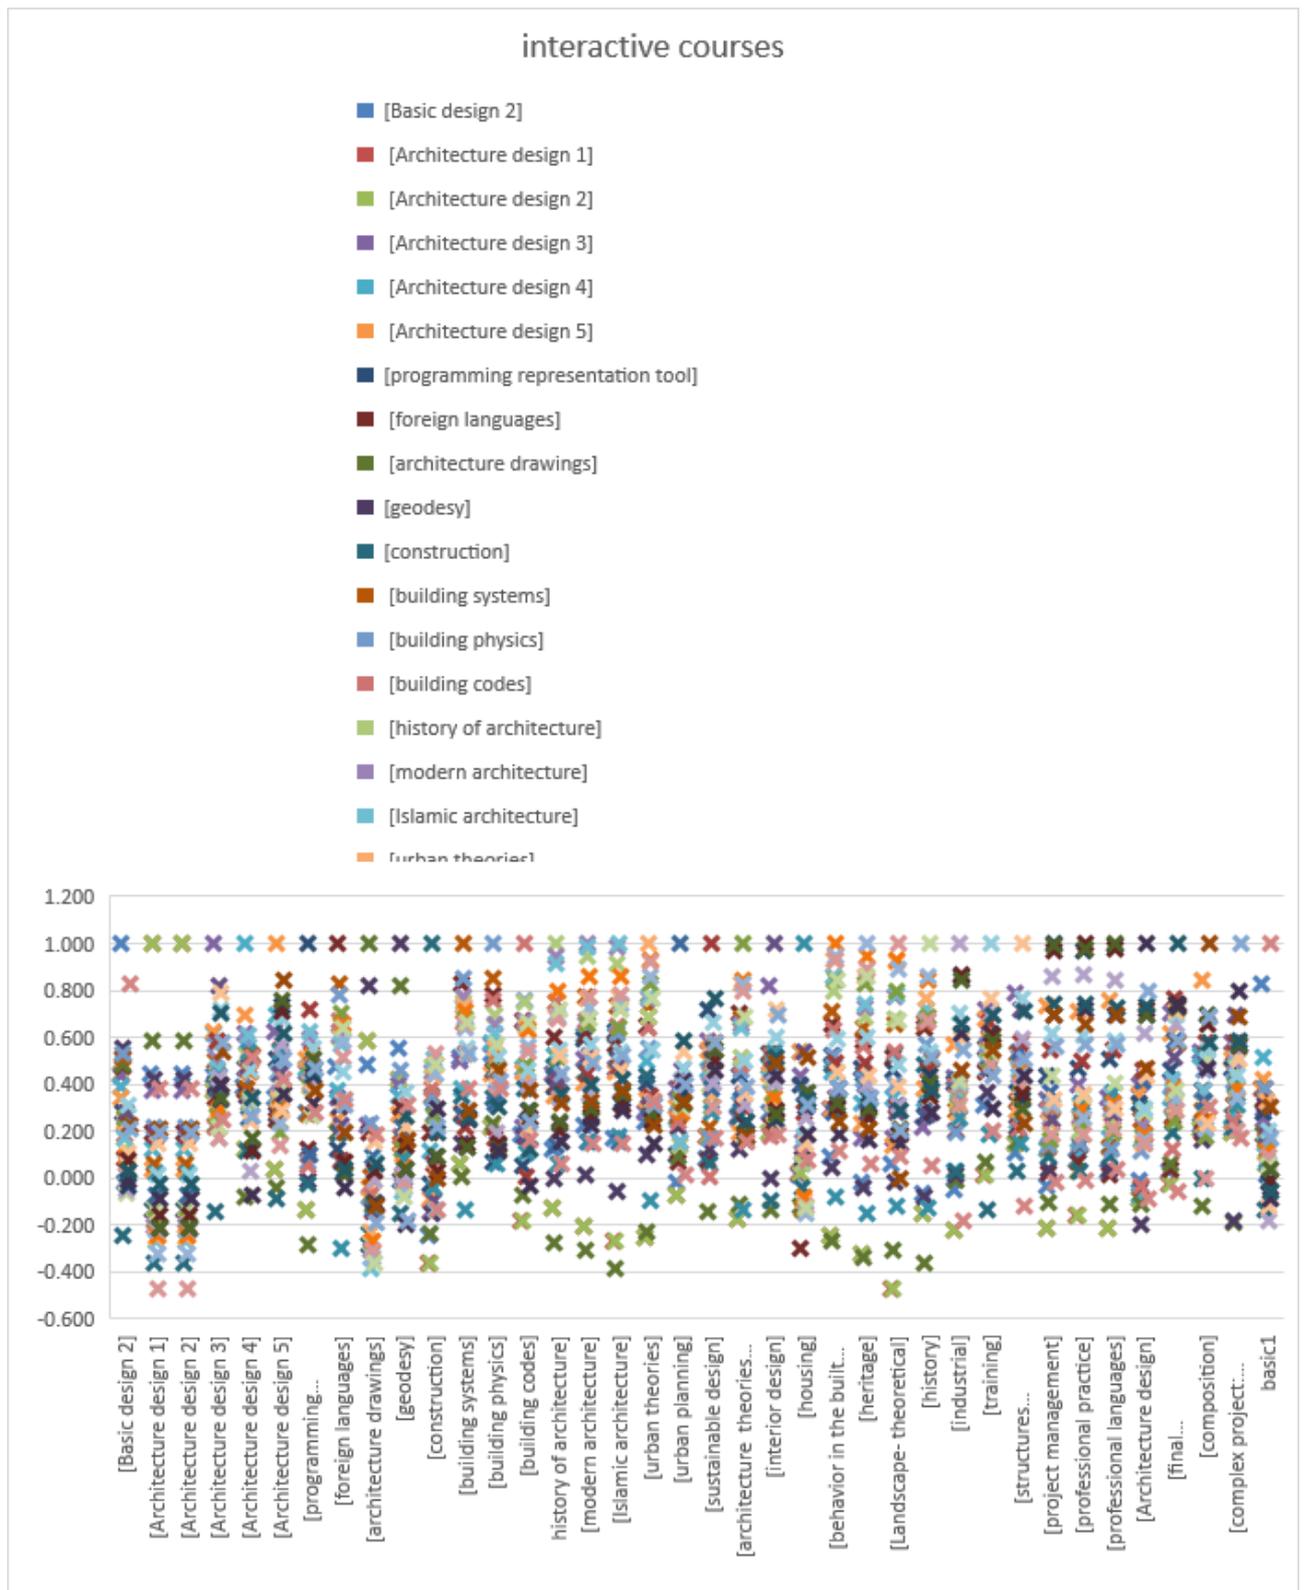
By asking to interrelate digital programs into courses: Academic architects arrange digital programs integrated into curriculum courses. Also, professionals give their views, and then the researcher conducts factor analysis using SPSS to discover the pattern of digital programs and explore how it interacts with other courses. Researchers conclude the following model,figure 2.


Figure (2): Horizontal and vertical relations between courses group. Source: Researchers.,using factor analysis in SPSS

The researchers noted from tables 7-12 that the participants suggested the link between electronic programmes in the educational process at different levels. However, most agreed that cad and sketch can integrate with all courses; it is appropriate to filter which programmes are more useful and include them in the study plans. The multiplicity of programmes may be helpful to be in harmony with the labour market's needs and the times requirements, where decision makers form a flexible framework for digital competencies.

5 CONCLUSIONS

(1) Researchers expect that the findings and discussion help AE programs evaluate their current study plans for Jordanian universities, as we conclude:

(2) There needs to be a consensus between the academic and professional points of view about the digital programmes needed that ensure the gap between the two.

(3) Emphasize using digital tools in architectural courses.

(4) It is necessary to study and develop study plans from time to time to achieve a higher level of the graduated architect who can work and keep pace with changes in the era of digitization.

(5) During curriculum development, it is essential to consider the stakeholder's views.

(6) There is a must to integrate courses with digital programs to enhance professional skills.

(7) Some digital programs are emerging according to the era's demand, and curriculum developers must consider them in AE study plans, such as BIM, RYNO, and GRASSHOPPER.

(8) The job market in Jordan needs trained workers who graduate from educational institutions and who need more advanced technology produced by educational institutions and for research that leads to increased production and improvement of its quality

(9) Teachers must integrate digital educational software, interactive learning, virtual schooling, and online education to simulate the learning process.

(10) The framework that AE schools require expands on the Core Curriculum while incorporating new components like Mandatory Competencies and Career Role Levels.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

(11) Researchers ensure the importance of reconsidering the engineering programs that are taught based on the needs of the practice market. Moreover, specify the most critical programs that new engineers should master.

One of the study outputs is a contextual framework that aims to provide a theoretical basis from which to understand and empirically establish a common language for describing domain-specific epistemic beliefs in architecture education to globalize the plan of work, figure (3) take the following actions:

Demand analysis:

(1) To specify emerging architect characteristics and skills from a professional point of view.

Supply analysis:

Analyses the current curriculums based on selected competence models or accreditation board standards.

To extract specifications that form the study plan guidelines from the stakeholder's point of view.

1 ABSTRACT

Die anthropogene Aufhellung des Nachthimmels durch künstliche Beleuchtung hat in den letzten Jahren stetig zugenommen. Straßenlaternen, Flutlichtanlagen, Skybeamer und Bodenstrahler erhellen mehr oder weniger große Flächen, die eigentlich nicht beleuchtet werden sollten. Dieses Phänomen wird als Lichtverschmutzung oder Lichtsmog bezeichnet. Überall verdrängt anthropogenes Licht die natürliche Dunkelheit, nicht ohne Folgen für die menschliche Gesundheit. Aber auch aus ökonomischer Sicht sind die Folgen der Lichtverschmutzung für Städte und Gemeinden eine nicht zu vernachlässigende Aufgabe.

Es ist festzustellen, dass ein ineffizient gesteuerter Einsatz von künstlichem Licht, gleich welcher Art, eine enorme Energieverschwendung darstellt. Für das langfristige Erreichen der gesteckten Klimaschutzziele, wie z. B. die Einsparung von CO_2-Emissionen, ist der unkontrollierte und ungesteuerte Einsatz von anthropogenem Licht kontraproduktiv. Die daraus resultierenden volkswirtschaftlichen Auswirkungen auf den Energieverbrauch unserer Städte und Gemeinden sind nicht zu vernachlässigen. Inzwischen hat das Phänomen der Lichtverschmutzung den Charakter einer „schädlichen Umwelteinwirkung" im Sinne des Bundes-Immissionsschutzgesetzes. Damit existiert ein konkretes System zur Bewertung der Auswirkungen von Lichtimmissionen auf den Menschen und die natürlichen Lebensgrundlagen.

Nutzungspotentiale von Licht können sich aus anthropogenen Lichtquellen ergeben, wenn diese z. B. touristisch vermarktet werden, architektonische Stimmungslagen hervorheben oder das individuelle Sicherheitsempfinden durch beleuchtete öffentliche Plätze und Straßen erhöht wird. Im kommunalen Bereich ergeben sich daraus Zusammenhänge, die für die Themen „Lichtverschmutzung" und „Sternenparks" von Bedeutung sein können. Öffentliche Beleuchtung emittiert Licht. Hier ist zu klären, wo es ankommt und welche Bedeutung dies für den jeweiligen Raum hat. Daraus ergeben sich finanzielle Aspekte, die eng mit dem Thema „Lichtverschmutzung" verbunden sind. Ineffiziente Lichtquellen einfach abzuschalten ist jedoch keine Option. Gefragt sind informelle Lösungen und ein innovatives Management des anthropogenen Lichtbedarfs, wie es beispielsweise durch die Einrichtung von „Sternenparks" bereits praktiziert wird. Durch den aktiven Schutz natürlicher Nachtlandschaften ergeben sich positive Nebeneffekte, da nicht nur Energie, sondern auch monetäre Mittel eingespart werden.

Bei dem Versuch einer theoretischen Einordnung von „Sternenparks" als informelles und kommunales Steuerungselement für den Natur- und Freiraumschutz lässt sich die aktuelle klimapolitische und umweltpolitische Diskussion als übergeordnete Struktur sehr gut heranziehen. Der Lichtverschmutzung wird in diesem komplexen Wirkungsgefüge auf den ersten Blick keine entscheidende Rolle zugeschrieben. Es lassen sich jedoch sozioökonomische und sozioökologische Zusammenhänge herstellen, deren Bedeutung für die angesprochenen Teilbereiche erstaunlich ist. Die „Sternenparks" können als ein Element betrachtet werden, das diese negativen Entwicklungen zwar nicht vollständig umkehrt, aber einen wichtigen Beitrag zum Natur- und Freiraumschutz leistet, indem sie sich für den Schutz der natürlichen Nachtlandschaften einsetzen.

Das Projekt soll einen Beitrag zur informellen Regionalentwicklung leisten und innovative Impulse für eine breite Vernetzung und einen Informationsaustausch der Akteure geben. Das Format des „Sternenparks" als informelles Steuerungselement für den Natur- und Freiraumschutz wird herausgearbeitet und als Grundlage für ein nachhaltiges Konzept einer ökonomisch und ökologisch orientierten Lichtkultur genutzt. Ebenso soll durch eine gezielte Analyse untersucht werden, wie einzelne Regionen dieses informelle Instrument für Natur- und Freiraumschutzmaßnahmen nutzen, um z. B. die öffentliche Straßenbeleuchtung ökologisch und vor allem ökonomisch umzurüsten.

Keywords: Naturschutz, Sternenparks, Treibhausgasreduktion, Klimaschutzmaßnahmen, Lichtverschmutzung

2 EINLEITUNG

Der Sternenhimmel ist ein faszinierendes Naturschauspiel, das viele Dichter und Denker inspiriert hat. Lange vor der Erfindung der Glühbirne wurden die Gedanken, die der nächtliche Sternenhimmel auslöste, in zahlreichen literarischen Werken festgehalten.

Diese Schlüsselerfindung, die Glühlampe, war Licht und Schatten zugleich. Während sie Generationen die Möglichkeit zu nahezu unbegrenzter Produktivität bot, galt sie mit ihrem erhellenden Licht in vielen Bereichen der Kulturgeschichte als Symbol für Fortschritt und Wohlstand (Porsch et al. 2013).

Die Menschen der Moderne leben in einer erleuchteten Welt, doch rückblickend muss man feststellen, dass dieser beeindruckende Meilenstein des Erfindergeistes auch der Ursprung der heutigen Lichtverschmutzung ist.

Die anthropogene Aufhellung des Nachthimmels durch künstliche Beleuchtung hat in den letzten Jahren weltweit stetig zugenommen. Neben den vielen positiven Wirkungen des Lichts wird in letzter Zeit immer deutlicher, dass Licht auch negative Seiten hat.

Anthropogene Beleuchtung überlagert nicht nur das natürliche Licht der Himmelskörper, sondern hat auch negative Auswirkungen auf natürliche Nachtlandschaften mit ihrer Tier- und Pflanzenwelt.

In letzter Zeit werden die negativen Auswirkungen auf den Menschen immer deutlicher, denn als eher tagaktive Lebewesen ist es uns von der Natur vorgegeben, nachts zur Ruhe zu kommen und zu schlafen. Jeder weiß aber aus eigener Erfahrung, dass der Schlaf selbst sehr unterschiedlich sein kann. Viele wichtige Körperprozesse laufen nachts ab, es gibt also eine Art „Nachtschicht" im und für den Körper (Natur, 2016). Nur wer tief und fest schläft, fühlt sich wirklich erholt. Doch für viele Menschen ist das nur ein Traum, der immer seltener in Erfüllung geht. Überall vertreibt das anthropogen hervorgerufene Licht die natürliche Dunkelheit, nicht ohne Konsequenz für die Gesundheit des Menschen. Unser Schlaf-Wach-Verhalten wird nicht einfach durch den Wechsel von Hell und Dunkel beeinflusst, oder völlig bewusst durch den Menschen gesteuert, sondern unterliegt dem strengen Diktat einer inneren Uhr, die endogen und autonom für die Steuerung der Zirkadian-Rhythmik verantwortlich ist (Wissen, 2023). Diese Rhythmik hat sich im Laufe der Evolutionsgeschichte weiterentwickelt, mit dem Ziel, den natürlichen Übergang zwischen Hell und Dunkel zu antizipieren, um physiologische und biochemische Prozesse unseres Körpers optimal auf die Rotation abzustimmen.

3 LICHTVERSCHMUTZUNG – WAS IST DAS?

Es ist unbestritten, dass der Mensch heute einen erheblichen Anteil am Ende der Nacht hat. Verantwortlich dafür ist das Phänomen der Lichtverschmutzung. Der Begriff Lichtverschmutzung beschreibt das Phänomen der Aufhellung des Nachthimmels über besiedelten Gebieten durch physikalische Brechungseffekte in der Atmosphäre. Sie breitet sich, wie bereits beschrieben, weltweit aus und hat den Charakter einer „schädlichen Umwelteinwirkung" im Sinne des deutschen Bundes-Immissionsschutzgesetzes (BImSchG). Auch Licht zählt rechtlich zu den Emissionen im Sinne des BImSchG. Mit der Verabschiedung der „Licht-Richtlinie" im Mai 1993 existiert ein konkretes System zur Bewertung der Auswirkungen von Lichtimmissionen auf den Menschen und zur Konkretisierung des Begriffs „schädliche Umwelteinwirkung" im Sinne des BImSchG (BImSchG, 2021).

Durch Reflexionen an Schwebeteilchen in der Atmosphäre kommt es zu einer Streuung des Lichts, die dann die künstliche Aufhellung des Nachthimmels, auch „Skyglow" genannt, „begünstigt" (LRC, 2023). Beispielsweise erhellt das Licht einer konventionellen Straßenbeleuchtung nicht nur die zu beleuchtende Fläche, sondern auch weite Teile der unmittelbar angrenzenden Objekte, bis hin zur unsystematischen Aufhellung des natürlichen Sternenhimmels.

Streng genommen ist der Begriff Lichtverschmutzung eine irreführende Wortbildung, da der englische Begriff „light pollution" wörtlich übersetzt „verschmutztes Licht" bedeutet (Darksky, 2023). Die Quelle der Verschmutzung ist jedoch das Licht selbst, das in die Umgebung abgestrahlt wird. Hierbei handelt es sich um die Verschmutzung der Umwelt durch ein Übermaß an künstlichem Licht unterschiedlicher Intensität, das durch den Menschen verursacht wird.

Vor allem nachtaktive Tiere wie Fledermäuse sind von diesen anthropogenen Störungen ihrer Umwelt besonders betroffen (Svensson, 1998). Beobachtungen haben gezeigt, dass Fledermäuse aufgrund der Lichtverschmutzung ihr Jagdverhalten geändert haben. Unter anderem können sie ihre Quartiere erst später verlassen, da es draußen durch die künstliche Beleuchtung heller ist. Das verkürzt die Zeit der Nahrungssuche und hat langfristige Folgen für die Entwicklung der Tiere und ihrer Nachkommen (Frank & Schmidt, 2015). In einigen Regionen Deutschlands geht das so weit, dass ganze Generationen durch Lichtverschmutzung gefährdet sind. Lichtverschmutzung wirkt sich auch auf die Beutetiere der Fledermäuse aus, denn auch nachtaktive Insekten sind von Lichtverschmutzung betroffen.

Der so genannte „Staubsaugereffekt" an starken Beleuchtungskörpern ist vielen Menschen heute kein unbekanntes Bild mehr (s. Abb. 1)

Abb. 1: Exemplarische Darstellung des „Staubsaugereffektes" (Quelle: WDR, 2023).

4 AUSGANGSSITUATION

Um sich das Phänomen der Dunkelverschmutzung – besser bekannt unter dem aus dem Englischen abgeleiteten Begriff „light pollution" „Lichtverschmutzung" – vorzustellen, legt Abbildung 2 exemplarisch Nachtaufnahmen dar, die vom Luitpoldturm beim Hermersbergerhof (Rheinland-Pfalz, Deutschland) aufgenommen wurden. Mitten im Pfälzerwald gelegen, bietet er einen 360°-Rundblick auf die Umgebung. Während der Himmel über dem Turm noch sternenklar ist, zeigt sich am Horizont der Regionen um Mannheim, Karlsruhe und Straßburg in der Rheinebene sowie Pirmasens und Kaiserslautern in der Pfalz deutlich eine künstliche Aufhellung des Nachthimmels. Mehrere Lichtglocken sind zu sehen, die durch ihre Leuchtkraft die einzelnen Regionen nachts über weite Strecken gut sichtbar machen. Die Lichtsäule bei Ramstein sticht hier deutlich hervor, da durch die besondere technische Anordnung der Leuchten eine massive Aufhellung des Nachthimmels erreicht wird.

Abb. 2: Nachtblick vom Luitpoldturm; ISO:1600, Belichtungszeit: 30 Sekunden, Brennweite: 50mm; eigene Aufnahme.

Am Flughafen der Air Base Ramstein sind die Scheinwerfer unterhalb der Spiegel angebracht. Diese werfen das Licht nach oben, von wo es wieder nach unten reflektiert wird und so die Start- und Landebahn und den „Taxiway" beleuchtet. Bei diesem Vorgang ist jedoch gut zu erkennen, dass sehr viel Licht nach oben in den natürlichen Nachthimmel abgestrahlt wird und diesen fast vollständig erhellt. Diese Beispiele sind jedoch keine Einzelfälle, denn die Aufhellung des Nachthimmels hat in den letzten Jahrzehnten kontinuierlich zugenommen. In einigen europäischen Ländern geht man von einer jährlichen Zunahme der Lichtverschmutzung von bis zu 5 % aus (Porsch et al., 2013).

Diese Zunahme lässt sich durch eine Kombination aus einer steigenden Anzahl von Beleuchtungskörpern und steigender Lichtausbeute der einzelnen Lampen erklären, die in der Regel auch mit einer Zunahme der suburbanen Lichtglocken einhergeht.

Doch woher kommt diese Lichtverschmutzung? Die Langzeitaufnahme einer mit Bodenstrahlern beleuchteten Kirche in Fischbach bei Dahn um 02:00 Uhr nachts zeigt deutlich, dass nur ein kleiner Teil des Lichts den Kirchturm erreicht, der größte Teil aber weit in den Himmel strahlt. Hier wird nicht auf die richtige Helligkeit, Intensität und Dauer des Lichteinsatzes geachtet. Es werden Bereiche beleuchtet, die gar nicht beleuchtet werden müssen. Wenn das Licht nicht gebündelt nach unten oder am Ziel vorbei in den Nachthimmel strahlt, wird es in der Atmosphäre gestreut. Dies führt zu einer Aufhellung des Himmels, die sich wie ein Schleier über den natürlichen Nachthimmel legt. Dadurch werden lichtschwächere Himmelskörper überstrahlt und verdeckt (Händel, 2014; s. Abb. 3).

Abb. 3: Exemplarisches Beispiel der Lichtverschmutzung durch eine nicht zielgerechte Beleuchtung einer Kirche in Fischbach bei Dahn (Quelle: Hänel, 2014).

Einfache Methoden, die Lichtverschmutzung zu reduzieren, sind zum einen eine genauere Ausrichtung des Scheinwerfers, eine Abschirmung zur Vermeidung von Streulicht oder die Montage des Scheinwerfers am Mast, so dass er nach unten strahlt. Zum anderen sollte aber auch überlegt werden, ob die Beleuchtung an dieser Stelle und zu dieser Zeit überhaupt noch notwendig ist, denn eine komplette Abschaltung kann neben dem Schutz der Umwelt auch Strom und Geld sparen.

Nicht nur die Beleuchtung von Gebäuden, sondern auch die normale Straßenbeleuchtung trägt zur Lichtverschmutzung bei. Wie bei der Gebäudebeleuchtung ist auch hier die Ausrichtung entscheidend – auch hier gibt es zahlreiche negative und positive Beispiele der Straßenbeleuchtung. Hierbei wird deutlich, dass Leuchten, die nicht oder nur teilweise nach oben abgeschirmt sind, ein Problem darstellen, da sie den Himmel übermäßig aufhellen.

Wie bei der Gebäudebeleuchtung sollte auch hier über die Lebensdauer nachgedacht und neue Technologien wie Bewegungsmelder in Betracht gezogen werden. Da insbesondere der Großteil der funktionalen Beleuchtung in deutschen, aber auch in europäischen Städten und Gemeinden im Allgemeinen noch aus den 1960er und 1970er Jahren stammt, sind in Ballungsräumen und über Großstädten sehr intensiv strahlende Lichtglocken zu beobachten. Zum Zeitpunkt der Errichtung dieser Beleuchtungen spielten der Umweltschutz und die gezielte Anstrahlung von Objekten eine sehr untergeordnete Rolle. Ziel war es in erster Linie, gut ausgeleuchtete Straßenräume zu schaffen. Hohe Lichtemissionen gehen auch von Flughäfen, Bahnhöfen, Flutlichtanlagen auf Sportplätzen, großen Parkplätzen oder Industrieanlagen aus. All diese Elemente kommen in Ballungsräumen zusammen, was die starke Aufhellung des Himmels in der Umgebung dieser Räume erklärt.

Die für den Menschen sichtbarste Auswirkung der Lichtverschmutzung ist der Verlust des Sternenhimmels über den Städten. Von etwa 3.000 mit bloßem Auge sichtbaren Himmelsobjekten sind über Großstädten

teilweise weniger als 100 sichtbar (Welt der Physik, 2023), was vor allem für die Astronomie ein großes Problem darstellt. Zumindest jedoch viel gravierender sind die Folgen für Flora und Fauna (s. dazu Kap. 3).

5 STAND DER FORSCHUNG

Eine Organisation, die sich für den Schutz der Nacht einsetzt, ist die International Dark Sky Association (IDA). Sie wurde 1988 in den USA als Vereinigung von Astronomen mit dem Ziel gegründet, die Lichtverschmutzung durch den Einsatz vollständig abgeschirmter Beleuchtungssysteme zu reduzieren (Darksky, 2023). Die IDA hat Partnerorganisationen in anderen Ländern und ist die Dachorganisation weiterer nationaler Vereinigungen. Sie zeichnet international Gebiete aus, in denen die Verantwortlichen einen wichtigen Beitrag zum Schutz der natürlichen Dunkelheit leisten. Damit will sie die Bevölkerung und die Öffentlichkeit für das Thema sensibilisieren. Ausgezeichnet werden "*Dark Sky Parks*", "*Dark Sky Reserves*", "*Dark Sky Communities*", "*Dark Sky Sanctuaries*", "*Urban Night Sky Places*" sowie "*Dark Sky Developments of Distinction*" (Darksky, 2023). Solche Sternenparks und Sternenreservate dienen in erster Linie dem Umweltschutz und der Erhaltung des Nachthimmels. Auch in Deutschland gibt es zwei solcher Schutzgebiete - im Westhavelland und in der Rhön. Sternenparks nutzen zusätzlich die touristische Attraktivität der besonderen Lage, während Sternenreservate noch strengere Regelungen zum Schutz von Flora und Fauna in Form von nächtlichen Beleuchtungsvorschriften haben und zudem deutlich größer sind als ein Dark Sky Park.

Dark Sky Communities sind von der IDA ausgezeichnete Städte, die sich besonders für den Schutz des Nachthimmels einsetzen und sich dem Problem der Lichtverschmutzung aktiv annehmen.

Das Biosphärenreservat Pfälzerwald wurde dahingehend untersucht, ob die notwendigen Voraussetzungen für eine Eignung als Dark Sky Park gegeben sind. Dazu wurden zunächst geeignete Mess- und Beobachtungsstandorte gesucht, die einen ausreichend großen Himmelsausschnitt zeigen. Dies erwies sich im dicht bewaldeten Pfälzerwald als besonders schwierig. Die von IDA geforderte Mindestanzahl von zwölf Standorten wurde jedoch ohne Probleme erreicht. Die Eignung der Flächen wurde durch eine Tagesbegehung festgestellt, bevor die Flächenhelligkeit (angegeben in mag arcsec⁻²) nachts vor Ort gemessen wurde. Der von der IDA festgelegte Mindestwert von 20,00 wurde meist erreicht, ebenso Werte über 21,00 (IDA, 2015). Zum Vergleich: Der dunkelste Ort Deutschlands im Westhavelland hat eine Flächenhelligkeit von 21,78. Eine Besonderheit ist, dass die Messungen in der Nähe der Sommersonnenwende durchgeführt wurden. Zu dieser Zeit werden die Nächte von Tag zu Tag kürzer und kurz vor der Wende sinkt die Sonne nicht mehr vollständig unter den Horizont.

Der zweite wichtige Faktor neben den natürlichen Bedingungen ist die Beteiligung der Öffentlichkeit und der Entscheidungsträger. In den IDA-Rahmenbedingungen für Sternenparks ist festgelegt, dass die Gemeinden bestimmte Anforderungen an die Beleuchtung erfüllen müssen. So muss z.B. die gesamte Straßenbeleuchtung innerhalb eines bestimmten Zeitraums an diese Richtlinien angepasst werden.

Es zeigte sich, dass die meisten der untersuchten Gebiete aufgrund ihrer örtlichen Gegebenheiten als Dark Sky Park geeignet sind. Diese Annahme wurde durch ausreichende bis gute Messergebnisse bestätigt. Das Monitoring dieser Gebiete wird derzeit fortgesetzt, um Veränderungen detailliert zu dokumentieren. Gleiches gilt für die Sensibilisierung der Gemeindeverantwortlichen und der Bevölkerung für das Thema Lichtverschmutzung. Denn ineffiziente Lichtquellen einfach abzuschalten, ist für Kommunen schon aus Sicherheitsgründen oft keine Option.. Gefragt sind vielmehr praktische Lösungen und ein innovatives Management des anthropogenen Lichtbedarfs, wie es beispielsweise durch die Einrichtung von Sternenparks bereits umgesetzt wird. Durch den aktiven Schutz natürlicher Nachtlandschaften ergeben sich positive Nebeneffekte, da nicht nur Energie, sondern auch monetäre Mittel eingespart werden.

6 THEORETISCHE HERLEITUNG DER PROBLEMSTELLUNG

Bei dem Versuch einer theoretischen Einordnung von Sternenparks als nachhaltiges informelles und kommunales Steuerungselement für den Natur- und Freiraumschutz kann die aktuelle klima- und umweltpolitische Diskussion sehr gut als übergeordneter Rahmen herangezogen werden. Der Lichtverschmutzung wird in diesem komplexen Wirkungsgefüge auf den ersten Blick keine entscheidende Rolle zugeschrieben. Es lassen sich jedoch sozioökonomische und sozioökologische Zusammenhänge herstellen, deren Bedeutung für die angesprochenen Teilbereiche verblüffend ist. Sternenparks können als ein Element angesehen werden, das die angesprochenen negativen Entwicklungen der unnatürlichen

Aufhellung des urbanen Raumes zwar nicht gänzlich umkehrt, aber in seinem Bemühen um den Schutz natürlicher Nachtlandschaften einen elementaren Beitrag zu einem nachhaltigen Natur- und Freiraumschutz leistet.

7 ZIELSETZUNG UND METHODIK

Die Ursachen der Lichtverschmutzung lassen sich klar benennen. Vor allem die ineffizient geschalteten Beleuchtungssysteme der Kommunen sind für die zunehmende Verschmutzung durch künstliches Licht verantwortlich. Ein Ziel der aktuellen Forschungsarbeit ist es, Sternenparks empirisch zu untersuchen und durch eine gezielte Analyse miteinander zu vergleichen. Der Vergleich soll Aufschluss darüber geben, ob Sternenparks als nachhaltiges informelles und kommunales Steuerungselement für den Natur- und Freiraumschutz in Deutschland und Europa in Frage kommen. Dies soll anhand konkreter Fallbeispiele geschehen. Die Fallbeispiele sollen Aufschluss darüber geben, wie detailliert die Projekte der Sternenparks gerade zu den Themen Lichtverschmutzung, Natur- und Freiraumschutz umgesetzt werden und welche Planungskultur darüber hinaus in den einzelnen Ländern gelebt wird. Die Forschungsarbeit soll damit einen Beitrag zur informellen Regionalentwicklung leisten und innovative Impulse für eine breite Vernetzung und einen Informationsaustausch der Akteure geben. Das Format des Sternenparks als informelles Steuerungselement für den Natur- und Freiraumschutz wird herausgearbeitet und als Grundlage für ein nachhaltiges Konzept einer ökonomisch und ökologisch orientierten Lichtkultur herangezogen. Ebenso soll durch eine gezielte Analyse untersucht werden, wie einzelne Regionen dieses informelle Instrument für Natur- und Freiraumschutzmaßnahmen nutzen, um z.B. die kommunale Straßenbeleuchtung ökonomisch und vor allem ökologisch umzurüsten oder ehemals genutzte Flächen zu rekultivieren, um der Natur wieder Ansiedlungsmöglichkeiten zu geben. Die Ergebnisse sollen am Ende der Forschungsarbeit durch erarbeitete Handlungsempfehlungen ergänzt werden, die für die Arbeit in den Sternenparks in den nächsten 10 bis 15 Jahren hilfreich sein können.

Im Rahmen des Projektes werden verschiedene Kategorien von Sternenparks, vor allem in Deutschland und Europa, aber auch einige ausgewählte internationale „Dark Sky Parks", die von der „International Dark Sky Association" anerkannt sind, identifiziert, beschrieben und bewertet. Darüber hinaus sollen aus der Analyse der unterschiedlichen Parkkonzepte (DSP, DSC, DSR; s. Kap. 5) Handlungsempfehlungen für die Praxis abgeleitet werden.

In diesem Zusammenhang ist es auch notwendig, die unterschiedlichen Planungssysteme und Planungskulturen der jeweiligen Länder, in denen sich die potentiell zu untersuchenden Sternenparks befinden, miteinander zu vergleichen. Es soll dargestellt werden, wie in den einzelnen Ländern die Planung speziell für den Bereich der Sternenparks zielgerichtet durchgeführt wird. Denn planungskulturelle Unterschiede ergeben sich vor allem aus den rechtlichen Rahmenbedingungen des jeweiligen Landes und den unterschiedlichen raumstrukturellen Gegebenheiten der jeweiligen Regionen. Der Schwerpunkt des Vergleichs, die spezifische planerische Identität, soll auf den Ländern der untersuchten Sternenparks liegen.

8 ERSTE ERKENNTNISSE

Die Einrichtung eines Sternenparks als informelles Steuerungselement für den Natur- und Freiraumschutz im Biosphärenreservat Pfälzerwald wäre theoretisch möglich. Die praktische Umsetzung ist jedoch mit erheblichem Aufwand verbunden, da viele Kommunen bereits vor einigen Jahren ihre kommunale Straßenbeleuchtung auf LED umgestellt haben, allerdings mit Leuchten, die eine Etablierung erschweren. Diese entsprechen in der Regel nicht den Anforderungen der IDA. Eine weitere Umstellung wird daher in den nächsten Jahren nicht ohne enormen finanziellen Aufwand möglich sein. Auch die Akzeptanz in der Bevölkerung wird kaum vorhanden sein, da diese den derzeitigen Bestand bereits durch Steuerbeiträge mitfinanziert hat. Dennoch sollten gerade diese Leuchten langfristig durch nachtsichttaugliche Beleuchtungssysteme ersetzt werden.

Es gibt jedoch Orte, an denen eine ökologisch und ökonomisch sinnvolle Umrüstung auf LED durchgeführt werden kann. Diese Orte sollen identifiziert und die Bevölkerung durch Fachvorträge über die Möglichkeiten einer sternenparkfreundlichen Umrüstung der Beleuchtung informiert werden. Nahegelegene Freiflächen, die eine Mindestgröße (etwa die Größe eines Fußballfeldes) aufweisen, werden anhand eines standardisierten Formulars nach den geforderten Kriterien auf ihre Eignung untersucht. Auf diese Weise können alle in Frage kommenden Flächen miteinander verglichen werden. Um eine zusammenfassende und objektive Aussage

treffen zu können, ist die Vergleichbarkeit der Datensätze von elementarer Bedeutung. Dementsprechend wurden im Projekt verschiedene Ansätze gebündelt und für alle vereinheitlicht.

Als Beispiel wird hier die Gemeinde Horbach (Pfalz) im Landkreis Südwestpfalz (Rheinland-Pfalz) betrachtet. Der Ort liegt am Übergang des Pfälzerwaldes zur Sickinger Höhe am westlichen Rand des Biosphärenreservats Pfälzerwald. Die Gemeinde ist derzeit dabei, die gesamte veraltete Straßenbeleuchtung planerisch umzustellen. Dieser Prozess soll aufgegriffen werden, jedoch nicht nur aus rein wirtschaftlichem Interesse, sondern vielmehr unter dem innovativen Aspekt des Einsatzes einer ökologisch modernisierten, „sternengemeindetauglichen" LED-Umstellung.

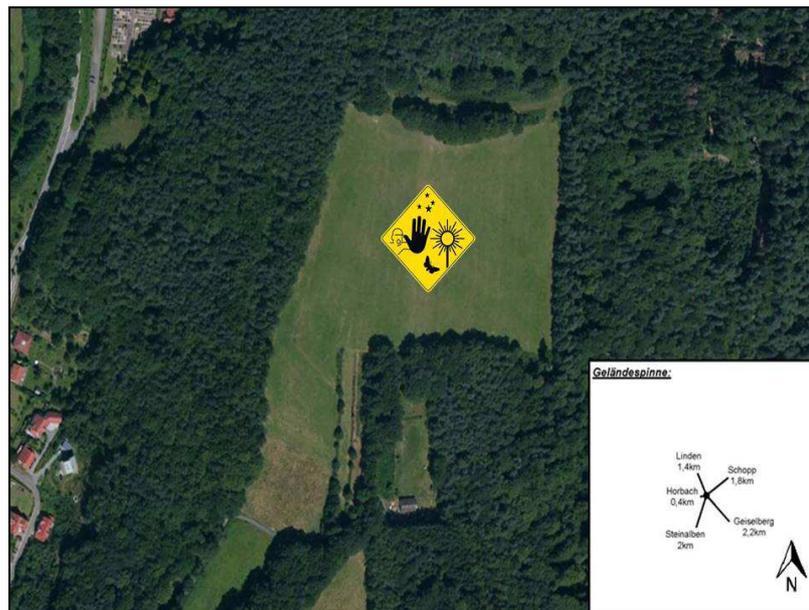
Im Zuge einer Ortsbegehung wurde eine potentielle Fläche zur Ausweisung als „Sternenbeobachtungsfläche" identifiziert. Sollte die Umrüstung nun erfolgen und der Antrag auf Anerkennung als „Dark Sky Community" durch die IDA erfolgreich sein, könnte hier bald ein Lichtschutzgebiet ausgewiesen werden, in dem ein aktiver Beitrag zum Natur- und Freiraumschutz geleistet werden kann (s. Abb. 4).


Abb. 4: Untersuchungsfläche in Horbach/ Pfalz (Quelle: Eigene Darstellung nach Google.de/maps, 2023).

Die Hürden der IDA sind mittlerweile sehr hoch. Es wird den Regionen sehr viel schwerer gemacht, eine entsprechende Anerkennung zu erhalten. Dennoch gibt es regionale Ideen zur Reduzierung von Lichtemissionen. Generell sollte jede Art von anthropogener Beleuchtung in dunklen Gebieten vermieden werden. Hier zeigt sich, dass es in den verschiedenen Regionen auch eigene, sehr heterogene Ansätze gibt. Eine Vielzahl unterschiedlicher Richtlinien und Vorgaben zur Erlangung der Zertifizierung als „Nachtfreundliche Gemeinde oder Region" sorgt für viel Verwirrung. So gibt es beispielsweise im Untersuchungsgebiet des Biosphärenreservats Pfälzerwald das Zertifikat „Gemeinde unter den Sternen" - unterteilt in die Kategorien Bronze, Silber und Gold (Pfälzerwald, 2023). Die Voraussetzungen für ein solches Zertifikat sind im Vergleich zu IDA weniger anspruchsvoll, dennoch gibt es derzeit nur eine „Gemeinde unter den Sternen" mit dem Status Silber - Rumbach. In der Gemeinde gibt es zwei Plätze, die zum Sternengucken einladen und somit im Zuge der Forschungsarbeit in den Fokus des aktiven Natur- und Freiraumschutzes gerückt sind.

Eine weitere Erkenntnis der Sternenparks bzw. des Forschungsprojektes zum Schutz der natürlichen Nacht ist die Multifunktionalität der natürlichen Dunkelheit. Die Interessen der vielen verschiedenen Akteure an der Reduzierung der Lichtverschmutzung und der Wiederherstellung bzw. Erhaltung der natürlichen Nachtlandschaft sind sehr unterschiedlich. Astronomen wünschen sich eine gute Sicht auf den Sternenhimmel, Umwelt- und Naturschützer versuchen, lichtempfindliche Tier- und Pflanzenarten vor anthropogenen Lichtquellen zu schützen, während Touristen Übernachtungsplätze mit möglichst geringem Lichteinfall suchen, um einen gesunden Schlaf und die Erholung des Körpers zu fördern. Unter Berücksichtigung dieser unterschiedlichen Interessen würde sich die Lage eines „Lichtschutzgebietes" von Fall zu Fall sehr unterschiedlich darstellen.

Im Idealfall überschneiden sich die Interessen der verschiedenen Akteure auf ein und derselben Fläche. So ist eine Fläche mit guter Sicht nach Süden für Astronomen zur Beobachtung des Sternenhimmels geeignet und gleichzeitig aus ökologischer Sicht eine Fläche, die vor Lichtverschmutzung geschützt werden muss.

9 FAZIT

Das Ausmaß der Umweltbelastung durch anthropogene Lichtemissionen wird durch eine Reihe schädlicher Umwelteinflüsse bestimmt. Lichtverschmutzung hat dabei einen starken Einfluss auf die Entwicklung von Fauna und Flora sowie auf die menschliche Gesundheit. Die bisherigen Erkenntnisse zeigen, dass es kumulative Zusammenhänge gibt, die sich in unterschiedlichem Ausmaß direkt auf einzelne Bereiche oder komplex auf mehrere Bereiche auswirken können. Die Tatsache, dass Licht in der modernen Architektur auch ein gestalterisches Element ist, wird bei der Betrachtung des Themas berücksichtigt. Der architekturgestalterische Aspekt des Lichts wird von Kommunen nicht nur touristisch genutzt, um Sehenswürdigkeiten marketingtechnisch ins „rechte" Licht zu rücken, sondern spielt auch für das individuelle Sicherheitsempfinden der Bevölkerung und die Ausleuchtung öffentlicher Plätze und Räume eine zentrale Rolle. Hier kann ein Ansatzpunkt für den Natur- und Freiraumschutz liegen, denn das vorhandene Potenzial sollte von den Kommunen bewusst gesteuert und genutzt werden.

Die derzeit angespannte finanzielle Situation vieler Kommunen erlaubt eine intensive Auseinandersetzung mit dem Thema „Sternenpark" und eine damit verbundene kontinuierliche planerische Bearbeitung. Der aktuelle russische Angriffskrieg veranlasst viele Kommunen, ihre noch aus den 60er und 70er Jahren stammende Straßenbeleuchtung zu überdenken und eine rasche Umrüstung auf LED vorzunehmen - einerseits aus rein wirtschaftlichen Gründen, andererseits aber auch mit dem positiven Nebeneffekt der Reduzierung der Lichtverschmutzung.

Die Sensibilisierung der breiten Öffentlichkeit für das Thema Lichtverschmutzung und den ressourcenschonenden Umgang mit Energie und natürlicher Dunkelheit wurde vor einigen Jahren noch mühsam durch Vorträge versucht. Durch die aufkommende Problematik der Energiekrise rücken die oben genannten Themen immer mehr in den Fokus, so dass u.a. Kommunen in Zukunft nicht mehr umhinkommen werden, den Energieverbrauch zu reduzieren. Denn ein wenig Verzicht wäre in vielen Bereichen gar nicht so schwer, da der Großteil der Bevölkerung diese Einschränkung gar nicht wahrnehmen würde, sondern sie einfach ignoriert.

Digitales Parken der Zukunft – Planungen zu einem Reallabor auf dem Campus der Universität der Bundeswehr München

Tobias Wiemers, Frederik Gügel, Markus Holzmair

(Dipl.-Ing. Tobias Wiemers, Universität der Bundeswehr München, Werner-Heisenberg-Weg 39, 85577 Neubiberg, tobias.wiemers@unibw.de)

(M.Sc. Frederik Gügel, Universität der Bundeswehr München, Werner-Heisenberg-Weg 39, 85577 Neubiberg, frederik.guegel@unibw.del)

(Dipl.-Ing. Markus Holzmair, Universität der Bundeswehr München, Werner-Heisenberg-Weg 39, 85577 Neubiberg, markus.holzmair@unibw.de)

1 ABSTRACT

Im Rahmen des dtec.bw -Forschungsprojekts MORE partizipiert die Professur für Raumplanung und Mobilität mit einem Destillat aller seiner infrastrukturellen und raumplanerischen Forschungsüberlegungen: Das Leuchtturmprojekt „digitales Parken der Zukunft", vorgesehen auf dem Campus der Universität der Bundeswehr München (UniBw M), um vor Ort am realen Objekt forschen zu können.

Dieser Reallabor-Demonstrator setzt sich aus den im Rahmen des dtec.bw-Forschungsprojekts MORE erforschten Komponenten der Professur zusammen:

- Nachhaltiges (Verkehrs-)Flächenmanagement, Flächeneffizienz und -gerechtigkeit

- Elektromobilität mit Sektorenkopplung

- Räumliche Implikationen der Digitalisierung von Mobilität und Verkehr/autonomes Fahren

- Multimodale Anknüpfungspunkte/Mobilitätshubs im urbanen Raum

- Emotionale Mobilität/gesellschaftlicher Wandel

- Beschleunigte Umsetzung von Baumaßnahmen der Bundeswehr

Die Erkenntnisse sollen dabei sowohl intern, durch weitere MORE-Forschungsaspekte, wie auch extern, durch Partner in Wirtschaft und Forschung, validiert und erweitert werden. Mit den im gemeinsamen Institut verankerten Professuren für Intelligente, multimodale Verkehrssysteme und Verkehrstechnik, den Professuren für Fahrzeugantriebe und für Elektrische Energieerzeugung & -verteilung sowie dem Institut für Technik autonomer Systeme demonstriert dieses wegweisende Reallabor die facettenreiche und engverzahnte Forschungsanwendung des MORE. Gemeinsam mit den Partnern aus der Wirtschaft, BwFuhrparkService (BwFPS) als Mobilitätsdienstleister der Bundeswehr, Daimler AG (Elektrifizierung, Automatisierung Pkw und Nfz), JACOB Elektronik GmbH (digitale Mess- und Leittechnik), SOPAGO GmbH (Solar Carports mit Ladeinfrastruktur) und VePa Vertical Parking GmbH (automatisch gesteuerte, kompakte Parksysteme) wird intensiv interdisziplinär kooperiert und eine weitgehende und umfangreiche detaillierte Planung mit mehreren Varianten erstellt. Weiterhin sollen zudem neueste und zum Teil zukunftweisende Technologien zum Einsatz gebracht und die Erkenntnisse unmittelbar im Demonstrator auf Alltagsfähigkeit erprobt werden. Den Anforderungen an flächensparendes Bauen und an die Anpassung an die Folgend es Klimawandels soll zudem Rechnung getragen werden, indem vorhandene versiegelte Flächen nachhaltig entwickelt werden.

Es wurden insgesamt vier Hauptvarianten entworfen, die an unterschiedlichen Stellen auf dem Campus Aufschluss zu den zahlreichen gemeinsamen grundsätzlichen Fragestellungen, aber auch individuellen Besonderheiten am jeweiligen Mikrostandort geben. Nachfolgend werden die vier Varianten mit ihren Gemeinsamkeiten und Unterschieden dargestellt.

Keywords: Nachhaltigkeit, Parkraum, Digitalisierung, Verkehrsmanagement, Verkehrsflächenmanagement

2 VARIANTE 1

In einem Innenhof karreeartig angeordneter Gebäude ist auf einer bisher extensiv genutzten Verkehrs-/Grünfläche (ca. 5.000 m²) ein neues Büro- und Verwaltungsgebäude entstanden. Die verbleibenden 3.000 m² Fläche (Abbildung 1, orange Markierung) soll aufgewertet und nach modernsten Erkenntnissen flächensparend zu einem digital-vernetzten Parkraum entwickelt werden. Im Sinne der Nachhaltigkeit soll der Versiegelungsgrad dabei minimiert und der Anteil an hochwertiger Grün-/Freifläche maximiert werden, sodass die Anrainer künftig nicht nur auf eine „Asphaltwüste mit Blechlawine" blicken müssen.

Abbildung 1: Standort des Demonstrators Variante 1 | Kartengrundlage: Google Maps (2020)

Der von Grund auf neu gestaltete, attraktive Innenhof liegt in unmittelbarer Nähe zur Hauptwache der Liegenschaft. Diese stellt den primären Zutrittspunkt für Gäste, Mitarbeitende und Studierende auf den Campus der Universität der Bundeswehr dar. Zusätzlich liegt der Gebäudeblock, der die zu entwickelnde Fläche umschließet, an der Schnittstelle vom Außenbereich der Liegenschaft, zu welchem alle Fahrzeuge Zufahrt haben, zum verkehrsberuhigten Innenbereich, zu dem leidglich ein beschränkter Kreis an Beschäftigten, Gästen sowie Liefer- und Dienstfahrzeugen Zufahrt mit Kraftfahrzeugen hat.

Ein geplanter Mobilitätshub ermöglicht an dieser exponierten Lage den Übergang von motorisiertem Individualverkehr zu den Microsharing- und Campusshuttle-Angeboten der letzten Meile auf dem Campus. Mit deren Hilfe lassen sich sowohl die zentral gelegenen Lehr-, Labor- und Verwaltungseinrichtungen wie auch randlich gelegene Sport- und Forschungsanlagen sowie Unterkunfts- und Stabsgebäude in Minutenschnelle erreichen. Beispielhaft seien an dieser Stelle genannt:

Campus-Destination	Entfernung
Bibliothek	700 m
Fahrbereitschaft/BwFPS (Abholpunkt für Dienst- und Leihfahrzeuge	650 m
Hauptwache	150 m
Hörsaalzentrum/Audimax	750 m
Laborgebäudekomplex 35	375 m
Laborgebäudekomplex 80	1.000 m
Mensa/Truppenküche/Restaurant	800 m
Präsidialbereich/Zentrale Verwaltung	450 m
Rechenzentrum	250 m
Schwimmhalle	550 m
Sportanlagen mit 400 m-Bahn, Groß- und Kleinspielfeldern u.v.m.	725 m
Sporthalle mit Kraftraum (Innenbereich)	300 m
Unterkunftsbereich/Stabsbereich	975 m
Offiziercasino	450 m

Tabelle 1: Entfernungen vom Demonstrator Variante 1 zu Campus-Destinationen (Fußwegebeziehung)

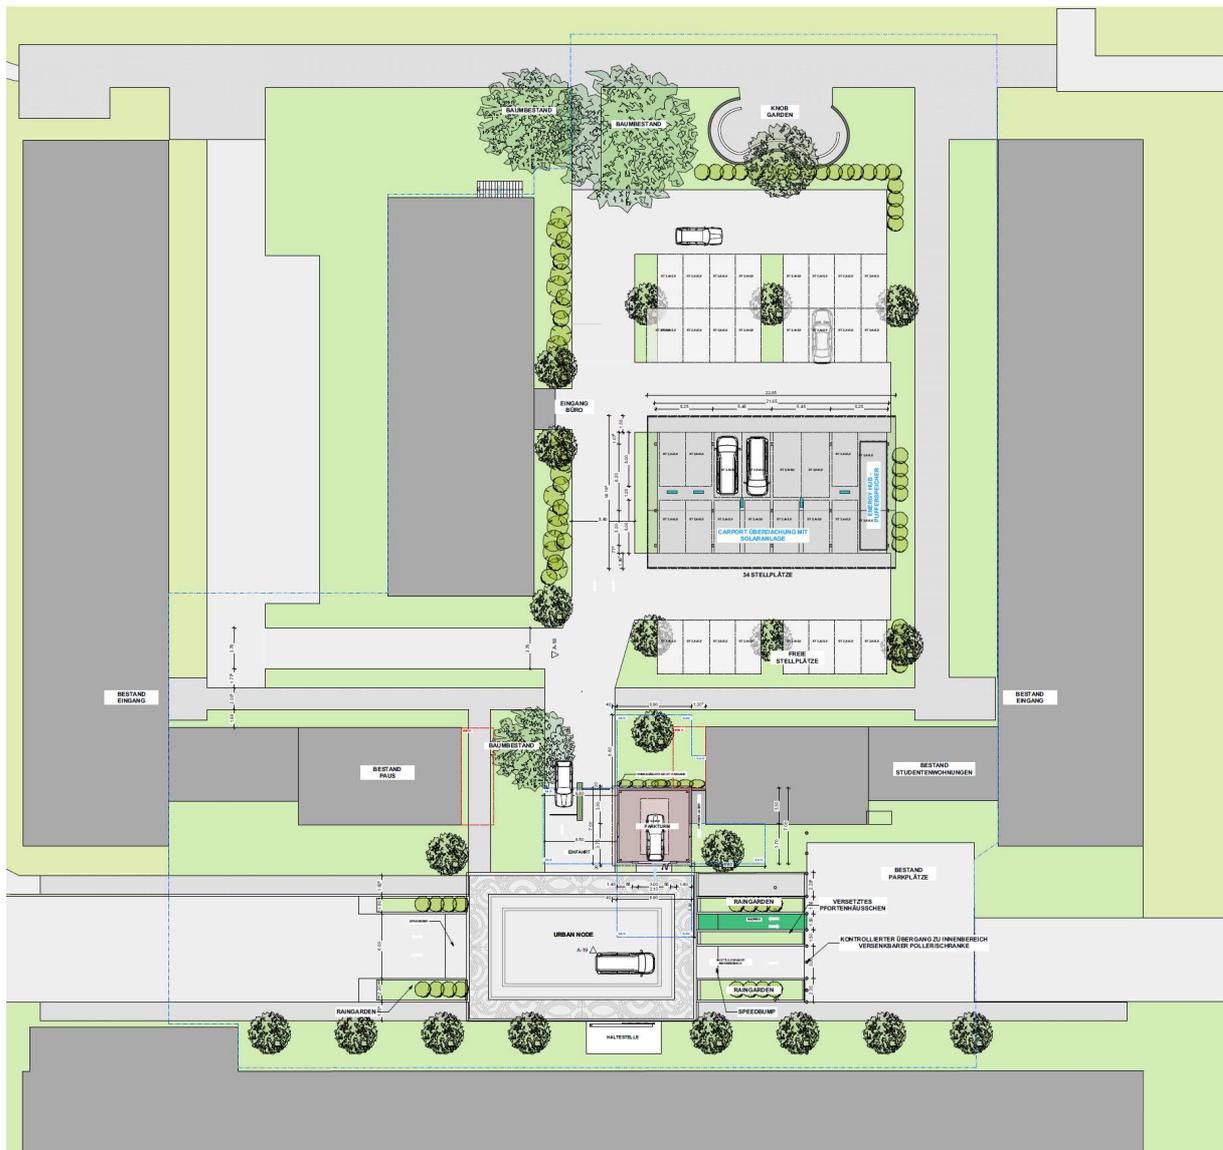
Insgesamt sollen auf der Fläche etwa 40 Stellplätze entstehen. Gemäß den aktuellen Vorgaben aus EU-Richtlinien und deutscher Gesetzgebung sollen min. 25 % der Stellplätze elektrifiziert werden, davon zwei Ladepunkte ausgebildet als Ultraschnelllader (HPC, min. 100 kW-Ladeleistung). Die übrigen Ladepunkte sollen aus einem Mix mit unterschiedlichen AC-/DC-Ladetechniken ausgestattet werden.


Abbildung 2: Entwurfsplanung Variante 1 (2021)

Besonderer Fokus soll auf zukunftsgewandte Technik und Schnittstellen gerichtet werden. Alle Ladepunkte werden mittels smartem Lastenmanagement vernetzt und erfüllen mindestens den Standard OCPP 1.6 (sofern verfügbar OCPP 2.0) und die Anforderungen der ISO 15118 (insb. bidirektionales Laden). Die gesamte Fläche wird ergänzend mit modernster Sensorik zur Erfassung von fließendem und ruhendem Verkehr überlagert, um Informationen zu freien Stellplätzen und Ladepunkten sowie Stromgewinnung/-speicherung zu liefern.

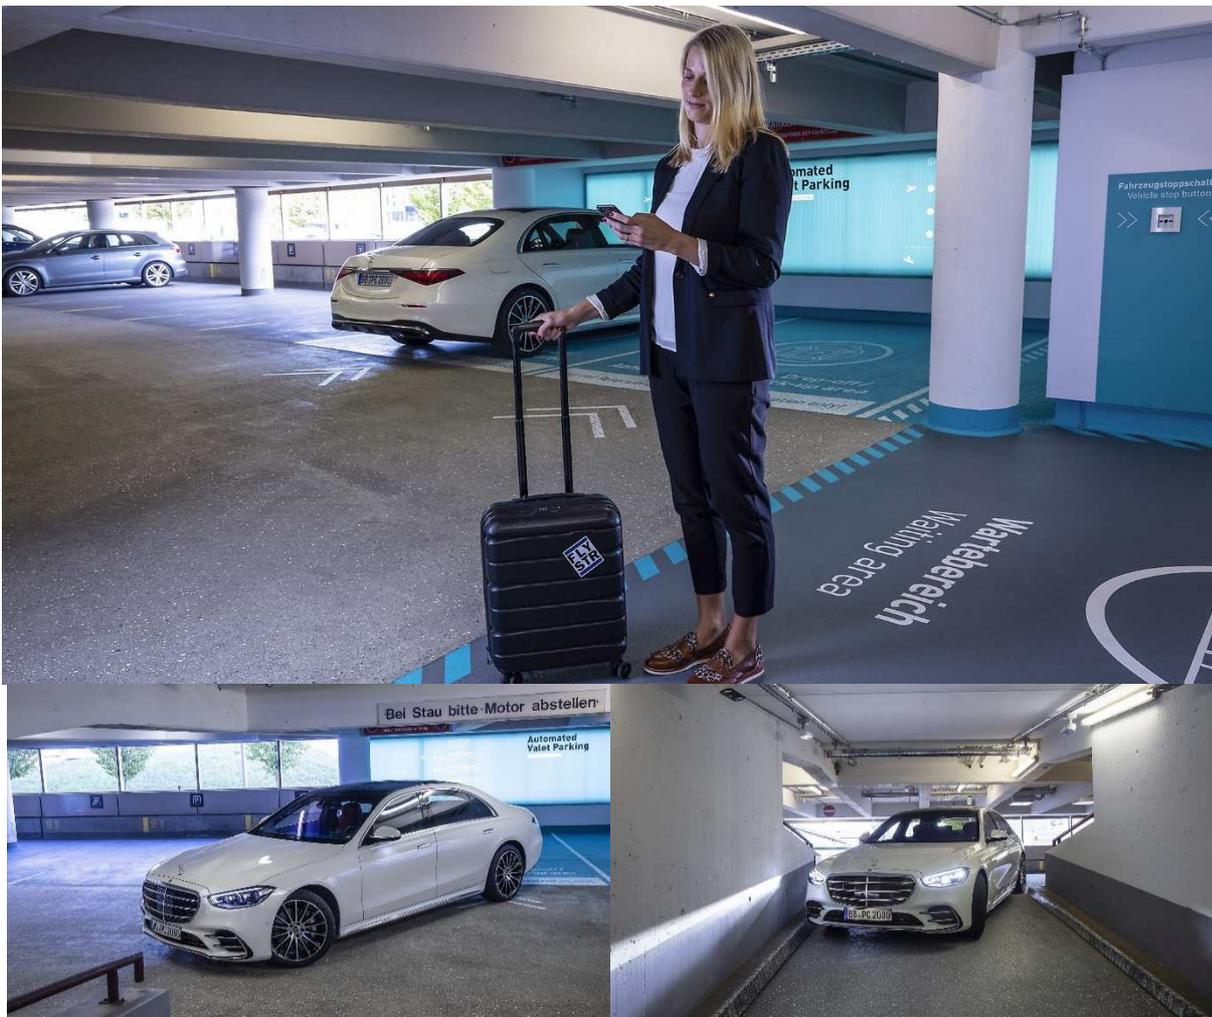
Neben Ladeinfrastruktur und regenerativer Stromerzeugung sind auch dezidierte Parkplätze für das Quartiers-Carsharing (gemeinschaftliche Langzeitnutzung) vorgesehen. Diese können in einem Parkturm weithin sichtbar sein (Verfügbarkeiten). Als architektonische Dominante des Demonstrators sind hier weitere zwölf Parkpaletten bzw. eine weitere, vertikal angeordnete Doppelparkreihe untergebracht. Ein automatisch gesteuertes Parksystem, ergänzt mit (automatisierter) Ladeinfrastruktur sitzt auf einem Übergabepunkt für autonomes Parken (vgl. Automated Valet Parking des Mercedes-Benz-Museum, Stuttgart).


Abbildung 3: Mercedes-Benz Fahrzeug parkt aus und navigiert selbstständig durch ein Parkhaus | Quelle: Daimler AG (2021)

Ein Shared Space am Fuß des Turmes definiert einen Haltepunkt für das autonome Campusshuttle und den Mobilitätshub mit Übergang zur Micromobilität der letzten Meile (Fahrrad, Lastenrad, eBike, eScooter etc.).

Abbildung 4: Blick über den Shared Space mit Haltepunkt für autonomes Shuttle (Stand 2021)

228

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Abbildung 5: Ansicht Innenhof mit Carports (Stand 2021)

Zur Überbrückung von Strom-Angebots-/Nachfrageungleichgewichten wird die gesamte Anlage mit einem hochmodernen Stromspeicher ausgestattet. Dieser speichert überschüssigen Strom der Peakstunden und gibt diesen in Phasen niedriger Erträge (bedeckter Himmel, Nachtstunden) wieder ab.

3 VARIANTE 2

Nach der Festlegung des Standorts der Variante 1 wurde eine weitere Variante entwickelt, die sich einem bereits laufenden Genehmigungsprozess einer Baumaßnahme am Haupttor des Campus anschließen soll. Damit soll ein langer Verwaltungsakt vermieden und eine zeitnahe Realisierung gesichert werden.

Abbildung 6: Ansicht Haupteingang UniBw M, Universitätsstraße

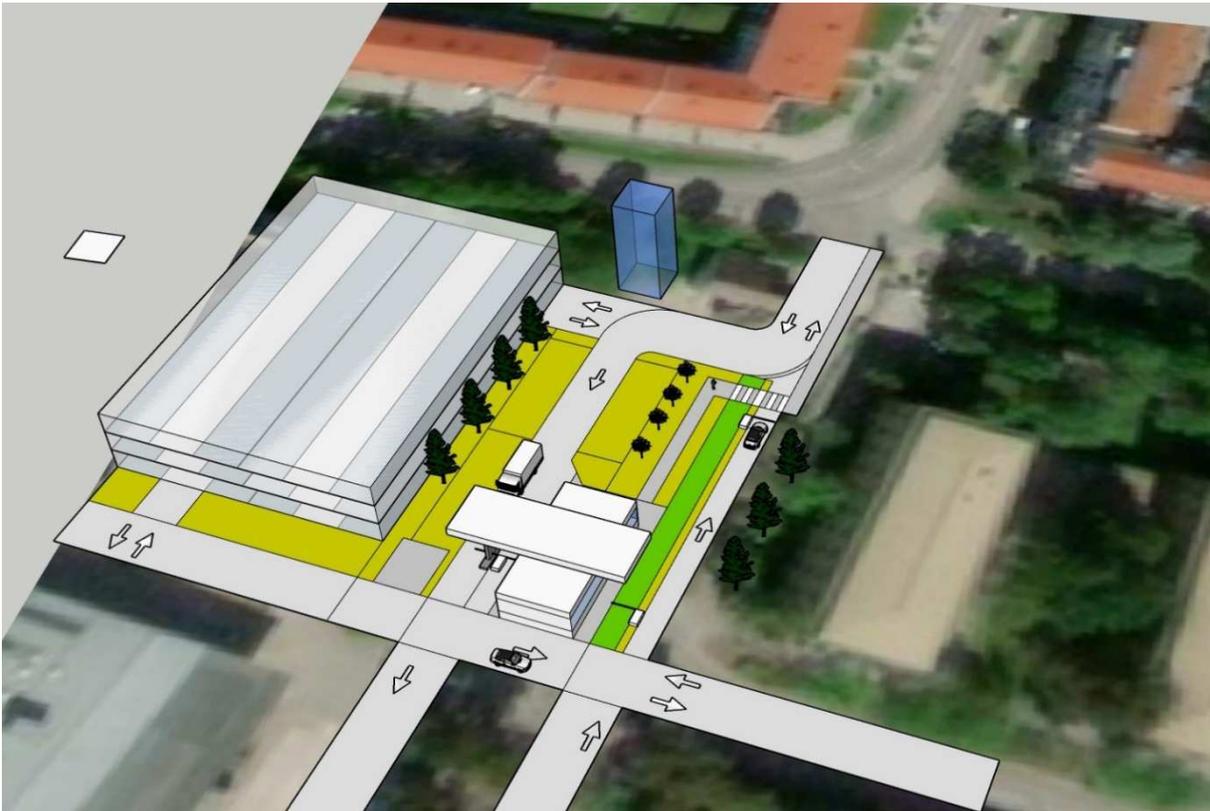
Ein dafür aufgestelltes, neues Konzept sieht vor, die Stellplatzkapazität an der Hauptwache zu erhöhen, um den Besucher- und Lieferverkehr besser steuern zu können. Dazu wird die Variante 2 an der westlichen Seite des derzeit bestehenden Besucherparkplatzes, der 26 Stellplätze umfasst, geplant.


Abbildung 7: Planung für Demonstrator Version 2 am Haupteingang der UniBw M (Stand 2022)

- Um die temporäre Überlastung des Haupttors durch Liefer- und Besucherverkehr zu vermindern und um die verschiedenen Verkehrsströme zu entflechten, wurde durch das Team der Professur Raumplanung und Mobilität eine gesamtheitliche Umplanung des Haupttor-Areals durchgeführt. Wichtige Bausteine dieser Umplanung sind:

- Separate Verkehrsführung aus Richtung der Zubringerstraße für einfahrenden Verkehr

- Kontrollstelle der Hauptwache auf Fahrerseite, dadurch verbesserte Kontrollmöglichkeit

- Schaffung von mehr Kontrollkapazität zu Spitzenzeiten

- Trennung von Lieferverkehr und Personenverkehr durch separate Schranken und Fahrstreifen

- Separater Fahrradstreifen an der bisherigen Einfahrt für beidseitigen Verkehr (vgl. Abb. 7, grün dargestellt)

- Verminderung von Konfliktpunkten mit Schwerlastverkehr und Fahrrädern

- Neuer Fußgängerweg zur Hauptwache, der nur einen Radstreifen und den ausfahrenden Verkehr queren muss

- Weiterleitung des Verkehrs Richtung Liegenschaftsmitte/Hauptparkplatz parallel zur vorhanden Verkehrsachse zur Verminderung des bisherigen Konfliktpunkts unmittelbar nach dem Wachgebäude

- Parkturm (vgl. Abb. 7, blau dargestellt) am Rand der Liegenschaft als Leuchtturmprojekt schon von außen gut sichtbar

- Individuelle Anpassungsmöglichkeit der Parkturmfassade an Bedürfnisse und Gestaltungswünsche der Universität

- Symbolcharakter und Orientierungspunkt durch Höhe des Parkturms

Bei der Planung dieser Variante war auch der Parkturm-Hersteller VePa unterstützend wirksam und hat sofort auf die wechselnden Ansprüche reagieren können. Insbesondere Anforderungen an die militärische Sicherheit haben sich jedoch hemmend auf die bauliche Realisierung ausgewirkt.

4 VARIANTE 3

Durch den Beauftragten für Sonderinfrastruktur der UniBw M wurde an anderer (dezentraler) Stelle des Campus eine kompakte Lösung gesucht. Nach intensiver Planung und Schnittstellenkoordination mit den zuständigen Verwaltungs- und Baubehörden sollte ein Nachtrag zu einer bereits in der Ausführung befindlichen benachbarten Baumaßnahme umgesetzt werden.

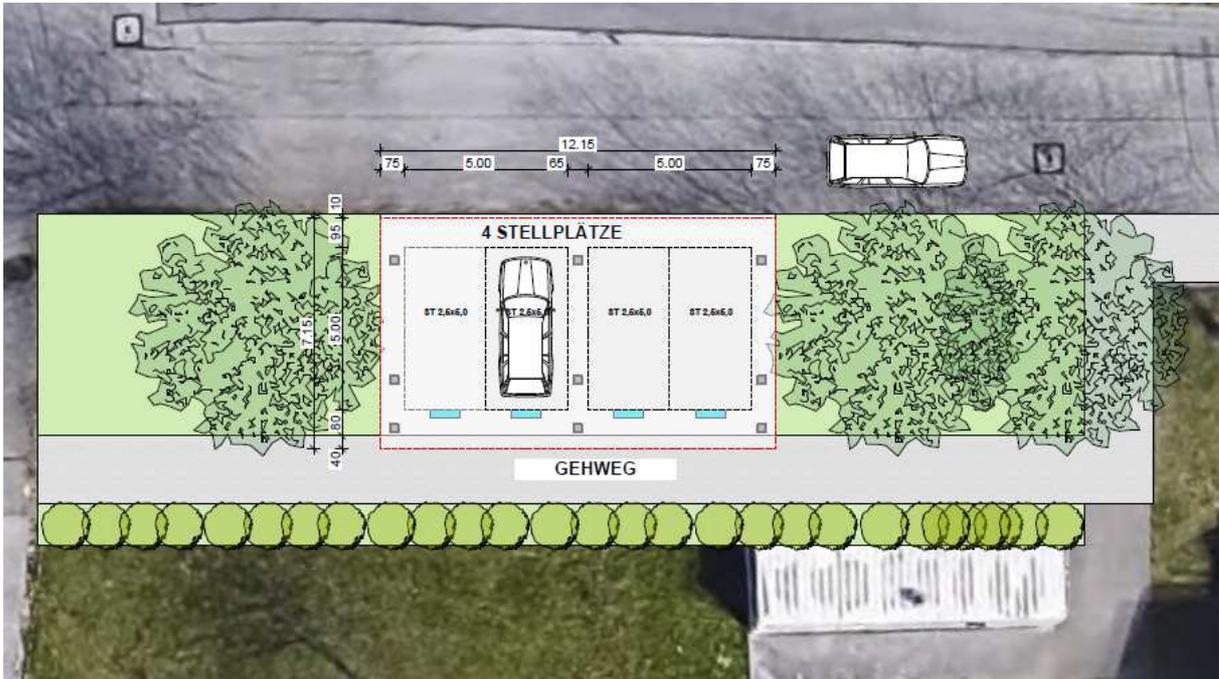
Im zufahrtsbeschränkten Innenbereich der Liegenschaft steht ein kleines Baufeld zur Verfügung, welches mit einer stark reduzierten Version eines Demonstrators bebaut werden kann. Da der Umfang des Demonstrators Variante 3 baulich weniger anspruchsvoll ist als die beiden ersten Varianten, wurde großes Potenzial in einer zügigen Errichtung und Inbetriebnahme gesehen.


Abbildung 8: Vorplanung Demonstrator Variante 3 (Stand 2022)

Abbildung 9: SOPAGO Solar-Carport | Quelle: sopago.org, Abbildung verändert (Stand 2022)

Das Baufeld ermöglicht den Bau eines Solarcarports von vier bis maximal sechs Stellplätzen und bedient wichtige und zielbedeutsame Bausteine wie den vorgelagerten „Shared Space" und den vertikalen Parkturm nicht, solange die umgebende Flächennutzung nicht umfassend verändert wird. Um zumindest die Aspekte einer Ladeinfrastruktur mit eigenerzeugtem Ladestrom zu untersuchen, wurde nach einem Hersteller gesucht, der als Generalunternehmer eine Lösung für einen Solarcarport mit integrierter Ladeinfrastruktur anbieten bzw. liefern und errichten kann. Variante 3 ist somit als Minimallösung zu verstehen, die modular erweiterbar ist.

Das Münchner Unternehmen SOPAGO bietet ein System mit bifokalen Solarelementen mit Ost-West-Ausrichtung an und wäre dank smarter Materialketten auch binnen kurzer Frist liefer- und baufähig. Das umfangreich recherchierte modulare System steht in Drei- und Vier-Stellplatz-Modulen zur Verfügung, die ohne Linien- oder Flächenfundamente errichtet werden können. Das System wird mittels Schraubfundamenten im Boden verankert, welches auch bei einem möglichen Rückbau keinerlei bleibende Schäden im Erdreich hinterlässt. Lediglich elektrische Zuleitungsschächte und die gewünschte Parkplatzoberflächen müssen im Vorfeld erstellt werden. Zusätzlich wird so versickerungsfähiger Grund erhalten und durch die lichtdurchlässigen Solarelemente können auch extensiv begrünte und bewachsene Flächen überdacht werden.

Zu den Vorteilen dieser Variante gehören unter anderem:

- Keine Betonfundamente notwendig
- Modularer Aufbau als Drei- oder Vier-Stellplatz-Module möglich
- Mehr Tageslicht durch bifokale Solarelemente
- Teilversiegelter, wasserdurchlässiger Boden möglich
- Begrünung unter Carport möglich
- Durchfahrtshöhe für Forschungsvorhaben/Forschungsfahrzeuge kompatibel
- Integrierte Ladeinfrastruktur

5 VARIANTE 4

Das erarbeite Gesamtkonzept der Variante 3 wurde der Verwaltung zur Durchführung der Beschaffung vorgelegt. Nachdem dieses Konzept gut realisierbar schien, waren der räumlich weniger gut gelegen und kleiner als ursprünglich angedachte Standort erneut überdacht. Dafür wurde kurzfristig ein größeres Baufeld in rund 100 Metern Entfernung vorgeschlagen. Dabei handelt es sich um ein derzeit als unstrukturierte Parkplatzfläche genutzten, gepflasterten Bereich zwischen zwei Straßen im Innenbereich der Liegenschaft. Erneut wurde von Seiten der Professur für Raumplanung und Mobilität das bereits entwickelte und verfeinerte Planungskonzept über das neue potenzielle Baufeld gelegt und detailliert in 2D-Karten und 3D-Ansichten ausgearbeitet.

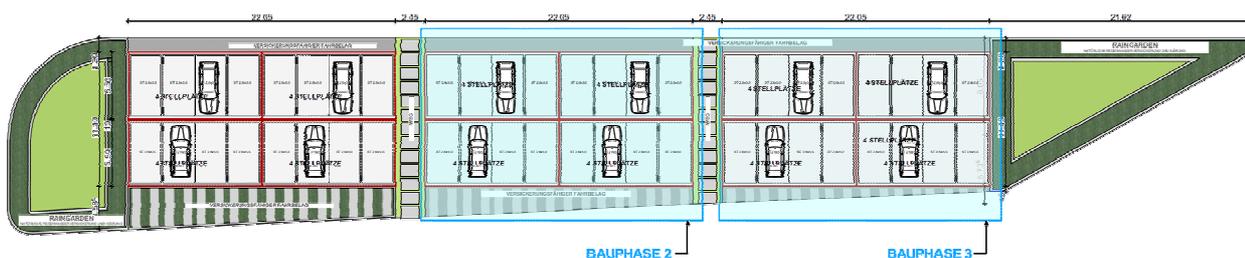
Ein besonderes (neues) Merkmal der Forschungsplanung lag dabei in der Beurteilung der am Standort vorhandenen Begrünung. Diese wurde als ökologisch wenig wertvoll klassifiziert. Durch den bei allen Varianten geplanten reduzierten Verkehrsflächenverbrauch kann der Verlust einzelner Grünelemente durch eine für die Forschung gleichsam große Betrachtungsdauer zu ermöglichen, wurde diese Variante 4 in drei Bauphasen ausgeplant. Dies erlaubt eine zeitversetzte Realisierung jeder einzelnen Phase mit den bereits aus Variante 3 bekannten modularen Solar-Carports.


Abbildung 10: Vorplanung Demonstrator Variante 4 (Stand 2022)

Bauphase 1

- 16 Stellplätze mit vier Carport-Modulen à vier Stellplätzen
- Photovoltaik-Elemente auf dem Carport
- Ladeinfrastruktur für Elektrofahrzeuge inkl. intelligentem Lademanagement und Abrechnungssystem
- 32 Stellplätze auf teilversiegelter Parkplatzfläche als Vorbereitung für spätere Überdachung
- ortsnahe Niederschlagsversicherung in ökologisch aufgewerteten Randbereichen

Bauphase 2 und 3

- je 16 weitere Stellplätze mit Carport-Modulen (Überdachung der freien Bestandsstellplätze aus Bauphase 1 bzw. 1 und 2)

6 AUSBLICK

Da eine Solar-Carportanlage mit Elektroladeinfrastruktur auch unabhängig von den MORE-Forschungsinteressen als sinnvolle und notwendige Investition am Campus der UniBw M angesehen wird, bestehen große Chancen, dass sich diese Baumaßnahme auch in anderen Bundeswehr-Liegenschaften realisieren lassen. Die bisher geleisteten planerischen und wissenschaftlichen Untersuchungen zur Standortfindung und architektonischen Entwürfe haben eine hohe Wertigkeit für eine nachhaltige Verkehrs- und Raumplanung an der UniBw M. Mit den gewonnenen Erkenntnissen können auch zukünftig infrastrukturelle Maßnahmen der Bundeswehr planerisch unterstützt und ausgerollt werden. Da alle Entwurfsarbeiten als virtuelle Variante im VR-Labor der Professur zur Verfügung stehen, können gemeinsam mit der Professur für Verkehrspsychologie die Wirkung der geplanten Maßnahmen durch die künftigen Nutzer bereits vor dem Bau getestet und ggf. angepasst werden. Das Team der Professur Raumplanung und Mobilität wird den weiteren Verlauf des Infrastrukturprozesses aus eigenem Forschungsinteresse in enger Zusammenarbeit mit dem Bundesamt für Infrastruktur, Umweltschutz und Dienstleistungen der Bundeswehr begleiten. Darüber hinaus wird eine Planungshilfe für Gestaltung, Allokation und Nutzung eines digitalen Parkraums der Zukunft ausgearbeitet, die die Kernkomponenten der hier aufgezeigten Planungen idealtypisch miteinander kombiniert.

1 ABSTRACT

Our world faces multiple challenges: The energy crisis is one of them and must be addressed at a local and regional as well as national and global level. In this transformation process of phasing out fossil energy sources, technical and social innovation must work closely together to foster long-term and sustainable changes. Generating energy from solar sources is one of the key sustainable and resource-efficient options we presently have . As stipulated in the European Green Deal, the goal is to phase out fossil fuels by 2050 with no net greenhouse gas emissions (European Commission, 2019). Sun and renewable energy sources are therefore key drivers for resilient and livable cities, societies, and economies. Just as the challenges of global change processes are unevenly distributed across the world, so are financial resources. People who are threatened or affected by poverty are more likely to be affected by energy poverty. According to a study from 2021, low-income households are significantly more affected by the rising energy prices (Maier-Kubala, 2021). Measures for energy transition and climate change adaptation are often associated with high costs and are therefore more likely to be implemented by people with higher incomes.

To include vulnerable groups in the process of energy transition, the project "Energy WITH Spirit," solidarity-social energy communities, was established. The main aim of the project is for socially disadvantaged and poverty-affected households, as well as people in basic services and low-income earners , to benefit from the sustainable and solidary produced energy. 10 % of the energy produced in kWh or 10% of the profit generated in Euro will be donated to vulnerable groups. How this goal is implemented technically (e.g., smart metre rollout; photovoltaic systems and storage, optimal consumer mix), economically (e.g., billing modalities, digital billing), and organisationally (e.g., proof of household income and expenditure; selection of recipients of energy quotas) will be explored within the project.

- The following target groups are involved in the solidarity-social energy communities: producers invest in sustainable energy generation through photovoltaic systems and set them up on their own properties, prosumers produce and consume part of their produced energy themselves (production and use under one roof) and consumers receive part of the energy produced by photovoltaic systems in the form of electricity. As consumers only, the project addresses the following groups: Socially disadvantaged and/or low-income households, people in basic services and the in-work impoverished who do not receive any government grants.

- To better involve the target groups, knowledge-transfer and awareness-raising workshops are held to address and sensitise them to urban energy, environmental, and climate issues. According to the solidary approach, "Energy WITH Spirit" aims to overcome the challenges of the energy crisis by generating sustainable energy in a solidarity energy community by actively involving vulnerable groups in the energy transition process. The next steps of the project are the technical construction of the photovoltaic plants as well as the economic preparation of the solidary energy community. This process is accompanied by target group orientated and simple energy education workshops for the vulnerable groups.

Keywords: sustainability, transition, cooperation, energy communities, vulnerabilities

2 BASELINE

2.1 European Context

- The climate crisis highlights numerous challenges at the global, national, and local level. In response to this, the European Green Deal was formulated in 2019 by the European Commission (European Commission, 2019a). As a new growth strategy and transformative process, the Green Deal aims to facilitate the European Union and its member states' transition towards a fair society with a resource-efficient and competitive economy (European Parliament; European Council, 2018/2001). The European Green Deal, introduced by the European Commission in December 2019, is a comprehensive policy framework aimed at making Europe climate-neutral by 2050. It encompasses various initiatives to accelerate the transition to a sustainable and low-carbon economy. Energy communities align closely with the objectives of the European Green Deal by fostering renewable energy deployment, energy efficiency, and citizen engagement. The European Green Deal acknowledges the importance of energy communities as a key pillar in the transition to cleaner energy systems. It aims to facilitate the establishment and operation of energy communities across Europe through supportive policy measures, regulatory frameworks, and financial instruments. The overarching goal is to democratise the energy sector, empower local communities, and ensure a fair and inclusive energy transition.

- The ongoing energy crisis, particularly triggered by Russia's attack on Ukraine, has resulted in a rapid escalation of energy prices, impacting not only the economy and administration but also individuals and their daily lives. A study conducted in 2021 indicates that s low-income households are significantly more affected by the rising energy prices (Maier-Kubala, 2017).

- The Clean Energy for all Europeans Package (CEP) has incorporated energy communities into the European Union's legislation (European Commission, 2019b). The directive includes common provisions for the internal electricity market, enabling active participation of end-users in all markets by generating, consuming, sharing, or selling electricity (EU 2019/944).

- Alongside technological and digital advancements, social energy communities adopt a strong social approach. They encourage end-users to become part of the solution and foster an understanding for sustainable energy usage and behaviour.

2.2 Renewable Expansion Act (EAG Package) in Austria

- The Renewable Expansion Act (EAG Package) represents the implementation and execution of the European Green Deal and was passed by the Austrian National Council in 2021 (Republik Österreich, 2022). One of its goals is to transition Austria's electricity supply to 100% renewable energy sources by 2030. This law amendment allows individuals to collaborate across property boundaries to collectively produce, store, consume, and sell energy. The Renewable Expansion Act serves as the legal framework for energy communities in Austria.

2.3 And the social dimension

In the energy transition, a collaboration between technical and social innovations is necessary to bring about long-term and sustainable changes (Knoll, 2016). Measures for energy transition and climate change adaptation are often associated with high costs and are therefore implemented primarily by individuals who have sufficient income. It is known that a portion of the population (especially the elderly, migrants, students, job seekers/unemployed individuals, and low-income earners) or vulnerable groups (socially disadvantaged households, people living in poverty) are not fully involved in the energy transition due to a lack of resources (financial, spatial, knowledge-related) (Maier-Kubala, 2017; Räty, 2010). The experiences of existing energy communities demonstrate that standard communication and dissemination measures are important but insufficient. Technical terms need to be translated into understandable language for all population groups to effectively convey the benefits, meet expectations, and actively involve all demographic groups in the energy transition.

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3 HOW ENERGY COMMUNITIES EMPOWER SUSTAINABLE CHANGE

3.1 Roles within Energy Communities

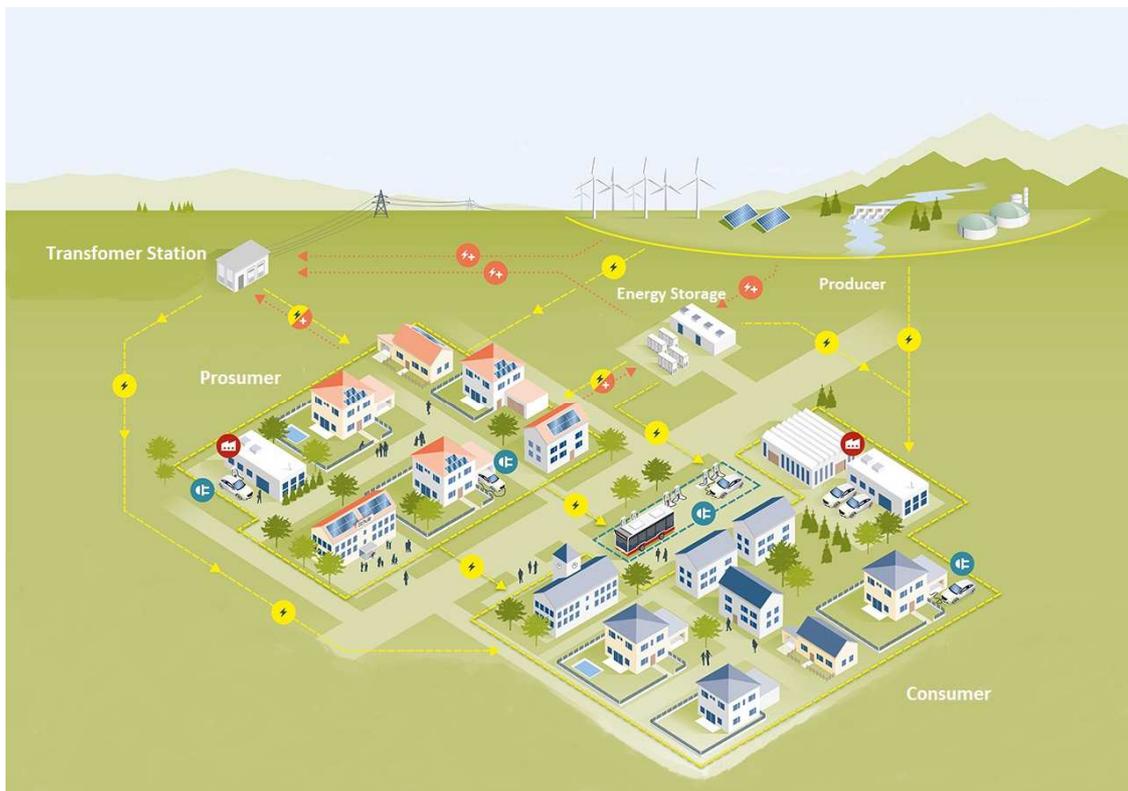
In an energy community, at least two participants come together to achieve a collective production and utilisation of energy (Erneuerbaren-Ausbau-Gesetz, 2021). This is now possible beyond property boundaries. The electricity supply is provided by renewable energy sources, mostly photovoltaic systems. This is because the Renewable Expansion Act Package (EAG) aims to have Austria's electricity supply come 100% from renewable energy sources by 2030. Energy communities play an important role in this transition. By utilising renewable energy sources such as solar power, energy communities can help reduce our dependency on fossil fuels while ensuring a sustainable and clean energy supply. They promote a decentralised approach, where citizens actively participate in energy production and can collectively generate and utilise their energy. The concept of an energy community goes beyond mere electricity supply. It creates a closer community and promotes the exchange of know-how and resources. By pooling their efforts, people can collaboratively shape a sustainable future and make a positive contribution to climate protection.


Fig. 1: Illustration of an Energy Community (https://energiegemeinschaften.gv.at/downloads/energiezukunft-gestalten/) (used with permission)

- Producers: Investing in sustainable energy generation, producers install photovoltaic systems on their own properties, contributing to the production of clean and renewable energy.

- Prosumers: Institutions acting as prosumers not only utilise the properties where photovoltaic systems are installed but also consume a portion of the energy produced on-site. This concept of production and consumption under one roof applies to various entities, including our two frontrunners the Protestant Boarding School Bad Goisern, catering to children with socio-pedagogical support needs and their caregivers, as well as the community of students, teachers, and non-teaching staff at the Protestant Secondary School Donaustadt.

- Consumers: Benefitting from sustainable energy practices, consumers receive a share of the electricity generated by photovoltaic systems, ensuring a cleaner and more sustainable energy supply.

3.2 Benefits of Energy Communities

The benefits of energy communities are numerous. According to legislation, the primary contribution of energy communities is the benefit they bring to the community (Erneuerbaren-Ausbau-Gesetz, 2021).

- Ecologically, energy communities provide advantages through localised energy generation. This eliminates the need for long-distance transmission, as energy is consumed in close proximity. Consequently, it reduces the carbon footprint not only for individuals but also for the region and the entire country. The proximity of energy generation also fosters a greater understanding and connection to the topic of electricity production.

- From an economic standpoint, energy communities offer several advantages. When the generated energy is sold or purchased, the energy community itself determines the price. Supporting local value creation helps minimise reliance on large imports of fossil fuels and leads to increased financial benefits for the region.

- Socially, energy communities contribute to increased awareness of climate and energy-related issues, by promoting renewable and sustainable energy sources. They enhance interaction and communication among community members and foster therefore a sense of social cohesion.

- Furthermore, sector coupling, achieved through the integration of electricity, heat, and mobility sectors, can elevate self-sufficiency levels. For instance, the utilization of a neighborhood storage system enables the use of self-generated electricity for charging electric vehicles at a later time.

4 THE LIGHTHOUSE PROJECT "ENERGY WITH SPIRIT"

To involve and actively engage vulnerable population groups in the energy transition, a consortium of 11 project partners from the business, scientific, research, and Protestant Church and its social welfare organisations came together for the project "Energy WITH Spirit. Pioneering implementation of a solidarity energy community in the Protestant Church Community Action sector in Austria." The project is led by B-NK GmbH Office for Sustainable Competence and involves the following organizations: AEE INTEC, akaryon GmbH, Diakonie Bildung gem. GmbH, Diakonie Eine Welt gem. GmbH, Diakonie Flüchtlingsdienst gem. GmbH, Dipl.-Ing. Ralf Dopheide e.U., Evangelische Superintendentur A.B. Wien, Evangelisches Haus Hadersdorf Wobes, Schülerheim Bad Goisern GmbH, and TRIGONplan Planning and Consulting Company for Landscape Ecology and Technical Environmental Protection. The three-year project started on March 1, 2023, and is funded by the Austrian Climate and Energy Fund under the "Lighthouses for Resilient Cities 2040" programme.

The project aims to ensure that the energy generated by the photovoltaic system not only meets the needs of the on-site facilities but also contributes to the well-being of socially disadvantaged and impoverished households, as well as individuals who rely on basic supplies and those who fall into the category of in-work poverty. This will be achieved through a solidarity-based approach, where approximately 10% of the energy produced in kilowatt-hours or 10% of the generated profit in euros will be allocated to these vulnerable groups. To address these objectives, first of all technical aspects, such as the implementation of smart metres, photovoltaic systems, and storage solutions, as well as different models for an optimised mix of different members and load profiles have to be examined. In addition, economic considerations will be considered, including billing methods and the implementation of digital invoicing systems. Organisational aspects, such as verifying the income and expenditure of households and selecting recipients for energy quotas, will also be carefully managed. By tackling these technical, economic, and organisational challenges, the project seeks to ensure that the benefits of the photovoltaic system extend beyond the immediate facilities and positively impact the lives of those in need, fostering a sense of solidarity within the community.

4.1 The Frontrunners

The project involves a pioneering implementation of a solidarity-based social energy community with two "fixed-starter buildings" (= "frontrunners") as prosumers, as well as the preparation for a nationwide roll-out.

As stated before, there are two frontrunners, one is the Protestant Boarding School in Bad Goisern.

The Protestant Boarding School Bad Goisern provides accommodation for 45 children (both girls and boys) aged 6 to 16, with a socio-pedagogical focus. The institution collaborates with child and youth services from

the provinces of Upper Austria, Salzburg, and Styria. Recently renovated in 2022, it is one of the most modern boarding schools in Austria. With the aim of embracing sustainability, the Protestant Boarding School Bad Goisern is in the process of installing a large-scale photovoltaic system. By holding both the "producer" and "prosumer" roles in the energy community, the boarding school seeks to meet its own energy demands while also demonstrating solidarity by allocating 10 % of its energy generation to support others in need. This endeavour not only enables the facility to become self-sufficient but also empowers it to contribute to the well-being of the wider community.

Fig. 2: Technical and Economic Pre-Dimensioning of the Photovoltaic System, Bad Goisern.

The second frontrunner is the Protestant Secondary School in Vienna Donaustadt.

The Protestant Secondary School Donaustadt is run by Diakonie Bildung gem. GmbH and is part of the Diakonie Eine Welt Group. The facilities of Diakonie Bildung are open to people of all denominations. In the Protestant educational institutions in Vienna and the surrounding area, Diakonie Bildung cares for around 3,800 children and young people in kindergartens, schools and after-school care centres.

The Protestant Secondary School Donaustadt already has an educational focus on "Ecology and Environment" and is certified with the eco-label "Österreischische Umweltzeichen Schule". The planning and installation of a photovoltaics system at the school is also an excellent opportunity for the students to learn in a practical on-site manner about renewable and sustainable energy production.

Fig. 3: Technical and Economic Pre-Dimensioning of the Photovoltaic System, Vienna Donaustadt.

4.2 The "Energy WITH Spirit" Real-Estate Database

To assess the potential for a rollout within the Protestant community, beyond the two frontrunners in the Energy WITH Spirit project, namely the Protestant Boarding School Bad Goisern and the Protestant Secondary School Donaustadt, Vienna, a survey will be conducted among Protestant institutions, congregations, organisations, and associations. The survey will address the following questions:

- What is the real estate inventory in Protestant institutions, and what are the potential factors related to photovoltaic installations (locations, climate factors, etc.) (= potential prosumers)?

- Where, and in what form, could solidarity energy communities be best established?

- Who could be additional prosumers of the energy community? Who could be additional consumers?

However, for the successful dissemination of the project, a detailed recording of relevant currentstate parameters of the potentially suitable properties in the Protestant church community is essential. This includes a database of its technical characteristics, equipment, and energy needs, as well as socio-structural input parameters within the framework of church and political communities. Methodologically, these surveys are based on both the traditional survey instrument and data from original sources regarding legal status, technical building documentation, and natural planning parameters, selected and based on the respective expertise of the project partners. The storage of the building and environmental data is managed through a database management system, for which the data model has already been developed in a draft version. The goal is to establish a web-based information system that supports project partners not only in the establishment of energy communities in the project, which is the main project objective but also in their ongoing operation by providing fundamental data.

4.3 The Context: Protestant Church in Austria

The Protestant Church A.B. in Austria has a three-tiered structure. The first level consists of 191 parish communities, which act autonomously in many matters towards the regional church through their representative bodies: the Community Council and the Presbytery. The parish community is led by a pastor and a curator who jointly fulfill their spiritual and secular leadership roles within the Presbytery of the parish community. The Community Council, from which the Presbytery is elected, serves as a supervisory body over this governing body.

The parish communities are grouped into seven dioceses, known as superintendencies, which generally correspond to the boundaries of the federalprovinces. The representative bodies of the superintendencies are the Superintendential Assembly and the Superintendential Committee. The superintendency is led by a superintendent and a superintendent's curator.

According to their own count in 2022, this church structure represents 252.233 individuals in Austria who are registered as active members of the Protestant Church A.B. (Evangelische Kirche in Österreich, 2022).

5 THE SOLIDARITY APPROACH: 10 % FOR THOSE WHO NEED IT

Diakonie is the social welfare organisation of Austria's Protestant churches. In its basic statement it is stated: "Church community action begins with the perception of need: Just as the first community in Jerusalem recognized the plight of Greek widows, Martin Luther addressed the impoverishment caused by currency devaluation, Johannes Calvin addressed the plight of refugees in Geneva, Countess de La Tour addressed the misery of illegitimate children, and the brothers Ernst and Ludwig Schwarz addressed social impoverishment, we too must concretely identify and name the general social situation and specific needs of certain groups and individuals. Church community action is directed to the poor and needy in our world. Poverty and social exclusion are often kept silent and ignored by society. In Christian communities, however, these specific problems are recognised, andlead to actions. These communities are places for all people, regardless of their origin and social situation, or their faith." (Diakonie, 2013).

Building upon this foundational statement and supported by a theological concept developed by the Faculty of Protestant Theology at the University of Vienna, the "Energy WITH Spirit" project aims to realise its fundamental objective: to share the energy produced in a spirit of solidarity. This entails allocating either 10% of the generated energy in kilowatt-hours or 10 % of the generated profits in euros to support socially disadvantaged households and individuals affected by poverty.

5.1 How to gain access to vulnerable groups

There are two primary approaches to accessing vulnerable groups: through the project consortium itself and through collaborations with charitable and social welfare institutions. For example, the Evangelischer Waisenversorgungsverein (Protestant Orphan Care Association) has implemented a scholarship model that considers not only financial income but also expenses and social circumstances.

In accordance with their charitable orientation, the Evangelischer Waisenversorgungsverein and Diakonie Bildung gem. GmbH provide financial resources for school fees to socially disadvantaged and/or impoverished families. As the oldest charitable association in Austria, founded in 1861, the Evangelischer Waisenversorgungsverein has supported approximately 900 children over a span of more than twenty years, often throughout their entire schooling period (Evangelischer Waisenversorgungsverein, 2023). The Evangelischer Waisenversorgungsverein, along with the institutions of Diakonie, as the social welfare organisation of Austria's Protestant churches, as part of the energy community, plays a key role in reaching out to socially disadvantaged households.

The solidary approach of the "Energy WITH Spirit" community is designed to benefit the following vulnerable groups:

- Socially disadvantaged and economically impoverished households. The Evangelischer Waisenversorgungsverein and Diakonie Bildung gem. GmbH specifically target these groups.

- Individuals in basic care or with subsidiary protection status, who have experienced displacement, are directly supported, and addressed by the Wohnberatung (Housing Counseling Service provided) by Diakonie Flüchtlingsdienst gem. GmbH.

- The in-work impoverished who do not receive state subsidies. It is the core competency of Diakonie to accompany such precarious living situations and mitigate their impact, particularly for children.

5.2 How to allocate the 10 %

The Faculty of Protestant Theology at the University of Vienna is currently working on the development of a theological concept, which is grounded in fundamental theological principles. By the end of 2023, this concept aims to establish a framework for sharing energy in a spirit of solidarity, specifically by allocating 10 % of the generated energy in kilowatt-hours or 10% of the generated profits in euros to support socially disadvantaged households and individuals affected by poverty.

The administrative procedures for implementing this allocation system will be devised and tested as part of the project. As a starting point, we will focus on two frontrunner buildings and energy communities in Bad Goisern and Vienna. These pilot projects will allow us to refine and validate the concept.

Once the concept has been thoroughly evaluated and proven effective, we plan to implement it on a larger scale across Austria by 2025. This nationwide rollout will enable us to extend the benefits of the solidarity-based energy sharing approach to a broader range of communities and individuals in need.

6 ENERGY EDUCATION WITH THE MOTTO "LEAVE NO ONE BEHIND"

The successful implementation of the two frontrunner energy communities relies heavily on the active engagement of staff members and users, including socially disadvantaged children and young people, students, and individuals in basic care. To enable these target groups to become fully integrated members of the energy community, communication and knowledge transfer processes are essential. Therefore, an integrated objective of the energy community is to provide accompanying "energy education" in the form of knowledge dissemination and awareness-building workshops. This is done to engage the target groups, raise awareness and sensitivity towards energy, environmental, and climate-related topics, and create awareness for the goals and measures surrounding "Energy WITH Spirit." In this regard, employees (social educators, therapists, counsellors, psychologists, teachers, facility technicians, administration) in the energy-producing facilities play an important role as multipliers. The project focuses on the inclusion of vulnerable individuals and equal opportunities.

Their participation is essential in the prosumer facilities, such as the Protestant Boarding School Bad Goisern and in the Protestant Secondary School Donaustadt, as well as in the Wohnberatung (Housing Advice) provided by the Diakonie Flüchtlingsdienst gem. GmbH. To achieve this engagement, the project will

develop and implement targeted knowledge transfer and "energy education" initiatives that are easily comprehensible for the respective target groups.

These initiatives will address various energy-related questions, covering topics such as

- the fundamental understanding of energy,
- the significance of sustainable and renewable energy production,
- the workings of photovoltaic systems,
- the implications of energy crises and rising prices,
- the importance of energy conservation,
- the concept of solidarity and energy communities,
- and the specific rationale behind installing photovoltaic systems.

The primary objective is to emphasise the value of energy as a precious resource and establish a clear connection between everyday life and energy-saving practices.

Through these educational activities, the "Energy WITH Spirit" project strives to raise awareness among staff members of the institutions and socially disadvantaged groups regarding the critical interplay between energy production and consumption. By fostering a deeper understanding of these dynamics, the project aims to empower individuals to make informed decisions and actively contribute to a more sustainable energy future.

7 CHALLENGES ENCOUNTERED THUS FAR

7.1 Equipping Buildings with Photovoltaic Systems: A Challenging Task

As "Energy WITH Spirit" is a research project focusing on energy communities in the Protestant-Community Action sector, church buildings and their annexed buildings are a significant portion of the Producers and Prosumers buildings. Religious communities often own rooftop spaces in urban areas where complex ownership structures of apartment buildings can make the installation of photovoltaic systems very difficult.

In Austria, churches and their roofs are subject to heritage protection regulations. The legal framework for heritage protection is established in the Denkmalschutzgesetz (= Heritage Protection Act) which serves as the basis for safeguarding cultural monuments and historic buildings throughout the country. Consequently, specific legal provisions and approval procedures must be followed when making alterations to these buildings. Currently, there is no unified statutory regulation specifically addressing the installation of photovoltaic systems on church roofs within the context of heritage protection. The legal situation can vary depending on the federal state, as heritage protection laws in Austria are governed at the regional level (Denkmalschutzgesetz, 2013).

While churches and their roofs are subject to heritage protection in Austria, the same does not apply to their annexes. We have already conducted initial exploratory discussions with representatives from the Federal Monuments Office regarding selecting "friendly customer" churches and Protestant religious communities aiming to install photovoltaic systems on their churches and establish a solidarity energy community involving their members, neighbours, municipalities, and other charitable institutions (Bundesdenkmalamt, 2022).

Currently, numerous factors are at play in the dynamic tension between climate protection and heritage preservation, necessitating the consideration of new parameters. As of now, there is no definitive decision from the Bundesdenkmalamt (Austrian Federal Monuments Office) that comprehensively addresses this issue. However, it is noteworthy that the year 2022 has been explicitly designated by the Federal Monuments Office as a focal year for the theme "Heritage Preservation = Climate Protection." This declaration underscores the growing awareness of the mutual significance and inseparable connection between these two spheres.

7.2 Legal Framework

According to the Erneuerbaren-Ausbau-Gesetz (EAG) (= Renewable Expansion Act) in Austria, large companies are not permitted to be members of energy communities (Erneuerbaren-Ausbau-Gesetz, 2021)

The EAG defines large companies as companies that meet the criteria of a large enterprise according to European law. The law stipulates that energy communities can only be formed by households, small businesses, small and medium-sized enterprises, and certain non-profit organisations. Large companies are excluded from participating in such communities. This regulation aims to ensure that energy communities align with the goals of decentralisation, democratisation, and participation of local communities. They are intended to enable citizens and smaller actors to actively participate in the generation and use of renewable energy and benefit from the associated advantages.

However, it should be noted that certain non-profit organisations, although primarily pursuing development and humanitarian objectives, may be classified as large companies according to European law based on criteria such as the number of employees and other factors. It is important to note that this specifically applies to the Austrian EAG. In other European countries, the regulations regarding the participation of large companies in energy communities may vary.

7.3 Dimensioning and Supply Chain Optimization for Photovoltaic Systems

Supply bottlenecks and extended delivery times have become a familiar topic of discussion. The demand for photovoltaic systems has significantly increased in the past year, driven by high energy prices and an unsettling sense of insecurity in the energy sector. Adding to the complexity is the vast array of photovoltaic modules, mounting systems, and storage solutions available. As a result, accurately estimating the kilowatt peak power to be achieved depends not only on the roof's surface area but also on the specific photovoltaic panel and mounting system employed. Proper sizing of photovoltaic systems and efficient management of the supply chain are crucial in the current market situation. Careful planning and coordination are necessary

7.4 Grid Membership

According to the Renewable Expansion Act, as of June 2023, two models for energy communities have been established. On one hand, there is the "renewable energy community" (EEG), which operates within local limitations, and on the other hand, the "citizen energy community" (BEG), which can operate without geographical restrictions. EEGs are limited to the "local area," requiring participants and their facilities to be located within the franchise area of a grid operator. A local EEG can be established when grid levels 6 and 7 (low-voltage grid) are interconnected, while a regional EEG encompasses grid levels 4 and 5. BEGs can operate across Austria, extending beyond the concession area of grid operators. Unlike EEGs, they are not restricted to renewable energy sources but are solely permitted to generate, store, consume, and sell electrical energy. However, economic benefits such as the elimination or substantial reduction of grid usage fees do not apply to BEGs. In rural areas, determining which neighborhoods belong to the same grid usage tier is often straightforward. However, in urban areas, this can be challenging. For instance, in Vienna, the closest transformer station (the boundary for local BEGs) is frequently located at the next street or apartment block boundary. As a result, the exchange of energy contingents within the EEGs can be severely limited in terms of space.

8 OUTLOOK

Based on the principles of solidarity, the "Energy WITH Spirit" research team is driven to address the challenges of the energy crisis. By establishing a solidarity energy community that generates sustainable energy, the project aims to actively involve vulnerable groups in the ongoing energy transition process. The next crucial steps of the project involve the technical implementation and construction of the photovoltaic plants. Simultaneously, the project team is undertaking economic and regulative preparations to ensure the smooth functioning of the solidarity energy community. This entails devising suitable billing and allocation systems, as well as developing strategies to encourage active participation and engagement from all members. In parallel with these technical and economic endeavours, the project recognizes the importance of energy education to empower and equip vulnerable groups with knowledge about sustainable energy practices. To achieve this, the initiative conducts targeted and easily understandable energy education workshops tailored to the specific needs and circumstances of the target groups. These workshops provide valuable insights into the benefits of renewable energy, energy-saving measures, and the overall importance of environmental sustainability. By fostering a deeper understanding of energy-related concepts, the project endeavors to empower vulnerable groups to make informed decisions, actively contribute to the energy transition, and contribute to climate protection.

1 ABSTRACT

Communities are grappling with environmental, social, and economic challenges due to rapid urbanization and physical changes, with coastal slums bearing the brunt of the impact. Unplanned urban development worsens pollution, inequality, and disaster risk for low-income households. Specific sustainable development plans are vital for tailored solutions based on each community's distinct needs and views. This study examines the socio-economic impacts of the establishment of the International Coastal Road (ICR) in the city of BURJ AL-BURULLUS in Northern Egypt, which marked the beginning of major urbanization efforts in the region in 2002. The physical landscape of the city has undergone significant changes due to urban expansion, with the extension of the city having grown to almost twice the size of the original city. The expansion of the city due to the ICR has caused significant changes to the area's environment, communities, and economies. In particular, the separation of the city from the nearby lake, which was its primary source of income, has had diverse impacts on various aspects of people's lives. This study employed a narrative method to assess ICR's impacts on the area's environments, communities, and economies. Nine villagers with diverse incomes were selected and encouraged to freely share their detailed views. The study focused on the socioeconomic impacts of the changes on the city, but it had significant impacts on all economic, social, and environmental levels. Community participation enhances research outcomes regarding the challenges experienced by impoverished communities due to urbanization. It also assists in the creation of improvement strategies responsive to the distinct requirements of each community by incorporating important perspectives and first-hand experiences of those affected by urbanization.

Keywords: narrative method, Nile delta, physical changes, coastal cities, socio-economic impacts

2 INTRODUCTION

In 2008, half of the global population was located in urban areas, and this trend is expected to continue in the future. Projections indicate that the gradual shift of people from rural to urban areas, combined with population growth, could result in an additional 2.5 billion urban dwellers by the year 2050. This change is likely to accelerate in the coming years (Nations 2018). Urbanization has important implications for demographic changes and the physical landscape, but unplanned, unsystematic, and rapid urbanization can have profound impacts on social, economic, and environmental components. In Thailand, for example, population growth and increased migration have led to challenges experienced across various domains of life, while climate change and urbanization have affected urban governance. The usage of new technologies can also have worrying implications for the labor market and social welfare (United Nations 2020). Addressing the impacts of unplanned urbanization is crucial, as it violates children's rights and has negative effects on cultural diversity, environmental conservation, and urban greening. Effective land policies can play an important role in shaping society and controlling urbanization's character. (Patra et al. 2018).

Constructing new transportation routes is often viewed as the initial stage of urban development and progress. However, developing infrastructure without considering sustainability and environmental concerns can cause harm to natural ecosystems and lead to social and economic inequities (Singer 2018). Therefore, it is critical to adopt alternative approaches that take into account potential negative impacts and address them during the development of infrastructure and urban areas. Rapid and inadequate planning can generate harmful long-term effects, emphasizing the need to ensure positive outcomes for society and the natural world by achieving a balance between growth, sustainability, and environmental concerns (Song et al. 2016).

In response to rapid global urbanization, the Nile Delta Coast has been identified by Egyptian decision makers as a key region for substantial investment in various industries and the growth of existing projects. This coastal area spans approximately 240 km between Abu-Quir city in the west and Port-Said city in the east, situated along the central Mediterranean coast of Egypt ,as shown in Figure 1 (Masria et al. 2014). Thus, in recent years, the Nile Delta has undergone significant physical changes. Some of these are natural

and others human in origin(Future Earth Coasts 2009). These physical changes increase the vulnerability of the coastal zone regard to environmental, social and economic aspects (Iskander and Water 2017).

The state has focused on developing infrastructure along the central coast (delta region) to support mega-projects, including the creation of new cities, private universities, tourist beaches, various ports, and commercial and industrial areas. One of the most notable infrastructure projects is the ICR, established in 2002. Plans for a new train project to transport passengers and goods, with a line running parallel to the ICR, have been announced by Eng. Ashraf Raslan, who serves as the head of the Egyptian National Railways. Phase one of the project will involve an electric train that runs for a distance of 240 km, passing through the new cities of Damietta and Mansoura, and linking the West Port Said Port and Abu Qir Port in Alexandria. Due to the significant effects these developments may have on the environment, economy, and society of the region, responsible planning and management will be necessary to ensure positive outcomes.

Figure 1: The North coast of Egypt extended on the Mediterranean Sea as well as The Central Coast Region (Delta Region) is highlighted.

The northern coast of Egypt boasts several natural lakes, with three located in the Nile Delta region, which have become significant due to their crucial environmental, economic, and social functions(Chu and Karr 2017). These coastal lakes host a thriving ecosystem and possess a unique environmental status owing to their ability to connect saline and freshwater. However, the increase in development and human activities in the area has had a negative impact on the lakes, leading to their deterioration, as reported by Abayazid(Abayazid 2012). In 2018, Egypt achieved a total fish production of 373.3 tons from natural fisheries such as lakes, freshwater, and marine water. Elrazi (Elrazi 2020) reveals that the fish production from BURULLUS, MANZALA, and EDKO lakes and the Mediterranean Sea in Delta cities accounted for 54% of the state's production, with BURULLUS being the most productive lake.

Commercial fishing is a global activity that encompasses various social, economic, and environmental factors that are unique to different regions. In the ELBURLLUS area, for instance, the local population, including 17,000 licensed fishermen and their families, depend on these resources for their livelihoods. As such, fisheries are a crucial support system for the people in the area (Shaltout 2010). The livelihoods of artisanal fishermen depend on coastal environments, which can be greatly impacted by anthropogenic activities such as rapid urbanization(Andrews et al. 2021). This can pose a serious threat to this traditional fishing method. In addition, the primary and secondary buyers in the production chain result in low profit margins for the fishermen, sometimes forcing them to increase their fishing efforts to maintain their income(Charvet-Almeida, Góes de Araújo, and de Almeida 2005). Having fisheries located near their homes can help them save time and involve family members in fishing activities, making their livelihood more sustainable(Diegues 2008) (Granzotto et al. 2004). Fishing not only provides food but also employment opportunities for local communities (Hacohen-Domené et al. 2020).

The research problem arises from the need to understand the social and economic impacts experienced by fishermen in the northern delta region due to the establishment of the International Coastal Road (ICR). The cities located along the ICR route have been affected differently , particularly those that depend on fishing in the sea or lake as their source of income. With proposals to build a railway parallel to the ICR, the issue becomes even more significant, especially given the lack of research in addressing it and the complexity of problems that fishermen's villages may face in the absence of solutions to counteract the effects of the ICR.

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3 STUDY AREA

The construction of the International Coastal Road (ICR) in northern Egypt in 1995 was completed in 2002 with the aim of improving connectivity between Mediterranean countries of northern Africa and southern Europe (Eldeep and Elkady 2022) . Its route spans from Libya in the west to Palestine in the east. The coastal area, including six administrative units and four lagoons, is a crucial source of income for the region; it is renowned for its biodiversity, natural plant life, wetlands, and bird species. However, the region has faced multiple environmental challenges such as erosion, subsidence, water pollution, poor management, land encroachment, and sea-level rise. Tracking these changes and ensuring sustainable development is essential for the region's well-being (Dewidar 2004).

Figure 2: Burg elburllus city region is highlighted as well as the International Coastal Road also coloured (ICR), author.

The Burullus region is located on the eastern side of the Rosetta branch of the Nile River in the central zone of the Mediterranean Nile delta coast of Egypt. Burg Alburullus is a coastal city situated along the Mediterranean shore, bordered by the Alburullus lake to the south and connected to the sea via El Boghaz, v

ICR had established creating a triangular area that separates Burg ALBURULLUS city and lake called EL GOUNA its area is about 50% of the old city, so this extension of ELBURRULUS city was a big physical change as shoown in Figure 3 (Eldeep and Elkady 2022) . During the period of 2005 to 2021, El GOUNA underwent construction in four stages, which were solely dedicated to residential plots. Unfortunately, urban design elements and foundations were neglected during construction. These residential plots were sold via public auction, leading to a significant increase in land prices due to the limited availability and high demand. Although the first three phases have been entirely sold, the fourth stage is yet to be sold, and some plot owners are not yet to build on their land due to various administrative and financial reasons. Currently, only 55% of El GOUNA's land area has been built on, presenting a sizeable opportunity for further development.

Figure 3: EL GOUNA area is highlighted , (Eldeep and Elkady 2022)

4 RESEARCH QUESTION

- What is the impact of the International Coastal Road (ICR) on the socio-economic aspects of the community?

- How effective is community participation in solving problems related to the ICR's impact on the region's socio-economic conditions?

5   MATERIALS AND METHODS.

Conducting a socioeconomic impact (SEI) assessment can help understand the potential effects of physical changes and the reactions of those affected by the changes. Due to marginalization and lack of research on the subject, a case study of Elburullus, a city in Egypt that has undergone major physical changes, was selected to analyze the impacts of these changes on various socioeconomic aspects. The study aimed to provide an overview of all affected socioeconomic factors, rather than focusing on a single aspect. The study included in-depth interviews with nine residents, and thematic narrative analysis was used to obtain as much information as possible about the different socioeconomic effects of the changes. Based on the Socio-economic Impact Assessment Toolkit (Program 2005), seven categories with multiple topics were identified to cover socioeconomic indicators. Organizing these topics with narrators' stories provided insights into the type and magnitude of each impact. Each topic was then analyzed separately to assess the positive and negative views of the narrators.

based on Socio-economic Impact Assessment Toolkit(Program 2005), there are seven categories including many topics as subtitles to cover socio-economic indicators. scheduling these topics with narrators' stories led to knowing the weight and type of effect on every topic. After that, analyze each topic separately to discuss the positive and negative views of the narrators

5.1 Why Why and how narrative method

Narrative inquiry has developed as a research methodology over the last thirty years. It provides a way to collect, examine and analyse stories of experiences and events. (Riessman 2003) assert that storytelling is the most common form of human communication and that it is used to convey the elements of experiences that have influenced an individual or a larger group. Andrews, Squire, and Tamboukou (2008) also argue that storytelling is the universal way in which people make sense of their experiences. People communicate and reinterpret their life experiences through stories (Kohler Riessman 2002). (Hatchell and Aveling 2010) also believe that stories can be used to demonstrate the ways in which people make sense of their experiences through narratives, while illuminating common threads of understanding. They offer "a way of gaining insight into this complex relationship between individuals' particular experiences, meanings and strategies for action and their social and societal contexts" (Stroobants, 2005, p.49, cited in(Hatchell and Aveling 2010)).

The following table presents in a structured way the process of obtaining narrative interviews:

Phases of the Narrative interview	Rules for the interview Exploring
Preparation	Exploring the field Formulating exmanent questions.
Initialization	Formulation of the initial topic for narration. Use visual aids
Main narration	No interruptions. Only non-verbal or paralinguistic encouragement to continue telling the story Wait for signals the end of the ("coda").
Questioning phase	only question: What happened then? no opinion or attitude questions no arguing on contradictions do not ask: Why? Go from exmanent into immanent questions
Small talk	Stop recording. Only question allowed is why? Make note immediately after the interview.

Table 1: main phases of narrative interviews, JovcHElovicH E BauEr (2002)

Narrative development criteria should follow the following guidelines (Muylaert et al. 2014)

- Need to be an experiential part of the interviewee. This ensures his or her interest and lead to a richly detailed narrative.

- It should be personal, social or communal significance.

- The interest and investment in the topic of the informant should not be mentioned, in order to avoid taking positions or taking on roles from the beginning.

- The topic should be wide enough to allow the in- formant to develop a long history, from initial situations, going through past events, leading to the current situation.

- Avoid indexical formulations, ie by not referring explicitly to dates, names or places, which should be brought only by the informant, as part of his/ her relevant structure.

- Shutze(Bauer and Gaskell 2017) , outlines a form of analysis of narrative inter- view quite didactically:

- After transcription, we separate the indexed from the non-indexed material:
  - The first corresponds to the rational, scientific, concrete content of who does what, when, where, and why, ie, it is ordained (consequently, it is consensual order, collective)
  - The second, the non-indexed information goes beyond the events and expresses values, judgments, refers to the wisdom of life and therefore is subjective.
- In the next step, using the indexed content, events are ordered for each subject what is called trajectories.
- The next step is to investigate the dimensions that are not indexed in the text.
- Then, we group and compare individual trajectories.
- The last step is to compare and establish similarities among individual cases thus allowing the identification of collective trajectories.

5.2 The sample selecting

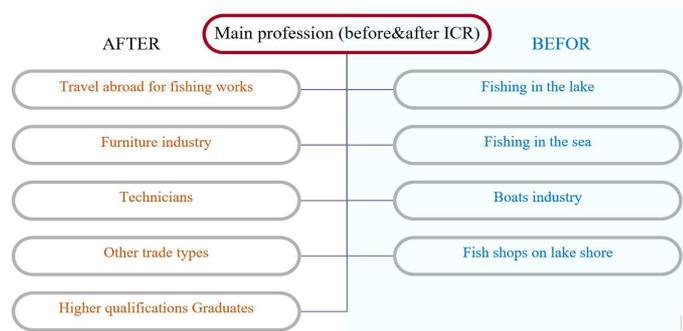
To gain a comprehensive understanding of the impact of a phenomenon, it's important to choose a diverse sample that includes all relevant variables. For the city of Burullus, two essential variables to consider are job and place of residence. Historically, fishing in the lake or sea, boat making, and fish trade have been the primary sources of income for families in the area. However, with the construction of the International Coastal Road, fishing has declined, leading to the rise of new income sources such as offshore fishing, furniture making, other types of trade, technical jobs, and higher education opportunities(Eldeep and Elkady 2022). The residents' place of residence is closely linked to their income level and to how much they have benefitted from the new road. Wealthier residents tend to live in El Gouna, while another group resides in the Old City. Poorer individuals migrated out of the city to live in villages close by where they can continue to practice fishing.


Figure 4: residents' profession after and befor the ICR construction

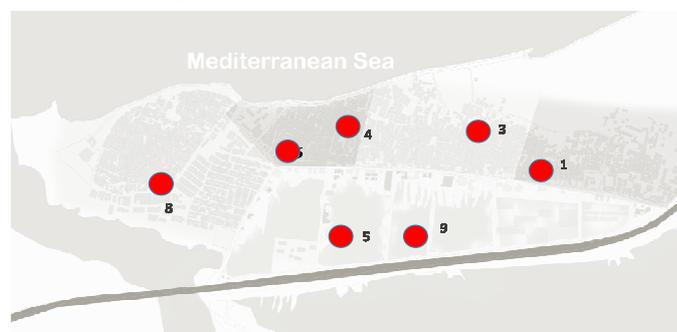
Figure 4 shows the diversification in the professions of the sample's narrators. Additionally, Figure 4 displays how the sample is distributed across the various regions of the city. This diversity is necessary to ensure that the study produces more comprehensive and realistic results.


Figure 5: Accommodation distribution of the nine narrators in the city, author

Although it's important to consider the full range of impacts, including environmental and socioeconomic changes, studying specific socioeconomic changes in depth can be highly useful. For this reason, the study will focus solely on the impact of establishing EL GOUNA on socioeconomic aspects. The information

gathered from interviews will be analyzed to identify the main effects and any associated side effects, and to evaluate whether each effect is positive or negative depending on the group affected. Ultimately, the study aims to determine the advantages and disadvantages of establishing the international coastal road and building EL GOUNA in terms of their socioeconomic impacts.

6 DATA AND ANALYSIS

Based on the research program titled "A guide to assessing the socio-economic impacts of Marine Protected Areas in Australia" (Program 2005) from 2005, the topics covered in the residents' stories were categorized into seven main categories. The author added an eighth additional category for other topics that could not be subtitled under these seven categories. The main categories of socio-economic indicators were income, population, society, education, employment, main profession, industry structure, and firm performance as shown in Figure 6.

Figure 6: main categories of socio-economic impacts assessing according the mentioned research program, author

Residents	income					Population							Society					Education			Employment					Industry Structure			other mentioned topics

Table 2: scheduling data and analysis for residents' stories.

These topics, along with other issues mentioned, were analyzed based on the stories of nine narrators. A symbol was used to depict a narrator's opinion on the type of effect of the physical change, which could be either negative or positive. A table 2 was also provided to assist in scheduling various data.

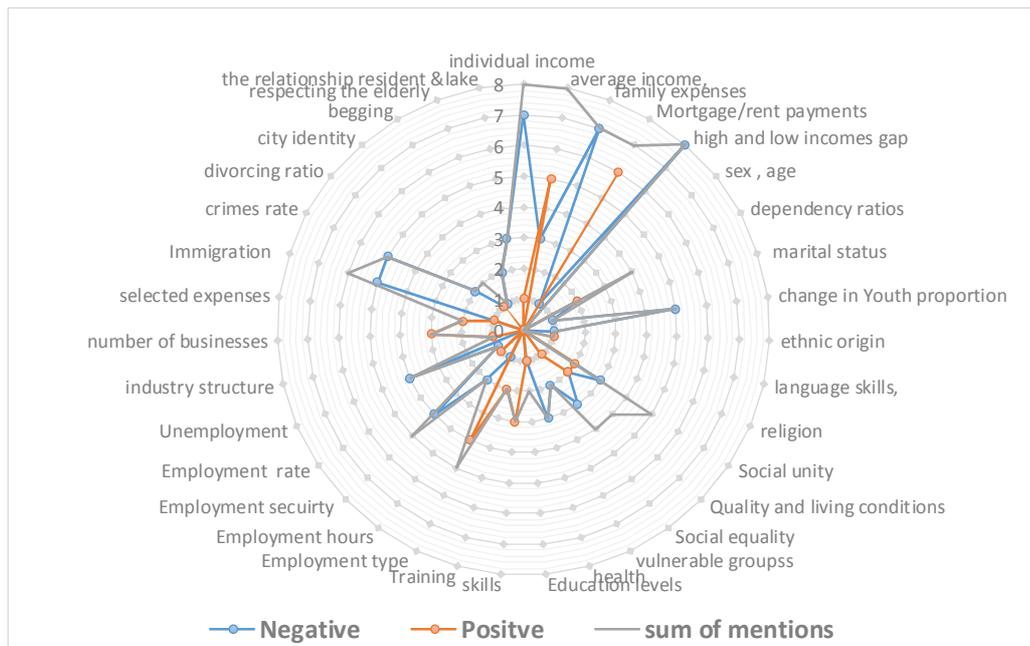
The chart (Figure 7) illustrates the results of interviews conducted with nine individuals regarding the topics they discussed, including the percentage of positive and negative mentions. The findings highlight income disparities, immigration, high crime rates, and living expenses as the most commonly cited negative issues. Conversely, access to housing, job quality, average per capita income, and multiple sources of income were the topics with the most positive feedback. Furthermore, the number of times a topic was mentioned serves as an indication of its importance to the population. Therefore, issues surrounding income, living expenses, migration, and social inequality were among the most pressing concerns for the residents.


Figure 7: positve and negative opinions of resident about socio economic topics

6.1 Income

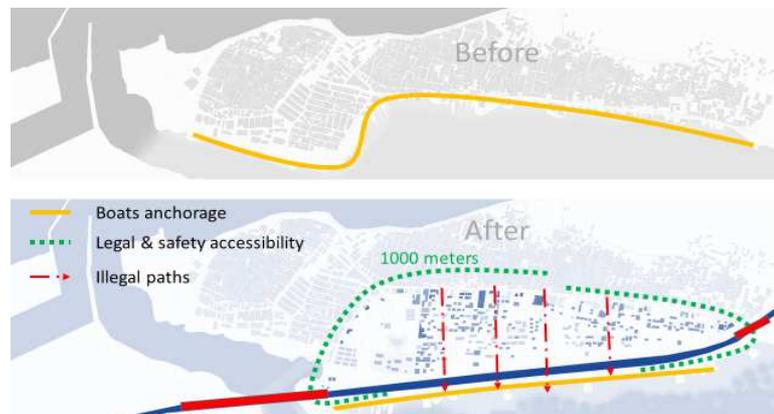
The issue of individual income was deemed significant by eight out of nine interviewees. Specifically, seven of them expressed negative sentiments toward the decline of basic professions, particularly fishing in the lake. This decline is attributed to various factors such as the increased distance between houses and boats, which range from 300 to 1500 meters once boats were anchored close to residences as shown in Figure 8 . Additionally, women's assistance in carrying fishing equipment became more difficult, as leaving them on the boat overnight made them vulnerable to theft. Some fishermen migrated to nearby villages along the lake's shore, while illegal fishing of small fish in AL-BAGHAZ became rampant, affecting profitability as criminals caught and sold them at high prices to fish farm owners.


Figure 8: the distance between boats anchorage and homes. after and before the road costrucrion

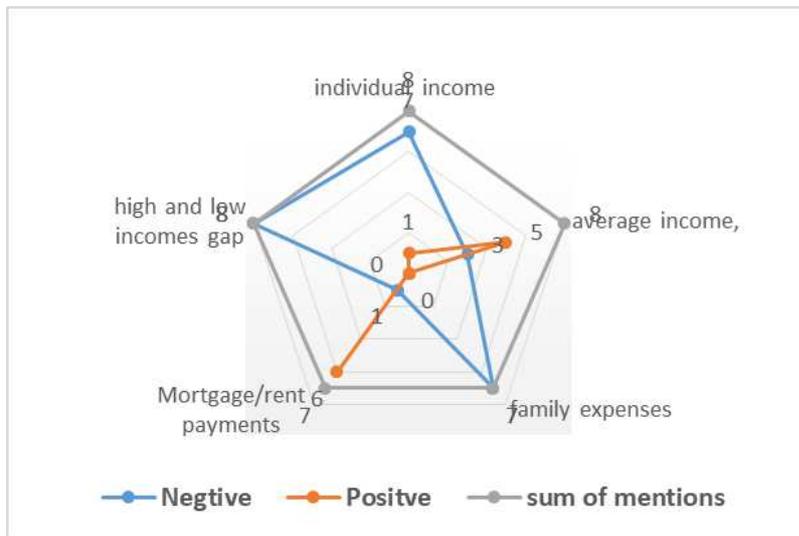
Fish merchants faced challenges after the construction of the road as they had to move their operations to shops on the shore of the old city. To transport fishermen from the new docks to the store premises, they used cars, which proved to be expensive, particularly since the fishermen's return dates varied. As a result, some rich merchants purchased shops in the east of the city, while others went to other villages in BARBAHRI. However, the majority of fishmongers abandoned the trade and started working in different professions or went travelling. Due to the decline in sea fishermen employment, individuals began travelling to other Egyptian cities or even outside the country to find work. Five out of the nine interviewees stated that travelling increased average income despite being expensive and requiring procedures, physical ability, and suitable dates for children. In contrast, the seven individuals who talked about family expenses noted that it had become an enormous burden, unlike in the past when fish were readily available daily, and houses on the lake shore allowed for raising birds and storing rice annually as shown in Figure 9. Almost all of the speakers mentioned the widening income disparity as a significant issue. For instance, some residents owned multiple plots in EL GOUNA, which cost more than 30,000 EGP per square meter, compared to 4,000 EGP in the old city. In contrast, several families still reside in their father's house in the old city and face difficulties finding affordable housing, forcing many to consider emigration.


Figure 9: the percentage of negative and positive mentions to income topics

6.2 Population

The dependency ratios, which indicate the proportion of working-age individuals to the total population, have changed as the average family size has decreased from eight to four people. Some people view this positively as it has reduced household expenses, but others feel the opposite as having many children used to be an advantage for working in fishing and helping parents as shown Figure 10.

Figure 10: children help their fathers, film of behar elatash,19980

One resident mentions that young people are finding it difficult to marry early due to the high requirements, especially the cost of housing and construction in soft clay soil in ELGOUNA as shown Figure 11 , as well as the lack of funded housing for youth. This has led to a decrease in the percentage of young people in the city, and some have even migrated due to the lack of suitable job opportunities . The researcher notes that the number of elderly people and females dominates the city, with some residents stating that the city is no

longer attractive to young people. Fishing used to be an easy and fast way to earn a living, but now, due to changes such as the increase in land prices, many have turned to migration or other forms of work. Furthermore, the travel of residents abroad has led to the appearance of people from diverse ethnic backgrounds in the city. There has been an exchange of cultures, which has resulted in the learning of new languages and has had a positive impact on society.

Figure 11: long-term stages of building because of high cost, taken by author

6.3 Society

According to some residents, social unity between families has not strengthened due to various factors, including the exodus of fishermen and college graduates, as well as the widening income gap. However, others have a different perspective and argue that there are still some large families that remain socially and financially intact, even though at least one member from each family usually goes out to improve the family's income. Regarding living conditions, opinions vary as well. Some residents view it positively due to factors such as travel opportunities, good buildings, and easy accessibility by road. On the other hand, several fishermen from the lake in the old city suffer from difficult economic, environmental, and social challenges, with increasing disease rates, rising expenses, and decreasing income as shown in Figure 12. Regarding social equality, some residents in EL GOUNA have expressed concerns about the fairness of land ownership, given that it is based on an auction system that neglects the actual need for housing. Some argue that the rich tend to monopolize the land for real estate investment, leaving many undeveloped lots and unoccupied buildings. While most residents seem to share this sentiment, there are some who see the auction system as a fair way to own land.

One of the vulnerable groups in the area are the families of the lake's fishermen who are unable to travel for work and have limited employment opportunities. Unfortunately, the state has not provided sufficient support for them, especially in terms of housing. Moreover, social housing is inadequate and has been allocated illegally to undeserving individuals. Another resident has raised concerns over the lack of progress in improving services and infrastructure in the old town. Although a study by Elkady, Fikry, and Elsayad in 2018 (Elkady, Fikry, and Elsayad 2018)suggests that a minimum area of 46 m² is necessary for a family, many families are unable to obtain this amount due to the increasing number of families in the area.

Residents have noted a decline in overall health despite the presence of new hospitals and health centers. This is partially attributed to several factors, such as the city's environmental problems causing numerous diseases, the high cost of sea fish leading to increased consumption of preserved and unnatural foods, and the unhealthy habits of youth. Some residents have compared the current state of healthcare unfavorably to the past, when doctors such as MUHAMMAD GHALY and Dr. ARAFA treated all families and the general community enjoyed better health. Others have pointed out that the lake's pollution from car sewage and treatment plants has affected fish quality. Education rates have improved due to easier and safer travel opportunities after road construction, as well as the realization that a son's education and travel abroad is crucial for future financial stability. However, some residents have expressed concerns that fathers' frequent traveling may lead to some students dropping out of school. Nonetheless, the community has benefitted from technicians' transfer of skills and knowledge after traveling and training.

Figure 12: the gap between A) rich home and B) fisher home, taken by author.

6.4 Employment

The types of employment were traditional occupations and for the service of fishing, such as fish trade, boat industry, trade in boat fuel, trade in fishing tackle, manufacture and distribution of snow, spinning and trading...etc. But as people began to leave hunting and travel, they gained new experiences and were interested in education, so better and better jobs were created. However, some storytellers noted that "the working hours for travellers or technicians were not suitable for their families. Those who travelled abroad to fishing had an annual holiday that lasted no more than a month with their family. Fishing in Egypt's neighbouring cities also remains uninterrupted for twenty days a month.

According to residents, Job security has become too low for all professions saying "It is a great risk for the fisherman in the lake to cross the road, and a large number of young fishermen have already died, and also suffer constantly from the theft of their equipment. The fishermen on the sea outside the city spend a long time on the sea, which increases the risks". Although the nature of new jobs is better, the employment rate has dropped significantly, so the lake absorbs all the existing unemployment at the lowest cost, so the road is blamed for the increase in unemployment in the city as shown in

Figure 13: the percentage of negative and positive mentions to employment topics

6.5 Industry Structure and Firm Performance employment

The construction of an international road has improved mobility between cities, particularly industrial areas like DAMIETTA, GAMASA, BALTIM, MOTUBAS, EDCO and ALEXANDRIA. This has resulted in increased employment opportunities for young people in factories and companies in these areas. Moreover, families of these travelers are able to invest their money in the nearby areas, creating business opportunities. The involvement of their relatives also helps reduce labor costs.

6.6 Other mentioned topics

Immigration occurred in various locations and under different circumstances. For instance, fishermen from the city migrated to neighboring villages both east and west. College graduates also moved to other cities where they could find employment more easily. Presently, a significant number of people are migrating

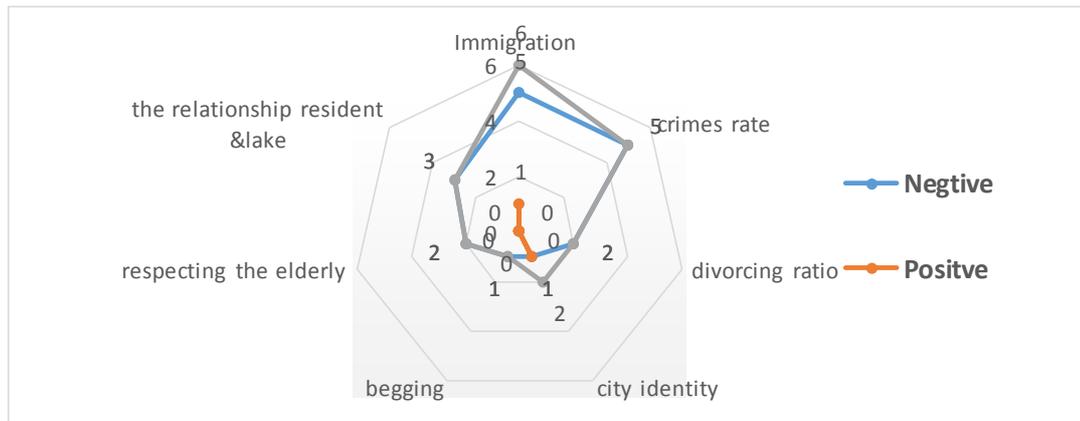
because they are unable to afford daily expenses and do not own their own homes. During discussions with more than five individuals, high crime rates, particularly drug abuse, drug dealing, theft, murder, and earthquakes, were mentioned. Reasons cited for these crimes included unemployment due to the decline of the fishing industry, lack of supervision from traveling fathers, and large income disparities, which drove youth to resort to illegal activities to improve their income compared to travelers that obtained large amounts of money illegally and encouraged their children to do the same as shown in Figure 14 .


Figure 14: the percentage of negative and positive mentions to other mentioned topics.

According to some narrators, divorce rates in the city have increased significantly due to several reasons. Firstly, some women are unable to assist their husbands with fishing because boats are positioned too far away. Secondly, mothers prevent their children from fishing with their fathers due to concerns over traffic accidents. Thirdly, husbands traveling for long periods for work cause problems that lead to divorces. Fourthly, women find that their low income compared to the rich is insufficient to meet their needs. Lastly, some women refuse to migrate with their fishermen husbands. Rapid and unplanned urbanization has had a negative impact on the town's identity, although individual attempts have been made to preserve it. Due to the native population's constant migration, the identity of the town has begun to change at the people's level. Conversely, some people argue that the buildings and El GOUNA have enhanced the city's beauty in terms of urbanization.

During discussions, one person mentioned that begging, which is widespread nowadays, did not exist at all before. Additionally, the lack of respect among sons for their fathers was a frightening phenomenon in the BURULLUS community due to the distance between them while traveling.

Two individuals addressed an interesting topic in their narratives regarding the relationship between the inhabitants and the lake. According to one person, "the lake is like my daughter. Touching it, looking at it, and sitting next to it on the shore was a source of our happiness. The road blocked our view, but we protected it, and no one dared to harm it with sewage or by catching small fish." Another participant stated that the lake contributed greatly to their education and daily life. In addition to studying, they could earn money during limited hours and used the lake as the main spot for picnics with friends.

7 CONCLUSION

The research results were divided by the researcher into two distinct categories; one focused on the social and economic repercussions of these effects, while the other centered on utilizing social participation to tackle and solve these problems."

On a positive note, some of the residents in the new area (El Gouna) have the privilege of owning high-quality homes that are well-ventilated and have good lighting as well as wide roads. The existence of various industries and businesses in the city has also led to some individuals experiencing an increase in their income. Additionally, residents in El Gouna also have the benefit of having easy access to different cities, and through such exposure, they are exposed to a variety of ideas and cultures. Education is also easily accessible in the city, and there is also an increasing trend towards investment in the area. Certain types of work such as fishing away the city have also proven to be a significant source of income for some residents of El Gouna.On the flip side, there are several downsides to physical change in the city. The average income

of most individuals in the city is lower, making it difficult to meet the increasing household expenses. The income gap between different families has widened, consequently leading to unequal access to housing. As a result, a lot of fishermen have migrated from the city due to the challenges that come with fishing, as well as rising family expenses. Other issues that the city grapples with include a late marriage age and an unbalanced population of adults, which makes it difficult to maintain social bonds in families. Crime rates in El Gouna are also alarmingly high and have been linked to issues such as income inequality, unemployment rates, and travel. Finally, there is an increasing disparity in the level of services and opportunities available to different residents of the city, which makes things even more challenging.

The use of the narrative method in El Burllus city proved useful as it allowed inhabitants to speak freely and offer excellent suggestions towards resolving problems before the proposed railway project goes forward. Some of the suggestions are as follows:

- One inhabitant suggested that the fourth stage of El Gouna, which has not been sold yet, could be used differently to provide a significant opportunity. For example, the state could construct multistory towers to accommodate a large population. Then, it could improve the old city and create wider pathways and roads within it. Affected individuals could be compensated with apartments in the new towers.

- Another individual proposed creating a new village for the fishermen on the shore of the lake, to solve the issue of fishermen in the city. The new village could also protect AL-BOUGHAZ from local fishers engaging in illegal fishing. Furthermore, the establishment of this new village would help preserve the unity of families, preventing their dispersion into different areas.

- Some of the inhabitants suggested creating canals between houses in El Gouna, using the traditional method to facilitate fishing, prevent equipment theft, and overcome the danger of crossing the highway. This suggestion would also solve environmental problems, including the drainage of rainwater and its consequences.

- One narrator expressed that if the international road had passed from the north of the city, it would have been more beneficial as it could have preserved the beach from erosion. as well as It would have also protected the area from rising sea levels in the future.

- Additionally, one of the fishermen suggested that encouraging people to open fish shops on the beach could motivate most fishermen to work in the lake.

1 ABSTRACT

It is undeniable that climate change effects are impacting our daily lives and need to be considered when shaping our living environment and therefore also included in matters of spatial and landscape planning. Climate change adaptation measures mostly address climate change effects in large cities – such as overheating and urban heat islands. New approaches and solutions to improve liveability and to act against the consequences of climate change are required – not only in big cities but also in smaller towns and rural communities.

Nature-based-Solutions (NbS) can tackle some of the most pressing urban environmental and societal challenges such as urban heat islands and by fostering adaptation to climate, halting biodiversity loss and promoting public health and social cohesion. Green and blue infrastructures are considered to be a form of urban sustainability as they not only reduce temperatures and other urban environmental effects, but also improve air and water quality, reduce stormwater runoff, and attract pollinators. Vertical greening and green walls have many advantages and combine a positive effect on the environment and microclimate with an improvement in the quality of life in urban areas.

During the research project "Strasshof. Klimafit!" a concept for "EVAPO+ transpiring green walls" was developed. In comparison to other forms of vertical greening, the EVAPO+ transpiring green walls have a particularly high cooling effect and primarily serve as natural air conditioning in the outdoor area. The name "EVAPO+ transpiring green wall" is derived from the term evapotranspiration, which is the evaporation from plants, water, soil and substrates. EVAPO+ green walls increase and maximise evapotranspiration and thus contribute more effectively than other green wall systems to cooling the microclimate surrounding us.

With the EVAPO+ transpiring green walls which have been innovatively developed, the quality of stay can be improved at many locations in microclimatic areas. Essential functions of green infrastructure and nature-based solutions, such as creating shaded spaces as well as reducing the reflection of incoming solar radiation and cooling of the surrounding environment through evaporation can additionally be strengthened.

Keywords: urban heat island, example, green infrastructure, microclimate, evapotranspiration

2 BASELINE

2.1 Climate Change and Urban Heat Island Effect

It is undeniable that climate change effects are impacting our daily lives and need to be considered when shaping our living environment and therefore also included in matters of spatial and landscape planning. Climate change adaptation measures mostly address climate change effects in large cities – such as overheating and urban heat islands.

The urban heat island (UHI) effect is a phenomenon in which urban areas experience higher temperatures than surrounding rural areas due to urbanisation and human activities. It mainly occurs due to the high percentage of sealed surfaces, asphalt roads and the density of high buildings. These surfaces heat up a lot when exposed to sunlight, and the lack of plants, green areas and unsealed ground means that little water can evaporate to cool the surroundings. Due to the high percentage of sealed surfaces, evaporation is reduced while the solar irradiation on building and road surfaces is stored at the same time. With climate change, the number of very hot days (temperatures exceeding 30°C) increases, and the heat island effect additionally causes an increase in temperature. The UHI effect can cause significant warming of the local climate and can

be especially troubling during summer heatwaves when temperatures are particularly hot. It is therefore necessary that we adapt our urban construction methods to keep the UHI effect as low as possible. This can be achieved, among other things, through shading, planting and evaporative cooling.

Due to the fact that the population in communities surrounding large cities is constantly growing, small towns and rural communities are burdened with severe influx and, as a consequence, densification and a growing percentage of sealed surfaces to create housing and infrastructure. This causes a loss of green areas which in turn intensifies the consequences of climate change. For this reason, even, in small towns and rural communities, there is a need to take measures to counteract climate change effects, such as heat waves, drought and heavy rain.

New approaches and solutions to improve liveability and to act against the consequences of climate change are required – not only in big cities but also in smaller towns and rural communities.

2.2 Nature-based Solutions and Green Infrastructure

Nature-based solutions (NbS) and green infrastructure (GI) are both approaches used to address environmental challenges and promote sustainability. While there is some overlap between the two concepts, they have distinct characteristics and areas of focus.

Nature-based solutions (NbS) refer to the use of natural processes and ecosystems to tackle societal and environmental challenges. NbS leverage the power of nature to provide sustainable and cost-effective solutions. They involve the conservation, restoration, and management of ecosystems and biodiversity to deliver multiple benefits, including climate change mitigation, adaptation, and disaster risk reduction. NbS can take various forms, such as reforestation and afforestation projects, wetland restoration, coastal management initiatives, and urban greening efforts. These solutions often mimic or restore natural processes, enhancing ecosystem services like water purification, flood regulation, carbon sequestration, and habitat provision. NbS are designed to be resilient and adaptive to changing conditions, providing long-term benefits for both humans and the environment. NbS can tackle some of the most pressing urban environmental and societal challenges such as urban heat islands, fostering adaptation to climate, halting biodiversity loss and promoting public health and social cohesion. Over the last decade, NbS have increasingly been promoted as cost-efficient, no-regret solutions to address urban challenges in cities. The benefits nature delivers have been highlighted in European and international frameworks such as the EU Biodiversity Strategy for 2030, the Urban Agenda 2030 or others. The successful implementation of NbS depends on a sound knowledge and understanding of NbS, the complex processes of natural systems and NbS design features and options. Whilst scientific evidence of the multifunctional benefits of NbS is plentiful and well-documented, and technical knowledge on NbS design and implementation abundantly available, there is a lack of coherent, market-orientated and scalable models for local NbS design and implementation.

On the other hand, green infrastructure (GI) refers to a strategically planned network of natural and semi-natural spaces that conserve ecosystem values while also supporting human needs. It is a systematic approach to land use planning and design that incorporates natural elements into urban and rural areas. In the context of EU policies, GI is defined as "A strategically planned network of natural and semi-natural areas with other environmental features, designed and managed to deliver a wide range of ecosystem services, while also enhancing biodiversity." (Directorate-General for Environment) GI aims to create a multifunctional network of green spaces that provide various environmental, social, and economic benefits. GI includes features like parks, forests, wetlands, green roofs, urban gardens, permeable pavements, and green corridors. These elements help manage stormwater, reduce urban heat island effects, enhance air quality, provide recreational opportunities, support biodiversity, and improve the overall quality of life in cities and regions. Green infrastructure is often integrated into urban planning processes to create more sustainable and resilient communities.

GI also includes vertical greening, such as complex façade-bound greening or ground-bound greening in outdoor areas, which are effective countermeasures. Because vertical greening hardly requires any additional space, it offers great potential for further application, especially against the background of urban densification. Green walls have many advantages: as a "natural air conditioning system", they cool the ambient temperature, absorb rainwater (water retention), improve air quality (pollutant filtering, fine dust binding, air purification, oxygen production, CO2 binding), reduce noise, create habitat for birds and insects

260

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

(biodiversity), protect buildings from negative external influences (weathering, heat, cold, UV radiation, rain), energy costs for air conditioning in summer and heating in winter can be saved. In addition, the aesthetic value of green walls has multiple positive effects on our well-being. The quality of life and housing of the urban population in their direct living and working environment is increased. Vertical greening therefore combines a positive effect on the environment and microclimate with an improvement in the quality of life in urban areas.

Both – NbS and GI – are a form of urban sustainability as they not only reduce temperatures and other negative urban environmental effects, but also improve air and water quality, provide space for recreation, reduce stormwater runoff, and attract pollinators – all in all they help greatly with climate mitigation and adaptation. For the sake of completeness, blue infrastructures are infrastructures with visible "blue" in the form of water. This can be e.g., artificial, newly created ponds, water areas or water features. On the other hand, this also includes existing natural bodies of water. The connection of green (land) and blue (water) infrastructure has many advantages for the quality of the environment and natural areas and improves people's health and quality of life. In view of the constant loss of inner-city green spaces with increasing global climate change, which leads to urban heat islands, especially in cities, greening of buildings is becoming increasingly important. While nature-based solutions and green infrastructure share a common goal of utilising nature for environmental benefits, the main difference lies in their scope and focus. Nature-based solutions encompass a broader range of approaches that can address diverse environmental challenges, including climate change and disaster resilience. Green infrastructure, on the other hand, primarily focuses on urban and regional planning, emphasizing the integration of natural elements into human-made environments. Nature-based solutions and green infrastructure are complementary approaches that leverage the power of nature to promote sustainability. Nature-based solutions encompass a broader range of approaches for addressing environmental challenges, while green infrastructure primarily focuses on integrating natural elements into urban and regional planning to create sustainable and resilient communities.

3 STRASSHOF. KLIMAFIT! – A LIGHTHOUSE DEMONSTRATION PROJECT

3.1 About the project

"Strasshof. Klimafit! Strasshof as a lighthouse: EVAPO+ green walls, green infiltration troughs, empowerment and practical transfer" is a lighthouse demonstration project that stimulates processes for climate change measures by empowering other municipalities and small towns. The project aims to implement resilient, multifunctional and "climate-fit" solutions that respond to heat and heavy rain, improve the microclimate, increase the quality of life and living while promoting biodiversity in existing areas of the municipality Strasshof an der Nordbahn in Lower Austria. With these measures, the municipality of Strasshof can act against climate change consequences and improve the liveability of the population. The transferability of the demonstrations will be guaranteed with the help of various regional, national and international exchange forums. In cooperation with other Austrian municipalities, the lessons learned from Strasshof will be reflected and transferred to the regional network "Climate-Fit Small Towns and Municipalities" along with step-by-step instructions for climate-fit municipalities.

The project is funded by the Austrian Climate and Energy Fund, Klima- und Energiefonds, under the Smart Cities Initiative in Austria, from April 2022 to March 2025.

3.2 About the municipality

Strasshof an der Nordbahn is located about 25 km northeast of Vienna (Austria) in the political district of Gänserndorf and is part of the northern Marchfeld region in the province of Lower Austria. Originally planned and laid out as a Viennese suburb as a kind of "garden city", the settlement had only about 50 inhabitants around the year 1900. With the construction of a marshalling yard of the northern railroad in Strasshof, the economic upswing began in 1906. In recent decades, the town has developed rapidly, and, with 11,786 inhabitants (as of January 1, 2023), it is by far the largest town in the Marchfeld region. With an average population density of 1,012 inhabitants per square meter, the municipality has a compact settlement area. With the help of construction bans, Strasshof has already been taking on municipal tasks that have become pressing in recent years due to enormous population growth. Equally urgent still is the development of climate change-adapted strategies, through which the community can prepare for changing climatic conditions. Since 1999, Strasshof an der Nordbahn has been an active climate alliance municipality with the

goal of continuously reducing greenhouse gas emissions because it is becoming increasingly important for municipalities to improve the quality of life and standards for their citizens by running projects that fulfil their targets.

4 EVAPO+ TRANSPIRING GREEN WALLS IN STRASSHOF

In the course of the project Strasshof. Klimafit! a concept for "EVAPO+ transpiring green walls" was developed. In comparison to other forms of vertical greening, the EVAPO+ transpiring green walls have a particularly high cooling effect and primarily serve as natural air conditioning in outdoor areas. EVAPO+ transpiring green walls consist of a horizontal vegetation carrier with a continuous vertical substrate body that increases evaporation of the substrate, provides more root space for plants and thus more leaf mass and transpiration. The substrate in the vegetation carrier in addition to the plants causes higher evaporation rates. This technique in combination with automatic irrigation systems leads to greater leaf mass of the plants and therefore higher transpiration. Overall, they increase evapotranspiration, which serves to cool the surrounding area. The irrigation system of the vertical substrate level has a relatively high-water absorption capacity and releases the water slowly. Automatically weather-controlled, this level is watered more on warm and hot summer days. To reduce the top-bottom gradient of green walls, where top and side areas tend to be too dry, a special version of the automatic irrigation system is used. EVAPO+ transpiring green walls make a significant contribution to the adaptation of urban spaces to climate change.

The name "EVAPO+ transpiring green wall" is derived from the term evapotranspiration. Evapotranspiration is the transpiration from plants and evaporation from water, soil and substrates. EVAPO+ green walls increase and maximise evapotranspiration and thus contribute more effectively than other green wall systems to cooling the microclimate surrounding us.

The EVAPO+ transpiring green walls fulfil multifunctional effects on different levels. In addition to microclimatic effects, these effects are in particular:

- As a space-dividing element, the green wall (in a free-standing variation) can counteract conflicts of use at busy open spaces and create protected areas.
- Due to the continuous vertical substrate layer and plant cover, the green wall absorbs sound and can provide low conflict use and pleasant quality of stay as noise protection is provided along roads or playgrounds and sports fields.
- The plants and the moist substrate surface bind dust and harmful air particles and thus increase the quality of stay in the vicinity.
- Plants have a calming psychological influence on people and thus increase well-being and the quality of stay in the open space.

Three different types of EVAPO+ transpiring green walls have and will be implemented as demonstration objects in Strasshof an der Nordbahn as microclimate-improving measures which have been further optimised with regard to evapotranspiration cooling effects, leading to a better quality of life and supporting biodiversity:

- Public buildings: The first EVAPO+ green wall was implemented on the east-facing roof terrace of the municipal office in Strasshof.
- School/outdoor classroom: The implementation of another green wall is planned in combination with a pergola at a school site in Strasshof.
- Central public area: The implementation of a free-standing green wall in combination with seating in a central public area in Strasshof is currently being discussed.

4.1 Construction details

EVAPO+ transpiring green walls belong to the wall-bound façade greening categories. Compared to ground-based and trough-based vertical greening with climbing plants, wall-bound vertical greening can increase microclimatic effects.

The special characteristic of the innovative EVAPO+ transpiring green wall is a horizontal vegetation carrier with a continuous substrate body. This enormously increases the evaporation of the substrate. In addition, the

larger root spaces in EVAPO+ transpiring green walls allow for more developed plants, which leads to greater leaf mass and thus increases the transpiration of the vegetation. This results in the effect of an overall increased evapotranspiration, which cools the surrounding area.

To increase evaporation, the EVAPO+ transpiring green wall has a special design with two different substrate levels and two separate water circuits. The substrate, which runs vertically through the entire construction as a base for the greening, is designed like a gabion wall with a technical, structurally stable, and humus-free substrate in a grid structure and provided with its own irrigation circuit.

The actual plant and substrate level in front is lined with a knobbed layer made of HDPE plastic as constructive wood protection and a layer of geofleece on top. It is filled with a substrate mixture for intensive roof gardens. Watering is automatic via drip hoses running horizontally in the plant troughs.

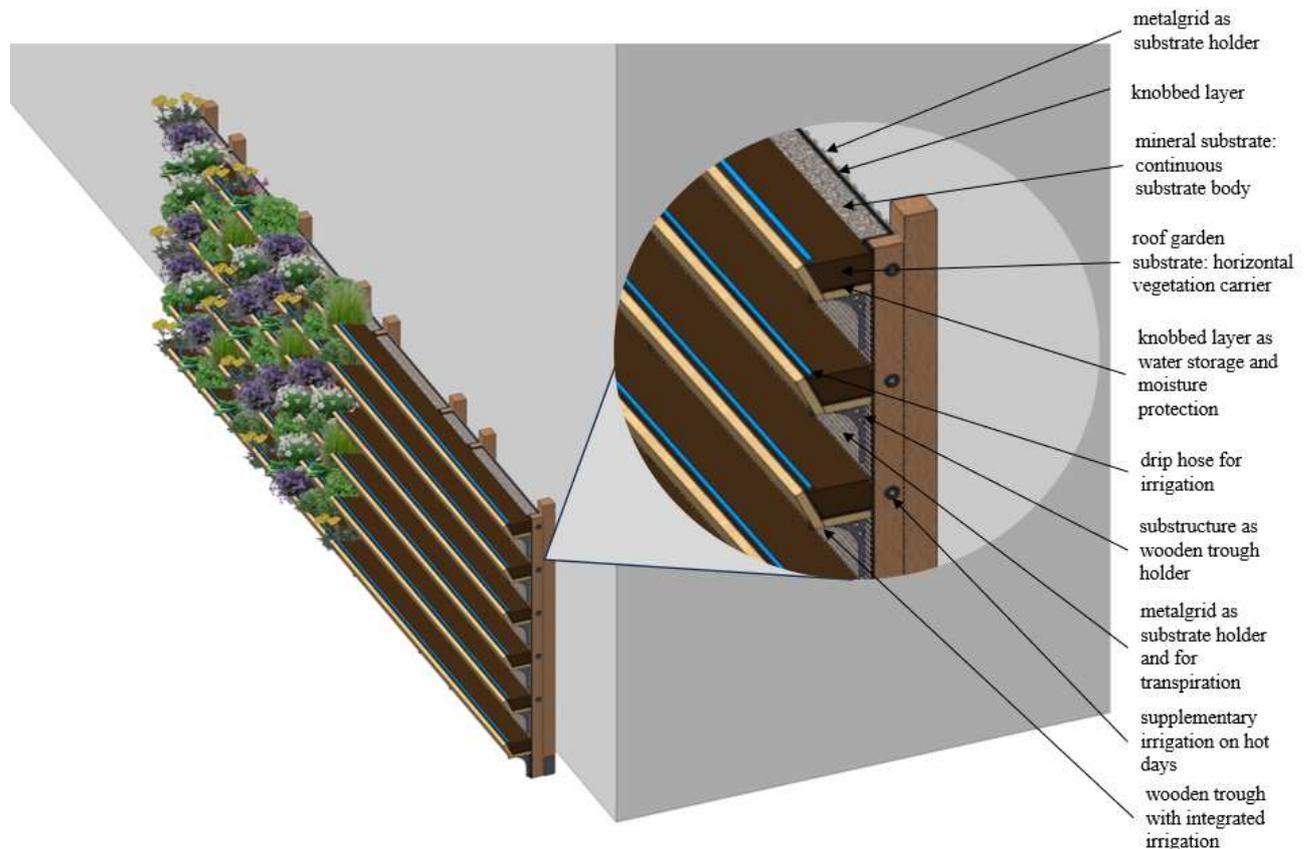
The following visualisation shows in detail how the EVAPO+ transpiring green wall is constructed and layered. To highlight is the continuous substrate body at the back of the green wall.


Fig. 1: Illustration of the EVAPO+ transpiring green wall on the roof terrace of the Strasshof municipal office building

4.2 Plants and rhizosphere

The root area is a crucial growth criterion for the plant. The planting is carried out with robust, perennials and herbs. A root space of 1.5 litre of roof garden substrate is available per plant in the vegetation level with the plant troughs alone. In the underlying, vertically continuous substrate level, additional root space can be developed by the plants. According to the standard (ÖNORM L 1136) for full-surface wall-bound green roofs, the minimum dimensions of one litre of available root space per plant is required which is thus well surpassed. The plant substrate consists of a mixture of organic or mineral components that form the vegetation layer. A combination of ready-to-use materials such as crushed bricks and pumice, and filling materials such as sand and compost with an admixture of perlite, is applied.

4.3 Irrigation system

To optimise the performance of EVAPO+ transpiring green walls in dry periods and hot summer days two automatic irrigation systems for the rear substrate are designed. The first type of automatic irrigation system has a relatively high-water absorption capacity and releases the water slowly. The other type of irrigation

system is automatically weather-controlled. This means, the substrate is watered more on warm and hot summer days. This special irrigation system causes an increase in evaporation via the substrate surface on hot days and a reduction in the top-bottom gradient of green walls where top and side areas tend to be too dry on hot days. The substrate consists exclusively of mineral fractions with a grain size of 2 to 8mm, a maximum water capacity of 40% by volume and a water permeability mod. Kf of 0.68 cm/s.

The following illustration shows the two automatic irrigation systems: the main irrigation system for plantgrows in the horizontal vegetation carrier respectively the front substrate level and the additional irrigation system for hot summer days integrated in a continuous vertical substrate body (rear substrate level).

Fig. 2: Separate water circuits for watering the EVAPO+ transpiring green wall on the roof terrace of the Strasshof municipal office building

4.4 Demonstration 1: EVAPO+ transpiring green at the terrace of the municipal office

The EVAPO+ transpiring green wall is built on the east-facing roof terrace of the Strasshof municipal office and attached to the façade. The green wall is 6m long and 2.40m high. The frame construction for the green wall is made of larch wood, which forms the substrate and plant carrier in the form of rows arranged one on top of the other. Over 300 plants were used. The following plant species (perennials and herbs) where planted in the Demonstration 1 EVAPO+ transpiring green wall: Alchemilla sericata, Allium schoenoprasum, Armeria maritima, Aster ageratoides, Bergenia cordifolia, Dianthus deltoides, Geranium wallichianum, Geranium x cantabrigiense, Geranium sanguineum, Geranium pratense, Iris x barbata-nana, Levisticum officinale, Melissa officinalis and Thymus x citriodorus.

Fig. 3 and 4: EVAPO+ transpiring green wall on the roof terrace of the Strasshof municipal office

Most perennials are deciduous. About a third of the perennials are evergreen so that a relatively green wall can be seen, even in winter.

Fig. 5: EVAPO+ transpiring green wall on the roof terrace of the Strasshof municipal office building

4.5 Demonstration 2: EVAPO+ transpiring green as part of a newly built outdoor classroom

In the Middle School in Strasshof, an outdoor classroom is currently under planning. This design will combine an EVAPO+ transpiring green wall with a pergola construction providing additional shade through climbing plants. The climbing plants form a ground-based vertical greening with climbing frames and aids.

Fig. 6 and 7: Construction details and visualisation of a draft of the outdoor classroom with EVAPO+ transpiring green wall

The EVAPO+ outdoor classroom will be set up near a south-east-facing large window area of the school building to produce shade and a cooling area for the school library, while creating a cool outdoor lounge for school lessons and breaks. In addition to the microclimatic advantages of the EVAPO+ green wall, climbing plants will be applied to the pergola on stainless steel cable elements and thus reduce the solar input into the school building. The deciduous climbing plants shade the library in summer and let the sun through in winter after the leaves have fallen.

Compared to the wall bound EVAPO+ transpiring green wall at the Strasshof municipal office, the EVAPO+ transpiring green wall within the outdoor classroom will be two-sided, meaning that both sides of the free-standing wall will be filled with plants. For that purpose, wide plant troughs are embedded in the pergola construction, which creates the possibility of two opposing vertical vegetation areas. Partitions with structurally stable technical substrates in grid structures are also installed in the middle of the plant troughs to increase evaporation.

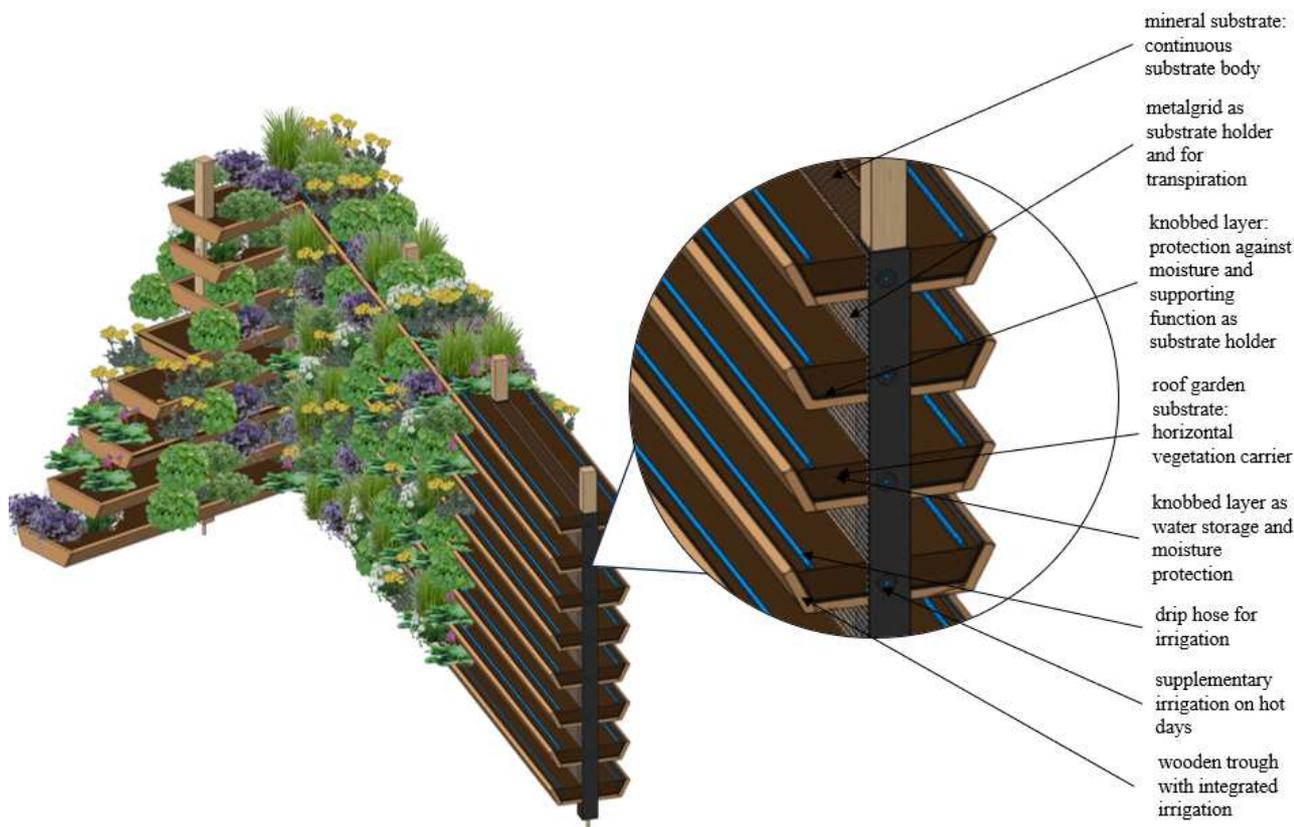
The following visualisation shows in detail how the EVAPO+ transpiring green wall within the outdoor classroom at the Middle School in Strasshof is constructed and layered. To highlight is the double-sided design of the free standing wall.


Fig. 8: Construction of the EVAPO+ transpiring green wall within the outdoor classroom at the Middle School in Strasshof

The EVAPO+ outdoor class will be designed using versatile perennial planting that will be home to a wide variety of flowering and fragrant perennials as well as herbs and, if desired, fruit or vegetables for cooking classes.

The outdoor classroom includes several categories of vertical greenery. The EVAPO+ transpiring green wall is a combination of wall-bound vertical greening with partial vegetation and wall-bound vertical greening with full-surface vegetation supports. The vertical greening with climbing plants is surrounded by a wooden border respectively a trough without a bottom. It is only recognisable as ground-based vertical greening at second glance.

The excess irrigation water of the EVAPO+ transpiring green wall is directed into the root area of the climbing plants via an underground supply pipe. Generally, there is a natural irrigation through rainwater and groundwater extraction in the case of ground-based vertical greenings.

The irrigation of the EVAPO+ transpiring green wall will be combined with rainwater harvesting (sustainable rainwater management, careful use of potable water). To save tap water for watering the EVAPO+ transpiring green wall, the installation of a rainwater tank is planned. The rainwater storage tank will receive the precipitation water from the roof of the school building. With the potential to use rainwater for irrigation, the goals of sustainable rainwater management and more careful use of drinking water can be achieved. Irrigation is carried out with low pressure and drip hoses and can thus also be fed with rainwater in public spaces.

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Construction work started during the school summer break 2023. With school starting again in September 2023, the plants will be added with the participation of students, so that the EVAPO+ outdoor class will be ready to use starting in autumn 2023.

Fig. 9 and 10: Ground construction/substructure of the EVAPO+ transpiring green wall within the outdoor classroom at the Middle School in Strasshof

5 CONCLUSION AND OUTLOOK

EVAPO+ transpiring green walls are a version of vertical green walls that can be seen as nature-based solutions and form a part of green infrastructures. Through the increased evapotranspiration, essential functions and benefits of green infrastructure and nature-based solutions are enhanced. EVAPO+ transpiring green walls are an easy solution to improve microclimates by cooling the surroundings, improving air quality and quality of stay for different users in urban open areas. They also lead to improvements in urban infrastructures, and in the settings of living and working spaces, etc. The innovatively developed EVAPO+ transpiring green walls can improve the quality of stay for many varying locations: they come in different shapes and sizes and can be combined with other built infrastructures (see outdoor classroom). EVAPO+ green walls can be used e.g., as wall-bound vertical greenery on buildings, in combination with pergola constructions to produce shade, or as free-standing room dividers, for example for terraces and seating areas. Furthermore, the choice of plants can be adapted to individual needs and situations. The evapotranspiration effect increases of course with the size of the EVAPO+ transpiring green wall. Generally, the team aims for construction heights of a maximum of 4 to 5 meters.

The developments around the EVAPO+ transpiring green walls aim to create the most robust, resilient vertical greenery possible in the immediate living and working environment and have exceptional microclimatic advantages. To prove these advantages, the EVAPO+ transpiring green walls will be monitored throughout the project. Measurable goals include microclimatic effects and positive effects regarding rainwater management. Further, it will be important to monitor the quality of stay for the immediate users. The following measurements will lead to a monitoring of the anticipated effects:

- Microclimatic effects through shading and evapotranspiration of the plants and the substrate body. Measurement sensors have been and will be installed and will measure temperature, humidity, and solar radiation through the entire duration of the project for monitoring. The results will be compared to reference measurements.

- To monitor the use and impact on the users, surveys will capture discernible effects of the EVAPO+ transpiring green walls on summer/heat days. Various needs and possible uses and applications of the green wall will be considered. Attention will also be paid to different needs and possible conflicts of use and interest.

Overall, the EVAPO+ transpiring green walls demonstrate an easy way to cool down microclimates with aesthetic effects. The increased and resilient transpiration effect of the plants, together with the evaporation over the extensive substrate surface, creates a particularly efficient evaporation coolness. Further, the vegetation develops much better and is many times more resilient than all wall-bound vertical green walls

available on the market, even in the event of disruptions or failure of the irrigation system. The demonstrations in Strasshof an der Nordbahn provide a good example for other municipalities or locations.

(Karl Matthias Wantzen, UNESCO Chair "River Culture-Fleuves et Patrimoine", CITERES – UMR 7324 CNRS, University of Tours & LIVE – UMR 7362 CNRS, University of Strasbour, France, karl.wantzen@univ-tours.fr)

1 ABSTRACT

In cities, river restoration is widely recognised as an essential Nature-based Solution (NbS) that delivers a wide range of benefits. However, rapid urbanisation and economic growth over the past four decades have led to the degradation of Chinese rivers. In response, the Chinese government introduced the Sponge City (SC) concept in 2013 as part of the 'Ecological Civilisation' era. The SC, considered a hybrid NbS, was designed to foster urban resilience, particularly against severe disasters such as floods. The nationwide SC Program (SCP) commenced in 2014. Since then, the number of participating cities has continued to grow. As a result, a large number of Chinese cities have been transitioning from traditional grey infrastructure to green/blue infrastructure with substantial investments, leading to the restoration, redesign and revitalization of urban rivers. Despite these efforts, there is a noticeable lack of research that examines urban river restoration from a multi-beneficial NbS perspective, a current global research trend. To address this research gap, the present study adopted a mixed-methods approach, combining expert interviews with bibliometric analysis, to explore the specific role of urban rivers as an NbS within the SC framework. Our study revealed an increasing scientific interest in urban river restoration beginning in 2013, viewing them as elements of sponge construction. Alongside this, there's a progressively nuanced understanding of rivers as multifunctional NbS. In addition, we identified specific challenges that impede the successful implementation of these NbS in Chinese cities. To overcome these barriers, we formulated a set of recommendations that are in harmony with China's new River Chief System policy and the Ecology Oriented Development (EOD) model. The aim is to enhance the sustainable governance of urban rivers as an NbS in the long term, thus contributing to overall sustainable development in China.

Keywords: social-ecological system, interview analysis, bibliometric analysis, nature-based solution, urban river restoration

2 INTRODUCTION

In 2013, China first proposed the construction of an ecological civilization, which was later incorporated into the country's constitution in 2018. As part of this initiative, the Chinese government introduced the concept of Sponge City (SC) as a scalable NbS in 2012 and launched the nationwide SC Program (SCP) in 2014. SCP aims to develop a holistic urban water management system to adapt to climate change impacts, particularly in response to extreme weather events. This involves replacing traditional grey infrastructure with green/blue infrastructure capable of infiltrating, absorbing and storing excess rainfall during floods, as well as releasing it during droughts. Constructing SC infrastructures includes restoring rivers and floodplains, building artificial wetlands, installing sunken green spaces, rainwater tanks, and green roofs, transforming permeable pavements, and more (Song, 2022).

In 2015, 16 Chinese cities were selected for the first batch of pilot SCP, which expanded to include an additional 14 cities in 2016. The central government covers about 15-20% of the program costs, while the remainder is shared between local governments and the private sector through public-private partnerships (PPP). As of 2018, the fixed subsidy for pilot SC projects amounted to 600 million RMB per year (87.8 million USD) for municipalities, 500 million RMB (73.2 million USD) per year for provincial capitals and 400 million RMB (58.5 million USD) per year for other cities. The development of the SCP in China has been a rapid process; the number of pilot cities reached over 370 in 2018. By 2030, the national goal is anticipated that over 80% of municipal areas will recycle 70% of incident rainfall (Griffiths et al., 2020).

Research on river restoration in China emerged in the late 1990s with the introduction of the concept of „ecological hydraulic engineering" (Dong, 2013). Since 2015, efforts to eliminate black-odorous surface water bodies have significantly improved the water quality of rivers across the country (Cao et al., 2020). Many urban rivers have undergone restoration or rehabilitation under the SCP, attracting considerable investments and serving as integral components of green infrastructure within NbS. The creation of various

recreational riverfront parks in densely populated Chinese cities also provides urban green, open spaces and contributes to social well-being. While some research has focused on the role of urban river restoration within the SCP, it has not been thoroughly examined as an integrated NbS. Furthermore, the practical experiences of implementing restoration projects across various Chinese cities remain fragmented among practitioners and have not been in-depth documented or researched by scholars. To bridge this gap, this study endeavours to investigate the following research questions: 1) What is the research trend of studying river restoration within the SC concept? 2) What practical challenges does river restoration face while being implemented in sponge constructions? 3) What is the link between river restoration in China"s SCP and the global advancement of NbS research? The process involves analyzing research trends, identifying practical challenges, discussing findings from an intensive literature review, and providing recommendations for future efforts.

3 METHOD

The study adopted a mixed-methods approach, combining expert interviews with bibliometric analysis. Firstly, a bibliometric analysis was employed to identify research trends in river restoration under the SCP, as reflected in both Chinese and English literature. Subsequently, we carried out semi-structured interviews with SCP practitioners to gather information on the practical challenges associated with the design, implementation, and evaluation of restoration projects—challenges that scientific publications do not typically unveil. The bibliometric analysis was conducted using CiteSpace, a Java application for knowledge mapping, to examine scientific publications from 2012 to April 2023, through keyword frequency statistics and clustering. CiteSpace visualises the research structure within a specific domain by creating co-citation networks and keyword clustering (Chen, 2006). The Web of Science (WOS) was selected as the literature search engine, and both the WOS Core Collection (WOSCC) and the Chinese Science Citation Database (CSCD) were used as data sources, for their authoritative journals, publications, research field and time span, as well as for their compatibility with both Chinese and English literature. The CSCD contains Chinese literature with translated titles, authors, keywords and abstracts in English, facilitating a further examination in combination with English literature. We used a search query with the following criteria: TS=„Sponge City" AND TS=„river", DOP=all years (1900-2023), resulting in 333 pieces of literature published between 1999 and 2023. Of these, 210 were from the WOSCC, and 137 were from the CSCD, comprising various publication types such as articles, meetings, reviews, books, and early access. After eliminating duplicates and irrelevant documents, 272 relevant records were obtained, comprising 153 from the WOSCC and 119 from the CSCD. These records, published between 2013 and 2023, were extracted for bibliometric analysis.

In the second step, from 2020 to 2022, we conducted five semi-structured interviews with urban planners and landscape designers actively involved in the SCP. These individuals, based in Beijing, Guangdong, and Sichuan Provinces, provided their firsthand experiences related to specific urban river restoration projects. We thus gained insight into the challenges they encountered in the field through content analysis methods (Downe-Wamboldt, 1992). We then compared the findings from the interviews with the analysis of scientific literature, interpreting them through the lens of NbS. Finally, by synthesizing expert perspectives with the results of the bibliometric analysis, our study offered practical recommendations to bolster the future management of NbS for urban rivers.

4 RESULTS

4.1 Research Trend of River Restoration under SC

4.1.1 General Trend

Out of the total publications analysed, 228 were journal articles, 27 were conference proceedings, 17 were review articles, and 4 were early access publications (Table 1). From 2015 to 2020, there was a consistent growth in the number of publications, with the peak number (58) recorded in 2020, accounting for 21.3% of the total 272 articles. However, starting in 2021, there has been a decline in the number of publications. In 2021, the number of publications dropped to 40 (14.7% of the total), followed by a further decrease to 33 publications (12.1% of the total) in 2022. In 2023 (until April), there were only 3 publications (1.1% of the total), but this number is incomplete as the year is still ongoing.

270

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

In summary, the trend shows a growing interest in 'river restoration' and 'SC' research from 2015 to 2020, followed by a decline in the number of publications from 2021 onwards (see Table 1 and Figure 1). The research domains related to 'river restoration' and 'SC' cover a wide range of disciplines, reflecting the interdisciplinary nature of these topics. The Science and Technology domain was the most dominant, with 263 publications (96.7% of the total). Within this domain, the research areas of Environmental Sciences and Ecology (39.3%), Construction and Building Technology (28.3%), Engineering (25%) and Water Resources (22.8%) were the most prominent. The Technology domain, accounting for 55.9% of the total publications, emphasised the importance of technological innovations in fields such as Construction and Building Technology (28.3%), Engineering (25%), Materials Science (2.6%) and Computer Science (2.2%). Life Sciences and Biomedicine involved 112 publications (41.2% of the total), indicating the connection between river restoration, SC construction and the living (primarily aquatic) environment. Research areas in this domain included Environmental Sciences and Ecology (39.3%), Biodiversity Conservation (1.5%), Marine and Freshwater Biology (0.7%) and Public Environmental and Occupational Health (0.7%). The Physical Sciences domain included 92 publications (33.8% of the total), highlighting the relevance of Geology (8.5%), Meteorology and Atmospheric Sciences (2.6%), Oceanography (1.1%) and Physical Geography (1.1%) in understanding the physical processes associated with river restoration. The domains of Arts and Humanities and Social Sciences accounted for 7 publications (2.6% of the total) and 4 publications (1.5% of the total), respectively, indicating relatively less consideration of social and cultural aspects in the literature.

Theme	Results
Year of study	72.1% were published from 2013 to 2020; 27.9% were published from 2021 to 2023
Article type	228 articles, 27 meetings, 17 review articles, 4 early access
Article language	153 in English (WOSCC); 119 in Chinese (CSCD)
Research domains	96.7% Science Technology, 55.9% Technology, 41.2% Life Sciences Biomedicine, 33.8% Physical Sciences, 2.6% Arts Humanities, 1.5% Social Sciences
Research areas (top 10)	39.3% Environmental Sciences Ecology, 28.3% Construction Building Technology, 25.0% Engineering, 22.8% Water Resources, 9.2% Science Technology Other Topics, 8.5% Geology, 4.0% Energy Fuels, 2.6% Architecture, 2.6% Materials Science, 2.6% Meteorology Atmospheric Sciences

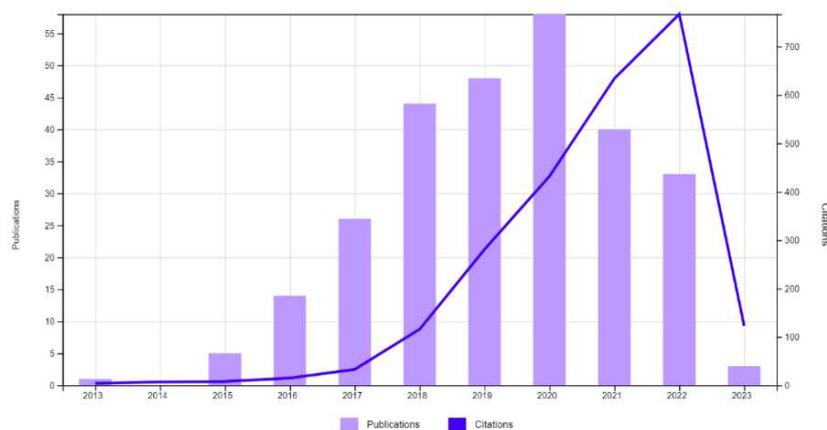

Fig. 1: Number of publications and citations per year from 2013 to 2023

4.1.2 Keyword Co-occurrence Analysis

A knowledge network was constructed based on keyword co-occurrence analysis using the top 36 calculated keywords. This network is visualised in Figure 2, where each node represents a keyword. The most frequently mentioned keyword was „SC", appearing in 129 articles. Other notable keywords included „climate change" (24 articles), „low impact development (LID, an approach to land design that uses natural features to manage stormwater runoff)" (29 articles), „urbanization" (22 articles), „model" (14 articles), „impact" (20 articles), „system" (19 articles), „stormwater management" (14 articles), „performance" (17 articles), „management" (24 articles), „runoff" (15 articles), „urban" (12 articles), „SC construction" (16 articles), „water quality" (10 articles), „challenge" (11 articles), „China" (11 articles) and „land use" (9 articles). These keywords suggest that the research focuses on the potential of restoring rivers to address challenges related to climate change, urbanization and stormwater management under the SCP. The prevalence of keywords such as „model", „impact", „system", „performance", and „management" indicates an understanding of the functioning, effectiveness and optimization of the river restoration process.

However, there seems to be less emphasis on the watershed perspective, as keywords such as „catchment" (7 articles) and „river basin" (6 articles) appeared less frequently (see Figure 2).

During the early stages of the research, particularly around 2015, the primary focus was on understanding the "SC" concept and controlling urban runoff, e.g., "LID". Between 2017 and 2018, several keywords gained prominence, reflecting a shift towards practical aspects of river restoration. These keywords included „impact", "SC construction", "stormwater management", "performance", "model" and "land use". This suggests an emphasis on understanding the real-world implications and practical considerations involved in implementing river restoration projects in SCP. As the field progressed, there was a growing interest in exploring the context of „climate change" and „urbanization". Around 2021, the emergence of the keywords „ecosystem service", „quality", and „green infrastructure" was observed, following "management" and "system", indicating the latest recognition of the regulating, supporting, provisioning, cultural ecosystem services that rivers provide and the aspect of their long-term governance. This shift highlights a deeper understanding of the social-ecological interactions of urban rivers and their potential to deliver multiple benefits as an NbS

Furthermore, the top 6 keywords with the strongest citation bursts (see Figure 3) provide additional insights into the temporal change trends of hot keywords:

- "Ecological restoration" (2016-2019, strength: 1.53) suggests a focus on the improvement of river ecosystems during this period, reflecting an emphasis on restoring the natural state of urban rivers.

- "Water ecology" (2017-2018, strength: 1.84) highlights the ecological dynamics of freshwater systems, indicating a growing interest in the interplay between hydrology and ecology.

- "Urban flooding" (2019-2020, strength: 2.15) emerged as a significant concern, reflecting the need to address flood risks in urban environments, in which river is often considered an infrastructure.

- "Challenge" (2021-2023, strength: 2.27) indicates that researchers are now focusing on identifying the difficulties and obstacles encountered in implementing river restoration initiatives under SCP.

- "Quality" (2021-2023, strength: 1.98) and „Ecosystem Service" (2021-2023, strength: 1.98) show increasing study numbers in the multi-dimensional outcomes of river restoration, such as improved water quality and the provision of multiple ecosystem services.

The analysis of citation bursts and the temporal change trend reveals a transformation in research focus over time. Initially, the emphasis was on flood risk mitigation, but there has been a subsequent shift towards a more comprehensive understanding of rivers as dynamic social-ecological systems. This shift further addresses the emerging practical challenges in river restoration projects and the need for sustainable management.

Fig. 2: High-frequency keyword map, based on the frequency and patterns of co-occurring keywords in the literature. The thickness of the rings within each circle reflects the number of papers within a given time frame. The colour of the rings corresponds to the publication time, as indicated by the time bar at the top of the figure. The links between different keywords indicate co-occurrence within the same papers.

Keywords	Year	Strength	Begin	End	2013 - 2023
ecological restoration	2016	1.53	2016	2019	
water ecology	2017	1.84	2017	2018	
urban flooding	2019	2.15	2019	2020	
challenge	2018	2.27	2021	2023	
quality	2021	1.98	2021	2023	
ecosystem service	2021	1.98	2021	2023	

Fig. 3: Top six keywords with the strongest citation bursts.

4.1.3 Cluster Analysis

We applied the log-likelihood ratio (LLR) algorithm to group the keywords which are closely related to one another and identified five distinct research clusters (Figure 4). The cluster modularity Q=0.6009 and weighted mean silhouette S=0.7885 indicate that the cluster structure is significant and effectively delineates the boundaries of research directions within these five clusters. The silhouette value provides a quantitative measure of the coherence and separation of the clusters. Keywords within different clusters are subsequently summarised into specific research themes (Table 2). Specifically, cluster 0 represented urban flooding, cluster 1 focused on SC, cluster 2 dealt with stormwater management, cluster 3 highlighted low-impact development and Cluster 4 addressed flood risk. The overlapping key terms indicate shared research topics, particularly in the domains of hydrology. This can be attributed to the interdisciplinary nature of the field and the need to address different aspects of river restoration simultaneously. Additionally, the citation network structure might have contributed to the overlapping themes, with influential papers shaping multiple clusters. The interconnectedness of the five clusters also suggests that they are part of a larger research framework tackling common objectives.

Cluster 0 (silhouette value=0.70), with an average publication year around 2016 (Figure 5), focused on urban flooding and the application of the Storm Water Management Model (SWMM; e.g., Kong et al., 2017; Luan et al., 2017) in SC. Key terms included „urban flooding" and „LID practices". The milestone papers by Xia, Zhang, et al. (2017) and Xia, Shi, et al. (2017) investigated urban water regulations facilitated by SC construction and proposed an integrated approach that combines green infrastructure, such as rivers, lakes and wetlands, with grey infrastructure. Seeing SC as a hybrid NbS, technical guidance was made (Jia et al., 2017), and the combined effectiveness was assessed (Kong et al., 2017). Luo et al. (2021) took the Shenzhen-Shantou Special Cooperation Zone (SSCZ) as a case study, identifying riparian areas as ecological buffer zones with higher flood risks and lower resilience to engineering solutions. They proposed restoring them to act as natural sponge bodies that could effectively mitigate urban floods (Luo et al., 2021).

Cluster 1 (silhouette value=0.81), with research papers published on average around 2016, focused on sponge techniques for sustainable urban development. Key terms included „SC", „LID", „total runoff control rate" and „water system". Zhang et al. (2016) analysed the SC concept from an urban hydrology perspective and proposed designing flood prevention measures at the river basin level and connecting rivers and lakes to enhance overall drainage capacity. However, Qiao et al. (2020) contended that the SC initiative should not be classified as a LID program since conventional grey infrastructure remains a significant component in its implementation, and there was limited space in compact Chinese cities and an absence of documented efficiency for green infrastructure (Qiao et al., 2020).

Cluster 2 (silhouette value=0.71), with an average publication year around 2018, focused on specific designs and impact evaluation for urban river systems in stormwater management. Key terms included „stormwater management", „uncertainty", „rainwater zone", „design ecology" and „stormwater quality and quantity". The article by Zhang et al. (2014) identified the effects of urbanization on the hydrological regime, including the degradation of river ecology, straightening and channelization of rivers and covering or transforming ponds and streams. Booth et al. (2016) and Walsh et al. (2005) further suggested identifying the Urban Stream Syndrome (Wantzen et al., 2019). Liu et al. (2017) explained SC construction guidelines, addressing the protection of natural ecological features, such as wetlands, the maintenance of natural flow regimes of rivers and the reduction of impervious surfaces in river beds. Li et al. (2019) proposed an evaluation system that quantifies the environmental, economic and social benefits of different combinations of LID units for SC

construction, incorporating indicators such as water quantity, water quality, landscape and ecological service functions. Using similar methods, Mei et al. (2018) evaluated the cost-effectiveness of GI in urbanised watersheds for flood mitigation under SCP using an SWMM.

Cluster 3 (silhouette value=0.79), with an average publication year around 2018, delved into the role of river restoration in adaptive urban development facing climate change effects. Key terms included „LID“, „town & city planning“, „urban rain island (a phenomenon in which precipitation levels in urban areas are higher than those in the surrounding suburban areas)“, „constant pipe drainage“ and „drainage ratio“. Jiang et al. (2018) examined the root causes of the vulnerability to urban pluvial flooding. Traditional approaches to managing urban rivers, such as channelization and dredging, were insufficient for tackling current challenges (Chan et al., 2018; Wang et al., 2018). Chan et al. (2018) suggested that the SCP offered opportunities to protect rivers and other inland water bodies while dealing with broader environmental issues. More integrated and localised (Nguyen et al., 2019) land-use guidance and assessment tools were recommended (Chan et al., 2018). River"s role in urban heat reduction in the SCP was underlined (Nguyen et al., 2019). Furthermore, developing urban drainage systems needed to consider factors at the watershed scale (Nguyen et al., 2019) and safeguard the watershed's integrity and the health of water resources (Li et al., 2017).

Cluster 4 (silhouette value=0.72), with an average publication year around 2016, emphasised an integrated flood risk management approach that included perspectives from society and decision-making processes. Key terms included „flood risk“, „perceptions of flooding“, „guideline“ and „integrated water management“. Using Wuhan as a case study, Shao et al. (2019) examined the impact of urban impervious surface coverage on hydrological processes and monitored interconnected urban watersheds by calculating impermeability ratios. It also highlighted the absence of integrated decision-support information. With a social survey, Wang et al. (2017) discovered that the public predominantly regarded incomplete drainage systems as the main cause of urban flooding, while impermeable surfaces were considered less significant factors.

By analyzing the characteristics of each cluster, we gain a general understanding of the temporal evolution of research topics related to river restoration and SC. Clusters with an average publication year around 2016 (Cluster 1 and 4) primarily concentrated on hydrological subjects, such as LID, flood risk management, urban runoff and water systems. In a contrasting shift, clusters with an average publication year around 2018 (Cluster 0, 2, and 3) redirected their focus towards more detailed issues, including river design in urban planning, drainage management, climate mitigation and specific case studies such as the SSCZ. Constructed wetlands were also discussed in relation to river restoration, and watershed scales started to receive attention.

Table 2: Summary of cluster size, silhouette value, average year and top terms of each cluster

4.2 Practical Challenges

4.2.1 Knowledge Gaps and Spatial Inequality

The bibliometric analysis indicated that the subjects related to ecological restoration had gained prominence since 2016 in scientific research. However, the findings from the interviews revealed a gap in practical knowledge, with conventional methods such as river channelization and dredging still being widely implemented in river restoration efforts, despite their inadequacy in addressing complex water management issues (Chan et al., 2018; Wang et al., 2018). Many river restoration projects simply dredged the river channel—removing sediments and debris from the riverbed—to tackle issues with black and odorous water bodies. This method is often implemented by the local Water Resource Bureaus, reflecting their engineering-centric tradition and lack of ecological knowledge, as river dredging can harm the ecosystems by disrupting aquatic life and destroying natural filtration layers that are essential for maintaining potable water reserves.

Furthermore, the interview analysis highlighted the challenge of convincing local government officials to allocate space for floodable riparian areas in cities, which would benefit biodiversity instead of building higher concrete embankments. This process can be time-consuming due to the knowledge gap among government officials regarding river-floodplain systems. An example is the „river restoration" project in Dali, Yunnan Province, China, in 2020. Despite its aim to control mudslides, the project resulted in the devastation of the natural riverbed and riverbank through the encasement of 18 small rivers in concrete. Although the project faced public criticism and had eventually been interrupted due to media pressure, these rivers in Dali remain channelised.

This phenomenon also presented a spatial inequality among Chinese cities. Practitioners widely believed that river restoration efforts under SC construction had made more progress in China's first and second-tier cities, primarily located in the eastern and southeastern coastal regions. These cities, such as Shenzhen, have superior economic performance and a higher standard of living, as evidenced in the case study by Luo et al. (2021). Conversely, third-tier cities, particularly those in less developed provinces such as Yunnan in the southwest, experienced more frequent channelization of rivers. These cities, with smaller populations and lower economic output, often rely on traditional engineering approaches to SC construction. This spatial inequality is also attributed to the knowledge gap and institutional path dependency of local governments.

4.2.2 Inadequate Evaluation of River Health and Failed PPP Models

River health assessment within the context of the SCP has not been a primary focus of scientific research. Rather, most scientific tools have been geared towards appraising the cost-effectiveness of green infrastructure, as evidenced by Mei et al. (2018). Similarly, investigations such as Li et al. (2019) have mainly focused on the various benefits of combinations of LID units rather than examining rivers in isolation. Regrettably, despite the pressing need for it, a proper evaluation of the health of rivers after restoration has yet to be established. China established standards for surface water environmental quality in 2002; however, the absence of biological indicators renders the current physical and chemical measuring methods insufficient for comprehensively assessing river ecosystem health (Cao & Wantzen, 2023).

In a groundbreaking move, the Chinese Ministry of Water Resources released the „River Health Evaluation Guide" in 2020, which united multiple performance indicators, including water quantity, quality and biology (such as invertebrates, fish and aquatic plants), as well as social service functions, to assess the overall health of river systems. This initiative was widely propagated to governments at all levels across the nation. Additionally, beginning in 2019, the notion of ecological flow was instituted into policy. The Yangtze River Commission has, therefore, established ecological flow targets for important rivers and lakes, and instituted an ecological flow rule platform to ensure those rivers do not dry up during droughts. However, urban streams are rarely addressed. The financial burden of conducting regular river health assessments has hindered progress; applying the „River Health Evaluation Guide" is not yet standard practice under the SCP.

Practitioners from the private sector also shed light on the dearth of a well-defined business strategy for the PPP model in SC funding (Wang et al., 2017), notwithstanding the endorsement of it by the central government. In recent years, private companies are gradually distancing themselves from investing in SCP due to the lack of immediate financial benefits. Local government investments and debt issuances become the only funding sources for current SC construction. The obstacles associated with the PPP model confirm those identified in prior research on obstacles to the Chinese PPP model, notably cost overruns, time overruns and wrong expected return (Bashar et al., 2021).

4.2.3 Fragmented River Management and Deficient River Basin Perspective

River restoration projects posed a challenge, which was not frequently mentioned in scientific papers but extensively observed in reality, on the collaboration and coordination between diverse departments involved in river management in Chinese cities. China follows a sectoral river management structure, where each department is only answerable for its tasks: The Environment and Ecology Bureau oversees water quality, the Water Resource Bureau looks after flood protection, the Planning and Natural Resources Bureau is responsible for land use and the Forestry and Parks Bureau is in charge of riparian vegetation, with little horizontal connections among them (Shen, 2021). This setup led to conflicts during the river restoration, with each department prioritizing its duties without any cooperation (Cao & Wantzen, 2023). Nevertheless, our interviews also confirmed the effectiveness of the newly introduced national policy in 2018, known as the River Chief System, as a crucial role in resolving inter-departmental conflicts and creating a shared vision for river management (Li et al., 2020; Wang & Chen, 2019). Integrated river basin management was also found to be a distant goal in China as the coordination mechanism at the basin level remains weak. Despite the existence of six river basin committees, including the Yangtze River Committee and the Yellow River Committee, they are still subordinate to the Ministry of Water Resources, leaving them with limited coordinative powers among the upstream and downstream provinces (Cao & Vazhayil, 2023). Administrative boundaries serve as the province and city's jurisdictional limit in managing rivers, with little motivation for co-managing transboundary rivers between administrative regions. This finding, in alignment with the bibliometric analysis, underscored the missing river basin perspective in current river restoration.

4.2.4 Limited Public Awareness and Participation

The final challenge lay in the public's limited awareness of rivers and restricted public participation in the river management process. The public sometimes failed to view the river as a 'sponge' entity, lacking an understanding of the river"s flood mitigation capacity. This finding was in line with the social survey results of Wang et al. (2017). Conversely, the public's expectations of SCP were found to be excessively idealistic, with many erroneously believing that it could entirely resolve urban flooding issues. When the Zhengzhou flood disaster struck in July 2021, the public thus criticised the Zhengzhou government"s sizable investment in SC construction, which still resulted in huge flood damage, leading to scepticism about the SC concept nationwide. However, as an NbS, SC needs time to demonstrate its effectiveness, and mitigating floods from intense rainfall events often requires hybrid measures (Vojinovic et al., 2021). As a relatively new policy, the application of SC in China is still underway. Lastly, due to the limited public participation in China's current river management scheme, many river restoration projects do not include societal stakeholders in decision-making. Public engagement is not only under-discussed in scientific studies, as revealed by the bibliometric analysis, but also overlooked by practitioners in SC design. On a positive note, the RCS has created opportunities for public involvement; despite being limited, the public can supervise RCs" work, thereby raising their awareness of urban rivers (Cao & Wantzen, 2023).

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

5   DISCUSSION

Implementing on a national scale, SCP is a mainstream effort by the Chinese government to implement NbS with hybrid solutions, supported by continuous government investment. Similar to sustainable drainage systems (SuDS) and LID, the SC concept is developing with Chinese characteristics during rapid urbanization (Griffiths et al., 2020; Lashford et al., 2019). Urban rivers, often reflecting the historical water city design in ancient Chinese dynasties (Liu et al., 2015), are critical to managing flood risks under the SCP (Xia, Shi et al., 2017) and restored by SC construction (Wang et al., 2016). As revealed by keywords' temporal analysis (see Figure 3), a growing scientific understanding has shifted river restoration focus from solely hydrological control to a more holistic approach incorporating social-ecological consideration (Zhao et al., 2019) and microclimate effects (Jiang et al., 2018), such as heat island reduction (Wang et al., 2018). This shift emphasises the sustained benefits of urban river restoration, in accordance with the cross-sectoral multifunctionality of NbS for sustainable urban development (Nesshöver et al., 2017).

However, the successful implementation of NbS in urban settings faces many barriers (Ershad Sarabi et al., 2019). By combining the results of interviews with practitioners and bibliometric analysis, we have identified several challenges in urban river restoration within China's SCP. The identified knowledge gap confirms the need to enhance the cognitive capacities of local policymakers to integrate NbS into daily planning practices and associated governance (Wamsler et al., 2020). In terms of flood management, there is still a prevalence of engineering mindsets (Qiao et al., 2018) and prioritization of quantifiable objectives within short time frames (Qiao et al., 2020) in river restoration projects. This phenomenon manifests as spatial inequality in Chinese cities, where less-developed regions often struggle to overcome path dependency in organizational decision-making to adopt NbS, compared to their more-developed counterparts (Davies & Lafortezza, 2019).

Although aquatic ecology has been increasingly emphasised in the literature, in practice, ecological considerations are not always prioritised in river restoration under the SCP. In Chinese cities, the restoration of urban rivers is predominantly achieved through site-specific landscape design (Qi et al., 2021); selected river sites are strategically transformed to maximise their functions for human use, overwhelmingly serving as riparian public parks (Liu et al., 2019). This approach underlines the high recreational values of rivers (Durán Vian et al., 2021; Zingraff-Hamed et al., 2018), but the integrity of the river ecosystem, such as supporting biodiversity, is often not a priority and lacks proper monitoring and evaluation. In the long term, this may lead to potential trade-offs among the ecosystem services that NbS provide (Seddon et al., 2020).

This study also addresses the common barriers to NbS uptake concerning inadequate financial resources and uncertainty regarding the implementation process and effectiveness (Ershad Sarabi et al., 2019). While many studies have proved the role of private sector involvement in ensuring the financial viability of the SCP, our interviews revealed that the PPP model faces difficulties in the operation and maintenance of water projects (Liang, 2018). This might necessitate a change in the measurement technique of the cost-effectiveness of NbS compared to engineered alternatives, particularly in terms of valuing their significance in addressing societal challenges (Dick et al., 2019). In 2020, China's central government introduced the Ecology Oriented Development (EOD) model intending to address the critical issues of inadequate funding sources for ecological engineering projects and convert environmental benefits into economic gains (Wang & Han, 2022). The first list of pilot projects, launched nationwide in 2021, has extensively encouraged the PPP (Ministry of Ecology and Environment, 2021). This EOD model may offer fresh opportunities for refining the PPP in the context of river restoration in Chinese cities.

Employing NbS extends beyond a technical issue and presents a new governance challenge. In China, persistent obstacles arise from institutional fragmentation in river management (Cao & Wantzen, 2023; Ershad Sarabi et al., 2019). Moreover, while effective communication, involvement, and feedback are crucial for public participation in NbS (Ferreira et al., 2020), these elements are notably lacking in the river restoration under SCP (Dai et al., 2018). The limited representation of social science and governance research in this field also confirms this gap. Designing collaborative governance for NbS (Malekpour et al., 2021) that actively involves stakeholders and the wider society aids in understanding the complexity of urban rivers as social-ecological systems (Wantzen et al., 2016, 2019; Zingraff-Hamed et al., 2021). This is particularly important for restoring the social connectivity of rivers (Kondolf & Pinto, 2017; Wantzen, 2022). China's RCS plays a pivotal role in this respect by assigning stewardship to Civil RCs, who often include NGOs, experts, and local communities. These groups are involved in preserving the environmental quality of

rivers and providing feedback on the work of the official RCs. This cooperative model (dual RCS) should be effectively implemented across all types of urban river restoration projects in China (Cao & Wantzen, 2023).

6 CONCLUSION

In summary, the steady increase in scientific publications on river restoration under SCP from 2012 signalled a persistent interest in promoting NbS as a critical component of sustainable development in China, with restoring urban rivers serving as a multifaced NbS example for generating both environmental and social benefits. The bibliometric analysis highlighted the interdisciplinary nature of these combined topics and a research trend evolving from primarily managing flood risk towards an integrated focus on aspects such as ecology, urban planning, climate change adaptation, and methodology of modelling and evaluation. However, while there was a strong emphasis on engineering-led river restoration approaches, both the current research agenda and practical application displayed an absence of the social science field. Insights from SCP practitioners identified firsthand challenges in implementing river restoration projects under the SCP, including knowledge gaps, spatial inequality, a deficient evaluation of river health, unsuccessful PPP models, fragmented river management, and limited public participation. These issues conformed to the existing obstacles to NbS adoption and mainstreaming, particularly the limited acknowledgment of local policymakers, insufficient funding resources, potential ecosystem service trade-offs, institutional path dependency, insufficient cost-effectiveness evaluation, and collaborative governance. In China, the RCS policy fostered cross-departmental cooperation and opportunities for public involvement in protecting the river environment. Moreover, the newly established EOD model could potentially revive PPP models at a local level for investing in comprehensive river restoration. Consequently, future research and projects should pursue a more expansive, trans-disciplinary view, considering urban rivers as social-ecological systems and encouraging stakeholder and societal involvement in the long-term management of NbS.

1 ABSTRACT

Cities in hot climates feature clear skies most of the year, guarantting the provision of daylight into the interior. With the use of large glazed façades, controlling the penetration of solar radiation that contributes to thermal discomfort with passive solutions is acheived through the use of shading devices.These devices decrease energy loads of mechanical cooling. The facade solar screens is one of the shading strategies used and reported to be succeful in such hot climatic regions, blocking solar radiation while allowing visual access to external views. Such a strategy of screening the opennings with perforated surfaces has cultural and historical significance in multiple urban environmnets, demonstrated by the use of the traditional mashrabeya which are the inspiration for contemporary screens design. However, throughout the last decade, a large body of research has been concerned with the negative impact of solar screens on daylighting performance in internal spaces, leading to an increase in energy loads of artifical lighting.

This paper aims to review the current research body concerned with the correlation between solar screens design parameters and daylighting performance. 21 articles fall under this paper's realm. They are reviewed according to multiple comparison points, including: aims, spatial configuration of the test spaces, types and design of the tested solar screens, design parameters tackled, daylighting simulation tools, daylighting metrics, and finally, findings including parameters impact, empirical process methodolgy, and coorelation with other enviromental aspects. Thispaper discusses how the curent reviewed research body informs the design process for an environmentally conscious design of optimized solar screens with respect to daylight availability thereby promoting the use of passive design strategies towards greener cities and urban environments.

Keywords: Parametric design, Passive design, Daylighting performance, Facade solar screens, Optimizing performance

2 INTRODUCTION

Since the inception of early modernist archtiecture, the use of large glazed facades has been an integral part of worldwide modernist and contempray arhcitecture. In regions with a hot climate, building facades are being designed to western standards with the aim to have a contemporary look by using specifically large glazed façades (Etman et al., 2013; M. ElBatran & Ismaeel, 2021; Mayhoub & Labib, 2015). With clear skies most of the year, the provision of daylight into the interior is guaranteed as a passive design strategy.

Shading devices are also being implemented to control the penetration of solar radiation which contributes to thermal discomfort and over-heating (Wagdy & Fathy, 2015). Yet, in the scientific discourse of the balance between diffused daylighting and solar radiation, several reviews have proven that the different shading devices may negatively affect daylight availability.(Eltaweel & SU, 2017; Kirimtat et al., 2016; Yu et al., 2020).

2.1 Problem

The previously mentioned reviews stated that the research concerned with the impact of shading devices on daylighting produces only recommendations for specific hypothetical design cases.These articles present no methodologies to study the correlation between daylighting performance and the parameters of shading devices. Such insightsand design frameworks may assist architects and designers in their decision making process about the impact of the variations in the values of a specific parameter on daylighting performance.

2.2 Scope

Among the different shading devices,the research focuses on facade solar screens, as it can block solar radiation and at the same time keep the users more in contact with external views (Kirimtat et al., 2016; Wagdy & Fathy, 2015). The same refrences agreed as well that solar facade screens provide successful shading, specifically in hot climatic regions, despite reportinga negative impact on daylight availability. Such

features also have cultural and historical significance in hot climate regions through different traditional architectural vocabulary including the mashrabeya of Egypt, the moshabak of Iran, and the jali of India.

The research body concerned with the impact of facade solar screens on daylighting performance has been on the rise since the beginning of the last decade. This study reviews the literature concerned with this scope to assess if a methodology is developed to investigate the statistical correlation between different solar screens design paramaters and daylighting illuminance values in interal spaces.A brief introduction is conducted on daylight performance evaluation in architecture and research in order to understand how the impact of solar screens on daylighting is assessed. And then, the review of 21 selected papers is conducted and discussed to assess the presence of a methddology that investigates the correlation between solar screens parameters and daylighting.

3 DAYLIGHT ASSESSMENT IN ARCHITECTURE

In order to understand the impact of façade solar screens on daylighting, it is necessary to understand how daylighting performance is evaluated in architectural design and research. The first mention of a daylight evaluation method was proposed by (Trotter, 1911): a fraction between the illuminance at a point inside and the illuminance outside under an unobstructed overcast sky excluding sunlight. This was known later as the daylight factor DF and expressed as a percentage, whereby the internal illuminace at a point is divided by the external illuminace and multiplied by 100 (Lewis, 2017; P. Tregenza & Mardaljevic, 2018). The same references stated that for its ease of use the DF is adopted to date in multiple design guidelines and building regulations. Yet, its reliability is questioned by multiple references. One critical argument is that the DF is idealistic as it regards only the overcast sky and excludes varying factors, such as different sky luminances and solar radiation interference. Thus, its simplicity compromises its reliabiltiy in realistic conditions (Lewis, 2017; Lou et al., 2019; Mardaljevic et al., 2000; P. Tregenza & Mardaljevic, 2018; P. R. Tregenza, 1980).

Concerns about the DF led to the introduction of the Climate Based Daylight Modeling method into the development of computer software.The CBDM approach was introduced first hand by Mardaljevic et al., (2000); and Reinhart & Herkel (2000). In brief, CBDM considers long term assessment for daylighting performance in a space comprising the range of sky luminace conditions and solar radiation on an hourly basis for a full year. This process is conducted using daylight simulation software where different sky luminance values are modeled based on a weather data file for the site and processed by a calculation engine that produces output results. As the results comprise hourly illuminance values at a number of test points in a space for a full year, the CBDM relies on metrics developed to handle evaluating daylighting performance based on these results. These performance metrics assess the illuminance values at a point of specific minimum/maximum illuminance thresholds, based on research work concerning human comfort and daylighting functional requirements. The daylighting performance at that point is then assessed accordingly as being adequate or not regarding the percentage of hours throughout the year when it meets or falls short of the minimum/maximum illuminance thresholds. The commonly introduced metrics to date are: Daylight autonomy (DA) (Reinhart & Walkenhorst, 2001), Useful Daylight Illuminaces (UDI) (Nabil & Mardaljevic, 2006), Daylight Availability (DAv) (Reinhart & Wienold, 2010), Spatial Daylight Autonomy (sDA) (Heschong et al., 2012), and, Annual Sunlight Exposure (ASE) (Heschong et al., 2012).

4 FAÇADE SOLAR SCREENS AND DAYLIGHTING PERFORMANCE

This section tackles how the current research body investigates the impact of façade solar screen impact on daylighting, and whether a methodology to investigate a statistical correlation exists. First, the methodology of selecting papers is explained, and then a breakdown analysis is conducted for a number of aspects.

4.1 Paper selection

First, a search was done on several paper databases using a combination of the following keywords: solar screen, perforated facades, perforated panels, mashrabeya, jali, daylight availability, and daylight performance. The databases are: Science Direct, Taylor and Francis, Sage Journals, and Springer Link. There were no restrictions concerning the year of publication or the number of pages.

The search produced 386 papers, filtered to 14 relevant to this review's scope: 11 from Science Direct, 3 from Taylor and Francis, and none from Sage journals nor Springer link (table 1). The 14 papers are published in 9 journals as follows in (figure 1). The second step of selection was done by adding papers cited

282

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

in the previous 14 papers found reliable to this review's scope. Seven conference proccedings papers were found relevant as follows in (figure 2).

Database	Results	Filtered Results
Science Direct	279	11
		(Chi, 2022; Chi et al., 2018; Chi, Moreno, & Navarro, 2017; Khidmat et al., 2022; Lavin & Fiorito, 2017; M. ElBatran & Ismaeel, 2021; Sabry et al., 2014; A. Sherif et al., 2012; A. H. Sherif et al., 2012; Srisamranrungruang & Hiyama, 2020; Wagdy & Fathy, 2015)
Taylor and Francis	73	3
		(Chi et al., 2021; Chi, Moreno, Esquivias, et al., 2017; Vazquez et al., 2021)
Sage Journals	34	0
Springer Link	0	0
Total	386	14

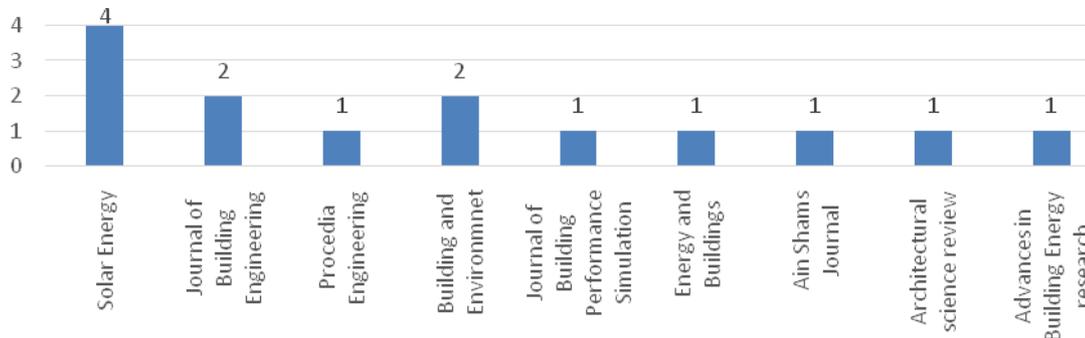
Table 1: Details of the search done in articles databases.


Fig. 1: Number of published papers per journal.
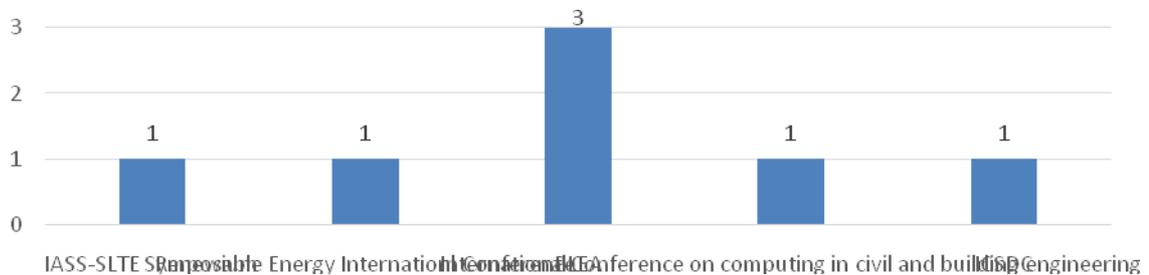

Fig. 2: Number of published papers per conference.

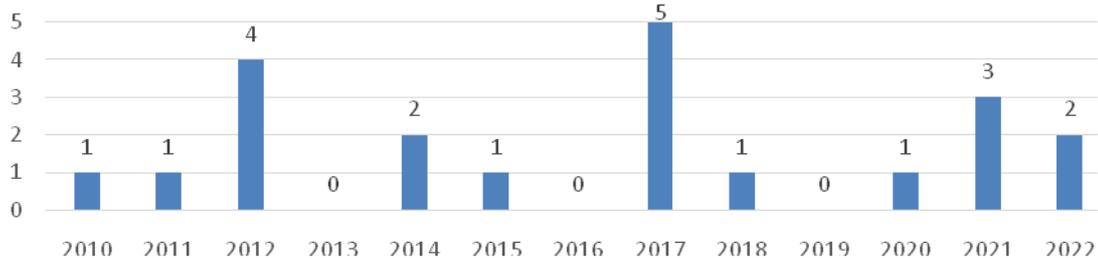
By reviewing the total selected 21 artilces, it is found that the first papers were published in 2010 by A. Sherif et al. (2010) in a conference proceeding. Since then until December 2022 a minimum of one paper was published each year except for years 2013, 2016, and 2019. Whereas 2017 marks the highest number of published papers proceeded by 2012, 2021, and finally 2022 (figure 3).


Fig. 3: Number of published papers per year.

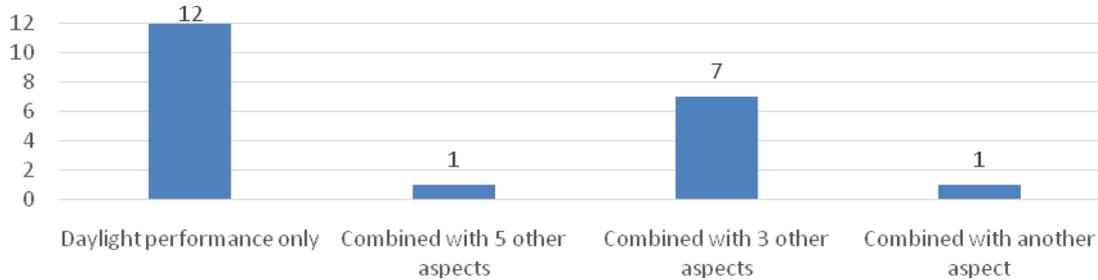
The papers are investigating the impact of façade solar screens on either daylighting performance only, or combined with other environmnetal performance aspects, including: cooling loads, heating loads, artificial lighting loads, shading coefficient, solar radiation energy and finally natural ventilation. Daylighting is evaluated only in 12 papers, and combined dfferently with other environmental aspects as follows in (figure 4). The most combined environmental aspect with daylighting is the cooling load, followed by both heating and artificial lighting loads. Solar radiation was considered two times and only once for both natural ventilation and shading coefficient (figure 5).


Fig. 4: number of papers testing other aspects performance with daylighting.
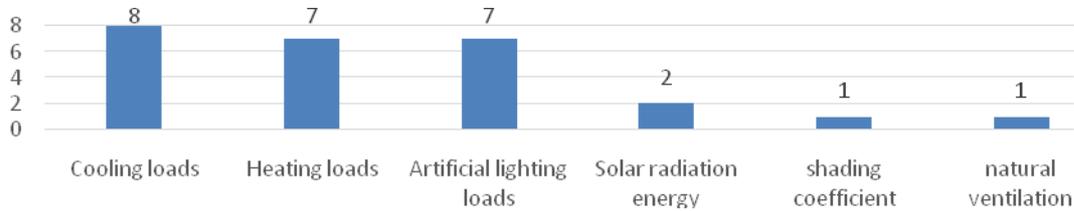

Fig. 5: Number of times specific aspects were tested with daylighting.

4.2 Review methodology

After selecting the papers, an analytical review was conducted. The selected methodology was related to the process in the reviewed papers of conducting their investigations about the impact of solar screens on daylighting performance. First, each paper proposes a space where the test is done, then, a solar screen type is selected along with variations in its paramters to generate test cases , finally a computer simulation is conducted and findings are deducted from the results. According to this process, the review methodology is conducted as follows (Figure 6):

(a) Review the test spaces: site, function, and physical configurations.

(b) Review the tested solar screens: types, parameters, and generated cases.

(c) Review the Simulation process: tools and performance metrics.

(d) Discuss the findings.

Fig. 6: Review methodology.

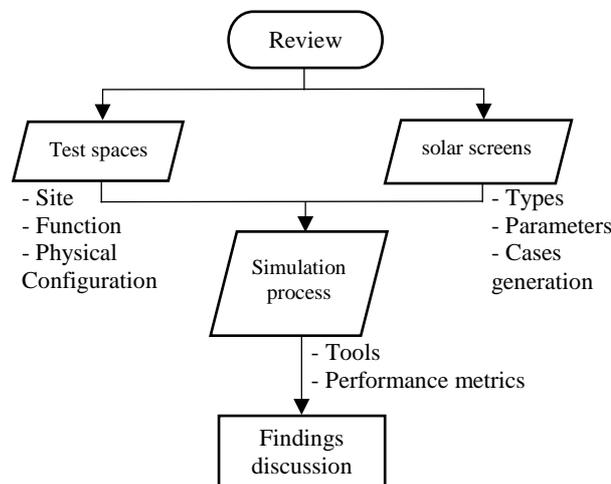
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


4.3 Test spaces

Each paper considered a space where the impact of the solar screenon daylight availability is evaluated. This section outlines these test spaces concerning site, function, and physical configurations.

4.3.1 Site

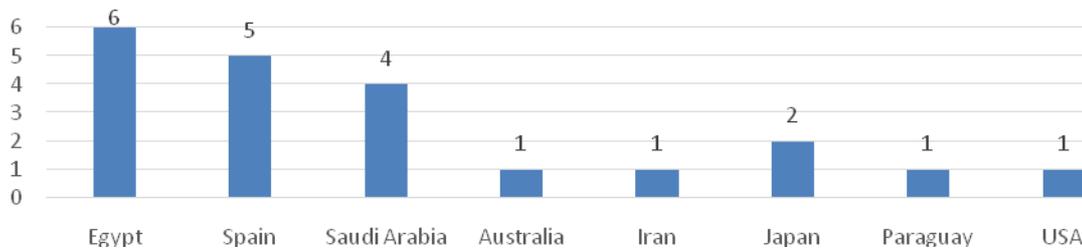
The methodologies of multiple papers reported that authors considered sites with clear and sunny skies most of the year, as shading screens were likely to be used. Egypt was the most common site with its cities Cairo, Al-Sadat and Alkharga Oasis, followed by Spain, mainly Seville. Saudi Arabia was next with its cities Jeddah and Riyadh, followed by Japan with Tokyo and Kitakyushu, and finally, there were single considerations in Australia (Sydney), Iran (Tehran), Paraguay (Asuncion), and USA (Phoenix) (figure 7).


Fig. 7: Number of papers per chosen site.

4.3.2 Function

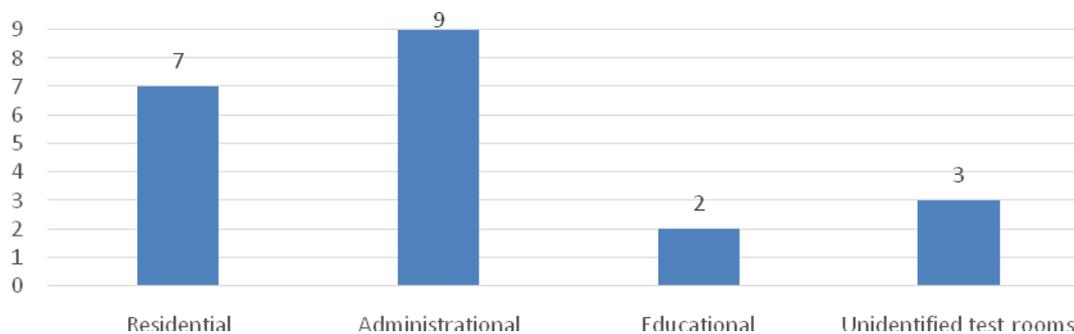
All test spaces are hypothetical, except one paper in which M. ElBatran & Ismaeel (2021) modelled the space after an office building in an administrative campus of the Smart Village campus in Cairo, Egypt. Three papers assigned no function to the test spaces and considered them as a test room. Administrative functions where adopted most in 9 papers, whereas 7 papers adopted residential functions, and finally educational functions were adopted in 2 papers (figure 8).


Fig. 8: Number of times a type of function was chosen the papers.

4.3.3 Physical configuration

The dimensions of the test spaces in all the papers were constant, as only one scenario was considered in each. The length of the spaces varied from a minimum of 3 meters to a maximum of 12 meters, and the widths varied from a minimum of 3.6 meters to a maximum of 12 meters, while the heights varied from a minimum of 2.6 meters to a maximum of 5.00 meters. Yet, only one space had a considerable difference in its physical configuration compared to the other 20 papers, namely the previously mentioned space modelled after an office building in Cairo, which had 42 meters length and 37.5 meters width. Apart from this space, the floor areas of the test spaces varied between a minimum of 10.8 m2 and a maximum of 144 m2.

Regarding the openings placement, 19 papers had a single façade opening, whereas 1 article had openings in adjacent facades and another had openings on all 4 facades. Concerning the opening design, 14 papers had singular continious openings, 6 papers had fully glazed facades, and finally one paper had patched windows along the façade. Each paper considered only one scenario, and no variations were adopted in the physical configurations. Yet, three articles (Chi et al., 2021; Oghazian, 2017; Wagdy & Fathy, 2015) conducted variations in the window to wall ratio WWR in their tests.

4.4 Solar screens

Each paper tested the impact of a solar screen on daylighting and other environmental aspects. This section reviews the types of solar screens chosen, the tested parameters, and the case generation process.

4.4.1   Types of solar screens

18 papers identified their solar screens as a perforated panel, sometimes as a specific design application, whereas for other cases the methodology was adopting a simple perforated plane to simplify the test and the modelling process. Three papers specified other façade solar screen types as follows: a screen of horizontal louvers (Wagdy & Fathy, 2015), a masonry brick wall (Vazquez et al., 2021), and an expanded metal mesh (Khidmat et al., 2022).

4.4.2   Tested parameters

A total number of 19 design parameters were tested in the 21 papers. Divided between the three types of tested solar screens, 8 parameters are related to the perforated panels, 4 parameters related to the screen of horizontal louvers, 5 related to the expanded metal mesh, and finally 2 related to the masonry brick wall.A description for each parameter is available in (table 2). Parameters are sorted by giving a code and a numbering for each indicating which type of screen it is related to:PP for perforated panels, HL for horizontal louvers., BW for masonry brick wall, and MM for expanded metal mesh.

Type/number of times tested		Code	Parameter / number of times tested		description
Perforated panel (PP)	18	PP01	Perforation percentage	11	Percentage of the panel's permeable surface area.
		PP02	Openings aspect ratio	5	Proportional relation between horizontal and vertical dimension of the openings/perforations.
		PP03	Screen axial rotation	4	Rotation angle of the whole panel.
		PP04	Screen depth	3	Identifies the panel's thickness.
		PP05	Matrix dimensions	6	Perforation distribution in horizontal and vertical directions.
		PP06	Geometry of openings	5	Indicates the geometrical shape of the openings/perforations.
		PP07	Non-uniform perforation	1	Targets the non-uniform distribution of the openings
		PP08	Gap screen and glazing	2	Distance between the glazing's plane and the perforated panel
Horizontal louvers (HL)	1	HL01	Louvers count	1	Identifies the number of louvers used to form the screen.
		HL02	Louvers tilt angle	1	Rotation angle of the louvers around its horizontal axis.
		HL03	Louvers depth	1	Louvers' depth in its horizontal plane.
		HL04	Louvers reflectivity	1	The finishing's reflectivity of the louvers.
Masonry brick wall (BW)	1	BW01	Bricks rotation angle	1	The rotation angle of each brick around its x,y and z axis.
		BW02	Bricks building pattern	1	The arrangement of bricks used to form the screen.
Expanded metal mesh (MM)	1	MM01	Diamond height	1	The dimensions of the diamond module.
		MM02	Diamond length	1	
		MM03	Diamond depth	1	
		MM04	Diamond angle	1	The tilt angle of the modules around its horizontal axis.
		MM05	Connecting bond length	1	length of bonds connecting the diamond modules

Table 2: coding, and description of tested parameters.

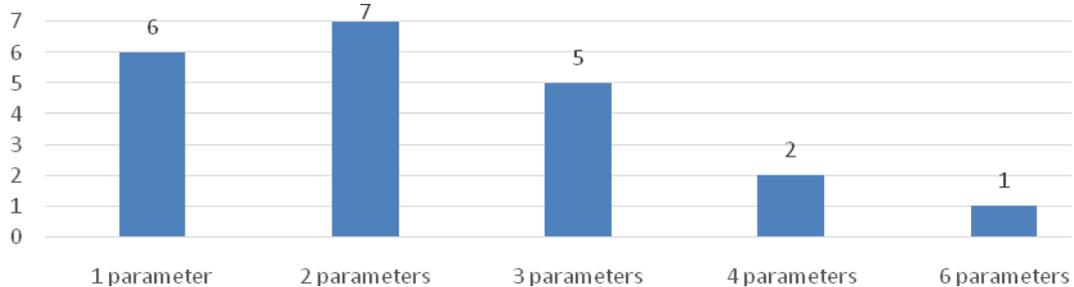
The parameters related to the horizonal louvers, masonry brick wall, and expanded metal mesh were tested each only once, as their types of screens were tested only once in the 21 papers. The perforation percentage PP01 was the highest tested parameter -11 times, followed by 6 times for the matrix dimensions PP05, 5 times for each of PP06 and PP02, 4 times for PP03, 3 times for PP04, 2 times for PP08, and finally once for PP07.The number of parameters tested in one study varies from one paper to another, 6 papers kept its testing limited to only one parameter, whereas the highest number of 7 paper tested on 2 parameters, 5 papers on 3 parameters, 2 papers on 2 parameters, and one article on 6 parameters (figure9).


Fig. 9: Number of times several combined parameters have been tested together.

4.4.3 Cases generation

Each paper generated a number of cases through creating systematic variations in the parameter(s) (table 3). The range varies greatly between the maximum and the minimum number of case 3176 and 5 respectively.

	Reference	screen Design	Studied parameters	Cases
1	(A. Sherif et al., 2010)	Perforated panel	PP01	9
2	(A. Sherif et al., 2011)	Perforated panel	PP02	6
3	(A. Sherif et al., 2012)	Perforated panel	PP01	9
4	(Sabry, Sherif, & Rakha, 2012)	Perforated panel	PP03	10
5	(A. H. Sherif et al., 2012)	Perforated panel	PP02, PP03	12
6	(Sabry, Sherif, Gadelhak, et al., 2012)	Perforated panel	PP02, PP03	8
7	(Sabry et al., 2014)	Perforated panel	PP02, PP03	12
8	(Emami et al., 2014)	Perforated panel	PP01, PP04	5
9	(Wagdy & Fathy, 2015)	Horizontal Louvers	HL01, HL02, HL03, HL04	1600
10	(Lavin & Fiorito, 2017)	Perforated panel	PP01, PP05	10
11	(Chi, Moreno, & Navarro, 2017)	Perforated panel	PP01, PP05, PP06	16
12	(Chi, Moreno, Esquivias, et al., 2017)	Perforated panel	PP01, PP05, PP06	16
13	(Oghazian, 2017)	Perforated panel	PP06, PP07	22
14	(Kotbi & Ampatzi, 2017)	Perforated panel	PP02	36
15	(Chi et al., 2018)	Perforated panel	PP01, PP05, PP06	64
16	(Srisamranrungruang & Hiyama, 2020)	Perforated panel	PP01	5
17	(M. ElBatran & Ismaeel, 2021)	Perforated panel	PP01, PP04, PP08	36
18	(Vazquez et al., 2021)	Masonry brick wall.	BW01, BW02	12
19	(Chi et al., 2021)	Perforated panel	PP01, PP05` PP06	64
20	(Chi, 2022)	Perforated panel	PP01, PP05, PP08, PP04	72
21	(Khidmat et al., 2022)	Expanded Metal mesh	MM01,02,03, 04, 05	3176

Table 3: Summary of solar screen's types, parameters, and cases generated.

Moreover, 8 articles proposed other approaches to generate cases as part of their studies aims as follows. (Wagdy & Fathy, 2015) used a parametric exhaustive research method that enabled them to explore all possible scenarios that can be formed by different parameters values. 1600 cases were generated from this

method, and to handle the computational load of simulations they proposed a "parallel computational algorithm" that uses all PC cores to run multiple simulations at the same time. (Chi, 2022; Chi et al., 2018, 2021; Chi, Moreno, & Navarro, 2017) used the "orthogonal arrays", a statistical method to find optimized solutions. It allows to test with the least number of experiments/simulations multiple variables; thus, the computational load is reduced while giving an insight into the impact of the variation in each parameter. Finally, (Khidmat et al., 2022; Lavin & Fiorito, 2017; Vazquez et al., 2021) used a genetic algorithm method. It is a process that mimics the natural process of selection where the fittest prevails. It requires defining genes (variables with values) and a fitness value. In the study case the fitness value is a daylighting performance metric, and the genes are the studied screen parameters.

4.5 Simulation process

Daylighting simulation tools are being used in all the 21 papers to test the impact of solar screens on daylighting. This section reviews the used tools, and the adopted daylighting metrics (table 4).

	Reference	Daylight simulation engine - Interface	Daylighting performance metric
1	(A. Sherif et al., 2010)	Radiance	Point in time illuminances
2	(A. Sherif et al., 2011)	Radiance - DIVA for Rhino	Point in time illuminances
3	(A. Sherif et al., 2012)	Radiance - DIVA for Rhino	Point in time illuminances
4	(Sabry, Sherif, & Rakha, 2012)	Radiance	Point in time illuminances
5	(A. H. Sherif et al., 2012)	Radiance - DIVA for Rhino	DAv, DGP
6	(Sabry, Sherif, Gadelhak, et al., 2012)	Radiance - DIVA for Rhino	DAv, DGP
7	(Sabry et al., 2014)	Radiance/Daysim - DIVA for Rhino	DA
8	(Emami et al., 2014)	Radiance/Daysim - DIVA for Rhino	DA DF
9	(Wagdy & Fathy, 2015)	Radiance/Daysim - DIVA for Rhino	sDA, DAv, ASE, DGP
10	(Lavin & Fiorito, 2017)	Radiance/Daysim - Ladybug and honeybee for Grasshopper/Rhino	UDI, DF
11	(Chi, Moreno, & Navarro, 2017)	Radiance/Daysim - DIVA for Grasshopper/Rhino	DAv, UDI
12	(Chi, Moreno, Esquivias, et al., 2017)	Radiance/Daysim	DA, DAv, UDI
13	(Oghazian, 2017)	Radiance	sDA,DGP
14	(Kotbi & Ampatzi, 2017)	Radiance/Daysim - DIVA for Grasshopper/Rhino	DAv

17	(M. ElBatran & Ismaeel, 2021)	Radiance/Daysim - DIVA for Rhino	sDA, ASE
18	(Vazquez et al., 2021)	Radiance - DIVA for Grasshopper	sDA, ASE
19	(Chi et al., 2021)	Radiance - DIVA for Grasshopper	DAv
20	(Chi, 2022)	Radiance, Daysim / DIVA for Rhino	DAv
21	(Khidmat et al., 2022)	Radiance, Ladybug and honeybee for Grasshopper	UDI, sDA, ASE

Table 4: Summary of daylight simulation: tools and metrics.

4.5.1 Metrics

Each paper uses one or multiple performance metric(s). The DF is used in only 2 papers coupled with another CBDM metric. The DA. and rough points in time illuminance values were used to explore the impact

288

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

in 4 papers. The authors of these papers decided their own minimum and maximum thresholds during the methodology phase, thus none of these articles used any CBDM metric. Finally, 17 papers used different CBDM metrics, either one or multiple per paper. The DAv was the most used metric followed by the sDA (figure 10).

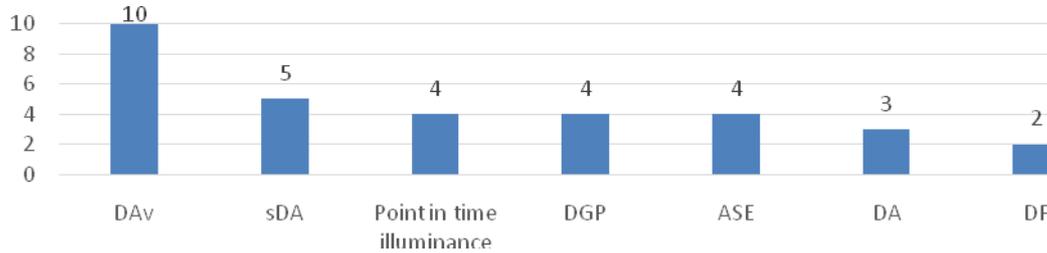

Fig. 10: Number of times a daylighting metric was used in the articles.

4.5.2 Tools

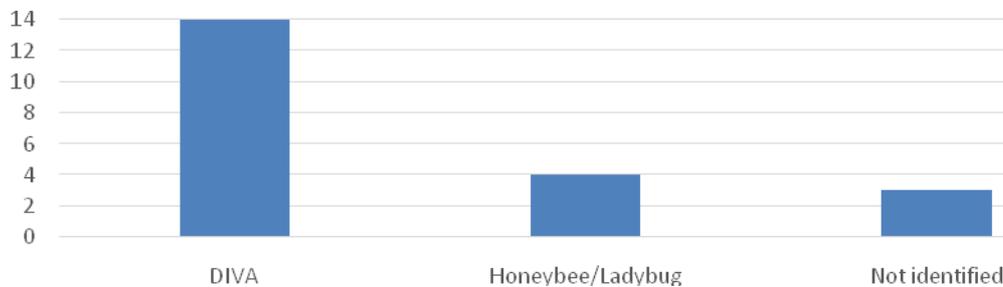
The Radiance simulation engine (and its method Daysim) is the only engine used in all of the 21 papers. The most used plugin/interface is DIVA for Rhino/Grasshopper to control Radiance in 14 articles. Honeybee and Ladybug for Grasshopper are used in 4 articles, and 3 articles did not identify the used interface (figure 11).


Fig. 11: Number of times an interface was used in the simulation process.

5 FINDINGS DISCUSSION

This section aims to discuss how the previously mentioned points of analysis impacted the findings of the papers, and whether they are relevant or not to the question of this study: whethere there is an investigation of the statistical correlation between daylighting performance and screens paramters. When the investigation of the daylighting performance was combined with other environmental performance aspects the aim shifted towards discovering optimized solution for screen design in specific cases. Such an approach led to the lack of in-depth insights concerning the targeted correlation, as the process was driven by a tradeoff between the different parameter values towards best case scenario for the overall environmental performance targeted. This approach to the optimization process was adopted in 9 papers.

The other 12 papers, concerned only with daylighting performance had more in-depth findings concerning the correlation between daylighting and design parameters. 11 papers targeted the perforated panels while only one paper targeted the screen of horizontal louvers. Five of these papers tested the impact of one parameter, and another five tested the impact of 2 parameters, only one article tested 3 parameters, and one article tested the impact of 4 parameters. The impact of the parameters on daylighting performance was addressed as follows:

(a) First, findings exploring the minimum and maximum parameter(s) value to achieve adequate daylighting. For example, A. Sherif et al., (2010) stated a minimum value of perforation percentage that can produce adequate daylighting. A. Sherif et al. (2012)stated that to achieve adequate daylighting in the depth of the test space higher values of perforation percentage is required, recommending the use of non-uniform values to achieve it. In another study, Oghazian, (2017)stated that different geometries of perforations with the same area affect daylighting performance differently. Such findings do not observe the presence of a statistical correlation between the parameter's values and daylighting. Moreover, the results are bonded to a specific physical configuration of a test space. Sabry, Sherif, Gadelhak, et al., (2012) and A. H. Sherif et al.

(2012)agreed on this,mentioning that other spatial configurations of test spaces may affect the concluded results.

(b) Regardless of the previously mentioned concern, Sabry, Sherif, & Rakha, (2012) is the onlypaper that observed the statistical correlation,they found an increasing linear relationship between average illuminance values and axial rotation angles. They suggested that such a correlation could be used by architects as a guide to choose suitable axial rotation angles knowing their impact on daylighting availability.

(c) The orientation and solar radiation impact was addressed in a number of findings. A. Sherif et al. (2012)observed that the impact of screens in the north with the absence of solar radiationis more effective. Similar findings were stated by Oghazian, (2017) who claimed that non-uniform perforation could deal with the efficiency/deficiency of other screen parameters when daylighting values are influenced by solar radiation. Sabry, Sherif, Gadelhak, et al. (2012) and A. H. Sherif et al. (2012) found that the aspect ratio of openings can improve daylighting while taking into consideration that it may cause over-lighting due to solar radiation for southern and eastern orientations.

(d) The previously mentioned findings prove that adopting solar radiation into the simulation process affects the insight of how the diffused daylight is impacted by tested parameters. Emami et al. (2014)agreed and stated that it is important to consider the DF in such a process as an indication of the percentage of diffused daylight blocked by the solar screen rather than CBDM metrics that considers solar radiation.

(e) Such insights put the finding of Kotbi&Ampatzi (2017)in question, who suggested a table for architects to use which indicates how several perforation aspect ratio values impact daylighting performance according to the DAv thresholds. Such a table is only valid when using the CBDM metric and when it is related to a specific spatial configuration.

(f) Several other findings relate to both studies which had the highest number of tested parameters (M. ElBatran& Ismaeel, 2021; Wagdy & Fathy, 2015). These papers addressed the impact of the trade-off between the different values of parameters on daylighting performance. Whereas the higher number of cases may give statistically a better insight for a correlation, the high number of addressed parameters makes the singular impact of each parameter unclear to observe.

6 CONCLUSION

This review of papers aims to observe how the impact of façade solar screen design parameters on daylighting is interpreted in research, and assessing if there is a methodolgy to fnd a statistical correlation between parameters of solar screens and daylighting levels. The topic relevance has been proven throughout the last decade, as an average of one to two papers per year are being published on it in journals or conferences proceedings. The tests in the 21 studies have been conducted on sites in different hot zones with hot climate, which proves awareness of the research community and their interest in the scope of this study.

Although there was only one study that observed and described the correlation between the variation in design parameters and daylighting levels, there is no reliable attempt towards devising a methodology to investigate the statistical correlation between a specific solar screen design parameter and daylighting levels. This failure could be related to the following:

(a) Using metrics that adopt the interferance of solar radiation which impacts the results of diffused daylight.

(b) Introducing no variations in the spatial configuration of test spaces, which renders the results relatingto only one specific spatial configuration.

(c) The combination of a large number of parameters in one study and the testing on other environmnetal aspects which leads to shifting the paper's aim into creating trade-offs and investigating a number of best-case scenarios.

However, the reviewed papers provide insight about what could be recommended to propose such a methodology in further research work, for example: adopting point in time illuminace values rather than CBDM metrics to exclude the interferance of solar radiation and have a clear judgmnet about the direct impact of solar screens on diffused daylight. Also, considering only one paramater with its variations per study, whereas introducing multiple cases in the test space's spatial configurations and compare their results to each other, thus any coorelation suggested would not be related to one specific spatial configuration case.

Finally, the reported ease of its modelling and manipulation made the perforated panel the most tested type of solar screen, together with its parameters. This conclusion may denote a lack in covering the reported growing number of screen types and morphologies. This leads to the need of reviewing a pool of international examples to create a catalogue to categorize screen morphologies into families and types with their respective design parameters.

FTN – Frequent Transit Network: Transit Strategies towards Achieving Transit-Oriented Development in Alexandria City, Egypt

Rowan Shebl, Hany Ayad, Mai Abdo

(Rowan Shebl, University of Alexandria, Department of Architecture, Alexandria, Egypt, rowanshepl1234@gmail.com)
(Prof. Hany Ayad, University of Alexandria, Department of Architecture, Alexandria, Egypt hany.m.ayad@alexu.edu.eg)
(Dr. Mai Abdo, University of Alexandria, Department of Architecture, Alexandria, Egypt, mai.abdo@alexu.edu.eg)

1 ABSTRACT

Land use policy and transport policy are normally integrated through transit-oriented development (TOD) strategies. (TOD) is a "mixed-use community", that encourages people to live near transit services and to decrease dependence on their driving. Instead of requiring riders to consult a timetable or wait for extended periods of time, transit service is most appealing when it is frequent enough that riders can arrive at a stop knowing that a bus or train will arrive soon. Frequent Transit Networks (FTNs) aim to deliver services in high-demand areas in a convenient, connected, and memorable. (FTNs) are intended to serve the locations that the majority of people want to visit most frequently and to make service convenient by operating at least every 15 minutes from early morning until at least mid-afternoon. This paper discusses, evaluates, and looks into the possibility of implementing TOD and FTNs in Alexandria, Egypt. Alexandria is experiencing a sharp increase in transport demand as a result of its rapid urbanisation. With the narrow streets and limited spaces the rapid urbanisation process has led to a significant increase in traffic volume. This paper adopts the Frequent Transit Network (FTNs) strategies in identifying corridors linking the city's urban centers and the nodes where these corridors intersect. The main purpose is to direct growth , development and to create a proposal for a "System Backbone" that provides a structure for other services. Expected findings from this study is to perform a framework that identify potential (FTN) solutions for the city. It also proposes a "Key Corridor Network" for the bus routes and light rail transit, emphasising corridors in which combined transport services could provide a more efficient operation of the city's public transport.

Keywords: Key Corridor Network, Convenient, Frequent Transit Network, Mixed-Use Community, Transit Oriented Development

2 INTRODUCTION

2.1 A brief overview

Frequent Transit Networks (FTNs) and Transit-Oriented Development (TOD) are related ideas with the same goal of enhancing urban areas' liveability and sustainability of transportation. An FTN is a high-frequency bus, train, or metro network that puts accessibility and dependability first and makes it easy for people to get around the city. TOD is a land-use strategy that encourages mixed-use, pedestrian-friendly, and compact urban development around transit stations in order to maximise the potential of FTNs. By reducing reliance on automobiles and fostering sustainable mobility, FTNs and TOD provide an all-encompassing solution to urban transportation issues that also improves livability, economic vitality, and social equity. Therefore, any city seeking to create a more sustainable and equitable future should prioritise planning and implementing FTNs and TOD.

2.2 The Essential Elements of Frequent Transit Networks

Frequent Transit Networks are intended to deliver service in highly populated areas in a convenient, connected, and memorable way.

2.2.1 Convenient

Frequent Transit Networks operate at least every 15 minutes from early in the morning until at least mid-afternoon, making service more convenient. The most direct route possible is planned for each route.

For example: Seattle's Frequent Transit Network (FTN), which was first mentioned in the Transit Master Plan, offers a long-term vision of connected bus routes crisscrossing the city, offering high-quality and frequent transit service to all residents, employees, and visitors of Seattle. This network aids in directing the service investments made by (Stock Tank Barrel per Day) STBD.

Three categories of routes are established by Seattle's FTN: Local, Frequent, and Very Frequentas shown in Fig 1. The FTN emphasises frequent service that is available every day of the week (18 to 24 hours). All Seattle residents now have more transport options thanks to this interconnected network of routes. The FTN actively develops a transit network for the Seattle of the future while adjusting frequency around times of the day when transit demand is at its highest.

Fig. 1: FTN Frequency Targets.(Source: Seattle's Frequent Transit Network)

2.2.2 Connected

Frequent Transit Networks are made to take passengers to the places they want to go most frequently, including downtowns, urban neighbourhoods, mixed-use corridors, employment centres, and significant institutions like universities. Additionally, they can establish a de facto "system backbone" that acts as a framework for other services. Frequent Service Networks can offer a similar framework for smaller systems, with lower frequency routes and specialised services acting as connections to the Frequent Transit Network, much like how large urban systems are built around the backbone that their rapid transit systems provide.

2.2.3 Memorable

Four main strategies are used by frequent transit networks to make their services memorable: distinctive branding, frequent transit network maps, straightforward service models, and simple schedules.

Distinctive Branding: To increase awareness of the services offered, many transit systems brand their frequent transit networks. Unique branding and clever marketing can help bring new users into the system, decreasing reliance on cars overall.

Frequent Transit Network Maps: Numerous systems create unique Frequent Transit Network maps that are intended to draw attention to and distinguish frequent services from other services.

Straightforward Service Models: Frequent Transit Networks have straightforward service structures that are made to be simpler to remember. They usually travel as directly as possible along the main roads.

Simple Schedules: Frequent Transit Networks also frequently have simple schedules, with scheduled transit services operating at regular intervals (clockface headways) that are simple for passengers to remember.

3 LITERATURE REVIEW

By analysing related scientific studies to determine the research gap that is most likely to be true between them, a meta-analysis of the literature is used. It was determined that:

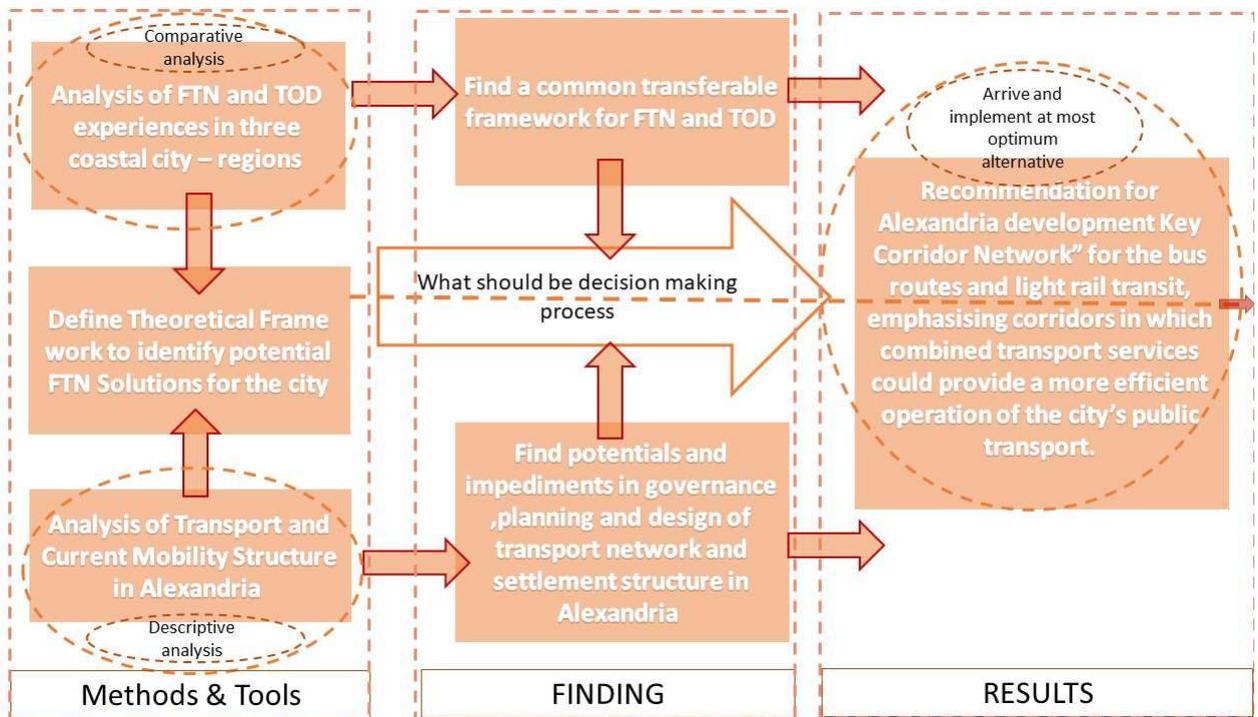
3.1 Problem definition

Planning guidelines for sustainable mobility have gaps from the perspective of sustainability principles. While issues like strategic land use and impacts on non-motorized travel are frequently overlooked unless they are a part of integrated land use and transportation studies (TOD) (Transit Oriented Development) or comprehensive urban development plans,transportation planning traditionally addresses various issues related to vehicles, safety, maintenanceand infrastructurerelated environmental impacts. Which led to the

294

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

observation that there is a general trend, "Modal shift from public transport to private transport" which is described below as shown in Fig 2. The challenge at the spot is to use a frequent transit network strategy to achieve transit-oriented development while directing the opposite "Modal shift from private to public transport" direction.

Fig. 2: Problem Definition (Negative effects of the increase in private motorized mobility). (Source:authers)


4 METHODS AND TOOLS

Fig. 3: Chart showing the sequence of work in paper (Methods &Tools – Finding – Results) constantly. (Source:authors)

4.1 Comparative analysis

Comparisons are made of the selected case studies through analysis of FTN and TOD experiences in three city regions.

NO	Name/ Description	Map	Service /Used Techniques
	Portland, OR: By enhancing infrastructure and increasing frequencies, TriMet developed its frequent service network. The regional hubs where many riders live and work are intended to be connected by lines of the frequent service network. For transportation to and from Portland International Airport in the wee hours of the morning and late at night, TriMet is adding a new bus line. In order to reduce wait times, TriMet is also splitting its longest bus line and increasing frequency in East Portland. Increased access to dependable, safe transport throughout the region, better connections to jobs and other destinations, and more service are all benefits of the expansion.	 Fig. 3: Map of Trimet Frequent service (Portland ,OR)	**Services:** • Every 15 minutes or better most of the day, every day • five light rail lines • 24-hour service • Later trips on MAX and all-night bus service to PDX • A new frequent service line • Serving the suburbs • Splitting our longest bus line • A more comfortable ride **Used Techniques:** 1. New shelters and sign poles with service information a(nd stop identification numbers . 2. Bus stop re-spacing and curb extensions . 3.Better pedestrian access . 4.Traffic signal priority . 5.Bus-only lanes .
2	**Austin, TX:** Capital Metro's "High Frequency Transit Routes" network is brand-new, and it serves Austin. The bus system in Austin underwent a redesign in June 2018. Since then, Capital Metro has seen a 4.5% increase in ridership, making it one of the few transit systems in the country to see rising ridership. With a focus on frequent service, Capital Metro launched its Cap Remap bus network redesign in 2018. There are 15 routes in the new extensive transit system.	 Fig. 4: Map of Austin's bus network (old - New) (Austin ,TX)	**Services:** - every 15 minutes from 6:00 AM to 8:00 PM, seven days a week. - 13 metro bus routes - 15 routes -Thirteen MetroBus routes that run every 15 minutes from 6:00 AM to 8:00 PM, seven days a week. -Two MetroRapid BRT routes that operate every 10 minutes during peak hours on weekdays **Used Techniques:** •Prioritize transit and walking. •Redesigning of its bus network . •Transit Joint Development
3	**Rhode Island:** (Potential Rhode Island Frequent Transit System) A "Key Corridor Network" consisting of the Rapid Bus line (the R-Line), key corridor bus routes and transit emphasis corridors where combined services on multiple routes provide frequent service was created by RIPTA for the Providence Metro area as part of its 2013 system redesign.	 Fig. 5: Map of Rhode Island Transit Master Plan (Rhode Island)	**Services:** • every 15 minutes. • the Providence Metro area • Rapid Bus line (the R-Line), key corridor bus routes **Used Techniques:** •Developping a "Key Corridor Network" . •Crosstown routes that connect service outside of downtown . •Additional radial routes to provide frequent service to additional areas.

Table. 1: Comparison of strategies that were used in three cities to applyFrequent Transit Network (FTNs). Source: authors after Tri-Met's Frequent Service Network Capital Metro's new frequent transit network -RIPTA's Key Corridor service

4.2 Descriptive analysis:

Analysis of transport and current mobility structure in case study (Alexandria):

With 35% of trips and a portion of the 40% of trips that are internal to the East zone, the "east - city centre" represents the main ridership potentialwhich is described below as illustrated in Fig 6. The city center's north and south corridors exhibit a moderate flow that is clearly on a different scale from the "east-city centre" flow. Today, the "west - city centre" is less significant. It may change in line with anticipated western development, but most likely in the medium- to long-term..

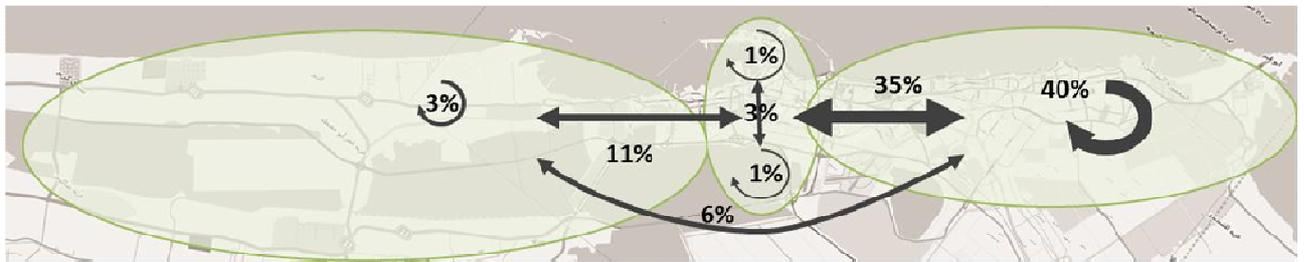
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Fig. 6: Main public transport flows in Alexandria (Source: Egis 2014 surveys)

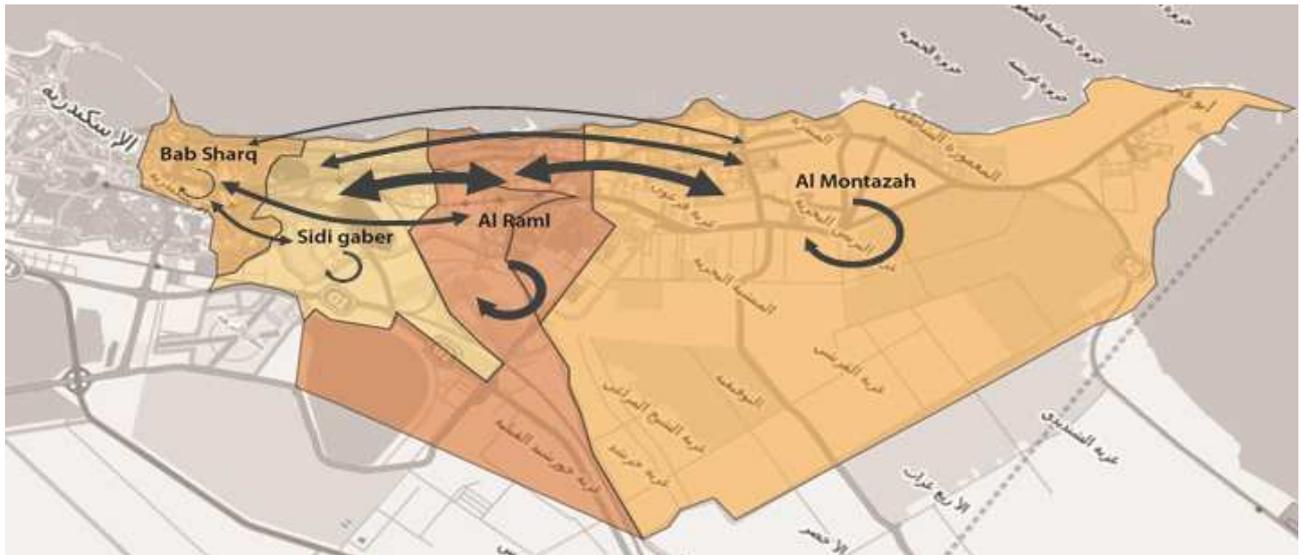
The sketch belowas illustrated in Fig 7 shows how the internal journeys of the eastern zone are represented. It demonstrates that the primary demand is also in an east-west direction there.This comprehensive analysis leads to the conclusion that the "East - City Centre" connection should be given priority (the scope of work) .


Fig. 7: Main public Transport flows in the east of Alexandria. Source: Egis 2014 Survey.

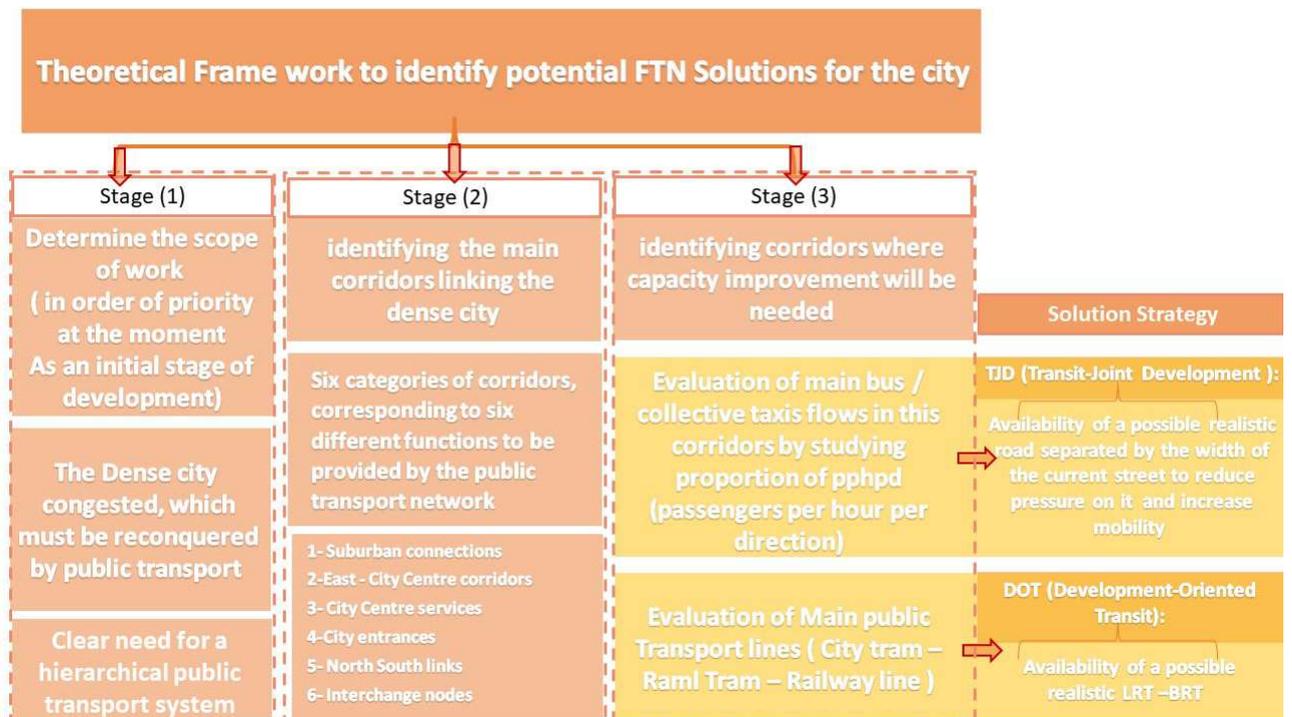
4.3 Define Theoretical frame work: to find potential FTN Solutions for the Alexandria case study


Fig. 8: Theoretical Frame work to identify potential FTN Solutions for the city (Source: authors)

4.3.1 Determine the scope of work

Alexandria dense city : there is a clear need for a hierarchical public transport system. The dense City, congested, which must be reconquered by public transport.In Alexandria, due to the linear structure of the city, the structure will naturally be based on one or several east-west axis combined with south-north feeding lines.

1	Road to Rashyd	~ 17 000pphpd
2	Corniche Road	~ 15 000 to 20 000 pphpd

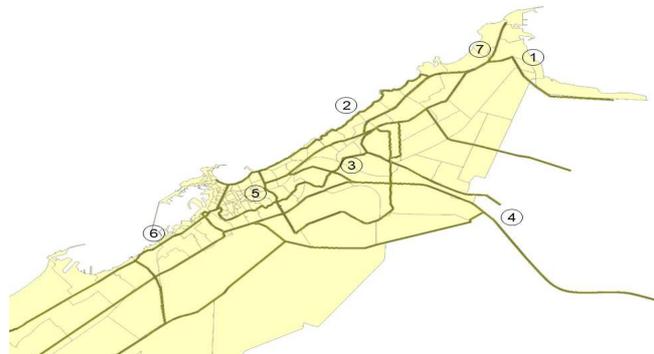

Fig. 9: Map of Alexandria dense cityMain bus/collective taxis flows (Current total publicridership-Passengers per hour per direction pphpd. Source: authors after French Development AgencyAlexandria Urban Transport StudyReport Phase 1.

4.3.2 Identifying the main corridors linking the dense city:

Through the diagnosis, six categories of corridors were discovered, each of which corresponds to a different service that the public transport system will offer.

4.3.3 Identifying corridors where capacity improvement will be needed

Evaluation of main bus/collective taxis flows in this corridors by studying proportion of pphpd (passengers per hour per direction):

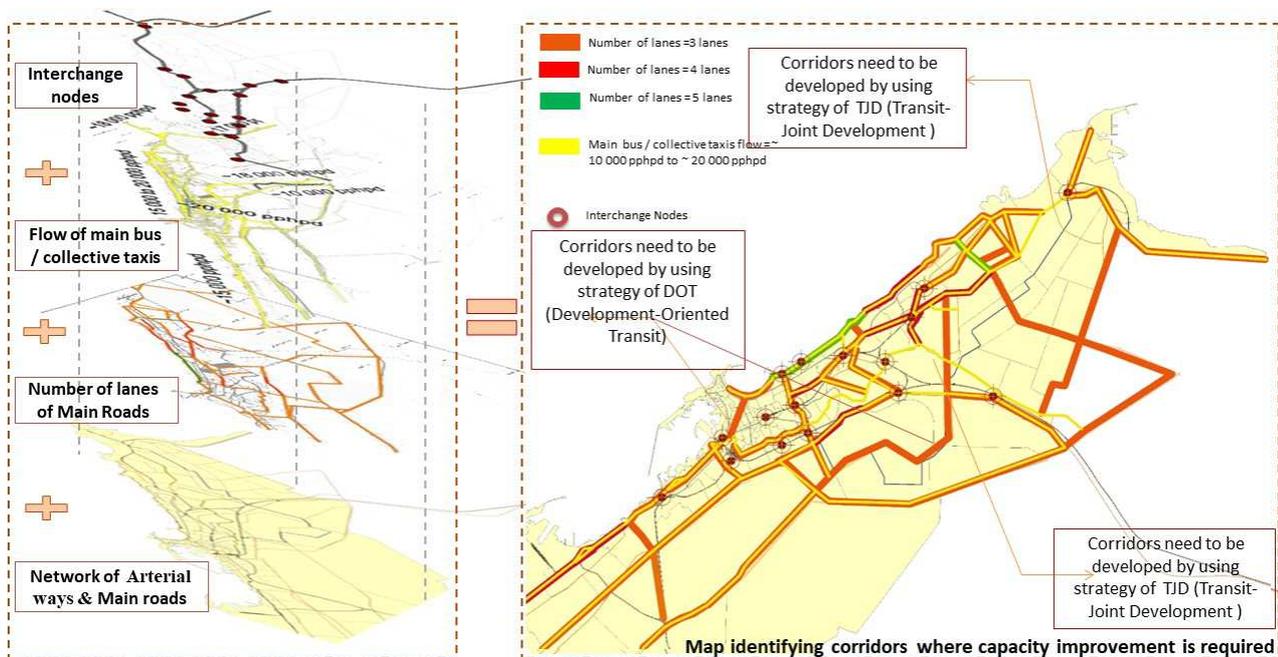
by layering mapon top of each other in order (Network of arterial ways and main roads + number of lanes of main roads + flow of main bus/collective taxis + interchange nodes) to produce a mapidentifying corridors where capacity improvement is required.


Fig.10: Proposed Digramatic Map of Alexandria dense city identifying corridors where capacity improvement is required. Source: authors.

Evaluation of Main public Transport lines (City tram – Raml Tram – Railway line)

(a) City Tram : is currently completely jammed in traffic, but could regain an important role if car traffic could be limited in the city center, and with an important renovation work. It could be the same also for walking, if increased space and safety was given to pedestrians.

(b) Raml Tram : where demand is high (more than 10 000 pphpd) and where the existing tramway could be upgraded into a modern tramway system with an improved right of way segregation. The existing line could be extended towards Mansheya Square or even Kabbary if it is possible to cross the city center.

(c) Railway Line / Regional lines : will also be the main structure for the public transport network and offer a possibility for quick move inside the city.)Jérémie Simon et al. , 2015(

5 RESEARCH FRAMEWORK

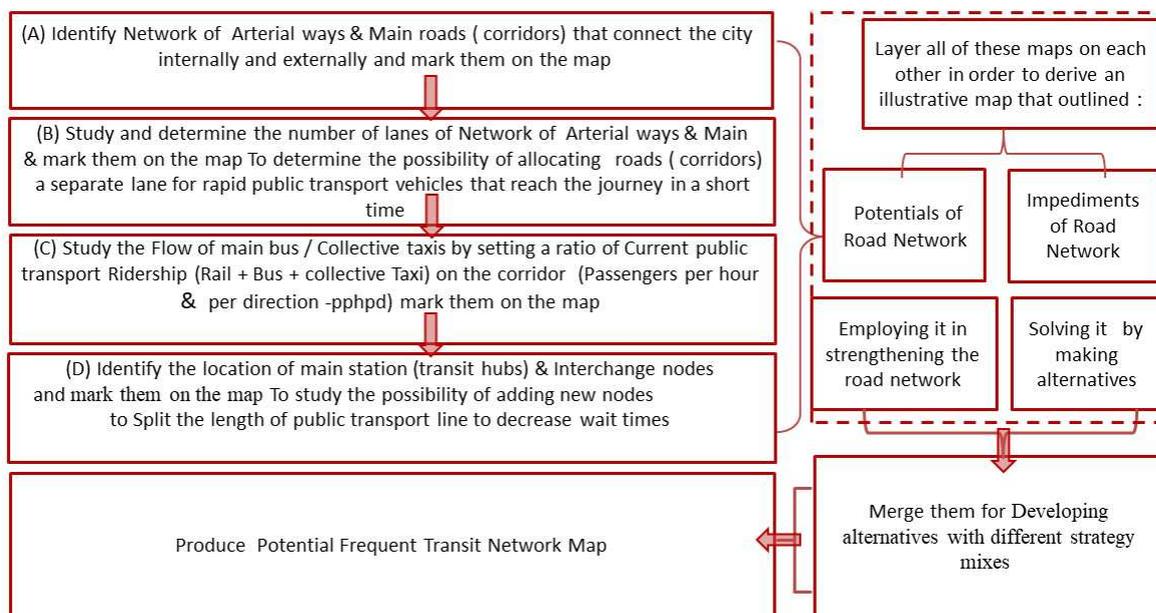
Common transferable framework for applying FTN Strategies towards achieving Transit-Oriented Development as shown in fig. 11.


Fig. 11: diagram show Common transferable framework for applying FTN (Source: authors)

5.1 Results

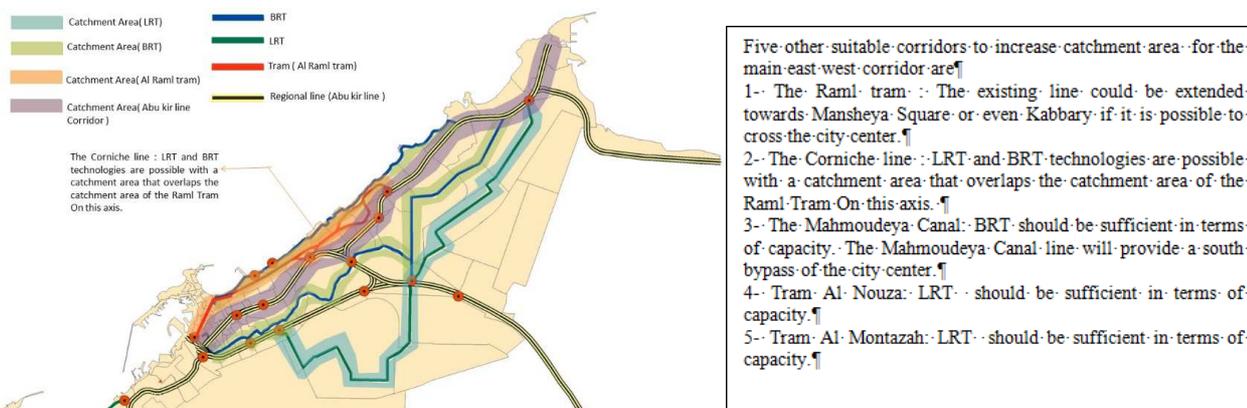
Recommendation for Alexandria development Key Corridor Network" for the bus routes and light rail transit, emphasising corridors in which combined transport services could provide a more efficient operation of the city's public transport as shown in fig. 12.


Fig. 12: Proposed Digramatic Map of Alexandria dense city framework development Key Corridor Network. Source: authors after French Development Agency Alexandria Urban Transport StudyReport Phase 1.

The main east west corridor: a mass public transport line such as a heavy metro or a LRT with high capacity to implement such a line is on the Abu Kir line corridor will operate as the backbone of public transport on the area; its stations will be fed by bus and collective taxis to improve the accessibility of the line and the attractivity of the whole public transport network. Those stations could also be used as nodal points for transport oriented development.

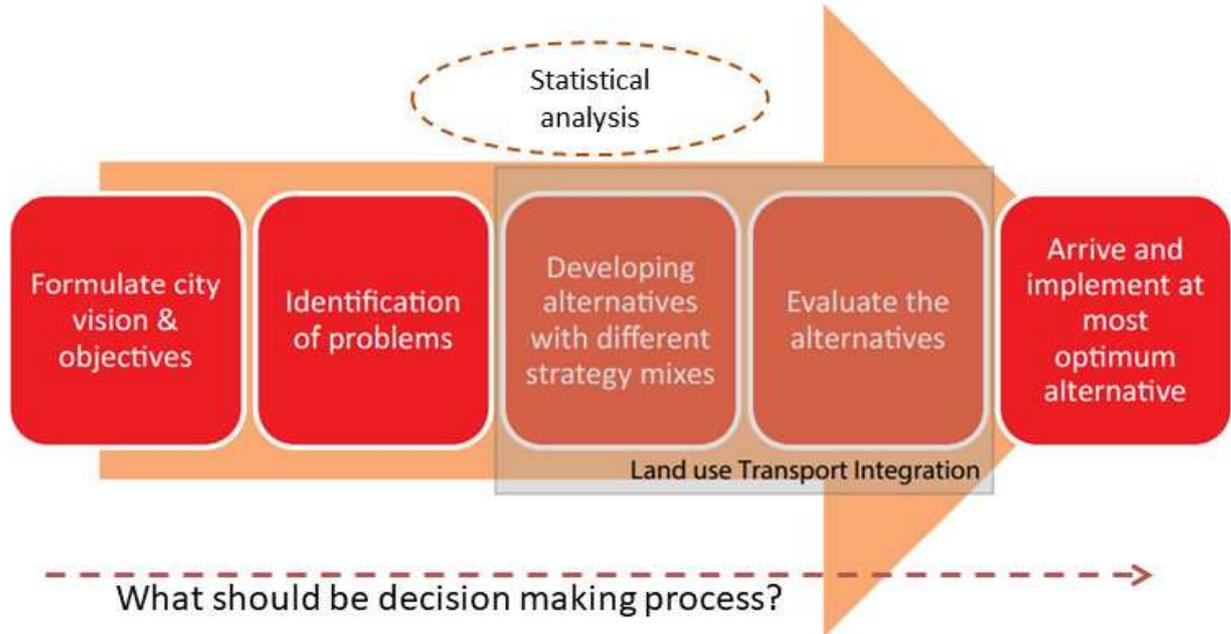
6 DISCUSSION


Fig. 12: Diagram show steps of decision making process as part of fig. 3.

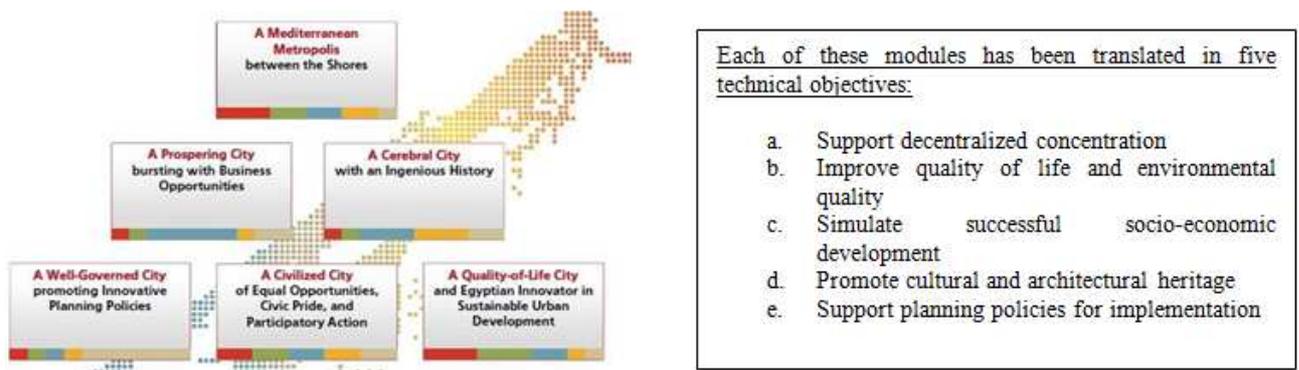
6.1 Formualte city vision and objectives

6.1.1 City Vision

The strategic Urban Plan 2032 describes the "city vision" in six modules:


6.1.2 Objectives

the Strategic Urban Plan 2032 identifies some priority objectives to improve the existing public transport system, which is currently not sufficient to deal with the large demand. These objectives are:

(a) Expand capacity: provide public mass transit along the primary communication axes.

(b) Prioritize public transport: in terms of space (dedicated lanes, priority at crossings) or finances, to show that public transport is faster and more convenient than driving.

(c) Connect subsystems and form a hierarchic public transport system.

(d) Make heavy maintenance on existing network: Raml tram line and Abu Kir railway line.

6.2 Identification of problems

No	Diagnosis	Problem	Strategic tools to be a dopted
1	Transportation	overall congestion; un-attractive public transport; limited catchment area	Limit car congestion, with higher performances of public transport lines increase catchment areas
2	Urban and economic development	un-sustainable urban development	develop a consistent planning between urban planning and transport Improve economic and touristic attractivity of the city – example of the Corniche
3	Environmental and social	there are major disturbances due to heavy traffic: air pollution, noise, unsafety.	Improve the quality of life, safety in the dense city
4	Financial	funds are lacking to develop and even maintain the public transport system	enhance the financial sustainability of new projects
5	Institutional diagnosis	coordination between public transport stakeholders is lacking	Integration, or at least coordination, between stakeholders in Alexandria

Developing alternatives with different strategy mixes: Strategy used: (1) Employment of potentials of existing road network, (2) Developing solutions for Impediments of existing road network.

7   CONCLUSION

The research deal with the problem of "Modal shift from public transport to private transport" and how to apply a Transit Strategies towards achieving Transit-Oriented Development .The challenge here is to steer the opposite "Modal shift from private transport to public transport direction" by using a strategy of Frequent Transit Network through Comparative analysis of (FTNs) and (TOD) experiences in three city – regions & Analysis of Transport and Current Mobility Structure in Alexandria conclude from it Theoretical Frame work to identify potential (FTNs) Solutions for the city. The research has finally arrived Recommendation for Alexandria development " Key Corridor Network" for the bus routes and light rail transit, emphasising corridors in which combined transport services could provide a more efficient operation of the city's public transport.

Fig. 16 FTN Frequency Map of Alexandria dense city by Merging alternatives showed in fig 14, fig 15 By classifying the routes into three categories (very frequent routes – frequent routes – local routes) suggestion three lines BRT (The Mahmoudeya Canal - The Corniche line – Mustafa kamal) three lines lines LRT (Tram Al Nouzza - Tram Al Montazah)口

1 ABSTRACT

Covid-19 pandemic has arguablely created an opportunity for urban planners to create cities that are more resilient and sustainable. This systematic review was aimed at analysing the potential of Unmanned Aerial Vehicle (UAV) technology as a tool for post-covid-19 urban planning and design. Specifically, the study reviewed the functional application areas that have leveraged the existence of UAV technology since its inclusion in non-military sectors in 2006. PRISMA method was used to retrieve journal articles that were published between 2006 and 2022 from scopus database and a total of 48 journal articles were included in the study. The results of the literature analysis revealed that there is a growing application of UAV technology in urban disaster managemnert, smartcities development initiatives, urban landscape management and urban road transportation management. The study also revealed that there is already a research increase on UAV integration in urban planning from 2019 which signifies the contribution of the pandemic towards UAV adoption. It has also been established that there is an increasing application of Machine Leaning (ML) and Computer Vision (CV) models for UAV data analysis. The study concludes that UAV technology has a lot of potential for improving urban planning processes with regard to time, cost, and safety and hence can be regarded as one of the sustainable tools in post-covid-19 urban planning efforts. Therefore, there is need for robust research to explore its potential in other application areas such as municipal waste management, urban developement control, and urban drainage systems among others. The study also recommends that basic courses on Artificial Intelligence (AI) be introduced in urban planning education to equip urban planners on the emerging AI applications.

Keywords: Unnamed Aerial Vehicles, Urban Planning, Artificial Intelligence, Machine Learning, Computer Vision

2 INTRODUCTION

2.1 Study Background

The impact of the covid-19 global pandemic has generally been seen as two-fold. While a significant proportion of the global population perceived the pandemic as a huge threat, some studies have revealed that the pandemic is an opportunity in some respect (Aboagye et al., 2021; Sharifi & Khavarian-Garmsir, 2020). One of the notable positive contributions of the pandemic is the increase in the invention of new digital technologies or at least an increase in the adoption of the already existing ones across different sectors whose impact has been far more positive in terms of production efficiency and cost-effectiveness. For example, Bukovska et al., (2021) investigated the impact of Covid-19 on technological adoption in the meeting and event industry and established that about 69 percent of the investigated events migrated to virtual or hybrid format and therefore increased the adoption of conferencing technologies. Similarly, Serbulova et al., (2020) and Farrugia et al., (2020) established similar findings in the business and the health sectors respectively.

In cities, Covid-19 pandemic has arguably created a new landscape that some scholars have deemed an opportunity for urban planners to create cities that are more resilient and sustainable (Sharifi, 2020). However, as history suggests, this new landscape is significantly parallel to the crises that gave birth to urban planning profession about two centuries ago (Smith, 2007, 2012; Smith & Lobo, 2019). It therefore implies that achieving the new dream of a sustainable cities calls for new planning techniques that match the current urban challenges. In this study, a systematic literature review was employed to assess the potential of Unmanned Aerial Vehicles (UAV) technology (popularly known as drones) in urban planning practice as

planning solution for the development of new sustainable cities. Specifically, the study intended to identify and analyse the functional application areas that have leveraged the existence of UAV technology since its inclusion in the civilian sectors and to understand its prospects for post-covid-19 urban planning and design. Additionally, we also analysed commonly used supporting technologies for performing UAV-based data analysis from the retrieved articles.

2.2 Background of UAV Technology

UAV technology is one of the state-of-the-art innovations that was invented in the 1800s. History indicates that in the past, the application of UAV technology was only limited to military purposes. For example, the first usage of drones was recorded in 1849 during the first Italian war of independence when Australian Empire devised a system of unmanned hot air balloons to drop bombs in Venice (Rakha and Gorodetsky, 2018). Later, the hot air balloons were also used during the American civil war and the Spanish-American war to gather and telegraph reconnaissance. Over time, however, UAV technology has gone through a series of evolutions to accommodate civilian applications. The major turnaround appeared recently in the 21st century when Frank Wang and his colleagues established DJI Technology company in 2006 which started producing drones for personal and commercial use (Mac, 2015). Since then, a lot of sectors including commerce, engineering, mining, and health, have all adopted this technology to improve operational efficiency among other things.

Similarly, the built environment sector has also leveraged the existence of UAV technology. Many studies documenting the application of UAVs in the built environment have shown that this technology can be successfully applied in building inspections, construction project monitoring, and infrastructure crack detection among others. For example, Patel et al., (2021) investigated the potential application of remotely Unmanned Aerial vehicles in construction management. In their study, they used a mobile-piloted drone to capture digital images of a seven-floored building that was under construction. Using a Pix4D software, they analysed the images and concluded that UAVs have the capability to capture building information like slab length, column dimension, and building area. UAVs also have secondary capabilities such as monitoring construction progress and updating project schedules. Again, Rakha & Gorodetsky, (2018) investigated how UAVs can be used to remotely detect cracks in buildings to facilitate maintenance planning. Drone-mounted cameras were used in the study to capture infrared images of a buildings. After analysing the infrared images, they concluded that UAV technology has the capability to effectively detect building cracks of all kinds and magnitude. Generally, the built environment sector is primed for growth in UAV applications, (Albeaino et al., 2019).

3 RESEARCH METHODS

To achieve the study objectives, the we adopted a systematic review approach. PRISMA protocol was used to retrieve journal articles related to UAV technology and urban planning from Scopus database. Scopus database was preferred, on one hand, for its wide coverage which guarantees comprehensiveness in the search results on the targeted subject (Onososen and Musonda, 2022). On the other hand, PRISMA protocol was preferred for its widespread acceptance, comprehensiveness, and wide variety of applications in numerous academic disciplines as well as for its ability to improve the accuracy and transparency of academic literature reviews (Samuel Adeyinka-Ojo, 2021; Shahruddin and Zairul, 2020).

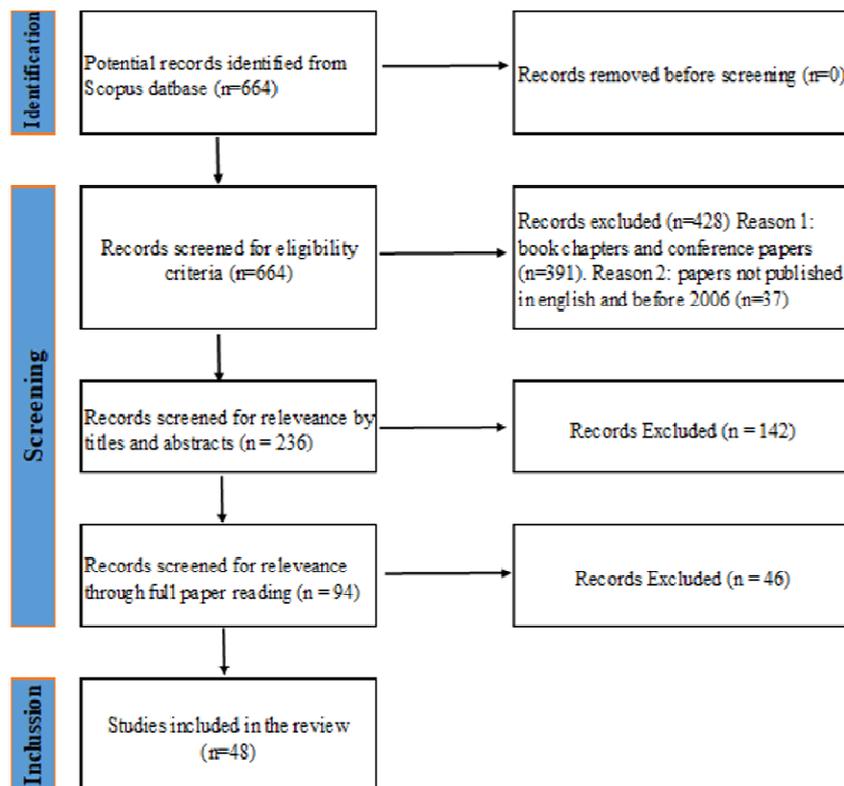
To obtain comprehensive results from the literature search, the following search combination was used: "Drones OR unmanned aerial vehicles OR unmanned aerial systems AND urban planning" AND "Drones OR unmanned aerial vehicles OR unmanned aerial systems AND city planning" AND "Drones OR unmanned aerial vehicles OR unmanned aerial systems AND town planning". A total of 664 papers were identified and 48 journal articles were included in the study after applying various screening criteria. Figure 1 shows the PRISMA flow diagram which summarises the search process. The 48 journal articles were classified into three research categories: application research, process optimisation research and mixed research. In the results and discussion section, we focused on the papers under the "application research" category.


Fig. 1: The PRISMA flow diagram.

4 RESULTS AND DISCUSSION

4.1 Publications by Year

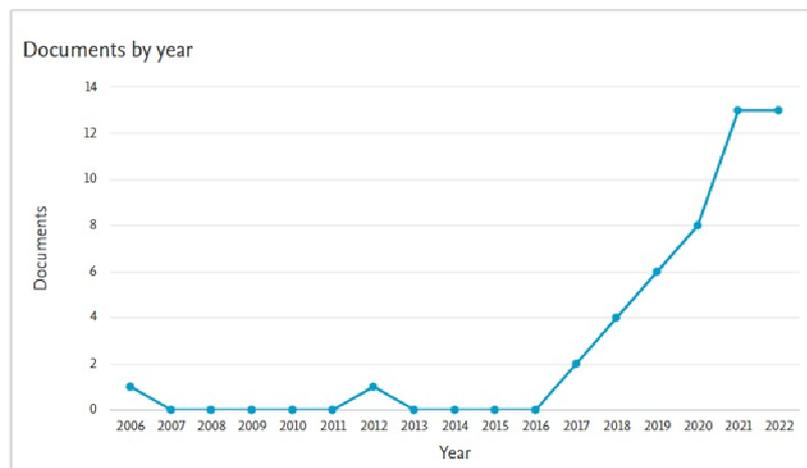
Scopus Analyst tool was used to analyse the 48 sampled journal articles to understand their distribution in terms of year of publication. Figure 2 summarizes the results. According to figure 2, about 92% of the sampled articles were published within the last five years between 2018 and 2022. From 2006 to 2017, only four studies (8%) related to UAVs and urban planning were published. This shows that UAV technology adoption for urban planning purposes is still a novel development. However, the trend shows a growth in the sense that from the year 2017, the publications have been increasing at a steady rate. If this trend continues, the technology might be widely adopted in few years to come. This aligns with the predictions by CIO Tech Outlook, (2020) that adoption of UAV technology across various industries such as agriculture, logistics, photography, mining, construction, and surveillance is going to increase at a rapid pace in the years to come. The steady boom of publications between 2019 and 2021 might also be attributed to the Covid-19 pandemic which necessitated minimization of physical contact between people.


Fig. 2: Distribution of the sampled articles by year of publication. Source: Author, 2023.

4.2 Emerging Research Categories

A comprehensive thematic analysis of the sampled papers was conducted to understand the key research categories relating to UAV technology and urban planning. The study derived that UAV research in urban planning can be categorized into three main groups: process optimization research; application research; and mixed research. Process optimization relates to all studies that are aimed at optimizing or improving the efficiency in the processes of integrating UAV technology in urban planning and management. For examples, some studies focused on developing algorithms or models for UAV flight path planning to ensure efficiency in energy consumption and increase flight time of UAVs in big cities; or algorithms for collision avoidance such as tall buildings in cities; or algorithms for multi-UAV communication when the targeted flight area is wide. Some process optimization studies have also focused on developing algorithms for post data (image/video) processing such as image segmentation or feature extraction (Boonpook et al., 2021; Pilinja Subrahmanya et al., 2021; Vazquez-Carmona et al., 2022). On the other hand, application research includes studies that relate to the actual usege of UAV technology to solve real-life urban problems. For example, Ullah et al., (2021) applied UAVs to map the extent of bushfire disaster to inform policy formulation for post-disaster recovery initiatives. Saputra et al., (2022) also employed UAV technology to simulate a flooding event and model the potential impact on vulnerable communities Indonesia to inform policy formulation for disaster prevention preparedness strategies. Lastly, the mixed research category includes those studies that involve the development of process optimization tools such as flight path or image processing algorithms but also involve the testing of the developed toolkits to solve real-life urban problems and ascertain their performance (Aljehani and Inoue, 2019; Escobar-Silva et al., 2022; Zhao et al., 2022).

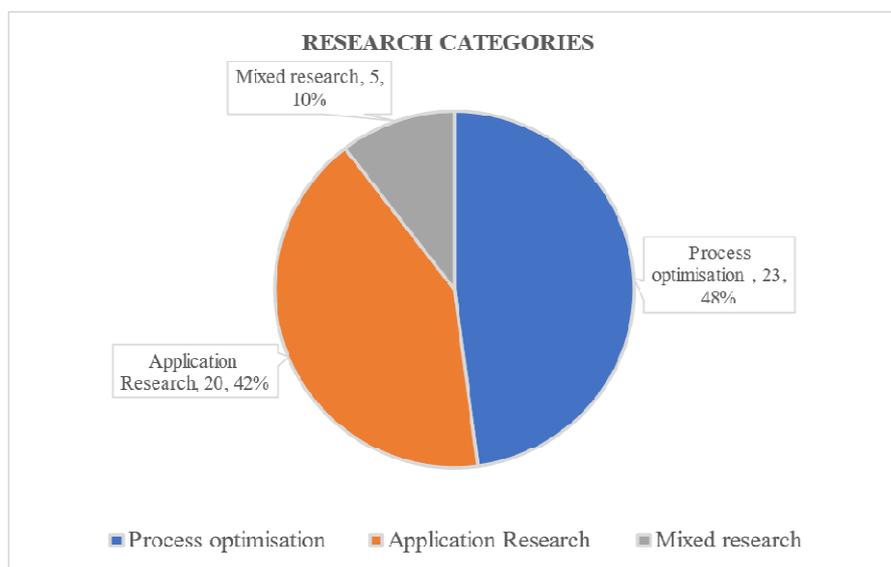
Figure 3 summarizes the classification of the sampled articles based on their thematic categories. The figure shows that the majority (48%) of UAV research in urban planning deals with process optimization. This means that the technology is still developing, and full integration has not been achieved yet. However, a significant proportion (42%) of application research was also recorded meaning that there is concurrency between research and application. The remaining 10% of the sampled studies were classified as mixed research.


Fig. 3: Emerging Research Categories in UAV Application in Urban Planning

4.3 Functional Application Areas of UAV Technology in Urban Planning Practice

As stated earlier, the study also intended to uncover the common functional areas of UAV technology application in urban planning discipline to derive its prospects in post-covid-19 urban planning and design. It has been established that the major areas of application include Urban disaster management (23%), smart cities development initiatives (19%), urban landscape management (15%), and urban road transportation management (13%). Landcover change analysis and Urban Heat Island (UHI) mapping are the least exploited application areas with a 2% score each. These results imply that there are still a lot more functional areas within the urban planning domain where UAV technology has not been explored yet. Therefore, further research is necessary to explore more application areas. Table 1 summarises the identified areas of

application and the major ones are expounded in subsequent sections focusing only on those studies that involve practical usage of drones rather than optimizing the process of UAV integration.

GENERAL AREA OF APPLICATION	SPECIFIC TOPICS TACKLED	NUMBER AND PERCENTAGE OF SAMPLED ARTICLES	SOURCES
Urban Disaster Management	Earthquakes, Flash floods, Volcanos, landslides, gully erosion, typhoons, bushfires,	11, 23%	(Aljehani and Inoue, 2019; Assis et al., 2020; Gudino-Elizondo et al., 2018; Huang et al., 2017; Li et al., 2012; Qadir et al., 2021; Saputra et al., 2022; Ullah et al., 2021; Wang et al., 2018; Wu et al., 2020; Zhan et al., 2018)
Smart Cities Development Initiatives	Smart Health; Smart transportation; smart energy; smart governance;	9, 19%	(Ahmed Hamza et al., 2022; Aloqaily et al., 2022; Dudek and Kujawski, 2022; Liu, Zhu, et al., 2022; Nelson and Grubesic, 2020; Sultonov et al., 2022; Templin and Popielarczyk, 2020; Teng et al., 2021; Vazquez-Carmona et al., 2022)
Urban Landscape Management	Monitoring urban vegetation cover	7, 15%	(Alvarado-Robles et al., 2022; Behera et al., 2022; Escobar-Silva et al., 2022; Feng and Li, 2019; Lee et al., 2021; Wu et al., 2021; Zhao et al., 2022)
Urban Road Transportation Management	Road traffic management; road infrastructure management; parking spaces management	6, 13%	(Coifman et al., n.d.; Jalayer et al., n.d.; Javadi et al., 2021; Li et al., 2019; Liu and Zhang, 2021; Luo et al., 2019)
Building Data Inventory	Identification and extraction of buildings and building attribute data from UAV images using various algorithms	4, 8%	(Ahmed et al., 2020; Boonpook et al., 2021; Pilinja Subrahmanya et al., 2021; Vacca et al., 2017)
Urban Security and Safety	Urban surveillance and security patrol	3, 6%	(Huang and Savkin, 2020, 2021; Liu, Bao, et al., 2022)
Urban Recreation	Parks and other public open spaces management	2, 4%	(Park, 2020; Rodríguez et al., 2022)
Urban Environmental Monitoring	Environmental quality monitoring; chemical pollution mapping	2, 4%	(He et al., 2019; Zhao et al., 2018)
Landcover Change Analysis	Mapping urban landcover changes overtime	1, 2%	(Hassan et al., 2020)
Urban Heat Island Mapping	Mapping urban surface temperatures	1, 2%	(Dimitrov et al., 2021)
Others	Cadastral data verification; energy optimization in built environments	2, 4%	(Arjoune et al., 2021; Cienciała et al., 2021)

4.3.1 UAV Technology in Urban Disaster Management

The nexus between cities and disasters is unequivocal. In general, urban areas tend to suffer more fatalities and economic losses from disasters than rural areas, possibly due to the aggregation of people, infrastructure and assets, urban expansion, and inadequate management. According to UNDES (2019), more than half (58%) of the world cities have a high level of exposure to at least one type of natural disaster such as cyclones, floods, droughts, earthquakes, landslides, and volcanic eruptions. With 68% of the global population projected to live in cities by 2050 (UN-Habitat, 2022), it transpires that cities or urban areas in general remain the central focus of disaster risk management. Besides, the rapid and often unplanned expansion of cities is exposing more people and economic assets to the risk of disasters and the effects of climate change (World Bank, 2012).

When it comes to urban disaster management, the current study has revealed that UAV technology has been used in managing different kinds of both natural and man-made urban disasters such as urban flooding (Gudino-Elizondo et al., 2018; Li et al., 2012; Saputra et al., 2022); typhoons (Wu et al., 2020); earthquakes (Assis et al., 2020); landslides (Huang et al., 2017; Wang et al., 2018); and bushfires (Ullah et al., 2021) among others. Aditya et al, (2022) applied UAV technology in urban flooding modelling in the small town of Java in Indonesia. Images from drones were used to create landcover maps and generate Digital Elevation Models (DEM) for simulating flood impact and predict the probability and the gravity of flooding events. Similarly, Li et al., (2012) used UAV images to simulate the potential level of impact that a dam break disaster from mass movement would have caused in Xiaojiaqiao city in China to inform future disaster preparedness strategies. Wua et al., (2020) used drone images to assess the level of damage from typhoon

disaster in Xiamen city in China. From the images, they were able to map and compute the extent of disaster damage for recovery planning purposes. The study concluded that drones could provide technical and decision-making support for urban disaster emergency rescue, ecological restoration, environmental monitoring and for urban planning in general. Furthermore, Gudino-Elizondo et al., (2018) applied drone technology to quantify and measure the attributes of gullies in urban areas after a storm event in Los-Laureles Canyon Watershed, in Tijuana, Mexico. Using various image analysis techniques, they were able to map the gully network extent and estimate different gully parameters such as gully heads. This informed the planning of recovery actions by various urban stakeholders.

4.3.2   UAV Technology and Urban Landscape Design and Management

Urban landscape management is defined as the management of open spaces and greenspaces, like residential green spaces, parks, playgrounds, etc. (Anguluri & Narayanan, 2017). Modern urban landscape management approaches incorporate various technologies to achieve sustainability goals and UAV technology is one of them. Research has shown that UAV technology can be successfully applied to estimate vegetation growth in urban green spaces, classify vegetation cover in an urban area, and map the distribution and trends in landcover changes. In this regard, Escobar-Silva et al., (2022) used drones to estimate grass growth in urban green spaces. The study involved integrating UAV technology and GIS to model and predict the growth of Bahia grass in Southeastern Brazil to facilitate the planning of grass cutting and mowing by city managers. Besides predicting growth, UAV technology was also able to capture vegetation parameters such as Leaf Area Index (LAI), soil water content, biomass, and evapotranspiration rate. It was also established that using this model would have a cost-cutting effect on landscaping processes.

Lee et al., (2021) developed vegetation detection model using UAV images. In this study drones were used to capture multispectral images that were then used to classify urban landcover to identify and analyse the distribution of vegetation in urban areas to support decision making in urban regeneration programs. The results showed that the model was able to differentiate real vegetation from other vegetation-like features such as green roofs and artificial grass. Related studies were also conducted by Feng & Li (2019); Zhao et al., (2022); and Robles et al., (2022). In their approach, they integrated UAV capabilities with other supporting technologies such as photogrammetry and Machine Learning models to reinforce UAV capabilities to identify, map the distribution, and compute vegetation parameters in urban green spaces.

4.3.3   UAV Technology and Urban Recreation

UAV technology has also been successfully applied in urban recreation. Rodríguez et al., (2022) applied drone technology to measure thermal comfort in an urban public space in Huelva, Spain. Thermal comfort simply means the level of comfort by public space users with park heat levels. Drones mounted with thermal cameras and sensors were used to collect infrared images of a public open space to measure thermal comfort. The estimated figures of mean radiant temperatures from the images were verified with the ones collected in real-time and the results showed high accuracy. It was then concluded that, this aerial thermography can be adopted as a way of measuring thermal comfort. Another drone technology application in urban recreation was conducted by Park, (2020). In this application case, drones were used to assess the level of park use in terms of number of people who use urban parks and their characteristics such as gender and age group at different times of the day and different days of the week. Drones were used to collect High Definition (HD) videos of the selected parks which were later assessed by a professional video assessor. By using this method, park use related information were collected at a lower cost compared to physical observation.

4.4 UAV Data Processing Tools and Techniques

A thorough analysis of the commonly used UAV data (Images and videos) processing techniques was also conducted in this study. An initial assessment revealed that about 90% (43 articles) of the sampled studies involved some sort of images/ video processing to achieve the intended objectives. The remaining 10% (8 articles) did not involve any data processing mainly because they are optimization research and their main study objective was merely to develop algorithms to improve some processes for UAV integration such as flight path planning (Qadir et al., 2021; Vazquez-Carmona et al., 2022) or to improve multi-UAV communication in urban an environment (Liu, Bao, et al., 2022; Teng et al., 2021). For the former, it has been established that to achieve maximum efficiency, the adoption and use of UAV technology in urban planning discipline is constantly fused with other supporting technologies. Out of the 43 studies that

involved processing of UAV images and/ or videos, only 5% (2 articles) involved the use of human intelligence for the analysis. In one study, Park, (2020) assessed the level of park use in terms of number of people who use parks and their characteristics such as gender and age group at different times of the day and different days of the week. He used UAVs to collect High-Definition videos of the selected publics parks which were later analysed by a professional video assessor to extract the park use related information. Further analyses were also conducted to assess the correlation of park use and the attributes of the surrounding environments or neighbourhoods. In the other study, Jalayer et al., (2019) used UAVs to capture images for inspecting and inventorying interchanges assets as a way of minimizing Wrong Way Driving (WWD) crashes on road interchanges. A visual analysis of the UAV images was used to identify the presence or absence interchange assets such as installed road signs, pavement markings, and geometric features and their condition.

However, for the rest of the studies (95%) various supporting technologies, other than human intelligence, were used. These technologies have been classified into five main groups: GIS-related technologies; Machine Learning (ML)/ Computer Vision (CV) technologies; Photogrammetry technologies; mixed technologies; and Others. Figure 4 summarizes the results.

GIS related technologies involve the use of Geographic Information Systems software to process UAV images to achieve research objectives. The commonly used software under this category was the Esri ArcMap. Only one study (Wu et al., 2021) applied a different GIS software, ENVI 5.3 Version, to analyse UAV images. Studies that used GIS related technologies accounted for 19% of the total articles.

Machine leaning/ computer vision technology involve the utilization of ML/ CV algorithms or models to perform image/ video analysis such as object segmentation, and feature extraction. In this study, it has been established that 44% of the total studies utilized ML/ CV algorithms to perform UAV image analysis. Deep learning algorithms such as You Only Look Once (YOLO), and Artificial Neural Networks (ANN) are the commonly used algorithms that were identified in most studies.

Photogrammetry technologies were classified as those technologies that support the pre-processing of UAV images such as image alignment and generation of orthophotos for further analysis. In this study, only 12% (5 articles) relied entirely on photogrammetry technologies for UAV image analysis. Agisoft Photoscan, Agisoft Metashape, and Pix4 Desktop Mapper software were commonly used under this category.

The mixed category involved an integration of multiple technologies to perform image/video processing. For example, Boonpook et al., (2021) integrated photogrammetry technology (Pix4 Desktop Mapper) and ML/CV based technologies (Deep Learning) to automatically extract buildings data from UAV collected images. On the other hand, Assis et al., (2020); Gudino-Elizondo et al., (2018); Lee et al., (2021); Nelson & Grubesic, (2020); and Wu et al., (2020) integrated various photogrammetry technologies with GIS technologies to analyse UAV images and videos in their respective studies.

From the analysis, it can be concluded that ML/CV is the most used processing technique in modern urban planning research and practice. Although Machine Learning is relatively a new branch of technology, its growth in application is rapid and has more potential for a technological takeover.

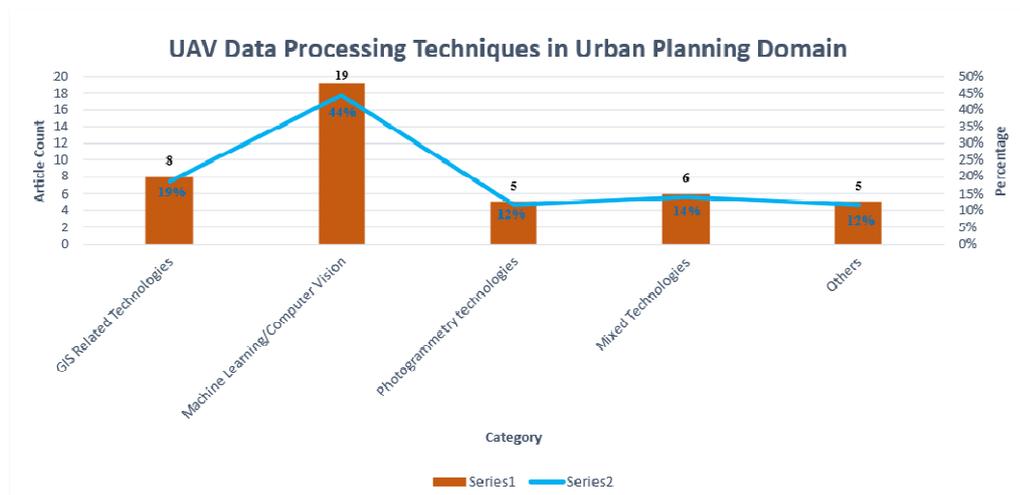

Fig. 4: Common UAV Data Processing Techniques in Urban Planning Research.

5 CONCLUSION

This study intended to review functional applications of UAV technology in Urban planning practice and understand its potential for post Covid-19 urban planning and design by using a systematic literature review approach. The results have shown that there are many success stories of UAV technology in different urban planning related area so far. Among the common areas discovered include urban disaster management, smart cities development initiatives, urban landscape management, and urban recreation. The study has also shown that there is a growing trend in UAV research in urban planning, including process optimization research, which signals high potential for future adoption of the technology in urban planning sector. The study has also revealed that there is a growing integration of Machine Learning models alongside Geographical Information Systems as the major techniques for UAV data analysis. Therefore, this study concludes that, UAV technology has a lot of potential and can be adopted as one of the sustainable tools for post covid-19 urban planning and design to carter for the increasing need for less physical contact between planning officials and city residents when executing planning roles.

1 ABSTRACT

In view of the growing threat posed by the effects of climate change on cities and regions, politicians and the public administration are increasingly called upon to create environmentally and climate-friendly as well as just framework conditions in urban spaces (IPCC 2022). The Covid-19 pandemic has underlined that urban green infrastructuresnot only benefit biodiversity, but arealso socially significant. In addition to providing a range of ecosystem services (MEA 2005), they equally support the diverse usability of urban landscapes, thus affirming the right to the (climate-just) city for all (Heindl 2022). Especially in denser settlement areas, where green and open spaces with important social and recreational functions are only available to a limited extent, different, sometimes contradictory needs of diverse social groups can lead to conflicts of use. Thereby, "vulnerable" persons or groups[1], who on average already have less access to high-quality green and open spaces anyway (Honey-Rosés et al. 2020), often give way to the more dominant user groups. In this context, approaches such as gender-sensitive planning and design (Terraza et al. 2020, Tummers et al. 2019) as well as attempts to design and manage public spaces sensitively according todiverse everydayneeds of the heterogenous urban populationare becoming increasingly important.

The research project "DraussenDaheim"[2](DDH) [German for: "At Home Outside"] is therefore developing a methodology and toolbox from a gender- and group-specific perspective, which serves not only the participatory evaluation of urban public spaces, but also the simulation-based development of different planning scenarios,which can, for example, be incorporated into space-time management concepts. Digital participation and simulation tools as well as tailor-made workshop designs are applied in the context of two Austrian use cases(Vienna, Zell am See) to identify spatio-temporal use patterns and group-specific requirements for the multifunctional use of space. In addition, the usability of the compiled tools (on the part of usersand process facilitators) is tested. The methodology to be developed also builds on knowledge from a well-tested target group segmentation approach with a special focus on active mobility (Markvica et al. 2020) to more accurately capturethe mobility and information needs of the (vulnerable) groups involved.

This contribution gives a comprehensive insight into the project, its conceptual and methodological approach, and provides first results of use case specific surveys and tool-tests. From this, key findings are derived that address the potentialof the gender-sensitive use and developmentof(digital) participation and analysis tools to supportequal and environmentally friendly access to open spaces in residential environments.

Keywords: gender groups, open space, participation, digital tools, urban planning

2 INTRODUCTION

In the ever louder demand for more ecological and social justice, public space in cities plays a central role. It is considered the space of action of public life and as such is constantlyre-produced through diverse social practices and relationships. It is social, political and material space at the same time, the importance of which became clear in the course of the Covid-19 pandemic (Reinwald et al. 2021).

Social justice in this context of spatial planning and development is influenced by three different aspects: distributive, procedural, and recognition-based conceptions of justice (Schlosberg 2007). Distributive justice

---

[1] Vulnerability refers to one or more aspects of people's everyday lives and draws attention to the needs of those groups of people who are often forgotten in planning decisions, and/or who are particularly locally bound and dependent on planning for everyday life due to low time or financial resources and low mobility. "Vulnerable" groups thus include persons with care responsibilities (more likely to be female), as well as younger and older or mobility-impaired persons who are care-dependent.

[2] Project website (in German): DraussenDaheim | ProjektWebseite (ait.ac.at), or DraussenDaheim Promoting climate-neutral mobility - AIT Austrian Institute Of Technology (for englich readers)

---

follows the principle of equity and refers to the fair distribution and access of urban amenities (Rawls 2005). Procedural justice refers to the planning processes and fair opportunities to engage in these processes. The third aspect of social justice is that of recognitional justice. This is the recognition and appreciation of different interests and needs and thus inclusion of different social groups (Nussbaum 2013).

The focus of this article is procedural justice,i.e. the possibilities to participate - with the support of digital tools - in specific phases of the planning processes (see Chapter 4). Similarly, the use of different tools and methods also supports the needs of different groups of people in a better and more differentiated way and thus also promotes the aspect of recognitional justice.

The accessibility and usability of public spaces such as green and open spaces in the residential environment not only determine the quality of life of different social groups, but also have significant influence on mobility habits. This is due to the possibly limited right to green and open space.If public spaces are designed in such a way that they are more accessible to all socialgroups, encourage more active mobility and reduce the need for longer recreational traffic, they can make a significant contribution to environmental and climate protection.Furthermore, public space reflects the social coexistence and culture of a city, which in the case of the City of Vienna leads to commitments such as increasing the quality of stay for all and contributing to unrestricted use for children, older persons and persons providing care (Fachkonzept Öffentlicher Raum 2018). As a constant space of negotiation and appropriation, public space is also a potentially conflictual space that must accommodate contradictory needs. Urban gender equality policy (e.g. Vienna City Administration 2014) addresses this by striving to create equal living conditions for women and men and by using gender-sensitive planning methods to specifically take into account different interests.

The use of innovative digital approaches in urban planning opens up new possibilities for evaluating open spaces, developing them in a participatory manner and achieving a gender-responsive design in the planning process and use of public space.Since digital analysis tools, as already emphasised in the previous project SMTG+[3], usually lack the integration of gender and group-specific aspects, a special focus is placed on this in the two use cases, starting with the gender-, age- and care-specific disaggregated survey up to the differentiated evaluation of the investigated space-time use patterns. Finally, the concepts of gender (mainstreaming) and gender planning from a care-perspective (Tummers/Wankiewicz 2021) are also applied in the actual process design and tool development.

3 DRAUSSENDAHEIM PROJECT AND RELATED CASE STUDIES

In view of the democratic relevance of open spaces as well as their recreational factor (as an important health aspect), a right to a good living environment can be stated in the urban planning context (Heindl 2022). It is derived from the human right to housing, which includes public space. According to this, all groups should be able to feel "at home outside"[German: "draussen daheim"].

This is the starting point and at the same time the objective of the project "DraussenDaheim". Based on the analysis of cycles of use of urban spaces and the identification of specific spatio-temporal patterns of use and requirements of different social groups, a methodology is developed that supports the design of gender-responsive open spaces.This methodology, which is applied and further developed in exemplary use cases, is intended to support the spatio-temporal organisation of open spaces (see corp paper Wankiewicz et al. 2023)andto help makingthem accessible to groups in vulnerable situations without displacing others at the same time.The development of this new methodology as a result of the gender-sensitive use of digital participation and analysis tools draws on tailored toolsets consisting of survey tools (using analogue questionnaires as well as an online survey tool), a digital participation platformusing the tool "Smarticipate"[4] (see Khan et al. 2017)and simulation and visualisation toolsusing the tool "Simulate[5]", "SUMO[6]" (see Lopez

---

[3] Project website (in German): SmartThroughGender+ (ait.ac.at)

[4] "Smarticipate" is an interoperable and expandable platform for interactive urban planning for a more transparent, democratic and inclusive implementation of urban transformation processes. Using the online smarticipate service platform, different stakeholders including citizens can interact with the system to initiate new proposals using inputs on a map and obtain automated feedback on any proposed changes based on Open Government Data (OGD) layers. The platform provides a carefully selected list of features, which enhance the ability of citizens to co-create, collaborate and participate in city decision making: https://www.smarticipate.eu/

[5] "Simulation, analysis and optimisation of customer and pedestrian flows": https://www.ait.ac.at/en/solutions/analysis-and-optimization-of-pedestrian-flows/simulate

et al. 2018) and a parametric design tool called Rhinoceros3D/Grasshopper[7].Within the framework of online surveys and co-creative workshop formats used in the use casesAumannplatz (Vienna) and Sonnengarten Limberg (Zell am See), group-specific spatio-temporal use patterns are collected and analisedin a first step. In a second step, further analyses (e.g. by means of WebGIS applications and simulation tools) will be carried out and user-friendly visualisation possibilities tested (e.g. heat maps on the group-specific use of open space during the day and week) in order to be able to feed the results back to the participants and thus stimulate further discussions on equal access to . Providing such possibilities can not only contribute to a more just balance in the use of open space, but also increase the acceptance of the respective needs of the different groups. As the project will continue until February 2024, we will focus in this paper on the already developed methodology based on the digitally supported analysis of spatio-temporal use patterns of different groups (rather than on the simulation and visualisation of results) as well as on first results and findings from the tool applications in the respective use cases.Finally, the learnings mainly refer to the (further) development of the tools, especially to the improved usability of the compiled tools from the perspective of the users and process facilitators, as well as to the design of participatory processes that enable a gender-sensitive use of (digital) participation and analysis tools.

3.1 Use case: Aumannplatz (Vienna)

The Aumannplatz, a central square in Vienna's 18th district, which represents one of the research project's use cases, no longer meets the multidimensional demands of its users due to its problematic traffic situation and poor design. Based on a functional and socio-spatial analysis carried out by the District Service of the City of Vienna [GebietsbetreuungStadterneuerung], which roughly outlines the main user groups (e.g. schoolchildren and older people), a large-scale participation process was therefore initiated with the aim of redesigning the square. The project "DraussenDaheim" was involved in the extensive process of collecting ideas and supported the identification of the spatial qualities of the square and the actual as well as future target group-specific possibilities of use. The participatory evaluation of the public square and its usability (e.g. crossing possibilities and quality of stay), and the simulation-based development of different planning scenarios (square with different spatial boundaries and elements) relied in particular on the successful interplay of the tools "Smarticipate" and "Simulate".

---

[6] "Simulation of Urban Mobility": https://eclipse.dev/sumo/
[7] https://www.rhino3d.com/

3.2 Use case: Sonnengarten Limberg (Zell am See)

Compared to the use case Aumannplatz, the starting point of the use case Sonnengarten Limberg is different in some fundamental factors: Sonnengarten Limberg, known as the "settlement of short distances", is not so much embedded in the urban fabric but is rather located on the outer municipal area and is therefore also less intrastructurally interwoven with the town of Zell am See.Even though basic infrastructure is provided within the settlement area most people living there (about 70% younger than 47 years) are using cars as their dominant means of transport. Furthermore, since the housing project has already been developed and implemented, monitoring and evaluation is carried out within the framework of the research projectby using the digital participation tool "Smarticipate" to investigate the use of open spaces close to or further away from the settlement and thus draw a first conclusion about the spatio-temporal use patterns of the residents. This was achieved with the combined use of an online survey and the creation of an open space use diary using "Smarticipate".

4   DIGITAL METHODS AND TOOLS FOR PARTICIPATORY PLANNING PROCESSES

Forms of participation can be categorised according to different criteria (Schoßböck et. al. 2018). We follow the classification according to the form of communication or type of information flow of Rowe and Frewer (2000).

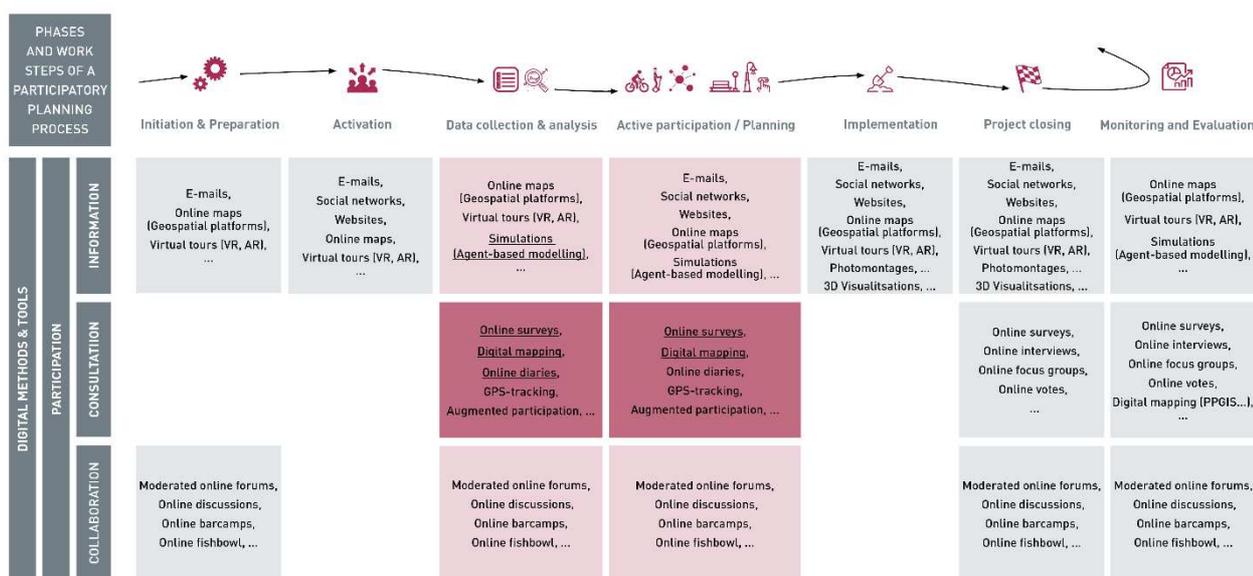
We listed digital tools for information, consultation and collaboration that can be used in each of these phases(see Figure 2). The result is that digital tools are used for different purposes in several phases of participation Processes, and they are usually combined by none-digital methods and tools.


Fig. 2: Digital methods and tools for the different phases of participatory planning processes, © BOKU & AIT

Since the use case Aumannplatz was in the phase of data collection and analysis accompanied by active participation, the focus was set on tools which support gathering information from the residents (consultation tools). For the co-creation processes, we chose an online survey tool (LimeSurvey) and a digital participation tool ("Smarticipate") and combined it with a simulation tool ("Simulate") to show the impact of workshop participants' suggestions and ideas on pedestrian flows. In the Sonnengarten Limberg use case, the same online survey tool as well as digital participation platform (this time over a longer period of time) were used, and later more detailed analyses will be carried out using a mobility simulation tool ("SUMO").

4.1 Combined assessment using the toolchain

An important step within the project is the thorough development of interfaces (APIs) to combine the differnet participatory tools.For example, the results of the online survey for the use case Sonnengarten Limberg were subjected to a detailed analysis before the actual tool workshop in order to be able to segment the surveyed target groups. With the help of a person ID ensuring the anonymity of users, the respondents could be clustered in the further use of the digital participation platform according to their mobility

behaviour (allocation to groups via pro:motion types, see chapter 5) and their use of open spaces could thus be better analysed. Likewise, conclusions could be drawn about the group-specific use of the tools themselves.Furthermore, in combination with other factors, such as care obligations, preferences of the different groups reached (DDH profiles) can be derived and qualified for the gender-sensitive use and development of the tools.

4.2 Toolchain evaluation

As part of the DDH project a toolchain evaluation by users and process facilitators is performed to understand the needs of the different groups regarding tool usability and visualisation of results. This ultimately helps to find out how they can be used most efficiently during the different participatory phases. Within the first half of the project tool tests with focus groups have already been performed and will be further extended till the end of the project (February 2024). The results of the first tool evaluation process already enabled to improve the tool usability during first and second use case application.

5 DDH PROFILES: TARGET GROUP IDENTIFICATION BASED ON SPATIO-TEMPORALUSE TYPES

To, first by means of use case -specific questionnaires, collect gender+[8] differentiated data in the selected case studies Aumannplatz (n=46) and Sonnengarten Limberg (n=59), specially developed spatio-temporal use types (DDH profiles) are identified. Their design is based on theoretical and practical considerations on different dimensions of spatio-temporal constraint as well as on the pro:motion typology (Markvica et al. 2020), which comprises a total of six mobility and information types: *Spontaneous – On the Go, High Informed Sustainability*, *Efficiency-oriented Information Pickers*, *Interested Conservatives*, *Low Demand and Digital Illiterates*. We also draw on the knowledge from the previous project Smart through Gender+ (Damyanovic et al. 2021, Tummers/Wankiewicz 2021) and the gender+ groups[9] defined therein.

The following dimensions of spatio-temporal constraint are considered:

- dependence on care
- obligation to care
- mobility restriction
- employment

The spatio-temporal use types were surveyed in that the question sets contained in the surveys for both use cases included demographic and care- or gender-related questions on the one hand, and mobility-specific and open space use-related questions as well as spatio-temporal questions which draw on practical experiential knowledge on the other. In the use case of Sonnengarten Limberg, the indicator statements from the pro:motion study[10] (Brauner et. al. 2016) were additionally asked in order to be able to cluster the respondents according to their pro:motion type. As a result of the survey with 46 participants, the following Figure shows the pro:motion types represented according to their care obligations. Only the pro:motion type *High Informed Sustainability* shows a significant lower rate of care obligation.

While the cross-sectional evaluation of the survey allows each pro:motion type to be considered from the perspective of a specific care focus, there is already general knowledge about their type-specific mobility behaviour (including willingness to switch to cycling or walking) as well as underlying motivations, values and attitudes (regarding efficiency, environmental protection and sustainability, costs, time factor, etc.).In addition, type-specific information needs and communication demands (e.g. on style or medium of communication - analogue, digital, personal) are known, which subsequently makes it easier to select and target suitable communication and participation methods (e.g. classic analogue vs. playful digital campaigns).The major advantage of this approach is that with the existing knowledge about the groups

---

[8] "The term "Gender+" describes an expanded concept of gender. It signals that gender is always overlaid with other characteristics on which structural inequality is based, such as age, origin, skin color, education, profession, disability, sexual orientation or religion (intersectionality)" (Verloo 2009)

[9] These groups are not only determined by sex, but also by further factors which are considered to shape a person's urban routines, such as age, household size, employment and country of origin.

[10] https://www.ait.ac.at/themen/integrated-mobility-systems/projects/promotion

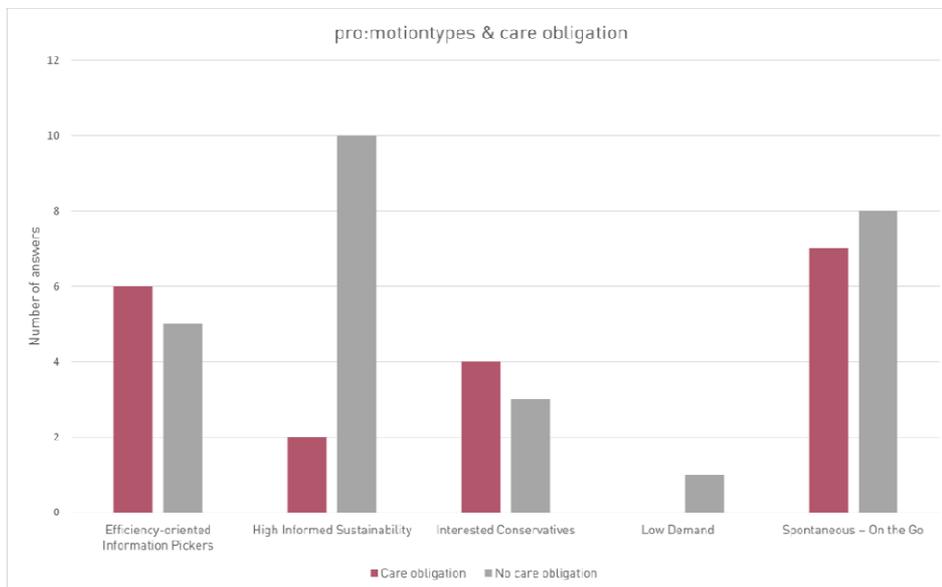
reached, the requirements for the methods and tools used in the project can be specified. With the help of this target group segmentation based on mobility and information behaviour, people with similar needs and values were finally divided into focus groups for the tool workshop. Moreover, for the future derivation of action scenarios, it is possible, for example, to work in the same way with the assumptions on group-specific attitudes such as the willingness to switch to a climate-friendly means of transport.


Fig. 3: Survey result use case Sonnengarten Limberg: pro:motion types by care obligation (n=46).

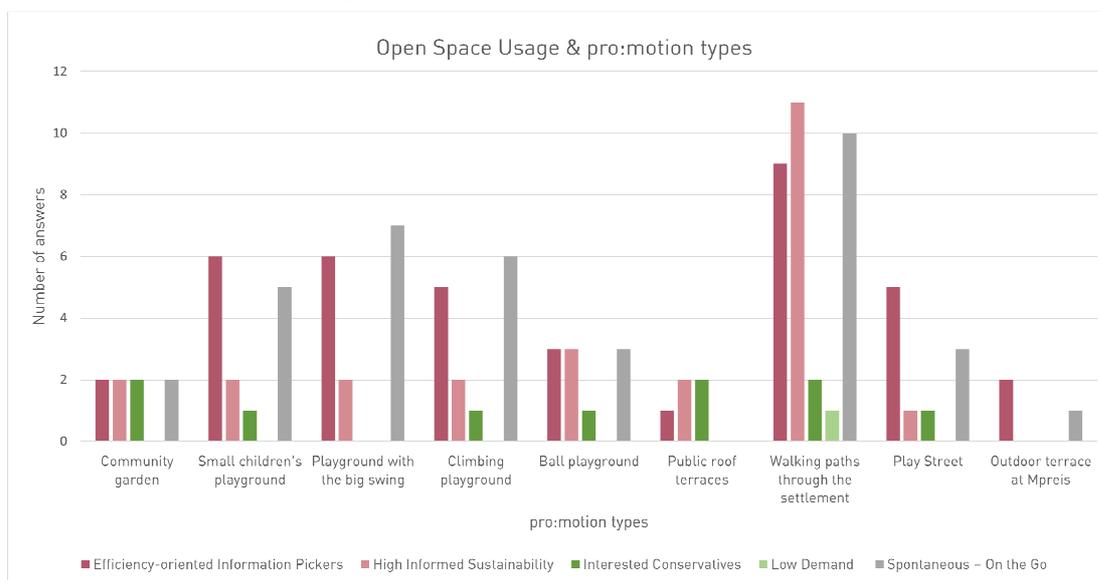
While the tool test in the Aumannplatz use case was conducted with mixed groups, not clustered by pro:motion types, thus enforcing an exchange beyond their own interests, the intention of the homogeneous group formation according to pro:motion types in the Limberg use case was a mutual reinforcement of the participants as well as the promotion of motivation and collective engagement potential. Finally, the evaluation according to pro:motion types and care obligation also allowed conclusions to be drawn about the open space use of the surveyed groups (see Figure 4).


Fig. 4: Survey result use case Sonnengarten Limberg: open space use according to pro:motion types (n=46)

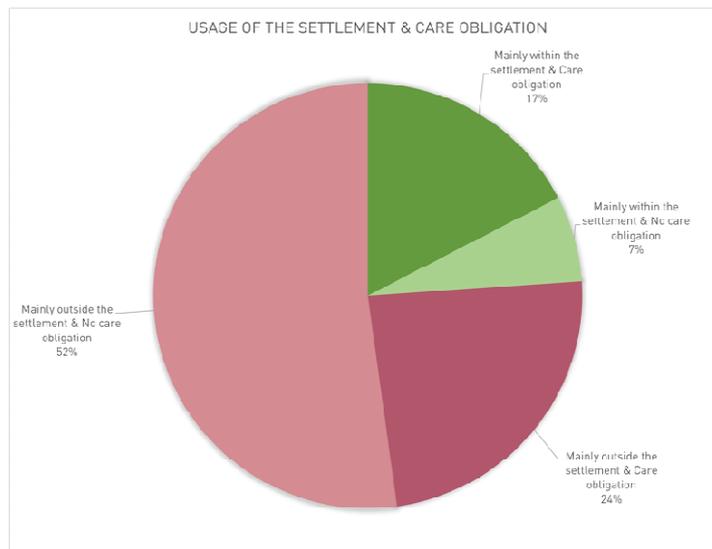
Moreover, as can be seen in Figure 5, which compares the rate of use of open spaces inside the settlement or outside, participants with care responsibilities use open spaces inside the area almost as often as outside.


Fig. 5: Survey result use case Sonnengarten Limberg: open space use inside and outside the settlement according to care obligation (n=46)

Through the gender perspective, which takes into account group-specific needs and demands, it can be seen that "vulnerable" groups due to their age, mobility, income or everyday situation related to care are precisely those who have a small radius of movement, are locally oriented or bound and thus depend on a high-quality living environment. This includes, for example: children, senior citizens, people with limited mobility and disabilities, and precisely people with care obligations (Zibell et. al. 2019).

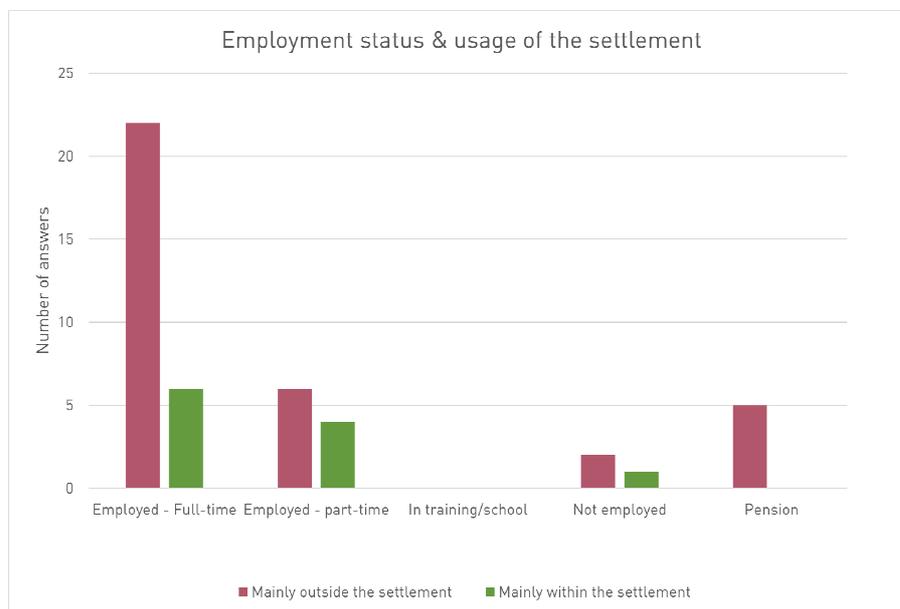
Also a very significant difference is seen between full-time and part-time employed as the full-time mainly use open-spaces outside of the area. One reason for this might be that during the week this people often use their private gardens due to time restrictions and on the weekend they use the private car to visit locations outside.


Fig. 6: Survey result use case Sonnengarten Limberg: open space use inside and outside the settlement according to employment status (n=46)

In order to be able to develop a digitally supported methodology in the long term that supports the research and design of gender-responsive open spaces, the pro:motion types identified in the initial survey need to be further embedded in different gender contexts. By combining them with the above mentioned dimensions of spatio-temporal constraints in the cross-sectional evaluation of the survey and evaluating them in a differentiated group-specific manner (according to gender, age etc.), a further refinement of the DDH profiles is made possible. The spatio-temporal use types will thus be enriched with the latest findings on

gender- and life-stage-specific spatio-temporal use patterns as well as type-specific disadvantages/vulnerabilities.

6 PARTICIPATORY IDENTIFICATION AND ANALYSIS OF SPATIO-TEMPORAL USE PATTERNS

Although the selected use cases considered here have different starting points and objectives in their participation processes, similar overall goals are pursued in the research. This concerns both the methodological approach for the participatory identification and analysis of spatio-temporal use patterns as well as the process design for the toolset applications in a co-creative workshop setting.

In a first step, the initial involvement and activation of different target groups for each use case was carried out with special attention to gender relevance and dimensions of spatio-temporal constraints (see DDH profiles).Accordingly, the target groups range from people with care dependencies (children or adults who are dependent on support in everyday life) and care responsibilities (care givers who support children or adults in coping with everyday life) to people with mobility impairments (physical, sensory or cognitive impairments) and people with limited spatial, temporal and financial resources (due to e.g. available living space, extent of employment, income). All these groups face different constraints and vulnerabilities due to their specific everyday situations and more or less flexible or rigid daily routines. With the basic aim of reaching as many different people as possible by means of various communication strategies, different ways of approaching them have been used. In both use cases, Aumannplatz (Vienna) and Sonnengarten Limberg (Zell am See), already established analogue and digital communication structures and channels (newsletters, mail shots, flyers, WhatsApp groups, etc.) have proven effective in promoting the research project and increase its reach. By approaching people personally (with great support from local partners and multipliers such as the District Service or Housing Coordination) and conducting on-site surveys in addition to the online survey, it was possible to question various (even less digitally affine) groups of people and recruit them for subsequent tool workshops. Nevertheless, the digital pre-surveys are at the heart of the preparatory process (before the actual tool applications), as they provide information on the socio-demographics as well as the mobility and leisure behaviour of the local population. Since the surveys also included questions on care obligations or dependencies, a more accurate picture of the current need and the people reached could be given.

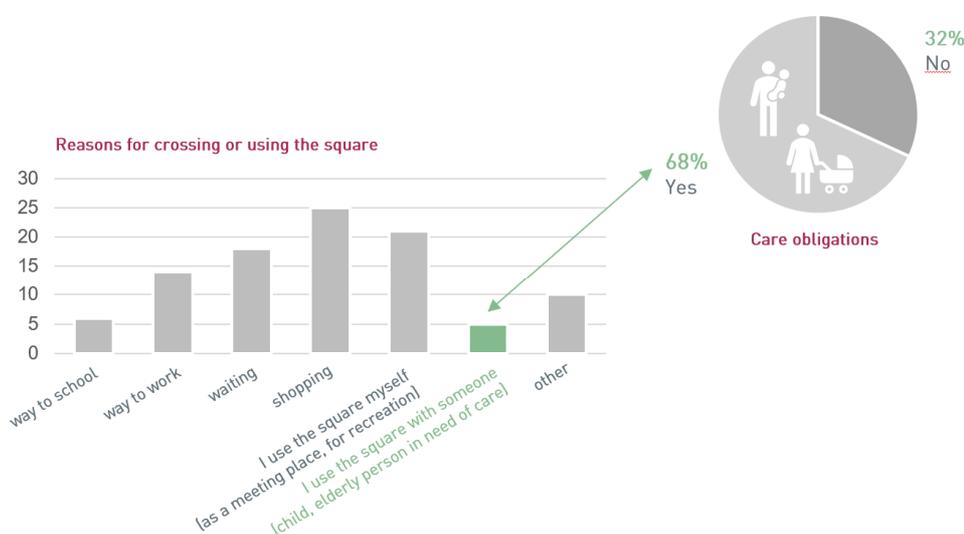
As the first broad online survey conducted at Aumannplatz shows, the results not only provide insights into complex spatio-temporal use patterns (e.g., the use of space over the course of the day during the week and at weekends) as well as mobility behaviour (e.g., preferred mode of transport), but they also give information on the socio-demographic background and care obligations of respondents. For example, with the help of an interactive analysis of complex correlations from a gender perspective, it was possible to show that although almost 70 % of the respondents have care responsibilities, they hardly use the open space (Aumannplatz) with children or senior citizens in need of care.


Fig. 7: Survey results use case Aumannplatz, reasons for crossing or using the square and care obligations (n=47)

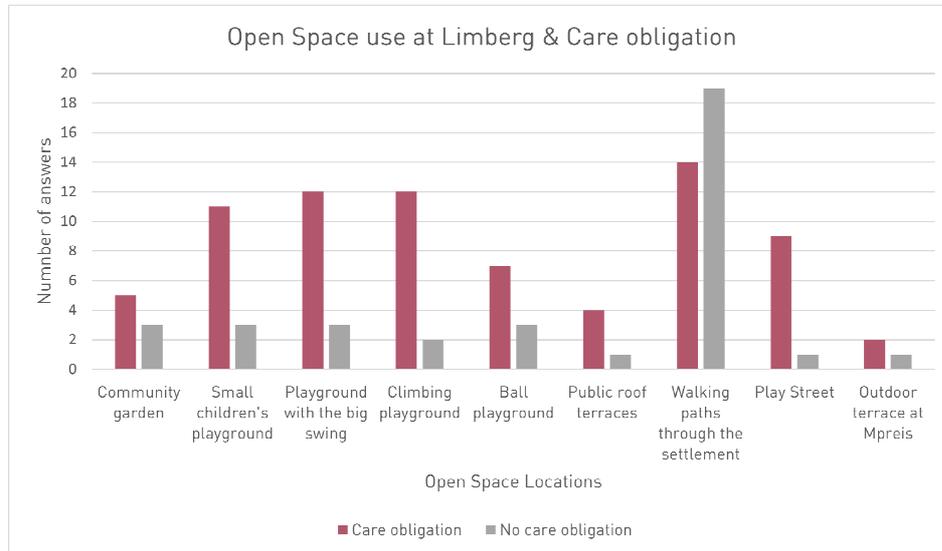
In Sonnengarten Limberg, an online survey was conducted on their leisure and mobility behaviour of the residents of the settlement, which was promoted via the e-mail distribution list and the private WhatsApp group of the housing coordination as well as in personal conversations. By also asking for information on the social background (gender, age group, employment status, care obligations towards children and elderly persons) and the housing situation (household and flat size) as well as information behaviour, it was possible to gain a first insight into the composition of the group, who committed to participate in the workshop with the digital participation tool "Smarticipate" and the following playful creation of the open space use diary. As expected, the playgrounds within the settlement are used a lot by people with care obligations (see Figure 8) and are thus extremely important for this group due to their spatiodiary-temporal constraints.


Fig. 8: Survey results use case Limberg, open space use in view of care obligations (n=46)

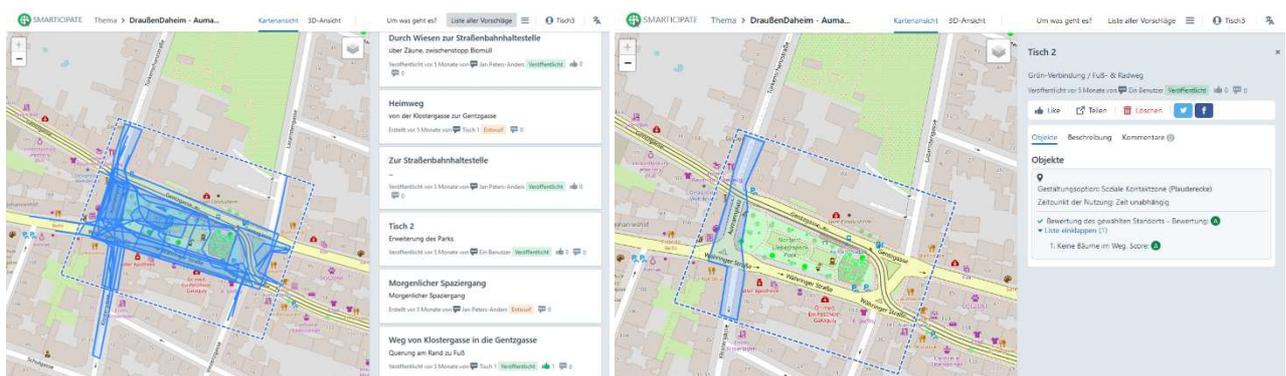
In a second step during the active participation phase using digital tools, the main focus of the Aumannplatz tool test was on the crossing possibilities and the function of the square as a place to stay and play. By discussing and mapping current footpaths in small groups of mixed age and gender (partly also with visual impairment), complex temporalities and rhythms emerged as can be seen in Figure 9.A dozen interested persons participated in the tool-supported identification of spatio-temporal use patterns and group-specific needs. In the process, different combinations of tool applications were used, the core of which was always the digital participation platform "Smarticipate".


Fig. 9: Mapping spatio-temporal use patterns with the help of the participation platform "Smarticipate", © AIT

In the second half of the co-creative tool workshop, the participants had the opportunity to draw desired paths and make new design proposals for the square in a joint negotiation process. For this, a square without spatial boundaries was assumed. However, existing green spaces were always included in the considerations. Afterwards, a pedestrian simulation was shown using the tool "Simulate" to see how these new design objects would affect movement flows in real time (morning, midday and evening)(see Figure 10). This considered the status quo of movements of people getting off the tram (at the nearby station), going to work or school, etc., which gave the participants an idea of the current dynamics of the square at different times. The result was various scenarios for the square with newly implemented design objects (e.g., a new water

playground) that take on new spatial boundaries and thus simultaneously change path-time relations, patterns of use and behaviour on the square.

Fig. 10: Simulation-based design of different planning scenarios with the help of "Simulate"

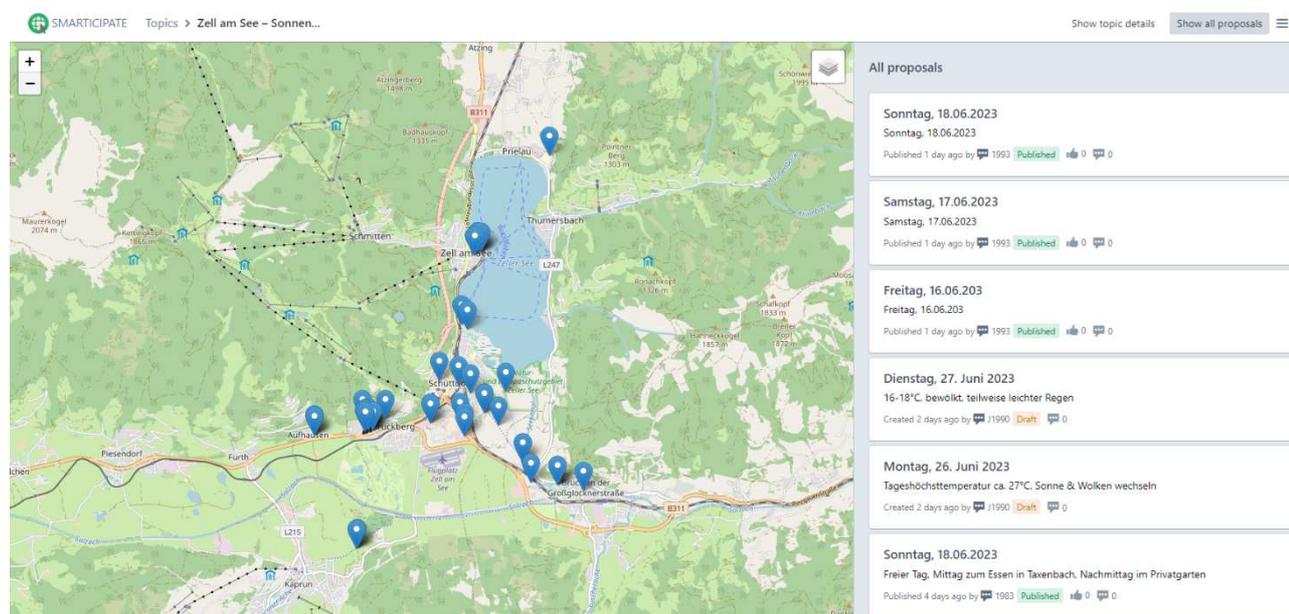
While the tool workshop at Aumannplatz took place in a local shop bordering the square, the on-site participation in Sonnengarten Limberg was organised directly in the premises of the Housing Coordination. This communal space provided the ideal setting to introduce the participants to the "Smarticipate" tool, which they were to use during two weeks to create an online diary on the use of open spaces. The target group-specific evaluation of the survey and allocation of the participants according to specific information behaviour types enabled the formation of heterogeneous focus groups (see chapter 5). Thus, for example, in addition to a young mother with a digital affinity, a childless couple interested in sustainability issues and an older lady with little technical expertise took part in the tool workshop. In preparation for working independently with the diary, the daily routines of a classic weekday and weekend day (use of open spaces and destinations inside and outside the settlement as well as additional information such as time, duration, purpose of use and the means of transport used) were reconstructed and entered into the "Smarticipate" tool (see Figure 11).


Fig. 11: Recording spatio-temporal uses of open spaces in the form of a diary with the help of "Smarticipate"

The group-specific differentiation will allow the presentation of different rhythms and possible overlaps of use patterns in specific open spaces. The result can therefore provide assumptions on the optimisation of the (semi-)public open spaces within the settlement and thereby shows potential to contribute to an inclusive (as e.g., conflicts of use are avoided) and gender-equitable as well as CO_2-avoiding (as e.g., longer recreational traffic is avoided) urban transition.

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

7 LEARNINGS AND OUTLOOK ON THE GENDER-SENSITIVE USE AND DEVELOPMENT OF AN INTEGRATED DIGITAL TOOL CHAIN

The extensive process documentation as well as the evaluation by means of a test and evaluation framework to check the gender-sensitive use of digital tools resulted in several learnings for (further) gender-sensitice tool use and development. In order to assess the possibilities and limitations of developing an integrated digital tool chain, the tool applications were meticulously observed and documented by the process facilitators.In addition, the participants were asked about the usability of the tools. In the course of reflection workshops, the results were then reflected on together with the tool developers in order to further improve them.

As a follow-up survey and analysis on the comprehensibility and usability of the tools showed, the "Smarticipate" tool increased the understanding of how the space works for most participants. This advantage of visualisation tools has already been confirmed in various research projects (e.g. Reinwald et al. 2014). The extension of this approach- the combination with the pedestrian simulation tool ("Simulate") - reinforced this effect, as in addition the impact of potential planning proposals by the participants is presented to them. Furthermore, a better understanding of the (sometimes competing) demands of different groups on the space could be achieved. The use of the toolchain consisting of several instruments (e.g. survey,"Smarticipate" and "Simulate"), especially the direct coupling (via technical interface development and target group segmentation), supports gender- and group-specific data collection and analysis and at the same time helps laypersons in participatory processes to reflect and classify their own proposals.

The evaluation by the process facilitators confirmed the importance of participatory negotiation processes in terms of awareness raising and strengthening the "Design for All" concept for the planning and design of urban infrastructures. It also provided valuable input for the further development of the tools and toolchain (especially regarding usability and target group-specific handling).

Summarising these learnings concerning the tool development, it can be said that the participants were very interested in the application and open to try new things, but also pointed out the weaknesses in the handling of the tool "Smarticipate". Especially the (mostly older) digitally inexperienced participants had to be taken by the hand, which is an argument for simplified applications to increase their inclusion. Moreover, recommendations were made regarding simple design, the preferred scale and layout of the used basic maps.

Looking at the learnings related to the specific design of participation process, it can be concluded that the case-specific application of tools must not only be very well linked to specific planning and design questions, but also be low-threshold (in terms of spatial and temporal accessibility).It also became apparent that the careful embedding of the tools in participatory formats is crucial, as it influences both the group dynamics and the results. For example, the direct pedestrian simulation feedback using "Simulate" connected to "Smarticipate" supported consensus-oriented discussions and negotiation processes within the workshop group, but also had to be explained in an understandable way. Finally, the thoughtful composition and representation of the different target groups also plays a key role in the successful promotion of the different views.

In summary, it can be deduced that through the use of different communication strategies and the use of a mix of (analogue and) different digital tools more groups can be reached in participation processes. Especially young people (who are usually not very involved in "normal" participation processes) and digital affine groups could be reached by the use of these tools. The use of digital tools can also help to involve groups that cannot come to "usual" participation events due to lack of time - e.g. people with care obligations. For this, however, the usability and low-threshold nature of the tools must be further improved so that they can be used independently (e.g., user-guides or webinars should assist this). The advantage for people with (mobility or visual) impairments still needs to be analysed in more detail. However, the possibilities of differentiating the specific requirements of these groups in participation processes as well as for the opening up of new perspectives on their use of time and space became clear. With these approaches and the gender-sensitive use of digital tools, procedural justice - as a part of social justice - can be promoted.

This approach also leads to an improvement in the downstream planning processes, as the different requirements are recorded in a differentiated manner. By incorporating and reflect different life worlds and space-time patterns, it can also contribute to recognitional justice. In the context of the research project, it is recognised that there are gender-specific differences in the use of space (and time) and in dependence on care

obligations, which is why great importance is attributed to the representation of caregivers (in many cases women), their achievements and activities in public space.

1 ABSTRACT

Carsharing gilt als wichtiger Baustein einer multimodalen nachhaltigen Mobilität und besitzt eine große Bedeutung für die Verkehrswende. Carsharing hat das Potenzial den Gesamtfahrzeugbestand und die Autonutzung zu reduzieren sowie Ressourcen einzusparen. Allerdings wird (E-)Carsharing derzeit von einer recht homogenen, männlich dominierten Nutzerinnen- und Nutzergruppe genutzt und die Systeme sind meist an deren Bedürfnisse angepasst. Mobilität und somit auch Carsharing sind in die bestehende Geschlechterverhältnisse hinsichtlich strukturellen Rollenzuweisungen eingebettet. Beispielsweise legen Frauen im statistischen Durchschnitt gegenüber Männern mehr, aber kürzere Wege und längere Wegeketten zurück – und oftmals weniger Wege aus eigennützigen Gründen. Weiters zeigt sich, dass Frauen seltener einen Pkw, dafür häufiger den Umweltverbund nutzen. Die Schwierigkeiten, mit denen Frauen im Hinblick auf ihre Mobilität konfrontiert sind, machen Carsharing für sie weniger attraktiv bzw. leistbar. Dies führt in weiterer Folge zur zusätzlichen Benachteiligung und Ungleichheit. Diese ergeben sich nicht nur aus dem Geschlecht, sondern aus mehreren Aspekten wie dem Alter (passgenaue Planung für ältere Personen kommt überproportional Frauen zugute), dem Leben mit und ohne Kinder, finanzielle Ressourcen oder kulturelle oder auch milieuspezifische Einflüsse.

Dieser Beitrag setzt sich daher mit genderspezifischen Anwendungs- und (Nicht-)Nutzungsverhalten, Nutzungserfahrungen und Nutzungshemmnisse von verschiedenen E-Carsharing Angeboten in Österreich auseinander. Im Rahmen von Fokusgruppen wurden genderspezifische Nutzungsbedürfnisse eruiert, Verbesserungsmaßnahmen ko-kreativ erarbeitet und Frauen in unterschiedlichen Lebenslagen in den Mittelpunkt des Erkenntnisinteresses gestellt. Die ersten Erkenntnisse aus den Gruppen in Wien und Bregenz werden mit verschiedenen Fokussen als zwei Fallbeispiele dargelegt. Zum einen handelt es sich um Angebotsverbesserungen eines bestehenden Carsharing-Systems in Wien mit flankierenden Veranstaltungen, um mehr Frauen zur Carsharing-Nutzung zu motivieren und zum anderen um die Etablierung von privaten, nicht-kommerziellen Carsharing-Gruppen, um den Bedürfnissen (wie Vertrauen und gegenseitiges Kennen) von Frauen gerecht zu werden.

Keywords: Mobility planning, Focus groups, Co-Creation, Carsharing, Gendersensitive

2 HINTERGRUND UND STATE OF THE ART

Die Genderthematik rückt immer mehr in den Diskurs der Mobilitätsplanung. Gender als soziales Konstrukt geht davon aus, dass Frauen wie auch Männer sich in unterschiedlichen Lebensbedingungen wiederfinden und somit jeweils verschiedene Chancen vorfinden. Ist von Mobilität im Zusammenhang mit Gender die Rede, kommen meist die benachteiligten Mobilitätchancen und Ungleichzeit von Frauen zur Sprache, die der damit verbunden Rollen begründet ist. Dass Frauen vermehrt Versorgungsarbeit (Kindererziehung, Betreuung alter Menschen, Einkäufe erledigen etc.) leisten, in geringerem Ausmaß an Erwerbsarbeit beteiligt sind und in weiterer Folge über geringere finanzielle Ressourcen verfügen (Wetterer 2002), hat auch Einfluss auf ihren Zugang zu Mobilität sowie ihre Ansprüche und Bedürfnisse hinsichtlich Mobilitätsangeboten. Häufig wird die Debatte auf Frauen fokussiert und vernachlässigt weitere Diversitätsdimensionen wie Alter, körperliche Beeinträchtigung, sexuelle Orientierung, Hautfarbe, Nationalität, Religion etc. (Knapp & Wetterer 2007, Bersch & Osswald 2021). Es ist daher wichtig die vielfältigen Lebensrealitäten sowie Rollen und persönliche Bedürfnisse in die Betrachtung mit zu integrieren, was auch zunehmend passiert (Bersch, Osswald 2021)

2.1 Gender und Mobilitätsverhalten

Die soziale Rolle einer Person in der Gesellschaft beeinflusst die Mobilität (Kawgan-Kagan 2015). So ist Mobilität in bestehende Geschlechterverhältnisse (mit den strukturellen Rollenzuweisungen von Versorgungs-, Haus- und Reproduktionsarbeit) der Gesellschaft eingebettet (Knoll & Szalai 2005, Nobis &

Lenz 2005). Obwohl Frauen in den westlichen Gesellschaften, wie die Statistiken zeigen, überwiegend am Arbeitsmarkt teilnehmen (in Österreich Frauen mit 68,1 % gegenüber Männer mit 76,7 % - Erhöhung seit 2011 um 3,1 % bei den Frauen, aber hoher Anteil der Teilzeitarbeit), übernehmen sie nach wie vor eher Haushaltpflichten und kümmern sich um Kinder und (pflegebedürftige) Verwandte (Bundeskanzleramt 2021; Schneebaum & Mader 2013, Dribe & Stanfors 2007). Daher zeigt sich (vor allem im Rahmen von Elternschaft) ein sogenanntes „Gender Mobility Gap": Gründe dafür sind u.a. soziodemografische Aspekte (z.B. geringeres Einkommen durch vermehrte Teilzeitarbeit bei Frauen) und der Verantwortung für Begleit- und Versorgungsaufgaben, die in unterschiedliche weisen Männer und Frauen unterschiedliche Mobilitätsmuster von Männer und Frauen resultieren (Kawagan-Kagan & Popp 2018). In der Litartur werden folgende Aspekt gehäuft gennant:

- Frauen haben im statistischen Durchschnitt gegenüber Männern häufigere, aber kürzere Wege und längere Wegeketten (Gauvin et al. 2022, Kawgan-Kagan & Popp 2018, Nobis & Lenz 2005, McGuckin & Nakamoto 2005).

- Frauen verfügen seltener über einen Pkw. Dafür nutzen sie häufiger den Umweltverbund (Stiewe & Krause 2012, VCÖ 2014), wobei eine gewisse geschlechterspezifische Konvergenz über die letzten Jahrzehnte zu beobachten ist (Konrad 2014).

- Frauen haben gegenüber Männern mehr Versorgungswege und weniger Arbeitswege (VCÖ 2022).

- Wichtige Faktoren für den Besitz eines eigenen Pkws bei Frauen sind Routinen und die Verantwortung für andere (Kinder, ältere Personen) (Kawgan-Kagan & Popp 2018).

- Indirekt hat auch die Umwelteinstellung einen Einfluss auf die Verkehrsmittelwahl: Frauen sind vorallem in städtischen Umgebungen umweltbewusster als Männer (Hinkeldein et al. 2015).

Genderthemen sind aber auch im Verkehrs- und Verkehrsforschungssektor relevant und dieser ist nach wie vor stark von Männern dominiert. Der Frauenanteil beträgt 22 % (BMK Infothek 2020). Diese männliche Dominanz manifestiert sich bis heute im öffentlichen Raum, welcher zugunsten des motoriserten Verkehrs angelegt ist (Hennicke et al 2022).

2.2 Gender und Mobility Sharing – ungleicher Zugang?

Besonders evident wird die Ungleichheit beim Blick auf die Nutzung von Carsharing. Carsharing als Teil der Shared Mobility gilt als wichtiger Baustein einer multimodalen nachhaltigen Mobilität. Ein Carsharing-Fahrzeug kann mehrere private PKWs ersetzen und somit Platz im öffentlichen Raum und Ressourcen einsparen. Ausgehend von kleinen oder elektrisch betriebenen Fahrzeugen, können auch Emissionen reduziert werden (Rid et al 2018).

Unterschiedliche Studien belegen, dass sich die Nutzerinnen und Nutzer diverser (E-)Carsharing-Angebote aktuell auf bestimmte soziodemografische Bevölkerungsgruppen bzw. soziale Milieus konzentrieren und damit den „klassischen" Early Adopter repräsentieren:

- Mehrzahl an männlichen Nutzern (Amirnazmiafshar & Diana 2022, Stadt Wien 2015) – zum Teil starke Unterschiede bei den Raumkategorien. Wobei offen bleibt, ob die Daten lediglich die Mitgliedschaft und nicht wirklich die Nutzung widerspiegeln (Hummer 2019).

- Überdurchschnittliches Bildungsniveau (Amirnazmiafshar & Diana 2022, Hülsmann et al. 2018, Gugg 2015, Stadt Wien 2015)

- Eher jüngere Nutzerinnen und Nutzer (Amirnazmiafshar & Diana 2022) mit Zugang zum Internet (Gugg 2015)

- Kleine Haushaltsgröße (meist 1-2 Personen) (Hülsmann et al. 2018, Gugg 2015, Stadt Wien 2015), minderjährige Kinder im Haushalt abhängig von konkreter Angebotsform, aber durchschnittlich etwa bei einem Drittel oder weniger der Nutzerinnen und Nutzer (Bundesverband CarSharing 2018)

- Keine Kinderbetreuungspflichten (Hülsmann et al. 2018)

- Milieus: Junge-adaptive Milieus, kritisch-kreative Milieus und gehobene Milieus überrepräsentiert (Hülsmann et al. 2018)

- Umweltbewusstsein, Technik- und Innovationsaffinität (Hummer 2019)

Auch beim Einsatz von (E-)Carsharing lassen sich geschlechtsspezifische und räumliche Unterschiede feststellen, beispielsweise in Bezug auf die zurückgelegte Strecke, die Fahrtzeit oder die zeitlichen Nutzungsmuster (Hummer 2019). In urbanen Gebieten nutzen Frauen beispielsweise E-Carsharing eher ab 15 Uhr bis in die Abendstunden, während in ländlichen Gebieten Frauen um 11 Uhr vormittags die höchste Fahrzeugnutzung aufweisen (Hummer 2019). Das resultiert darin, dass die aktiven Nutzer von Free-Floating Carsharing-Systemen überwiegend Männer 70-80 % ausmachen (Amirnazmiafshar & Diana 2022).

2.3 Nutzungshürden und -chancen

In der Literatur zeigen sich verschiedenen Nutzungshemmnisse. Beispielsweise haben ältere Altersgruppen tendenziell eine negative Einstellung gegenüber Carsharing (Gugg 2015). Neben der individuellen Einstellung und dem Festhalten an Gewohnten, spielt auch die tatsächliche Kostentransparenz eine Rolle (Hummer 2019). Die Wahrscheinlichkeit für (E-)Carsharing Nutzung hängt an (Riegler et al. 2016):

- Personeneigenschaften (z.B. Alter, Geschlecht, Mobilitätseinschränkungen, Bildungsabschluss, Führerscheinbesitz)

- Kontext des Haushalts, da Entscheidungen zum Pkw-Besitz und deren Nutzung meistens im Haushaltskontext in Abhängigkeit verschiedener Kriterien getroffen werden

- Angebotsentwicklung (räumlich und strukturell) als wichtige Rahmenbedingung für die Nachfrageentwicklung: Ausbau des Angebots generiert zusätzlich Nachfrage, weshalb es wichtig ist, dass das Angebot passgenau für diverse Nutzerinnen- und Nutzergruppen entwickelt wird.

Entscheidend für die Beitrittsabsicht von Nicht-Nutzerinnen und Nicht-Nutzern ist neben der positiven Einstellung zu Carsharing auch die subjektive Überzeugung, dass Carsharing die eigenen Mobilitätsbedürfnisse abdecken kann, leicht zugänglich ist und im sozialen Umfeld als Mobilitätsform anerkannt wird (Riegler et al. 2016). Kawgan-Kagan & Popp (2018) untersuchten mittels mixed-methods Ansatz (GPS-Tracker, Fragebogen, teilstrukturierte narrative Interviews) das Mobilitätsverhalten von Frauen mit Fokus auf E-Carsharing und fanden einige Nutzungshürden für E-Carsharing. Zum Beispiel die Nicht-Eignung von Carsharing für Familienausflügen und komplexeren Wegeketten, die fehlende Routinen bei wechselnden Fahrzeugtypen, die fehlende Ausstattung für Kinder oder die Distanz zum nächsten Carsharing Auto. Diese decken sich auch mit den in Kapitel 3.2. identifizierten Hürden und Herausforderungen in der Nutzung, welche allerdings noch etwas weiter gefasst werden.

Es wird deutlich, dass derzeitige Angebote verschiedene spezifischen Anforderungen an Mobilität (z.B. von Personen mit komplexen Betreuungspflichten) nicht nachkommen. Trotz einer Relevanz von umweltfreundlicher Fortbewegung wird eine Nutzung des Systems nicht angestrebt, da selbst finanzielle Vorteile die subjektiv erlebten Nachteile nicht ausgleichen (Kawgan-Kagan & Popp 2018). Deswegen ist es essentiell Nutzungshemmnisse noch tiefgehender zu erforschen, sodass eine passende Alternative zum Autobesitz entwickelt werden kann.

2.4 Carsharing-Landschaft in Wien und Bregenz

Da im Rahmen des Forschungsvorhabens die Workshops in Wien und Bregenz stattfanden und Unterschiede auch Einfluss auf die Ausrichtung der nachfolgenden Workshops hatten, wird die Carsharing-Landschaft im Folgenden kurz skizziert.

In der Stadt Wien gibt es zum einen Freefloating-Angebote wie ShareNow und Eloop. Die Fahrzeuge sind im öffentlichen Raum des Stadtgebiets zu finden. Zum anderen existieren stationsbasierte Angebote zum (E-)Carsharing wie u.a. Mo.Point und ÖBB Rail & Drive. Das Angebot wird kontinuierlich ausgebaut – hinzu kommen aktuell 100 stationsbasierte E-Fahrzeuge der Wiener Linien an Mobilitätsknoten (Stadt Wien 2023).

In der Stadt Bregenz bietet ein Betreiber stationsbasiertes (E-)Carsharing. Beim Bahnhof stehen vier Autos von ÖBB Rail & Drive zur Verfügung (ÖBB Rail & Drive 2023). Freefloating-Carsharing gibt es in Bregenz nicht, da dazu das Einzugsgebiet einer Kleinstadt zu klein ist. Der dritte Carsharing-Anbieter ist der als Verein organisierte Maronihof – mit dem Haupteinzugsgebiet von Bewohnerinnen und Bewohnern einer bestimmten Wohnumgebung. Der Maronihof umfasst rund 40 Familien und verfügt über vier sehr unterschiedliche Autos, von denen drei von Privatbesitzerinnen und Privatbesitzern zur Verfügung gestellt

werden. Viele der Userinnen und User des Maronihofs sind Frauen (Quelle: Workshops im Rahmen des Forschungsvorhabens).

3 FORSCHUNGSINTERESSE UND METHODISCHES VORGEHEN

3.1 Ziel des Forschungsvorhabens

Im Forschungsvorhaben „Gendersensibles (E-)Carsharing sollen genderspezifisches Anwendungs- und (Nicht-)Nutzungsverhalten, Nutzungserfahrungen und Nutzungshemmnisse von verschiedenen E-Carsharing Angeboten in Österreich eruiert werden. Das Projekt legt dabei den Fokus auf die potenziellen künftigen Zielgruppen von E-Carsharing, die das Angebot derzeit noch nicht nutzen, aber die grundsätzlichen Voraussetzungen erfüllen, E-Carsharing im Alltag nutzen zu können. In Hinblick auf genderspezifische Nutzungsbedürfnisse sollen Frauen in unterschiedlichen Lebenslagen in den Mittelpunkt des Erkenntnisinteresses rücken. Abgeleitet aus diesen Erkenntnissen werden anschließend gendersensible Maßnahmen für verschiedene (E-)Carsharing Angebote gemeinsam mit (Nicht-)Nutzerinnen, Nicht-(Nutzern), Betreiberinnen und Betreibern entwickelt.

3.2 Methodisches Vorgehen

Im Rahmen des Forschungsprojekts GECAR – Gendersensibles E-Carsharing wurden vom Projektteam in Wien wie auch in Bregenz Co-Creation-Begleitgruppen aufgebaut, die das Forschungsvorhaben die gesamte Projektlaufzeit über im Rahmen von Fokusgruppen-Workshops begleiteten. Hier konnten sie ihr Wissen, ihre Erfahrungen und ihre Ideen hinsichtlich Verbesserungsvorschläge rund ums Thema E-Carsharing einbringen sowie Feedback zu den Angeboten der Projektpartner MO.Point und Maronihof geben. In den letzten Jahren ist ein deutlicher Trend zu beobachten, dass Nutzerinnen und Nutzer verstärkt in Innovationsprozesse im Bereich der (technologischen) Forschung und Entwicklung eingebunden werden. Dieses Potenzial wurde auch in der Wissenschaft erkannt, indem das "versteckte Anwendungswissen" der Nutzerinnen und Nutzer bereits in einer frühen Phase des Innovationsprozesses genutzt wird (Dörrzapf et al 2019, von Hippel, 1986). Unter dem Begriff Co-Creation wird jegliche Form kollektiver Kreativität verstanden, bei der mehr als zwei Personen oder Parteien involviert sind (Sanders and Stappers, 2008). Dieser Co-Creation ist ein grundlegender methodischer Ansatz für dieses Vorhaben.

Die insgesamt drei Begleitgruppen – zwei in Wien und eine in Bregenz – bestanden aus Nutzerinnen und Nicht-Nutzerinnen von E-Carsharing-Angeboten und umfassten Frauen in unterschiedlichen Lebenslagen – mit und ohne Kinder im Haushalt, unterschiedliche Altersgruppen, verschiedene Haushaltsgrößen etc.

Die Akquise der Teilnehmerinnen in Wien erfolgte über das Projektteam in Wien. Es wurden zum einen Interessierte über den Verteiler von MO.Point sowie über Plattformen für Allein- und Getrennterziehende, Sharing-Netzwerke oder auch spezifische Wohnprojekte (Frauenwohnprojekte, fahrradzentriertes Wohnen u. ä.) zur Teilnahme eingeladen. Zum anderen auch Kontakte im persönlichen wie auch privaten Umfeld genutzt, um Teilnehmerinnen zu motivieren. Die Akquise in Bregenz erfolgte über den Kooperationspartner Maronihof und umfasst einerseits Frauen, die bereits das Carsharing des Maronihofs nutzten, andererseits weitere Interessierte, die Erfahrungen mit dem Angebot von Caruso oder auch noch keine Erfahrungen mit (E-)Carsharing hatten. Auffallend war, dass die Rückmeldungen insgesamt sehr gering waren. Trotz persönlicher Ansprache ist es auch nicht gelungen, Frauen mit Migrationserfahrung für die Teilnahme an den Begleitgruppen zu interessieren. Dies lag unter anderem auch daran, dass angefragte Personen z. B. über keinen Führerschein oder in ihren Augen zu wenig Fahrpraxis verfügten.

Die Begleitgruppen umfassten insgesamt 21 Frauen, von denen die jüngste 28 Jahre und die älteste 61 Jahre alt war. Etwas weniger als die Hälfte der Frauen war zwischen 28 und 40 Jahren alt, etwas mehr als die Hälfte zwischen 41 und 61 Jahren. Die meisten Teilnehmerinnen lebten allein oder zu zweit mit Partnerin oder Partner im Haushalt, neun der Frauen lebten mit Kindern unterschiedlichen Alters zusammen. Etwas mehr als die Hälfte der Teilnehmerinnen verfügte über ein eigenes Auto im Haushalt. Von der Teilnahme im Rahmen der GECAR-Begleitgruppen erwarteten sich die Teilnehmerinnen mehr Infos rund um das Thema Carsharing wie auch zu den Hintergründen des Forschungsprojekts. Sie wollten selbst dazu beitragen, fundierte Daten zur Fragestellung und in weiterer Folge bessere Bedingungen für Frauen zu schaffen und waren gespannt auf den Austausch mit den anderen Teilnehmerinnen.

332

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Die Co-Creation Workshops mit den drei Begleitgruppen erfolgten in vier „Runden", zum jetzigen Zeitpunkt haben bereits drei Runden stattgefunden. Die drei bereits erfolgten Workshop-Runden hatten folgende inhaltlichen Schwerpunkte:

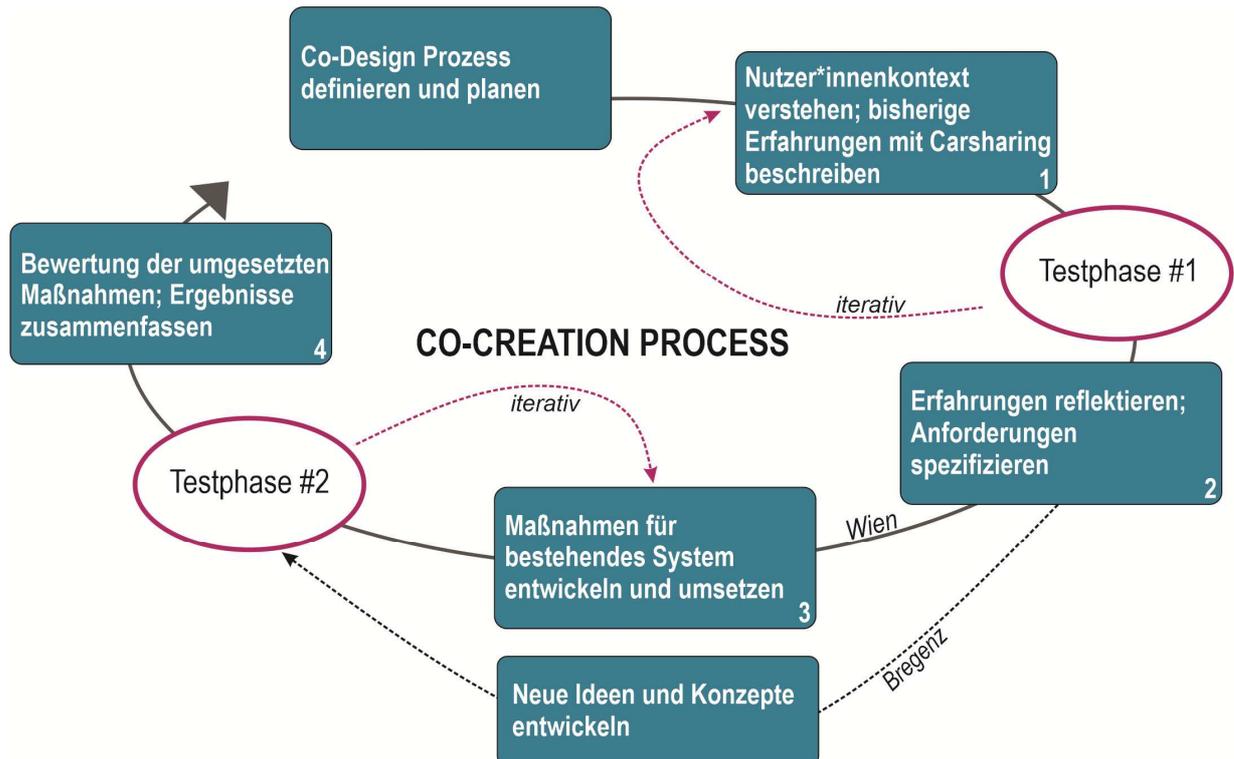
1. Runde: Kennenlernen der Teilnehmerinnen untereinander und Erwartungen an die Workshops, Vorstellung des Forschungsprojekts und der Rahmenbedingungen für die Begleitgruppen, Beschäftigung mit den eigenen Mobilitätsbedürfnissen und den bereits gemachten Erfahrungen mit (E-)Carsharing, Registrierung für einen Carsharing-Anbieter für die folgende Phase der Erprobung von E-Carsharing. Zwei Workshops fanden in Wien und einer in Bregenz im Herbst 2022 statt. Im Anschluss an die erste Runde der Workshops waren die Teilnehmerinnen eingeladen, mit einem Guthaben der Kooperationspartner MO.Point und Maronihof bis zum jeweils nächsten Workshop im Zeitraum von ungefähr einem Monat E-Carsharing auszutesten, um sich in der zweiten Workshoprunde über die gesammelten Erfahrungen mit den anderen Teilnehmerinnen auszutauschen.


Abbildung 1: Iterativer Co-Designprozess nach ISO 9241-210, eigene Darstellung

2. Runde: Austausch der Erfahrungen mit dem in der Zwischenzeit erprobten E-Carsharing sowie darauf aufbauend die Sammlung von konkreten Ideen für (gendersensible) Verbesserungsvorschläge für das E-Carsharing wie auch zur Frage, wie Carsharing insgesamt für Frauen interessanter (gemacht) werden könnte. Im Winter 2022 fanden zwei Workshops in Wien und einer in Bregenz statt. Die von den Teilnehmerinnen gesammelten Ideen und Verbesserungsvorschläge wurden im nächsten Schritt vom Projektteam thematisch gegliedert, strukturiert und dahingehend bearbeitet, welche im Rahmen des Forschungsprojekts konkret weiterverfolgt werden können und sollen.

3. Runde Fokusgruppen: Die dritte Fokusgruppen-Runde gestaltete sich in den Wiener Begleitgruppen und der Bregenzer Begleitgruppe sehr unterschiedlich. In den beiden Wiener Begleitgruppen wurde zum einen vorgestellt, wie die Inputs und Ideen der Teilnehmerinnen seitens des Projektteams und insbesondere des Sharing-Anbieters MO.Point aufbereitet worden sind, welche Maßnahmen bereits umgesetzt worden sind oder sich gerade in Umsetzung befinden und welche nicht umgesetzt werden können (z. B. da sie nicht im Entscheidungsspielraum des Sharing-Anbieters liegen etc.). Im Anschluss an die beiden Wiener Fokusgruppen gab es eine zweite Testphase, in der die Teilnehmerinnen gebeten wurden, nochmals E-Autos auszuborgen, um in der für Frühherbst anvisierten vierten und letzten Fokusgruppen-Runde nochmals Rückmeldungen zu den Veränderungen zu geben. Da die meisten bereits in der ersten Testphase die ersten Startschwierigkeiten hinter sich gebracht hatten, waren die eingeführten Hilfestellungen meist nicht relevant.

Jedoch wurden einige Maßnahmen (verbesserte Beschilderung, Etui mit Bedienungsanleitungen etc., s. 4.2.) als hilfreich empfunden. In Bregenz hingegeben war die zentrale Erkenntnis nach der zweiten Fokusgruppe, dass das Carsharing des Vereins Maronihofs sehr gut und zur Zufriedenheit aller Teilnehmerinnen funktioniert, so dass kein Veränderungsbedarf gesehen wurde. Da der Maronihof nicht plant zu wachsen, wurden gemeinsam mit der Gruppe erste Überlegungen angestellt, wie Carsharing über den Maronihof hinaus z. B. im privaten Umfeld vorangetrieben werden kann. Die Teilnehmerinnen testeten daher eine bereits existierende Sharing-App hinsichtlich ihrer Tauglichkeit für privates Carsharing. Credo war, dass die existierende App für privates Carsharing nicht übersichtlich ist und eine intuitivere Lösung benötigt wird, die in diesem oder im Folgeprojekt weiter verfolgt werden soll.

4. Runde Fokusgruppen: Die vierte Fokusgruppen-Runde ist für Frühherbst 2023 geplant. Ziel ist es, die umgesetzten Maßnahmen zu reflektieren und Ergebnisse mit den Teilnehmerinnen zusammenzufassen, um einen gemeinsamen Abschluss zu finden.

4 ERGEBNISSE UND MASSNAHMEN AUS DER BEGLEITGRUPPE

Die Fokusgruppen wurden je Runde inhaltsanalytisch ausgewertet und aufbauend auf den Erkenntnissen wurde die jeweils nächste Workshop-Runde konzipiert. Schon in der ersten Workshop-Runde zeigte sich, dass sich die Carsharing-Landschaften in Bregenz und Wien unter anderem aufgrund der unterschiedlichen Größendimensionen – Kleinstadt versus Großstadt – in ihrem Angebot wesentlich voneinander unterscheiden (siehe auch 2.4.).

4.1 Ergebnisse aus den Co-Creation-Workshops

Als strukturierende Momente für die Nutzung von (E-)Carsharing ließen sich sowohl Themen vor der ersten Nutzungserfahrung als auch Themen, die sich erst durch die Registrierung und Nutzung ergaben, ausmachen.

4.1.1 Vorannahmen und Vorwissen rund ums (E-)Carsharing

• Bei den Teilnehmerinnen bestand ein sehr hoher Informationsbedarf rund um Carsharing und das Fahren mit Automatikautos und E-Autos (Was ist stationsbasiertes Carsharing, was freefloating Carsharing? Kann ich mit dem Auto auch über die Stadtgrenze fahren? Wer darf fahren? Wie starte ich das Auto? Wie funktioniert der Scheibenwischer? Wie funktioniert das Laden? Wie lange dauert der Ladevorgang? Etc.). Das Bedürfnis, im Vorhinein über alles ganz genau Bescheid zu wissen, kann als sehr hoch beschrieben werden.

- Ein Großteil der Teilnehmerinnen und vor allem auch diejenigen, die noch keine Erfahrung mit Carsharing hatten, schätzten dieses von der Zugänglichkeit her als sehr kompliziert und sehr zeitaufwändig – in Hinblick auf die Registrierung, den Überblick über die Angebote, die Zahlungsoptionen etc. – ein. Carsharing setzt in ihren Augen Internetaffinität voraus und erfordert einen hohen Grad an Organisation und Planung im Voraus. Von vielen wurde der Wunsch nach persönlicher und niederschwelliger Ansprache, Unterstützung und Einschulung geäußert, da die Nutzungshemmschwelle als sehr hoch empfunden wurde.

- Die Teilnehmerinnen schätzten die (E-)Carsharing-Landschaft vor allem auch in Wien als sehr unübersichtlich ein, so dass die Orientierung und eine Entscheidung schwerfällt oder auch (zu) viel Zeit in Anspruch nimmt. Eine Folge der vergleichsweisen hohen Anzahl an Anbietern in Wien ist eine mangelnde Kostentransparenz und Kostenvergleichbarkeit.

- Allgemein kann die Haltung der Teilnehmerinnen gegenüber Autos in der Stadt als sehr kritisch bezeichnet werden – insbesondere oberirdische Standorte verstellen in ihren Augen den so dringend benötigten öffentlichen Raum. Die Teilnehmerinnen der Begleitgruppen sind bemüht, Autos u. a. aus ökologischen Gründen in ihrem Mobilitätsverhalten so wenig wie möglich zu nutzen. Viele sahen nach den Testphasen in ihrem Alltag nur wenige Situationen, in denen sie tatsächlich ein Auto benötigten – z. B. für größere Einkäufe oder Transporte zu tätigen oder die Brücke Stadt/Land zu überwinden. Auch bei konkreten Überlegungen, ein altes eigenes Auto aufzugeben, wird Carsharing interessant.

4.1.2 Registrierung und Buchung eines (E-)Carsharing-Fahrzeugs

- Bezüglich des Registrierungs- und Validierungsprozesses kamen seitens der Teilnehmerinnen sehr viele Anregungen, von denen wiederum sehr viele von der Wiener Kooperationsfirma MO.Point im Laufe des Prozesses mit den Begleitgruppen umgesetzt worden sind. Ein möglichst einfacher, intuitiver und niederschwelliger Zugang fördert hier die Zugänglichkeit von (E-)Carsharing für Frauen.

- Die Buchung eines (E-)Carsharing-Autos wurde – inklusive Umbuchungen oder Verlängerungen während der Fahrt – vom Großteil der Teilnehmerinnen als einfach, unkompliziert und selbsterklärend erlebt.

4.1.3 Die Bedienung des (E-)Carsharing-Fahrzeugs:

- Die erste Fahrt mit einem E-Carsharing-Auto bedeutete für nicht wenige der Teilnehmerinnen, das erste Mal mit einem Sharing-Auto, das erste Mal mit einem E-Auto und das erste Mal mit einem Automatikauto unterwegs zu sein. Dies stellte einen recht großen Teil der Frauen vor kleinere und größere Herausforderungen. Zwar wurden die Erklärungen in der App, die Schritt für Schritt das Starten und Fahren erklärt, als gut eingestuft, doch nichtsdestotrotz benötigten alle einige Zeit, um sich zu orientieren.

- Auch das Laden von E-Autos stellte viele der Teilnehmerinnen vor Herausforderungen – diese reichten von Schwierigkeiten mit dem Ab- und Anstecken, keine Information, wie lange ein Ladevorgang dauert und wo sich öffentliche Ladestationen finden lassen bis zur Reichweite von E-Autos, die sich bei höherer Geschwindigkeit und Kälte drastisch reduzierte. Es zeigte sich, dass das diesbezügliche allgemeine Wissen zu E-Autos eher vage war und hier auf jeden Fall Informationsbedarf besteht.

- Schließlich gestaltete sich die Rückgabe der E-Carsharing-Autos in vielen Fällen als nicht reibungslos, da es immer wieder zu Fehlermeldungen durch die App kam (z. B. sei die Zündung noch eingeschalten, das Auto sei noch zu laden; gleichzeitig kam aber die Aufforderung das Ladekabel rauszuziehen u. ä.). Die Sorge, dass möglicherweise nicht alles ordnungsgemäß funktioniert hat, stand für einige der Teilnehmerinnen länger im Raum und sorgte für Stress.

- Für die Teilnehmerinnen wäre es sehr wichtig, dass im Rahmen von (E-)Carsharing möglichst viele unterschiedliche Fahrzeugmodelle für eine Bandbreite an unterschiedlichen Bedürfnissen und Anlässen zur Verfügung stehen.

4.1.4 (E-)Carsharing mit Kindern

- Prinzipiell wird Carsharing vor allem für Alleinstehende oder Paare ohne Kinder als interessant eingeschätzt. Wirklich erleichternd und zeitsparend für den komplexen Alltag mit Kindern werden Sharing-Fahrzeuge im Vergleich zu einem eigenen Auto weniger eingeschätzt. Familiengründung war für einige der Teilnehmerinnen der Zeitpunkt, an dem das eigene Mobilitätsverhalten geändert und z. B. ein Auto angeschafft wurde.

- Wichtig für (E-)Carsharing mit Kindern und allgemein für eine unkomplizierte Nutzung ist auf jeden Fall, dass im Rahmen einer Fahrt unterschiedliche erwachsene Personen ein Sharing-Auto lenken dürfen.

4.1.5 (E-)Carsharing-Standorte

- Ein weiterer wesentlicher Aspekt für die Nutzung von (E-)Carsharing stellte für die Teilnehmerinnen die Nähe einer Carsharing-Station zum Wohnort dar. Gab es keinen Standort im näheren Umfeld, wurde das als zentrale Hemmschwelle für die Nutzung von Carsharing benannt. Carsharing muss sich unkompliziert und einfach in den eigenen Tagesablauf integrieren lassen, damit es den Frauen sinnvoll erscheint.

- Carsharing-Stationen in Tiefgaragen wurde von Teilnehmerinnen, vor allem der Wiener Begleitgruppen, immer wieder als etwas schwerer und zeitaufwändiger im Hinblick auf die Zugänglichkeit beschrieben. Der Zugang zur Garage sowie das Auffinden des Fahrzeugs braucht in

den meisten Fällen bei erstmaliger Nutzung etwas Zeit – bei häufigerer Nutzung fällt diese Hürde jedoch weg.

4.2 Abgeleitete Maßnahmen

Nach Abschluss der Testphase 1, die die erstmalige Erprobung der Fahrzeuge umfasste, reichte die Begleitgruppe sowohl mündliches als auch schriftliches Feedback bei dem Projektteam ein. Das Feedback wurde eingehend analysiert und anhand der aufgetretenen Probleme und Herausforderungen in fünf Kategorien klassifiziert:

- Registrierung
- Fahrzeugbetrieb und Nutzungsprozess
- Ladevorgang
- Zutritt und Rückgabe
- Tarife und Zahlung

Kategorie	Messen	Implementierung (begrifflich)	Form der Umsetzung (Begründung)	Status
Registrierung	Anweisungen zum Rabattcode	kurzfristig	FAQs zur Website + Verlinkung im Fahrzeug & App + Info-E-Mail	umgesetzt
	Infos zur Anzahlung	kurzfristig	FAQs zur Website + Verlinkung im Fahrzeug &; App	umgesetzt
	Beachten Sie die nächsten Schritte nach der Registrierung (Guide)	langfristig	Automatisierte E-Mail	Im Gange (Plattformbetreiber)
	Schritt-für-Schritt-Anleitung Registrierung	mittelfristig	Erweiterung &; Aktualisierung der Website	Im Gange (intern)
	andere Zahlungsmittel einführen / aktivieren		(Aus geschäftlichen Gründen nicht erwünscht)	Nicht umsetzbar
Fahrzeugbetrieb/ Nutzungsprozess	Home Garage als Privatadresse festlegen	kurzfristig	Im Fahrzeug	umgesetzt
	Handbuch für den Fahrzeugbetrieb	mittelfristig	Im Fahrzeug als Koffer	umgesetzt
	Video zur Fahrzeugbedienung	-	(Aus Kostengründen)	Nicht umsetzbar
	Details zur Fahrzeugausstattung	kurzfristig	Auf der Website und in der App	Umgesetzt
	Transparente Kommunikation der "15 Minuten vor Buchungsbeginn, die nicht verrechnet werden"	kurzfristig	FAQs auf der Website + Link im Fahrzeug &; App	Umgesetzt
	Markieren Sie das Öffnen des Handschuhfachs	-	(Vom Betreiber nicht gewollt)	nicht umsetzbar
Ladevorgang	Hinweis zu Ladezeiten & Reichweite	kurzfristig	FAQs auf der Website + Link im Fahrzeug &; App + Hinweis im Fahrzeug	umgesetzt
	Anleitung für den Ladevorgang	mittelfristig	Im Fahrzeug als Koffer	umgesetzt
	Ladestationen im Navigationssystem anzeigen	-	(Abhängig vom Fahrzeugmodell, nicht beeinflussbar oder veränderbar)	nicht umsetzbar
Anfahrt & Rückgabe	QR-Codes an Eingängen vergrößern	Langfristig	Berücksichtigen Sie zukünftige Standorte	Im Gange
	in der App bei Parkinfo exakte Lieferung an den Standort in der Garage	kurzfristig	In der App	umgesetzt
	Nutzen Sie den Parkplatz 2 am Standort Schwarzenbergplatz	Kurzfristig	Vor Ort	umgesetzt
	Entfernen von Beschilderungen in Garagen	-	(Kommt auf den Betreiber an, nicht erwünscht)	nicht umsetzbar
Tarife & Bezahlung	Zusätzliche Fahrten für längere Buchungen → Teilen von Fahrten unter Benutzern	Kurzfristig	FAQs auf der Website + Link im Fahrzeug &; App + Newsletter	umgesetzt
	Klare Informationen zur Abrechnung, wie sich die Kosten zusammensetzen	Kurzfristig	FAQs auf der Website + Link im Fahrzeug &; App + Newsletter	umgesetzt

Tabelle 1: Maßnahmen zur Verbesserung des Services

In einem weiteren Schritt wurden den identifizierten Problemen geeignete Maßnahmen zugeordnet. Es ist anzumerken, dass ein erheblicher Teil dieser Maßnahmen von den Teilnehmerinnen der Begleitgruppe stammt. Eine interne Diskussion erfolgte, um die Umsetzbarkeit der Maßnahmen zu bewerten. Anschließend wurden sie in einen zeitlichen Rahmen eingeordnet, um zu bestimmen, ob sie kurz-, mittel- oder langfristig umgesetzt werden können. Maßnahmen, die aufgrund technischer oder betriebswirtschaftlicher Gründe nicht

umgesetzt werden konnten, wurden entsprechend begründet. Das Projektteam legte großen Wert darauf, für jedes Feedback der Teilnehmerinnen eine angemessene Begründung zu geben.

Zusätzlich zur Verbesserung des Carsharing-Angebots von MO.Point wurde in den Workshop-Gruppen auch die Fragestellung "Wie kann die Teilnahme von Frauen am Carsharing erhöht werden?" erörtert. Zahlreiche Vorschläge wurden gemacht und wiederum vom Projektteam in verschiedene Kategorien eingeteilt, darunter Veranstaltungen, Marketing und Goodies.

Durch den systematischen Prozess der Feedback-Einholung von den Teilnehmerinnen und der darauffolgenden Zuordnung von geeigneten Maßnahmen konnten zielgerichtete Verbesserungsmaßnahmen für das Carsharing-Angebot entwickelt werden. Des Weiteren wurden konkrete Maßnahmen erarbeitet, um die Beteiligung von Frauen am Carsharing zu steigern.

Bei der Arbeit an den Maßnahmen zur Verbesserung des Services war es wichtig, Informationen auf verschiedenen Kanälen (Website, App, E-Mail, im Fahrzeug) zu platzieren. Ziel ist es, so viele Menschen wie möglich zu erreichen.

Die entwickelten Maßnahmen zur Überwindung der Hindernisse für die Nutzung von Carsharing und zur gezielten Ansprache von Frauen lauten wie folgt:

- Veranstaltungen: Durch die Durchführung von Veranstaltungen soll das Carsharing-Angebot auf niederschwellige Weise vorgestellt und getestet werden. Idealerweise sollten diese Veranstaltungen an Orten stattfinden, die von Frauen besonders häufig besucht werden. Aufgrund der Standortbeschränkungen von MO.Point wurden bestimmte Rahmenbedingungen festgelegt. Daher wurde der Karmelitermarkt als Veranstaltungsort ausgewählt, an dem im Juni ein Event stattfinden soll. Dabei wird das Thema Carsharing durch interaktive Methoden behandelt.

- Marketing & Information: Die Überwachungsgruppe betonte, dass bei Marketingmaßnahmen darauf geachtet werden sollte, zu komplexe technische Begriffe zu vermeiden und eine einfache und ansprechende Sprache zu verwenden, die bei vielen Frauen besser ankommt. Die Farbgestaltung und Bilder auf potenziellen Plakaten sollten Frauen ansprechen, ohne dabei Klischees zu bedienen. Die Werbung sollte alltägliche Anwendungsfälle zeigen und die Einfachheit des Carsharings hervorheben. Ein aussagekräftiges Statement wäre, dass Carsharing das Leben erleichtert, anstatt es komplizierter zu machen.

- Goodies (in Form von Rabattcodes bei Empfehlungen): Als zusätzliche Maßnahme wurden Goodies in Form von Rabattcodes eingeführt, die beim Teilen des Carsharing-Angebots mit Freundinnen verwendet werden können. Im Workshop wurde deutlich, dass Frauen gerne jemanden dabeihaben möchten, wenn sie Carsharing zum ersten Mal ausprobieren. Dies bietet eine gute Gelegenheit, ihre Erfahrungen mit der Carsharing-Nutzung an andere Frauen weiterzugeben.

5 FAZIT UND AUSBLICK

Im Forschungsvorhaben "Gendersensibles (E-)Carsharing" werden genderspezifisches Anwendungs- und (Nicht-)Nutzungsverhalten, Nutzungserfahrungen und Nutzungshemmnisse von verschiedenen E-Carsharing-Angeboten in Österreich untersucht. Im Hinblick auf die Genderthematik in der Mobilitätsplanung wird darauf hingewiesen, dass Frauen aufgrund ihrer Rollenzuweisungen oft benachteiligte Mobilitätschancen haben. Sie sind vermehrt in Versorgungsarbeit engagiert, haben seltener einen eigenen Pkw und legen häufiger, aber kürzere Wege zurück. Carsharing ist deshalb eine wesentliche Mobilitätsoption, die nutzerinnen- und nutzerfreundlich gestaltet werden muss. Im Rahmen der Co-Creation Begleitgruppe konnten verschiedene Anforderungen identifiziert werden, die sich teilweise mit der Literatur decken. Des Weiteren konnten aber viele neue, detaillierte Einblicke in die Nutzungshürden und -bedürfnisse von Frauen gewonnen werden. Zu nennen sind der hohe Informationsbedarf der Teilnehmerinnen bezüglich Carsharings und dem Fahren mit Automatik- und E-Autos sowie das Bedürfnis den Ausleihprozesse weniger kompliziert und zeitaufwändig zu gestalten. Persönliche Unterstützung und niederschwellige Ansprache spielen ebenso eine Rolle. Abgeleitet von den Bedürfnissen wurden Maßnahmen entwickelt, die allerdings intern nach ihrer Realisierbarkeit und ihrem Zeithorizont priorisiert wurden. Diese Maßnahmen sind noch ein „work in progress". In einer letzten Workshop-Runde werden umgesetzte Maßnahmen mit den Teilnehmerinnen diskutiert und gegebenenfalls weiter geschärft.

Es ist wichtig darüber hinaus, das Wissen und die Erkenntnisse aus diesem Projekt für andere Sharing-Anbieter verfügbar zu machen. Insbesondere im free-floating Bereich als marktstärkster Sharing-Service besteht hinsichtlich ausgewogener Nutzerinnen- und Nutzerzahlen noch Aufholbedarf. Die Berücksichtigung von gendersensiblen Angeboten kommt dabei allen zu Gute: Für Nutzerinnen und Nutzer wird zum einen der gleichberechtigte Zugang zum Mobilitätssystem verbessert und zum anderen aus gesellschaftlicher Sicht die Nutzung nachhaltiger Verkehrslösungen forciert. Auch aus Betreibersicht können dadurch die Nutzerinnen- und Nutzerzahlen von Carsharing erhöht werden, was die Auslastungen und Effizienz der Carsharing-Flotten maßgeblich erhöht. Dennoch ist darauf zu achten, dass nicht zur sehr zwischen männlichen und weiblichen Bedürfnissen unterschieden wird, da schnell die Gefahr besteht in Stereotypen zu denken und klischeehafte Verhaltensweisen anzunehmen. Die Betonung von Gender könnte dazu führen, dass individuelle Unterschiede und Bedürfnisse innerhalb der Geschlechtergruppen vernachlässigt werden. Es ist daher wichtig, dass zum einen Carsharing-Dienstleister nicht nur Geschlechteraspekte berücksichtigen, sondern auch andere Faktoren wie Alter, Einkommen und kulturelle Hintergründe. Zum anderen muss die Forschung weiter Daten zu geschlechtsspezifischen Unterschieden erheben, um fundierte Maßnahmen zu entwickeln zu können.

1 ABSTRACT

The world is changing quickly in all spheres, including, but not limited to, technology, cities, finances, society, and the environment. Regarding the latter, the prevailing themes or debated subjects have been the ozone layer, air quality, greenhouse gases, and climate change. As a result, there is now an even greater need to address present and potential climate change concerns. These initiatives are essential if society is to contribute to the development of cities and communities that are efficient, interconnected, and sustainable. The advent and evolution of green buildings throughout the 1990s, which saw the creation of the first-ever sustainability standard and rating system for the built environment, were regarded as turning points because they could be embraced as one of the methods employed to control the deteriorating climate and air quality while enhancing our infrastructure. To aid in the development of the nation's infrastructure, South Africa has its rating system known as the Green Star SA through the Green Building Council of South Africa (GBCSA). In addition to looking at how green buildings have been acting as a catalyst in reducing the challenge of the change in climate in the region, this paper will also look at how the overall commercial green building network in Gauteng can help improve the region's air quality, which tends to be on a "moderate" level according to the World Health Organization (WHO). Reviewing present frameworks and legislation concerning climate change, air quality, and green buildings was the strategy, moving from a global to a local level. The research also examines data from 180 case studies of green buildings in the Gauteng region, which were taken from the GBCSA archives. Observations in 4 buildings for 4 months and a building occupant survey in one of the 4 buildings were used to do additional research on the 180 case studies. According to the research findings, the government in the Gauteng region lacks the motivation to establish and enforce green building policies. This is especially evident given that more than 80% of the region's green buildings are built and owned by the private sector. According to the report, green buildings in Gauteng can accelerate efforts to mitigate climate change and improve air quality by using less energy, incorporating renewable energy sources, enhancing interior air quality, and lowering urban heat islands. Green buildings also have a positive socio-economic impact, creating new jobs and skills, promoting diversity and growing the local economy. The benefits of green building cannot be overlooked. Therefore, the study recommends that the Gauteng government review and develop robust policies to increase investment in green buildings.

Keywords: Climate change, green buildings, air quality improvement, greenhouse gases, Gauteng

2 INTRODUCTION

The primary drivers of climate change and poor air quality are several, including human activities such as burning fossil fuels, transportation activities, agriculture and industrial processes. A greater portion of the fossil fuel burnt is for energy production and according to (Ritchie, Roser and Rosado, 2022) buildings are responsible for more than 40% of global energy used, and as much as one-third of global greenhouse gas emissions. The impacts of climate change are quite vast and can have detrimental effects on both our natural systems and human societies ranging from health problems, economic impacts, rising temperatures etc. According to the IPCC (2020), Africa is one of the most vulnerable continents to climate change and climate variability, a situation aggravated by the interaction of „multiple stresses", occurring at various levels and low adaptive capacity. Hence it is not surprising that the challenges stated are not unique to Gauteng as a region and both climate change and air quality have impacted the region and are most likely to worsen in the future, thus there is a need to mitigate the effects caused to help improve the natural systems and lives of the society in the region. The relationship between buildings, climate change and air quality comes about as these buildings lead to the intensification of climate change and poor air quality and the effects they cause. Suzuki (2019) stated that the current rate is which the population is growing, and the expectation for 2050 is

10 billion people, of which 70% will be occupying space in cities. Subsequently, there will be more construction of buildings to accommodate the needs of these people. This does however pose a threat as stated previously in terms of the rise of emissions of greenhouse gases and energy demand from buildings. The problem is that this growth facilitates the acceleration of climate change and poor air quality hence the need to find ways to accommodate the needs of the current without compromising future generations. Indeed, the issue of climate change and air quality is rather complex, requiring a comprehensive approach that includes mitigation (reducing greenhouse gas emissions) and adaptation (building resilient systems & and infrastructures while adapting to change) (Howard-Grenville et al, 2014). The paper will look into how green buildings in the Gauteng region can act as a partial solution to address and accelerate the much-needed change in mitigating climate change and improving poor air quality. He (2019) suggested that green buildings can help by transitioning to renewable energy, promoting energy & and water efficiency, and adopting sustainable practices. hence it is quite important to understand the developed frameworks and policies developed at local, national and global levels about green building, climate change and air quality.

3 CONCEPTUAL SYNOPSIS

The concept of green buildings and its importance in society can be traced back to the early 1990s when the Building Research Establishment (BRE) developed the world's first sustainability standard and rating system/tool for the built environment known as the Building Research Establishment Environmental Assessment Method (BREEAM) (Doan et al, 2017). The development of green buildings internationally can be attributed to the concept of sustainable development in the period of the 1980s-1990s when international conferences were held to address the growing challenges of the society of climate change and global warming. There have been many conferences held to address climate change and air quality but some of the crucial ones which were also key turning points were:

- The 1987 World Commission on Environment and Development (WCED) known as the Brundtland Commission/Report led to the formal and commonly accepted definition of sustainable development (Brundtland, 1987).

- The United Nations Conference on Environment and Development also known as the Rio Earth Summit, or Rio Summit 1992, where member states of the Un cooperated on issues relating to sustainability, suggesting that this was an issue far greater for individual member states to handle which led to another conference in 1997. (Grubb et al, 2019)

- The Kyoto Protocol is an international treaty which came about as an extension of the 1992 United Nations Framework Convention on Climate Change (UNFCCC) committing member states to reduce greenhouse gas emissions due to impacts on global warming. (United Nations Climate Change, 2019)

- COP 27, the reaffirmation of commitment to limit the global temperature to 1.5 degrees Celsius above pre-industrial levels, in particular with Africa announcing the African Alliance for Sustainable Cities and the Built Environment. (ICLEI, 2022)

Frameworks, international treaties, and policies of this nature and those related which couldn't be covered in this scope have popularized the movement of green buildings and the development of other sustainable and building rating tools globally such as the Leadership in Energy and Environmental Design (LEED) by the United States of America Green building council, the Green Star Australia by the Green building council of Australia (Doan et al, 2017). The latter is the one on which the South African Green Building Council (GBCSA) rating system the Green Star SA is based and changed to accommodate various local conditions. According to Zuo and Zhao (2014), green buildings through their design and construction practices would significantly reduce and eliminate greenhouse gases which are the ultimate cause of climate change and poor air quality through sustainable site planning (efficient design), safeguarding water and water efficiency, energy efficiency and use of renewable energy, the conversation of material and resources, and improved indoor environmental quality. Even though there are international frameworks and policies that exist and act as standards from which countries can work, the development of green building varies from country to country due to many aspects such as the advancement of the country, governance, socio-economic level etc. In South Africa, the Green Building Council of South Africa is the organization responsible for advocacy, training and certification which functions through its membership community comprised of government,

342

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

private and educational stakeholders. The GBCSA (2021) reported in their integrated annual report that South Africa had around 740 certified Green Star buildings from the start of the organisation in 2009. Furthermore, the South African government through the Department of Public Works developed the Green Building Framework to help accelerate the movement of green buildings in the country especially with government infrastructure with the intent that these buildings will save water, and energy and lessen the emission of greenhouse gas.

4 LOCAL AND INTERNATIONAL EXPERIENCES OF GREEN BUILDINGS DEVELOPMENT

Through case studies, one can gain an understanding and insight into the realistic perspective of the theoretical work. South Africa (Gauteng) is advancing in their efforts to mitigate climate change and improve air quality through green buildings as stated that already over 700 green buildings have been developed however lessons can be learned from different regions in the world to understand their use of green building in curbing the challenge of climate change and poor air quality. To gain a better perspective and overall scope of the work of green buildings a sample of three case studies was randomly selected from Africa, Europe and Asia which represented developing (Africa, Ghana- Accra), transitional (Europe, Poland-Warsaw) and developed (Asia, Singapore-Singapore) economics respectively. The reason behind choosing the capitals is that most of the green building development advances and implementation of policies and frameworks to mitigate climate change occur in those cities. What was common in all these regions and considered pertinent is the issue of reducing energy consumption (greenhouse gases), meeting the international climate targets of the year 2050, and achieving most of the 2030 sustainable development goals (SDGs). From a local stand-point Gauteng as a region can learn and adopt various lessons from these three regions, the case studies showed that well-organized and competent urban governance is essential through the collaboration of the public and private entities to develop and efficient pipeline and implement green building policies that can help improve climate change and air quality. Another lesson was the need to start developing green buildings on a residential level as over 90% of green buildings in regions are from the commercial sector, hence the buy-in of residents is crucial in understanding the implication of climate change and air quality to the livelihoods, hence the sooner they jump onto the green building wagon these could improve their lives, especially from a health and economic stance.

5 METHODS AND MATERIALS

The research work done in the paper aims to give an understanding of how green buildings in the region of Gauteng can accelerate the mitigation of climate change and the improvement of air quality. The topic of climate change, air quality and green buildings is quite broad and requires thorough investigation, so to help prove the hypothesis of the study if indeed green buildings can reduce greenhouse gases which led to climate change and poor air quality factual and reliable data is crucial which can be obtained through quantitative research as this generates factual, reliable outcomes of the data that can be used to generalize larger quantity of the data (Steckler et al, 1992). Furthermore, the qualitative approach will be taken to gain insights from industry experts which can produce rich, in-depth validity on the basis of experience of how green buildings have an impact on accelerating climate change mitigation and building occupants who experience these green buildings on a frequent use basis. For the quantitative part of the study, the data was collected from 180 green building case studies files in Gauteng from the GBCSA archives and analysed through Python & and Google Data Studio for visualization. From the 180 case studies, 4 buildings were chosen for further actual in-person observations and investigation by the research over a period of 4 months wherein a building occupant survey was conducted through the BUS Occupant methodology in one of the buildings with 55 participants and yielded results of both quantitative & qualitative nature. For the qualitative part of the research 10 industry experts were interviewed through a semi-structured interview via Zoom and Microsft Teams, then analysed through the transcription software Otter which helped identify themes and topics within the conversations. The reason behind the use of semi-structured interviews assisted with open-ended data, explore the participants' thoughts, feelings and beliefs and help delve into their personal ideologies of climate change, air quality and green buildings (DeJonckheere and Vaughn, 2019). This was quite crucial as climate change as a topic has had critics in terms of whether we are really close to reaching the global warming levels of 1.5 degrees Celsius or not.

6 FINDINGS

This section of the paper discusses the findings and results of the hypothesis of green buildings acting as an accelerator in climate change mitigation and air quality improvement. These findings and results outlined here will help give an understanding of the general outlook of green buildings in Gauteng from the 180 case studies sample, furthermore, two aspects of how green buildings can contribute to combating climate change and air quality are energy efficiency & and renewable energy integration and water conversation. The challenges encountered by the green building movement for climate change and air quality improvement will be explored to give a more in-depth understanding of the topic.

6.1 Green buildings in the region of Gauteng, South Africa

The hotspots for green building development in South Africa are the Western Cape, Kwazulu-Natal and Gauteng with the latter being a leader in terms of the number of certified commercial green buildings in the country. The research discovered that a large portion of green buildings developed in Gauteng is concentrated in the City of Johannesburg, particularly in the Northern Subrburb of Sandton City. The reason behind this was the fact that Sandton is the economic hub of the country which houses many international and local corporations as well as the Johannesburg Stock Exchange. From the interviews industry experts indicated that such corporations are seeking the use of green buildings as a way to align with their environment, social and governance strategies. Some industry experts criticised the reasons why developers and investors build green buildings as just a way to just tick box exercises to meet environmental regulations such as carbon tax emissions and keep regulators and the government away. Regardless of what the motive might be at the moment, it becomes less important as these green buildings are contributing to the change in the climate and air quality. From the research, it was recorded that of the 180 case studies more than 80% were developed by the private sector regardless of whether the government is an investor in the GBCSA and even a custodian of the Green Building Framework and Policy. In the next section of the paper, two main topics are covered which relate to water and energy conservation and efficiency techniques and how they were implemented in the 180 case studies while further looking at how they help mitigate climate change and poor air.

6.2 Adoption of Water Conservation and Efficiency Techniques

Conversations with regard to water in green buildings are related to water efficiency in the planned management of water to prevent wastage, overuse and exploitation of this precious resource. It should be understood however that water efficiency and conservation shouldn't be achieved at the expense of building occupants not using water comfortably. Well-designed green buildings are key in achieving water efficiency while still providing comfort to occupants, In one of the 4 buildings observed it was noted that the particular green building could conserve $0.3m^3$ of water usage per annum as compared to a non-green star sa certified building. The Green Star SA awards points of certification out of 10 categories depending on the key features and category that particular green building focused on. The word cloud in (Figure 1), was extracted from the results of the 180 case studies, indicating that water was a key category for green building developers in the Gauteng region. Such just alludes to the fact that great efforts and measures are emphasized in terms of water conservation and efficiency techniques within the majority of the green buildings.

344

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

It is thus important to understand the measures that are deployed in green buildings for water conservation and efficiency as it is clear that it is an important and crucial category to measure the certification of green buildings. The first way is through water recycling and repurposing measures, the second is through water-efficient plumbing features and the last by irrigation and landscaping measures.

6.2.1 Water recycling and repurposing measures in Gauteng green buildings

The three ways in which green buildings in Gauteng have been adopted can either be any of these three methods, greywater harvesting, rainwater harvesting and blackwater system treatment, but of the three the latter is a rare and unique case which was notably deployed on one building due to being expensive in terms of operations. The rainwater and greywater are harvested from the rain through different channels on the rooftops of buildings and taken to the rainwater tank, while the greywater is harvested from showers, bathroom basins and other sources of this form. Once the greywater has gone through the treatment and filtration process it is usually stored in tanks located in the basements of buildings and supplemented with the harvested rainwater, which then will be used for WCs, urinal flushings and irrigation systems.

6.2.2 Water-efficient plumbing fixtures

Industry experts noted that the reason why the water category could be the leading category would highly be because of this particular feature of green buildings as it is the cheapest of all conservation techniques and strategies, which is low-flow plumbing from installation, operations and maintenance cost.

Fig. 2: Ultra-Low Flow plumbing fixtures (Source: Author, 2021)

All green-certified buildings will generally deploy low-flow fixtures and supplement them with either rainwater or greywater harvesting systems depending on the financial capability of the developer, these efficient water fitting as in Figure 2 reduce the use of potable water. Through the study, the paper found that a building with a rating of 6 Stars of the Green Star SA managed to save 0.52L/day/m2 of water.

6.2.3 Irrigation and Landscaping Measures

Landscape irrigation is another part of the building that consumes large amounts of water, which is why it is very important to reduce the amount of potable water used there. One of the green buildings from the case studies indicated that they could reduce 90% of potable water used for landscape irrigation, and this was achieved in collaboration with processed grey and rainwater to water the plants rather than using potable water.

6.2.4 Water Management Practices, Climate Change and Air Quality

The understanding is that by reducing water demand and promoting conservation, green buildings help address water scarcity issues exacerbated by climate change. It is without a doubt that water conservation and efficiency is a key performance category in the measurability of green buildings due to it being quantifiable in how it can save water usage and then recorded with the building's management systems

which are relevant for the developer and owners from an economic stance as they tend to save on utility bills in a long term run. Therefore the use of water management practices as a feature of green buildings can directly impact the conservation of water resources, enhance resilience to drought and aid sustainable water usage in a changing climate. These techniques can further indirectly help improve air quality and can help minimise water-related pollutants and air pollution from wastewater treatment processes.

6.3 Renewable energy integration, energy efficiency and greenhouse gas emission mitigation

There are various techniques, methods and technologies that have been developed to achieve energy efficiency and reduction of greenhouse gas emissions such as the use of solar energy. Green buildings will tend to incorporate measures such as solar energy to attain their status of being a sustainable building. Investigation into these techniques is crucial in understanding how they help curb climate change and improve air quality, and which in particular have been implemented in green buildings around the Gauteng region.

Notional Bldg	Discovery Sandton	Reduction %
38 059 177.00	18 004 741.00	53

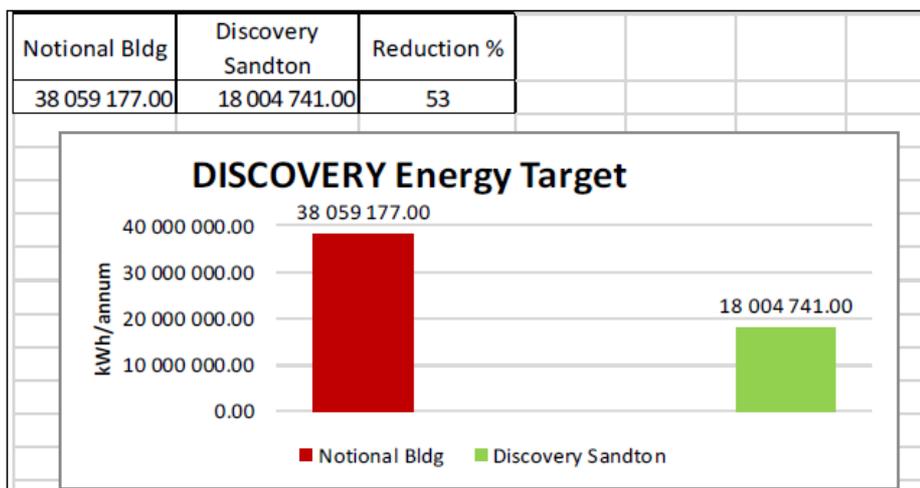
DISCOVERY Energy Target


Fig. 3: Projected annual energy consumption (kWh/annum) for Discovery Limited (Source: Discovery Limited, 2017)

(Figure 3) has projected the annual consumption of energy for one of the four green buildings evaluated in the region where the building manager indicated that their energy target was 53% less compared to a SANS 10400 non-certified building (Notional building). It is quite clear that green buildings have the capability of saving and conserving energy which part is what is being investigated through the direct and indirect techniques developed.

6.3.1   Direct energy-saving and greenhouse gas emission reduction techniques

These kinds of techniques and strategies are built-in within green buildings, which includes either technology installed to help conserve energy such as smart lights or through methods adopted in the design and construction of the building. There are quite a few of these measures which include but are not limited to sustainable construction, efficient lighting & and occupancy sensors, HVAC systems & and smart metering, a passive design, solar energy etc. For the purposes of this research paper, only the latter two will be discussed in-depth. Sustainable construction is building through the use of renewable and recyclable materials while minimising water and energy while making sure the waste products is also minimal as the harnessing of the building material such as tree further worsens climate change. Efficient lighting and occupancy sensor requires the cooperation of building occupants through their behaviours.

In (figure 4) a green building that incorporated the passive design approach of saving energy is seen. Passive design is wherein the buildings' architectural features take advantage of local climatic resources to provide an indoor environment that is as comfortable as possible while saving energy that would have been used to provide the indoor environment quality. Through the industry experts, it was noted that the most favoured method in energy conserving and saving strategies was the passive design and more than 60% of the 180 case studies used this method due to the low cost involved in construction and maintenance. Furthermore, the consultant who worked to design the green building in (figure 4) stated that the vertical panels shift with the direction of the sunlight. What these panels help with is daylight harvesting which allows the natural light to be infused into the building thus reducing the need for excessive artificial light and heat from the HVAC.

The building evaluation survey of the 55 occupants of this building does indeed substantiate this notion. The section on occupants' overall temperature comfortability indicates that their working condition was fairly good due to the proper passive design in supplication of the HVAC system.

Fig. 4: High-performance facades (Source: Author, 2021)

Fig. 5: Side view of Photovoltaic solar panels (Source: GLH Architects, 2011)

The building in (figure 5) was the first building to be awarded 6 Stars Green Star SA certification in Africa, which recognizes world leadership standards and the highest rating a building can obtain through the Green Star SA rating system. This building not only achieved this feat but achieved a status for net-positive ecology and net-zero carbon. Essentially this is the certification of projects that go beyond the partial reductions recognized in the current GBCSA tools and have taken the initiative to reach the endpoint of completely neutralizing or positively redressing their impacts (GBCSA, 2017). For this building, the net positive ecology was in recognition of the increasing pilot-level 1: site ecology - brownfield site, while the net zero carbon was a result of the hybrid use of the passive design method discussed previously and the renewable solar energy technology (figure 5). The building has 292 solar photovoltaic panels which deliver 230kWh of energy to the building, the building manager stated that this was more than double what the building required to function at full capacity, and the excess energy produced was fed back into the rest of the buildings of this company's campus.

6.3.2 Indirect energy-saving and greenhouse gas emission reduction techniques

The previous section discussed direct energy conservation methods applied in the construction and functioning of green buildings, the industry experts indicated that green buildings shouldn't be viewed from a segmented view as they are but rather from a holistic approach. Yudelson (2009) cited that green building forms part of an eco-system in the development of sustainable cities and communities hence the understanding of the external factor that in-directly affects green buildings can't be ignored. The reason why these methods are important is that they are particularly linked to the reduction and curbing of greenhouse gases which directly affect climate change and air quality. The location of where a green building is

developed is one of the in-direct strategies as we need to understand if this has an ecological impact on the environment, the other is transportation activities around the green building and how building occupants commute to these green buildings which is the strategy to be discussed. Transport is one of the categories 10 categories used in the Green Star SA rating tool as can be seen in (figure 1) hence the need to discuss it, and due to the fact that a white paper by the South African National Climate Change Response Policy identified that the transport sector is a significant contributor to greenhouses gases, the paper said the transport industry accounted for 70% of energy use and 38% of the region's emissions.

Fig. 6: Bicycle and Electric car charging stations (Source: Author, 2021)

The images in (figure 6) were initiatives from one green building that recognized that there is a need to involve the building occupants in building a sustainable community mitigating climate change and improving air quality by reducing greenhouse gases emitted by the vehicles used by occupants. The building manager indicated that only 10% of the occupants used electric vehicles and would use the facilities hence they provide bicycle stations as well for those occupants who can't afford electric vehicles, while for occupants who didn't have both electric vehicles or are farther away from the building and couldn't use bicycles carpooling was suggested as a way to reduce the vehicles on site.

6.3.3   Energy management practices, climate change and air quality

The use of energy-efficient designs and integration of renewable energy sources in green buildings around Gauteng was highlighted clearly. South Africa is still very reliant on the use of fossil fuels for energy sources but yet they still have challenges in this sector as can be seen through the load-shedding problem the country is facing. The various green buildings showed that the incorporation of efficient energy design such as passive design can help reduce the energy required to power and sustain buildings and harness renewable energy sources like the solar system adopted in one building which was able to produce surplus energy. Then thinking of a greater scale if all buildings were on this scale of green buildings it would definitely have an impact not only in the reduction of greenhouse gas emissions and meeting the goals of the country but also in providing an opportunity to reduce the energy challenges of the country.

6.4 Challenges in the Development of green buildings in Gauteng

The growing pressures of mitigating climate change and improving air quality to make sure that the global warming level doesn't reach 1.5 degrees Celsius have pushed South Africa to be one of the key players in green buildings as they try and adopt these buildings as a means to mitigate these challenges. The certification of over 740 buildings is a clear indication of the commitment to these efforts. As stated previously Gauteng is the top hot spot for green buildings and the largest contributing city in terms of greenhouse gas emissions. In sections 6.2 and 6.3, the paper outlined the benefits of green buildings and how they can mitigate climate change and improve air quality in Gauteng there are however challenges in the development and movement of green buildings that shouldn't be ignored as they can hinder their widespread adoption. The capital costs involved in green building development are quite high compared to building using conventional methods, in other instances, it might be operational costs which can be a problem. In one of the buildings investigated the building manager said that the cost of running the greywater system was

quite high and not viable to the point where it was turned off and not operational as the benefits could only be seen in the long term. Another issue is the lack of awareness from both the public and industry professionals which can be attributed to not being informed or not having the willingness to change from conventional ways of doing things. The industry experts indicated that the practice of implementing green buildings as a rating and tick box exercise was present in many property owners or developers as they just wanted to meet the minimum required standards but didn't have any ambitions to be innovative and implement different ways of building green which meets international standards. Last but not least was the implementation of the objectives within the various frameworks and policies developed in South Africa, it can be noted that such was affected by political challenges and a lack of stakeholder engagement in the development of green buildings

7 CONCLUSIONS AND RECOMMENDATIONS

Through the research, we came to understand that buildings generally consume a substantial amount of water and energy which directly influences water scarcity and the emission of greenhouse gases in the region of Gauteng. These resources in turn directly influence the contribution to climate change levels and poor air quality if not handled appropriately. Hence the hypothesis of the research was to investigate if green buildings had a positive impact by acting as an accelerator in climate change mitigation and air quality improvement within the region of Gauteng, South Africa. After careful investigation of both quantitative and qualitative findings and results, the hypothesis of the paper is correct in that green buildings if implemented at a large scale can act as a catalyst in climate change mitigation and improvement of air quality in Gauteng, South Africa. The recommendation would be an investment from the public sector (government) is quite crucial as the responsibility for the development of infrastructure in the region of Gauteng is primary for them to the society, this can even be explored from a public-private partnership where lessons can be learned from the private sector on how they have managed to achieve building more than 600 green building in just over 13 years in South Africa. Additional elaboration on the advice on methods that could inspire the public sector to invest more in green building development includes but is not limited to, the following. The formation of public-private partnerships would aid in the sharing of resources, expertise, and risk, as well as in finding a balance between sustainability and affordability through careful planning, inventive thinking, and a readiness to adapt and learn.

1 ABSTRACT

The paradigm of sustainable resilient cities underscores the importance of how to withstand and rapidly recover from natural disasters, pandemics, or chronic stresses associated with increasing urbanization, environmental degradation, and climate change through the use of advanced technologies and data analytics. Access to urban green spaces is a key requirement for developing and maintaining a sustainable, resilient, and healthy city, as described in Sustainable Development Goal 11.7 and the Sendai Framework. Due to necessary triple inner urban development processes that creates multifunctional spaces in urban areas, the resulting vertical and horizontal densification often leads to an impairment of visual access to urban green spaces. Green window views, which reveal visual access to green spaces from buildings, provide a significant impact on multidimensional aspects of urban dwellers. Still, few studies present how this form of access, in its quantitative and qualitative complexity, should be operationalized into a tool for urban planning. Given socio-technical advances, crowdsourcing, as an increasingly popular participatory method for collecting and managing data, has the potential to contribute to the realization of inclusive planning by incorporating passive and active participatory processes and open-source standards. Therefore, this study aims to integrate key aspects of crowdsourced-based approach and window view accessibility analysis. By leveraging the power of crowdsourcing, we investigate the potential of Volunteered Window View Imagery (VWVI) for green window view analysis. Incorporating VWVI enables informed decisions by urban planners, ensuring resilient, inclusive, and accessible urban green spaces. This integration of VGI and window view analysis advances sustainable and resilient urban development.

Keywords: sustainable resilient cities, urban green spaces, crowdsourcing, spatial planning, visibility analysis

2 INTRODUCTION

Owing to their multiple ecosystem services to urban populations, planning and ensuring high quality and accessible urban green spaces are crucial for a sustainable and resilient city, as SDG 11.7 requires (Semeraro et al., 2021; United Nations, 2017). In addition to the availability (number, size, and ratio) and accessibility (distance, travel time, and buffer zones), visibility gains a key role in ensuring accessible urban green spaces due to spatial and access consequences of natural disasters like floods or pandemics on the urban space and the urban population (Amerio et al., 2020; Hobeica & Hobeica, 2018; Labib et al., 2021; Yin et al., 2023). Additionally, increasing urbanization and the implementation of necessary triple inner urban development processes, which focus not only on built-up redensification but also on the planning of mobility offers and the increase of urban green spaces quantity and quality, lead to two- and three-dimensional changes of urban space and thus to a changed visual access to urban green spaces (Haaland & Konijnendijk van den Bosch, 2015; Umweltbundesamt, 2022). In order to meet these challenges and to guarantee a sufficiently accessible provision of urban green spaces, it is necessary to measure, evaluate, and investiagte the status quo situation as well as planned scenarios of built-up and urban green spaces. For this purpose, smart approaches, such as the use of digital twins or big data, are increasingly being used to gain the necessary insights (Farkas et al., 2023). In the digital era, leveraging alternative data sources like social sensing, crowdsourcing, and Volunteered Geographic Information (VGI) can enhance data capabilities. Accessing near-real-time geospatial information can lead to better-informed decisions, driving innovation in geospatial technology, improving the quality and applicability of spatial data, overcoming institutional barriers, and strengthening community resilience through enhanced access to geospatial information services (FIG, 2019; UNISDR, 2017; World Bank, 2020).

In this paper, recognizable limitations in the use of these approaches in the quantification of visible access will be addressed by the presentation of an integrated framework that leverages the power of crowdsourcing for visibility analysis of urban green spaces (Lei et al., 2023). The paper first presents the research context of visible urban green spaces and crowdsourcing including their methodologiocal state of the art as well as

challenges and research gaps and links both research areas into an integrated approach for using crowdsourcing to collect and evaluate Volunteered Window View Imagery (VWVI). The paper concludes with an outlook for planning practice and research.

3 RESEARCH CONTEXT

3.1 Visibility of Urban Green Spaces

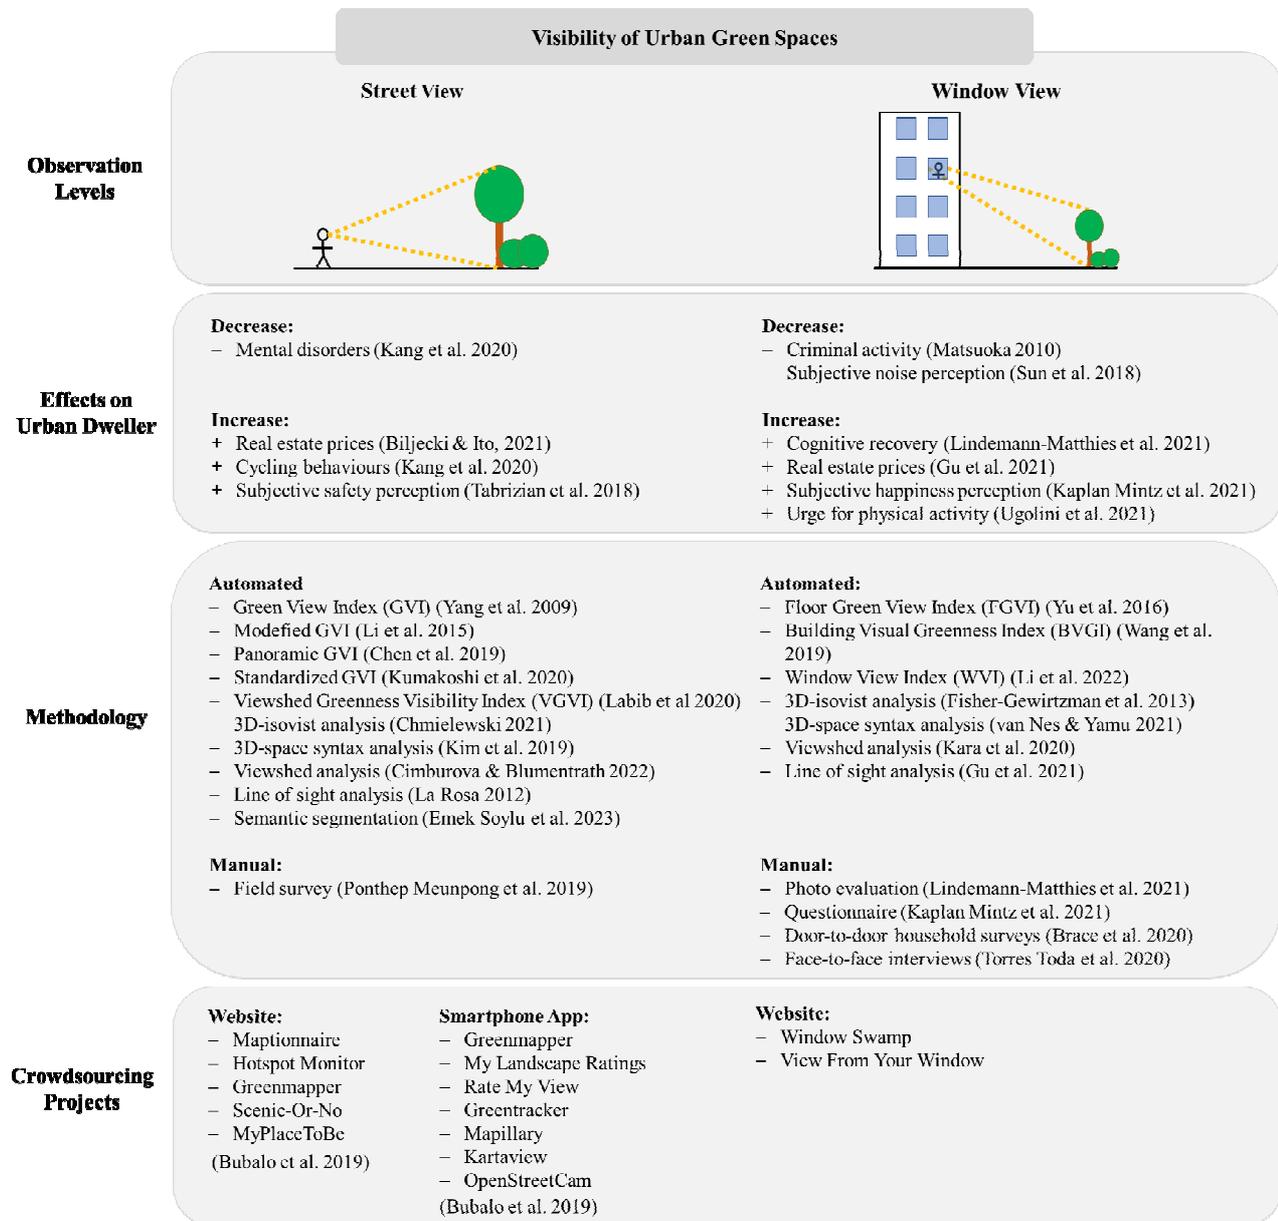
The visibility of urban green spaces can be understood as the visible connection between the urban dweller and urban vegetated areas (adapted from Wang et al. (2017)). Depending on the location of the observer, the observation level can be on the street (street view) or in the building (window view) (Bolte et al., 2019). Streets are primarily publicly accessible and can therefore be used by the general public, whereas in the case of buildings a distinction needs to be made between publicly accessible and usable (such as schools, and hospitals) or privately accessible and used (e.g. residential buildings or workplaces). In both access cases, the visibility of urban green spaces matters. The exemplary studies in Fig. 1 serve to illustrate the complex research field of visibility analysis of urban green spaces.


Fig. 1: Visibility of urban green spaces. Source: Own illustration.

3.1.1 Multidimensional Effects on Urban Dweller

Independent of the level of observation, the view of urban green spaces has significant positive effects on urban dwellers. Effect areas concerning the psyche or cognitive recovery as well as the subjective noise, and safety perception, for example are positively influenced (Kang et al., 2020; Kaplan Mintz et al., 2021; Lindemann-Matthies et al., 2021; Sun et al., 2018; Tabrizian et al., 2018). The view of green spaces leads to an increase in physical activity or in real estate values and to a decrease in criminal activity (Biljecki & Ito, 2021; Gu et al., 2021; Kang et al., 2020; Matsuoka, 2010; Ugolini et al., 2021). The consequently illustrated relevance for the integration of visibility analysis into planning practice includes street planning as well as building planning.

3.1.2 Methodology to Measure Quantity and Quality of Visible Urban Green Spaces

A variety of automated or manual methods can be applied by now in order to measure the quantity and quality of visible urban green spaces (Brace et al., 2020; Chen et al., 2019; Chmielewski, 2021; Cimburova & Blumentrath, 2022; Emek Soylu et al., 2023; Fisher-Gewirtzman et al., 2013; Gu et al., 2021; Kaplan Mintz et al., 2021; Kara et al., 2020; KIM et al., 2019; Kumakoshi et al., 2020; La Rosa, 2012; Labib et al., 2020; M. Li et al., 2022; X. Li et al., 2015; Lindemann-Matthies et al., 2021; Ponthep Meunpong et al., 2019; Torres Toda et al., 2020; van Nes & Yamu, 2021; Wang et al., 2019; Yang et al., 2009; Yu et al., 2016). The majority of automated indices to quantify urban green spaces on the street level rely on semantic segmentation of Street View Imagery (SVI), in which Google Street View® plays a key role as data provider (Biljecki & Ito, 2021; Chen et al., 2019; Emek Soylu et al., 2023; Kumakoshi et al., 2020; X. Li et al., 2015; Yang et al., 2009). For window view quantification, the majority of automated approaches are based on three-dimensional environment modeling and use viewshed analyses or line of sight analyses(Gu et al., 2021; Kara et al., 2020; Wang et al., 2019; Yu et al., 2016). Concerning manual quantification approaches to investigate window views, there is a noticeable focus on surveying the inhabitants or users of buildings. Especially these manual approaches are also used for the assessment of window views (Brace et al., 2020; Kaplan Mintz et al., 2021; Lindemann-Matthies et al., 2021; Torres Toda et al., 2020).

3.2 Crowdsourcing and Voluneteered Geographic Information (VGI)

The rapid progress in geospatial technologies, fueled by emerging data sources such as Digital Twins, Web 2.0, mobile communications, volunteer crowdsourcing, digital volunteering, georeferencing, and geotagging, has led to profound changes in urban studies. These advancements have prompted urban initiatives to reevaluate their core principles and approaches. By harnessing the power of these technological capabilities, urban initiatives can proactively reshape planning and practices. However, this requires embracing the potential of these technologies to adapt and effectively respond to evolving challenges, thereby optimizing the overall resilience and sustainability of urban areas for a livable city (Goodchild, 2007; Haworth & Bruce, 2015; Porto de Albuquerque et al., 2021).

Over a decade ago, VGI was defined by Goodchild (2007) as the utilization of tools to voluntarily create, compile, and distribute geographic data contributed by individuals. Since then, the landscape of VGI activities has expanded, encompassing a wide range of contributions such as online crowdsourced mapping and location-related posts on social media. This, coupled with the advent of digital transformation, has transformed the acquisition and provision of geospatial data, significantly impacting established authoritative systems and fostering new avenues of public engagement through voluntary contributions (Fernandes et al., 2020; Foody et al., 2017). Noteworthy attributes of VGI include its ability to capture the temporal dynamics of spatial information, enabling multidirectional communication, enhancing situational awareness, and harnessing collective intelligence, potentially surpassing the capabilities of traditional geospatial datasets (Haworth et al., 2018; Kankanamge et al., 2019).

Hence, incorporating VGI into sustainable green space initiatives offers numerous advantages. It not only helps bridge the data gap in geospatial information related to green spaces by involving volunteers in the collaborative creation, curation, and dissemination of free, up-to-date, and near-real-time geospatial data (Givoni, 2016; Solís et al., 2021), but also fosters self-organization within the digital volunteer network. This empowers remote citizens and volunteers to actively contribute their technical expertise, local knowledge, and on-site insights to enhance sustainable green space initiatives (Capineri et al., 2016; Johnson & Sieber, 2013). Furthermore, leveraging these collaborative data ecosystems can promote the accessibility of

geospatial information and associated techno-social tools for all individuals, while also facilitating the development of innovative customized tools that contribute to assess visibility and accessibility of green spaces (Arsanjani et al., 2015).

3.2.1 Existing Cowdsourcing Projects for Quantifying and Assessing Visible Urban Green Spaces

The integration of the mentioned potentials and strengths of crowdsoucing and VGI is mainly considered in the street view analysis (see Fig. 1, p.2). A plurality of projects focus on the collection of Volunteered Street View Imagery (VSVI), view locations, and view ratings and are operated through websites or smartphone apps (Bubalo et al., 2019; Hou & Biljecki, 2022; Mahabir et al., 2020; Qiu et al., 2023). The existing number of different projects initiates the quality check of data and information in terms of subjectivity and objectivity, as well as the comparison of applications, complementing the investigation of individual visibility effects at the street level with VSVI (Hou & Biljecki, 2022; Mahabir et al., 2020; Qiu et al., 2023). Considering crowdsourcing for window views, VWVI is collected via websites or on request in a blog forum and presented with further information about the location and time of VWVI. The artistic focus of both projects, with no discernible claim to research utility, is unifying.

4 UTILIZAZING CROWDSOURCING IN WINDOW VIEW ANALYSIS

4.1 Information Bundling from Volunteered Window View Imagery (VWVI)

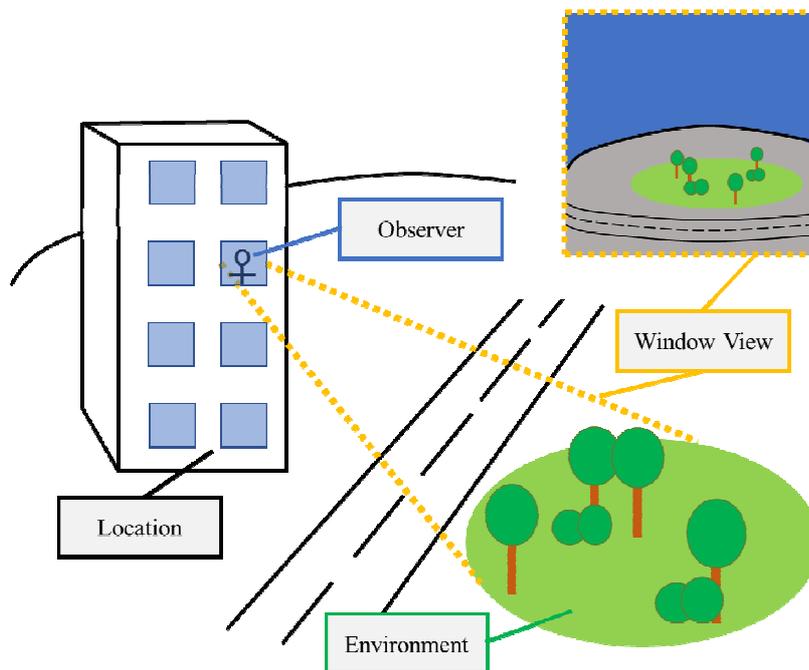
Despite the wide range of multidimensional effect areas of visible urban green spaces, the low level of integration of crowdsourcing to quantify and evaluate window views so far highlights the need to design an appropriate crowdsourcing application to benefit from a broad and comparable VWGI basis for research and planning pracise. By collecting VWVI, detailed information that was previously collected separately by automated or manual methodologies in window view analysis can be bundled together while maintaining consistent and transparent data resolution and quality. The information concerns the a) observer, b) location, c) environment, and d) window view (see Fig. 2.). They are explained in more detail below and are based on the insights of the studies mentioned in Fig. 1., p. 2:


Fig. 2: Information bundling from VWVI. Source: Own illustration.

4.1.1 Observer

The observer can be characterized in terms of age, gender, occupation and/or reason for staying in the building (Brace et al., 2020; Gu et al., 2021; Kaplan Mintz et al., 2021; Lindemann-Matthies et al., 2021; Matsuoka, 2010; Sun et al., 2018; Torres Toda et al., 2020; Ugolini et al., 2021).

354

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4.1.2 Location

The location can be described spatially and functionally: This includes the geographical localization and information concerning the building, such as the floor number where the observer is standing, as well as the observer's position in the room and their distance to the window. The primary function of the building should not be mistaken for the occupation or the observers's reason for staying, since different functions can be performed in the same building (e.g. hospital: work of the nurse and recovery of the patient) (Brace et al., 2020; Fisher-Gewirtzman et al., 2013; Gu et al., 2021, 2021; Kaplan Mintz et al., 2021; Kara et al., 2020; M. Li et al., 2022; Lindemann-Matthies et al., 2021; Matsuoka, 2010; Sun et al., 2018; Torres Toda et al., 2020; Ugolini et al., 2021; van Nes & Yamu, 2021; Wang et al., 2019; Yu et al., 2016).

4.1.3 Environment

The environment is described by the characteristics of the topography as well as the type, phenological characteristics, shape, and height of the urban green area and the distance of the area to the location (Brace et al., 2020; Fisher-Gewirtzman et al., 2013; Gu et al., 2021, 2021; Kaplan Mintz et al., 2021; Kara et al., 2020; M. Li et al., 2022; Lindemann-Matthies et al., 2021; Matsuoka, 2010; Sun et al., 2018; Torres Toda et al., 2020; Ugolini et al., 2021; van Nes & Yamu, 2021; Wang et al., 2019; Yu et al., 2016).

4.1.4 Window View

The window view is first described technically. This includes the window size, the observer's personal field of view (FOV), the window's direction and the time. Information on the quantity and quality of the window view describes the amount and type of visible targets in the view. Reduced visibility due to smog or weather conditions may also fall under this category. In addition to vegetated areas, other elements such as, sky or built-up as well as sealed structures could also be mentioned. Furthermore, the observer's personal assessment of the window view's content as well as their multidimensional effects on him need to be adressed (Brace et al., 2020; Fisher-Gewirtzman et al., 2013; Gu et al., 2021, 2021; Kaplan Mintz et al., 2021; Kara et al., 2020; M. Li et al., 2022; Lindemann-Matthies et al., 2021; Matsuoka, 2010; Sun et al., 2018; Torres Toda et al., 2020; Ugolini et al., 2021; van Nes & Yamu, 2021; Wang et al., 2019; Yu et al., 2016).

4.2 Key Aspects of Utilizing Crowdsourcing and VGI

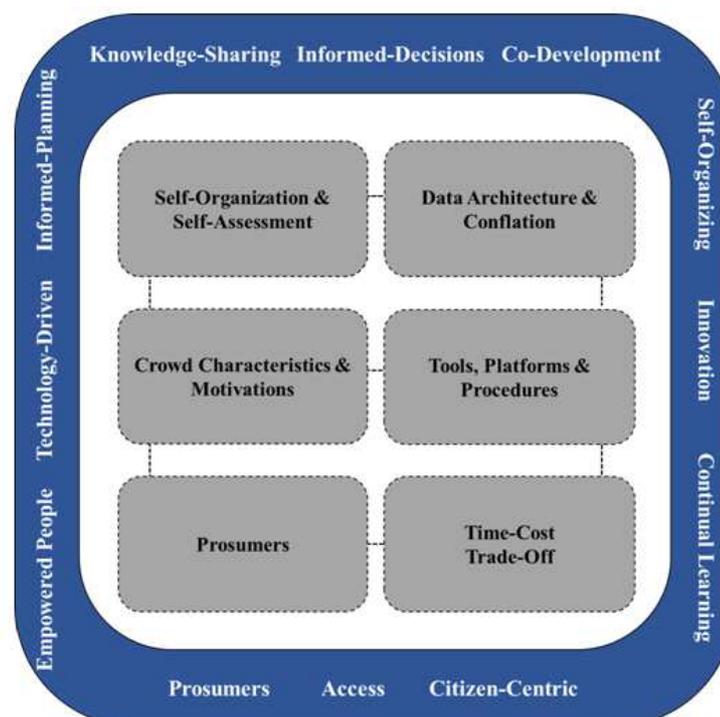
Adapted from Moghadas et al. (2022) core crowdsourcing and VGI aspects related to visibility analysis of urban green spaces were identified as below (see Fig. 3 for an overview):


Fig. 3: Key aspects of utilizing crowdsourcning and VGI for assessment of urban green spcae visibility. Source: Own illustration.

4.2.1 Self-Organization and Self-Assessment

The potential for self-organization and self-assessment becomes evident within VGI-based communities through the active engagement of citizens, community-led organizations, and digital technologies that promote e-participation (Malek et al., 2021). Self-organization, which involves internal reorganization and increased self-awareness, enables innovative problem-solving based on collective intelligence (Palen et al., 2020). Community platforms like OSM, Mapathons, and Missing Maps serve as channels through which local communities and remote volunteers collaborate in collecting, validating, analyzing, and sharing information, thereby fostering a people-centric approach to humanitarian efforts (Givoni, 2016).

4.2.2 Crowd Characteristics and Motivations

Within the realm of visibility of green spaces, VGI platforms can engage participants with diverse levels of expertise, experience, and responsibilities (Coleman et al., 2010). Motivations for contributing to crowdsourcing and VGI initiatives also vary, ranging from positive and altruistic motivations like social recognition, personal reputation, professional interest, community connection, and skill development (Elwood et al., 2012), to potential detrimental contributions such as the spread of misinformation or mass deletions (Coleman et al., 2010). Understanding the characteristics of the crowd and formulating effective motivational strategies play a crucial role in shaping the outcomes of VGI initiatives focused on assessing the visibility of green spaces (Senaratne et al., 2017). Since the nature of a crowd can be relative, it is essential to identify contribution patterns, types, and roles within the initiative's goals and roadmap at an early stage (Yan et al., 2020).

4.2.3 Prosumers

Prosumers, individuals who actively engage as both producers and consumers (Rifkin, 2015), have emerged as key contributors in assessing the visibility of green spaces. Enabled by VGI platforms and associated processes, citizens and remote volunteers can participate as prosumers, generating geospatial content that specifically addresses the assessment of green space visibility based on their own needs and community requirements. By bringing together prosumers, collaborative production and utilization of geospatial data for assessing green space visibility becomes possible. This empowers real-time access to information and minimizes duplication of effort, optimizing the use of resources (Yan et al., 2020) in the pursuit of assessing and enhancing visibility and accessibility of green spaces.

4.2.4 Data Architecture and Conflation

Data architecture plays a vital role in governing the standardized processes of data collection, analysis, and utilization within organizations (Steiniger et al., 2016). To effectively analyze the visibility of green spaces using VGI, it is essential for researchers to adopt a systematic approach that guides contributors in creating, curating, and analyzing relevant data. Establishing practical guidelines for data architecture, considering the potential absence of standardized metadata in VGI, is crucial to ensure a comprehensive understanding of green space visibility. VGI, as a socially constructed epistemology, encompasses distinct labor, reference, and governance relationships that should be treated independently (Sieber & Haklay, 2015). It serves as a valuable complement to authoritative datasets in analyzing the visibility of green spaces, addressing challenges such as cost, outdated information, and restrictive licenses (Grinberger et al., 2019). By incorporating VGI into a formalized data collection and collaboration process, initiatives can meet specific requirements, including real-time updates, additional attribute information, community engagement, and cost-effectiveness (FIG, 2019). Embracing hybrid epistemologies and data conflation processes, integrating VGI into the analysis of green space visibility, offers significant opportunities for data-driven decision-making (Yan et al., 2020). This shift enables the effective utilization of VGI alongside authoritative data, empowering stakeholders with valuable insights to assess and enhance the visibility of green spaces in a meaningful and impactful way.

4.2.5 Tools, Platforms, and Procedures

Location-based and GPS-based services, such as maps, social media apps, and tracking tools, offer valuable support in assessing the visibility of green spaces (Mooney & Minghini, 2017). By collecting user data and providing actionable information through map interfaces, these services aid in evaluating and the visibility of green spaces. Volunteer-driven methods, including OSM, WikiMapia, and Geo-Wiki, along with smartphone

356

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

apps enable the collection and sharing of geospatial data (Haworth & Bruce, 2015; Moreri et al., 2018). These tools empower citizens to contribute to the assessment of green space visibility, improving the availability and accuracy of information. Urban dashboards or urban digital twin platforms can serve as centralized platforms to aggregate various data sources, such as social sensing, facilitating real-time visibility assessment and promoting transparency and efficiency (Moghadas et al., 2023). To ensure effective assessment of green space visibility, practices like organizing community mapping events (Mapathons) and employing planning checklists, workflows, and data catalogs are crucial (Givoni, 2016). These practices enable the contextualization of visibility assessment initiatives based on specific goals, local values, and community needs.

4.2.6   Time-Cost Trade-Offs

In the realm of assessing green space visibility, the power of modern communication technologies allows individuals known as prosumers to share their location-based knowledge, goods, and services at reduced costs (Rifkin, 2015). VGI plays a pivotal role in this context, enabling the rapid and cost-effective sharing of diverse geographic information (Haworth & Bruce, 2015) related to green spaces. By engaging digital and on-site volunteers, internet-based platforms facilitate the real-time collection and dissemination of large volumes of geospatial data, contributing to better assessment of green space visibility (Moreri et al., 2018). These advancements, including crowdsourcing, digital volunteering, and mobile communications, empower dynamic monitoring and multidirectional communication, driving advancements in green space visibility assessments beyond traditional and costly methods (Pan et al., 2016).

5   OUTLOOK AND CONCLUSION

To cope with sudden shocks and chronic stresses that change the visual access to required urban green spaces, advanced technologies and data analytics must be used to ensure sustainable and resilient urban planning. The increasing popularity and importance of crowdsourcing as a participatory method for data collection and management is indispensable for the realization of inclusive urban planning. The introduced approach, which integrates crowdsourcing into window view analysis, effectively addresses these issues and presents the current state of the art. It not only identifies the research gaps in visibility analysis and crowdsourcing but also emphasizes the multifaceted potentials for an integrated planning application. Future research will focus on exploring concrete technical implementation possibilities to facilitate a comprehensive collection of Volunteered Window View Imagery (VWVI) to derive planning recommendations for planning buildings of private and public purposes and to strengthen both research and practical planning purposes. By utilizing crowdsourced data, consequently, planners gain insights into the visibility of green spaces from various vantage points, enabling them to make informed decisions about land use and development. Moreover, this approach aligns with the goal of designing accessible and livable spaces, promoting inclusive planning that considers the needs of diverse communities. The insights derived from crowdsourced data facilitate the creation of urban environments that positively impact residents' well-being. Moreover, the integration of crowdsourcing in urban planning strategies, such as the Urban Green Space Network, allows for smart growth and development. Planners can strategically connect green spaces, considering their visibility and accessibility, thus optimizing land usage and fostering sustainable urban expansion. In this way, crowdsourced window view data not only enriches urban planning processes but also contributes substantially to the evaluation of land suitability and its potential for enhancing the overall urban experience.

(Prof. Dina Sameh Taha, Alexandria University, Faculty of Engineering, Department of Architecture, ditaha@alexu.edu.eg)

1 ABSTRACT

The design of educational buildings can significantly impact the well-being of their users, both psychologically and physically. Hence, psychological and physical factors are key concepts in evaluating educational buildings' performance as they affect the occupants' well-being, comfort, productivity, and satisfaction. These factors are interrelated and influence each other in complex ways. Therefore, it is essential to design and maintain educational buildings that balance both psychological and physical factors to create optimal learning environments for students and teachers.

This paper aims to execute an analytical study of the relationship between the design of educational buildings and users' physical and psychological well-being. It focuses on the case of schools designed by the General Authority for Educational Buildings in Egypt, which are often characterized by typicality and lack of diversity. It examines the quality of educational institution design, which includes aspects such as Functional, behavioral, and aesthetic. It also highlights the importance of creating educational environments that are conducive to learning, health, and comfort for students and teachers.

Educational building design is a multidisciplinary and complex topic that requires a holistic and user-centered approach to optimize the users' well-being and performance. The methodology adopted for this study includes an analytical study of the relationship between architectural design and users' physical and psychological well-being. Certain methods for data collection will be adopted for this purpose: observations, surveys, and questionnaires.

Through this study, a conceptual framework model is developed that can guide the design and evaluation of educational buildings in Egypt. The model is based on a literature review of significant criteria and considerations that affect the quality and performance of educational environments. The criteria and considerations include aspects such as spatial organization, functional efficiency, environmental comfort, social interaction, and aesthetics. The model is then applied to a sample of high schools in Egypt to test its validity and usefulness. A questionnaire survey is also conducted to collect data on the user experience and satisfaction of students and teachers in these schools. The results of the study are expected to provide insights and recommendations for improving the design and assessment of educational buildings in Egypt.

Keywords: educational building design, users' well-being, design analysis and evaluation, psychology, standards of school design

2 INTRODUCTION

"One of the essential roles of architecture is to provide built environments that sustain the occupants' psychological well-being. This role is made even more important because, in modern society, more than 70% of a person's lifespan is spent indoors." (Kim, 1998).

Although every building's design is equally vital, the buildings that adolescents deal with are more important than others, because the effect of emptiness on the adolescent's psyche is deeper than if the person is an adult. Therefore, schools are among the most important built environments, the school building has a human and social role that is no less important than its functional role.

In fact, psychological and physical needs during school age are associated with educational success, the development of a healthy lifestyle, and reduced risk of adverse socioeconomic outcomes, psychiatric disorders, self-harm, and suicide in later life (Kidger et al., 2012). Over the last decade, evidence has been accumulating on the relationship between environments and users' health within a "user-centered" perspective (Gifford, 2007). This approach aims at planning and designing spaces that align with the needs, preferences, and behavioral responses of current and potential users, as well as with the instrumental goal for

which those spaces have been created. For this purpose, the interaction between the setting features and functions and the users' characteristics and activities should be taken accurately into account.

In sum, school building design is supposed to play a central role in the creation of environments that improve educational attainment. Promoting a higher level of design humanization in a school environment means taking into account its spatial-physical configuration, in order to increase the outcome in terms of both learning and well-being, especially when considering the high proportion of time that both staff and students spend at school each week.

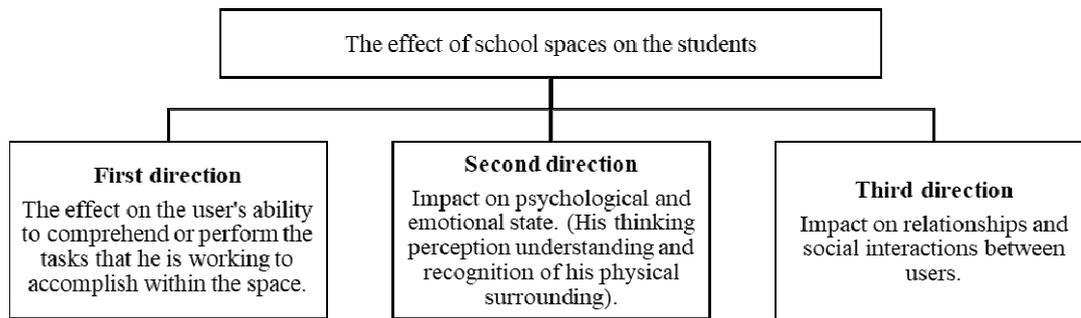
Consistent with the user-centered design approach, the construct of "design humanization" has been developed, particularly for school environments (Fornara et al., 2006) (Nagasawa, 2000) referring to those spatial-physical features that influence users' responses. Although the educational process is established for the sake of the human being, it often begins without paying attention to basic human considerations. It is logical for the designer to place physiological goals such as health, comfort, and security next to psychological ones such as belonging and privacy along with technological, legal, and economic determinants, as it was found that school spaces affect the student in three directions:


Figure 1: The effect of school spaces on the students (Source: Moharram, 2005).

As a result of these effects, human behavior is determined, which the architect must be aware of in order to avoid negative behavior and its design stimulates the positive behavior of the student towards the surrounding space (Moharram, 2005).

By presenting the psychological and physical requirements of the students during school time, as well as the design principles that are meant to fulfill their needs, and in order to monitor the possibility of applying this on the ground, a field study had to be conducted on a case study of a selected school.

Design principles provided a solution to the challenges produced by traditional school architecture while also allowing for the development of many schools in some global situations. In this paper, An example from an Egyptian high school is presented and analyzed in this paper. How pupils adjust to it and design requirements for schools that care about users' psychological and physical well-being are established. The example shows how the school environment affects the pupils' mood, motivation, and performance. The paper argues that schools should consider human factors in their design and provide a comfortable and stimulating learning space for the pupils.

3   MATERIALS AND METHODS

The methodology of this research is based on a descriptive and qualitative approach. An initial survey to investigate the relationship between the architectural design of educational buildings and the psychological and physical well-being of users was conducted. It focuses on three main factors (function, behavioral, and aesthetic). Function refers to how well the building meets the needs and expectations of users. While behavior refers to how the building affects the users' actions and interactions. Aesthetics refers to how the building appeals to the users' senses and emotions. Certain methods for data collection will be adopted for this purpose, observations, surveys, and questionnaires. The observations allow to capture characteristics of either space itself or its users; surveys allow essentially assist the analysis of the physical characteristics of space; the questionnaires identify and evaluate in a fast and structured way, the needs and satisfaction of users.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

The paper uses an analytical study method that examines a case study of a school in Egypt and identifies the key factors that contributed to its performance. The paper also discusses the implications and recommendations of the findings for the design of schools in Egypt.

The analytical method begins with providing descriptions of the samples. It covers the location of the school building, its components, the size of the project, its area, and the number of students in it through its engineering drawings, which were obtained from the Public Authority for Educational Buildings. The performance of the structures' interior spaces is then examined from a functional, behavioral, and aesthetic perspective. In addition to outlining the flaws and their causes, the results also document the benefits and drawbacks of the designs of those schools using the evaluation scale.

3.1 Selected case study

An architectural study of Abdel-Moneim Amer High School is conducted, a public high school located in Kafr El-Sheikh Governorate, Egypt as shown in Table 1. The study examines the school's physical components, such as its buildings, facilities, spaces, and layout, and evaluates their suitability for enhancing students' psychological and physical well-being. The study also identifies the strengths and weaknesses of the school's design, which guides in proposing criteria for improving existing schools or designing new schools in similar contexts. The criteria will be based on three main categories as follows:

- Functional aspects: building form, scale, accessibility, and circulation).
- Behavior aspects: social interaction, common spaces, and social spaces).
- Aesthetic elements: coloring and linking to nature

The main method employed to achieve the study's objective was filling out the evaluation tables with numerical ratings from 1 to 10 for different patterns, which aided in comparing and analyzing the patterns based on various criteria and dimensions. The evaluation analysis sought to document the evaluation of each section as well as the degree of achievement in each, in addition to the benefits and drawbacks of the buildings. Three sections make up the evaluation tables:

- Measuring the functional aspects of a building's performance, such as its shape, design, and circulation, is the focus of the first section.
- The behavioral components of building performance, which deal with psychological variables including privacy, productivity, and social interactions, are measured in the second section.
- The final section measures the aesthetic aspects of a building's performance, including color and Linking to nature (Physical variable).

To do this, we analyzed the building codes of nine countries that have different standards and regulations for this type of construction. We extracted the main elements of the evaluation from each code and assigned them a weight based on their frequency and relevance. This allowed us to compare and rank the elements according to their significance in the design process.

To find out and determine the weight of each element of the evaluation, the building codes for educational buildings were analyzed for nine different countries that have different standards and regulations. The main elements of the evaluation from each code were extracted and were assigned a weight based on their frequency and relevance. This allowed us to compare and rank the elements according to their significance in the design process as shown in Table 2.

For instance, the functional aspect is calculated as: their weight in the evaluation = X / 108, where 108 represents the total number of elements of the functional aspects, which is the product of multiplying 12 elements by the number of 9 different countries. Whereas, the behavioral aspect: their weight in the evaluation = X / 45, where 45 expresses the total number of elements of the behavioral aspects, which is the product of multiplying 5 elements by 9 different countries. While the elements that can be measurably expressed in the aesthetic aspect are two elements, therefore the aesthetic aspect: their weight in the evaluation = X / 18, which is the product of multiplying 2 elements by the number of 9 different countries.

As a result, components are rated from 1 to 10 after being evaluated in accordance with the chosen system evaluation. According to element weight. Each aspect was calculated independently (with a 100% internal computation that made up 33.33% of the overall result).

The functional, behavioral, and aesthetic aspects are fixed. Sub-aspects and indicators can be changed depending on the study's emphasis, the region it is conducted in, and the data that are accessible, which offers future studies more flexibility to add or delete indicators.

3.2 Analysis of the architectural design of the school (data analysis)

Abdel-Moneim Amer High School is located in the city of Al-Riyad - Kafr El-Sheikh Governorate, in Delta Egypt, and is affiliated to the Kafr El-Sheikh Educational Administration, on a Street with a width of 8 m, and it is one direction for vehicular traffic, and the school is located in the middle of a residential area (The General Authority for Educational Buildings, 2011). The school consists of one building consisting of 5 floors, and it contains one open courtyard. The following table shows the descriptive analysis of the school.

Item	Descriptive analysis
School name	Abdel-Moneim Amer High School
Major activity	High school
Designed by	Educational Buildings Authority
Project size	2219 m²
Main component	(12 ordinary classrooms, 2 laboratories, courtyard, Library, Multipurpose hall, football yard, and administration area)
Number of floors	5-Story school building
Number of students	430

Table 1: Descriptive analysis of Abdel-Moneim Amer High School (Source: Author).

3.2.1 Evaluation analysis

By observing the characteristics of the building and its components and analyzing it as illustrated in Figure 3, the evaluation analysis is displayed. As depicted in Figure 3, it clarifies the main criteria that influence school users from three different aspects.

Functional Aspects	Code of India	Code of USA	Code of UK	Code of Finland	Code of Japan	Code of Qatar	Code of Lebanon	Code of Saudi Arabia	Code of Egypt	Weight (108)
Spaces design and scale										
Size of classroom	1.2 m²/St.	2.1 m²/St.	2 m²/St.	1.5 m²/St.	1.5 m²/St.	1.5-2 m²/St.	1.5-2 m²/St.	1.6 m²/St.	1 m²/St.	9
No. of students in the classroom	40	30	30	24	30	-	-	25	36	7
Ratio of classroom	1:1.5	2:3/ 3:4	2:3/ 3:4	2:3/ 3:4	2:3/ 3:4	-	-	-	-	5
Exist storage area	1 locker/ St.	1 locker/ St.	3 m²/ class	1 locker/ St.	3 m²/ class					5
Accessibility and circulation										
No. of stairs and elevators	Min. 2	Min. 2	Min. 2	Min. 2	Min. 2	-	Min. 2	-	Min. 2	7
No. of school entrances	1	1	1	1	1	1	1	1	1	9
No. of school exits	1	1	1	1	1	-	-	1	More than 1	7
Comfortable corridors with enough spaces	1.5 m	1.2 m	1.2 -1.8 m	1.5 – 2 m	1.5 –2 m	2.5m	1.5m	-	2.4m	8
Building percentage of the land area, and student's area of the yard	1 m²/St.	3 m²/St.	0.3 m²/St.	0.6 m²/St.	0.6 m²/St.	-	-	400 m²	200 m²	7
School form										
Site area to be achieved	-	(400-1200) St.	(1400-1700) m²	-	-	3500 m²	-	180 St. or more	1250 m²	5
General orientation of the classrooms	North/ Northeast		North/ Northeast	North/ Northeast	North/ Northeast				North/ Northeast	5
Maximum height of the school	-	-	-	-	-	-	-	-	5 floors	1

Behavioral Aspects	Code of India	Code of USA	Code of UK	Code of Finland	Code of Japan	Code of Qatar	Code of Lebanon	Code of Saudi Arabia	Code of Egypt	Weight (45)
Social need										
Desirable average density in classrooms	40 St./ Class	30 St./ Class	30 St./ Class	24 St./ Class	30 St./ Class	-	-	25 St./ Class	36 St./ Class	7
Providing spaces to increase social activities (cafeteria)	-	1.1 m²/St.	0.9 m²/St.	-	-	-	-	-	-	2
Personal psychological needs

4 RESULTS OF EVALUATION ANALYSIS

To assess how well the school performed in relation to the case study's objectives, procedures, and data collection and analysis methods, the tables below are used to track and describe the school's elements and evaluate their outcomes. The functional, behavioral, and aesthetic aspects of Abdel Moneim Amer High School's performance are evaluated in Tables 3, 4, and 5, respectively, and each evaluation element is shown with its result.

School Name Abdel-Moneim Amer High School						
Evaluation (EV.) %					78%	
			Factor's weight	Total grade	750	585
Functional Aspects	**Spaces design and scale**				EV.	EV. by weight
	Classroom size: The minimum internal dimensions of the classroom = 6 * 8.15 in the case of a rectangular plan, and 7.25 * 7.25 in the case of a square plan, and the net area is 50m². The minimum area for each student in the classroom is 1.5-2m²/Student.		9X	1-------10 Not Achieved - Achieved	5	45
	The number of students in the classroom or group: 25 students and no more than 30 students.		7X		0	0
	Classroom scale: 2:3 / 3:4 widths to length.		5X		10	50
	The storage area in classrooms: Minimum storage area per student (1 Locker/St.)		5X		0	0
	Accessibility and circulation				EV.	EV. by weight
	Directly exits from classrooms to the outside, courtyards, or gardens. There must be at least 1 emergency exit.		7X	1-------10 Not Achieved - Achieved	10	70
	The number of elevators and stairs in the school, with an emergency ladder. (2 stairs/school = 5 floor), (1 elevators/school >5 floors)		9X		10	90
	The school entrances should be clear and easily accessible; there should be at least 2 entrances to the school.		7X		10	70
	Clear and comfortable corridors: Minimum width of one-way corridor = 2m. Minimum width of two-way corridor = 3m.		8X		10	80
	Courtyard or garden. The building percentage of the school is (25-30%) of the land area, and the yard area must be at least 200 m², with a minimum of 10m for its smallest sides. The student's area of the yard must be at least (0.6-1) m².		7X		10	70
	School form				EV.	EV. by weight
	The site area for the high school should not be less than 3,500m².		5X	1-------10 Not Achieved - Achieved	10	50
	The general orientation of the classrooms is to the north, but they can deviate 25 degrees to the east or west from the north.		5X		10	50
	The maximum height (ground + 4 floors).		1X		10	10

Table 3: Result of functional aspect evaluation analysis (Source: Author).

The results show that Abdel Moneim Amer high school achieved 78% of the functional criteria, but only 33.9% of the behavioral criteria and none of the aesthetic criteria, as illustrated in Tables 3, 4, and 5 respectively. These low percentages indicate serious deficiencies in the design of the school, especially in the behavioral and aesthetic aspects, which affect the users' efficiency and educational attainment negatively.

Therefore, this paper highlights the importance of addressing these deficiencies and improving the design quality of educational buildings.

School Name Abdel-Moneim Amer High School						
Evaluation (EV.) %					33.9%	
		Factor's weight	Total grade	280	95	
Behavioral Aspects	**Social need**	(Density)			EV.	E.V. by weight
	Desirable average density in classrooms would be about 30 Students / Classroom	7X	1-------10 Not Achieved - Achieved	0	0	
	Social need (Common spaces and active learning & social spaces)					
	Providing spaces to increase social activities among students, such as (Cafeteria, green areas, etc.). Cafeteria: (1 m²/student)	2X		0	0	
	Personal psychological needs			EV.	E.V. by weight	
	Providing spaces to increase communication: Laboratory: (1.5-2 m²/student).	7X	1-------10 Not Achieved - Achieved	5	35	
	Providing spaces to increase communication: Library: (1.5-2) m²/student.	6X		5	30	
	Providing spaces to increase communication: Sports area: 30% of the outdoor school area	6X		5	30	

Table 4: Result of behavioural aspect evaluation analysis (Source: Author).

School Name Abdel-Moneim Amer High School						
Evaluation (EV.) %				0%		
Aesthetic Aspects		Factor's weight	Total grade	50	0	
	Links to nature (Physical Environment)			EV.	EV. by weight	
	Views of indoor and outdoor spaces (garden, fountains, sitting areas, etc.), (0.5-1) m²/Student.	3X	1-------10 Non-Existing - Existing	0	0	
	Outdoor Classroom: the school provides outdoor classrooms that allow students to study overlooking a natural view, (area of classroom/2).	2X		0	0	

Table 5: Result of aesthetic aspect evaluation analysis (Source: Author).

Questions (n = 40)	Yes		No		Maybe	
	No.	%	No.	%	No.	%
Q1: Is the number of students in the class more than 25 students?	33	82.1	1	2.5	6	15.4
Q2: Do you feel that the classroom space is insufficient for the number of students?	17	41	13	33.3	10	25.6
Q3: Does the classroom have storage units for each student's personal belongings?	5	12.8	32	79.5	3	7.7
Q4: Does the school design contain at least two stairs?	37	92.3	2	5.2	1	2.5
Q5: Can you walk with your classmate next to each other in the corridors between classes?	38	94.9	1	2.55	1	2.55
Q6: Is there at least one emergency exit in the school?	26	64.1	10	25.6	4	10.3
Q7: Is the number of entrances to the school not less than two entrances?	36	89.7	4	10.3	0	0
Q8: Can schoolyard accommodate all the students during break, or when doing morning activities?	28	69.2	2	5.2	10	25.6
Q9: Do you feel thermal comfort in the classroom if the windows are open?	9	23.1	21	51.3	10	25.6
Q10: Is there a cafeteria (restaurant) where you can sit with your friends during a break?	2	5.1	37	92.3	1	2.6
Q11: Is the school has laboratories, not less than two laboratories (computer lab, science lab)?	36	89.7	1	2.6	3	7.7
Q12: Is there a school library through which you can search and study?	27	69.2	6	12.8	7	17.9
Q13: Are there sports fields (football, basketball, etc.) equipped and usable?	14	35.9	21	51.3	5	12.8
Q14: Does the school contain aesthetic elements (trees, fountains, seating areas, pergolas, etc.)?	16	38.5	12	30.8	12	30.8
Q15: Is there an outside study space (Outdoor classroom)?	11	28.2	25	61.5	4	10.3
Q16: Do you like the colors of the paints at school?	10	25.6	22	53.8	8	20.5

Table 6: Questionnaire results (Source: Author).

After analyzing and reviewing the results of the psychological and physical elements of the users in its three aspects (functional, behavioral, and aesthetic), for Abdel Moneim Amer High School, results of the questionnaire for high school students are presented in Table 6, as the number of students in the school reaches 430 students distributed over 12 classes, which makes the study sample for this level consists of (35-40) students.

From the questions and answers presented in the questionnaire, Figure 4 summarizes the response rate for each question separately. Through the percentages shown, we conclude that the functional aspect of the school achieves the highest rate of user satisfaction, despite the presence of deficiencies in some of the functional elements of the school. Then the percentage of users' satisfaction decreases for the behavioral

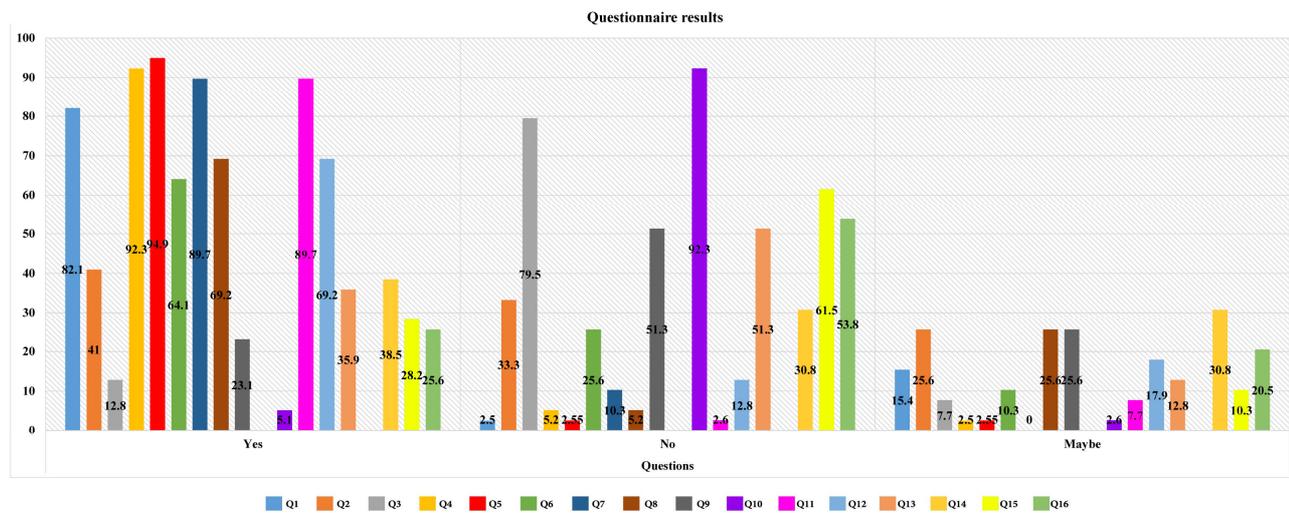
aspect of the school, but it is almost non-existent in terms of the aesthetic aspect, as it lacks many elements and thus does not capture the satisfaction of users.


Figure 4: Percentages of questionnaire results (Source: Author).

5 CONCLUSION

This study is considered a step forward in improving school design by keeping in mind the psychological and physical well-being of students, which affects their performance. The discussion follows the application of architectural design principles of psychological and physical well-being to the selected samples, which are divided into three sections. The discussed outcomes were the result of an evaluation sheet developed based on (C. Kenneth Tanner's, 2008) studies, which used an evaluation sheet filled out by designers to evaluate the performance of schools based on architectural psychology studies.

To understand the design tools that should be used to apply the architectural design principles of psychological and physical well-being on users, a case study proves that the design elements aspects of the architectural design of physical and psychological well-being are categorized into three aspects; Function, Behavioral, and Aesthetic aspects. Those aspects clarify the essential elements that help to achieve the best space performance.

Accordingly, the impact of applying these aspects in architectural spaces design by discussing each element's psychological and physical effect on users is a strong impact of architectural space design elements on users. These proofs lead to a link between the design of educational buildings and the psychological and physical well-being of users.

1 ABSTRACT

Creating livable, safe, healthy, and sustainable urban spaces requires the prioritisation of interactive urban environments (UE) and social connections in city design. Previous studies have examined the relationship between sustainability, health, and happiness, focusing primarily on macro-level factors like air pollution, temperature, wind speed, ambient noise levels, economics, and life satisfaction. Consequently, this research aims to address the following question: How can urban planners establish cities that promote happiness, health, and overall quality of life? This paper specifically explores these aspects in the context of Alexandria, Egypt, with a focus on mental health outcomes and the notions of an "all-inclusive city." Furthermore, the study examines the key elements of inclusive notions for creating happier spaces, as in the case study area (Pharos promenade (PP)), based on Alexandria's historical importance. Methodologically, this paper employs a systematic review approach, incorporating both quantitative and qualitative indicators to establish measurement tools and design principles for happier cities. Ultimately, the study concludes by presenting design principles relevant to creating a sustainable and healthy city that prioritises the health and happiness of its residents within the scope of Alexandria.

Keywords: Happier city, urban environment, mental health, all-inclusive city, measurements for the happier city

2 INTRODUCTION

Fig. 1: Model of the pathways linking the built environment to subjective happiness. Source: Researchers.

The growing interest in understanding and measuring happiness in society has led to a focus on the relationship between happiness and social, environmental, and health factors. The built environment of a city is crucial for creating liveable, secure, healthy, and sustainable cities, as illustrated in Figure 1 (Gehl, 2010). Factors such as urban sprawl (Rong, 2018), megacities, anxiety and depression disorders, and insufficient resources contribute to dissatisfaction with city life. A healthy environment affects human activities and characteristics, including individual happiness, intelligence, and talent. So, the present study highlights the potential of urban design to harness the attributes of the urban environment to promote mental health and happiness while simultaneously mitigating or minimising factors that pose a risk to these outcomes. Two sets of city planner concepts are developed and displayed, analysing how happiness is linked to city design and highlighting the city's enablers of happiness (Najmeh Bitaab, 2018). This discusses the most important notions of an "all-inclusive city", with a particular emphasis on Alexandria City for its historical importance. These concepts are investigated and analysed through three key pillars: influential factors, modifiers, and pathways (McCAY, 2021). The study area on (Pharos Promenade (PP)), Alexandria, Egypt, aims to support psychological and emotional happiness through strong and human-centred design. The paper also investigates how improvement strategies for urban environments impact people's happiness and how happiness is measured. It also presents a framework for designing happier cities and guidelines that will be flexible enough to design happier cities in the future while establishing a model unique to the city's identity.

3 METHODOLOGY AND SCOPE

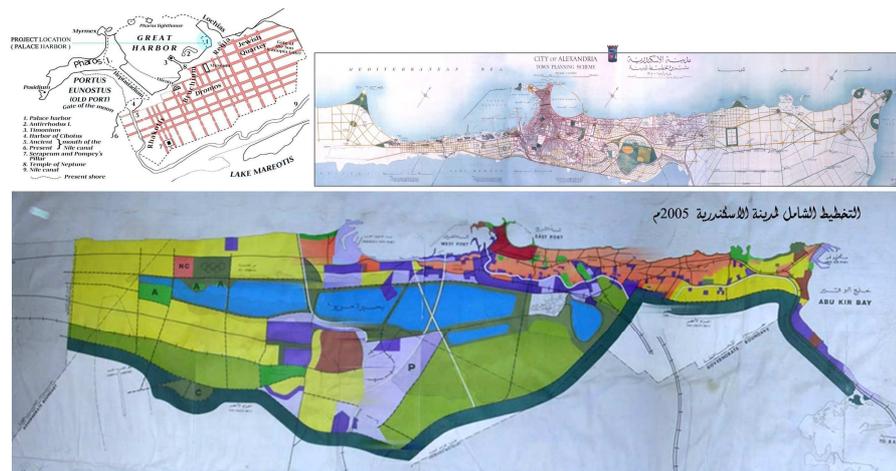
A literature review focuses on designing happier cities, particularly historical ones like Alexandria, Egypt. Through correlating various studies and examining their relevance by considering important factors such as environmental, potential, physical and mental health, and social connection aspects. following qualitative study (inductive and deductive approaches) are used to identify happiness-affecting factors and the link between urban design and happiness. Participatory Design Research (PDR) is used to analyse and evaluate design and environmental elements contributing to happiness. Alexandria, Egypt, is the scope of this study. As shown in Figure 2, since Mohammed Ali's reign (1805), the city has since extended east and west and has 2,679 km² (Pierre-Arnaud Barthel, 2020). Its recent unorganised expansion has generated urban restrictions and vulnerabilities. So, the study applies inclusive city notions. In addition, as shown in Figure 8 and Table 1, happiness in Alexandria might be affected by light, nature, access, surprise, sociality, and identity. Based on that, the happier city design framework and guidelines are designed to promote happiness, sustainability, and positive health for urban planners, architects, and decision-makers.


Fig. 2: Expansion of Alexandria during different periods of time. Source: Trethewey.

4 HAPPINESS ACROSS THE WORLD

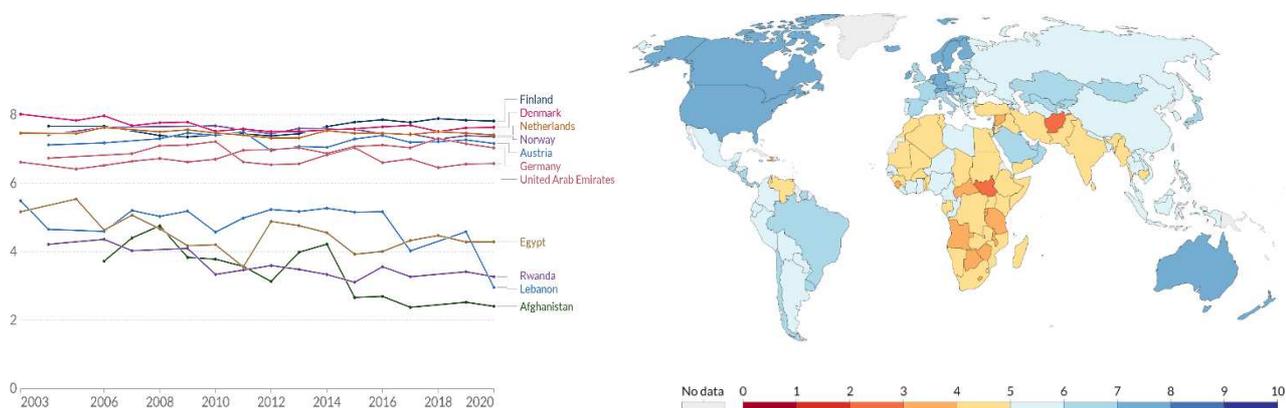
Nations vary widely, as in Figure 3; Finland, Norway, Denmark, and Netherlands, top 2022 stats (all with averages above 7). The Central African Republic, South Sudan, Tanzania, and Rwanda had the lowest national ratings (below 3.5), and Egypt in 2020 (below 4.5). Particularly, the Subjective Well-Being worldwide ranking for Egyptian cities is No. 158 for Alexandria with a rating of 4.660 and No. 177 for Cairo with a rating of 4.088. (John F. Helliwell, 2022)


Fig. 3: Self-reported life satisfaction,2003 to 2020. Source: World Happiness Report 2022. (Roser, 2020)

5 URBAN ENVIRONMENT AND HEALTH

Urban environments significantly impact mental health and happiness globally. Figure 4 shows the urban health implications at the city/neighbourhood, street, and building scales, with mental illness costs amounting to over 4% of GDP, as estimated by the OECD (2014). This includes increased risks of physical illness, education challenges, unemployment, and homelessness. Designing urban environments that promote

physical activity, green space, recreational facilities, and affordable healthy foods can be crucial for enhancing health and happiness.

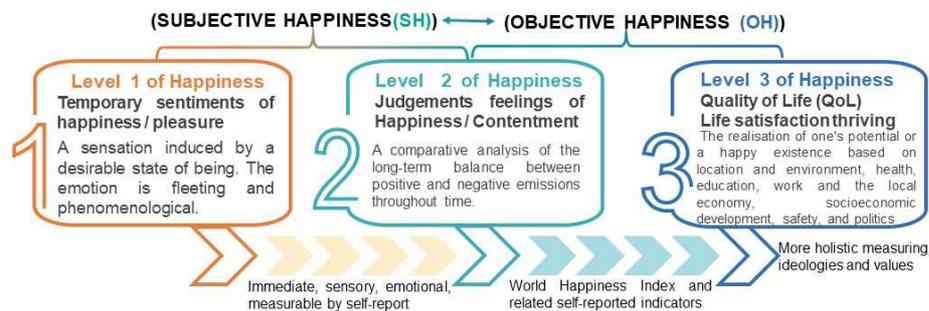
Fig. 4: Exposures and health effects at three scales (city/neighbourhood/street/building). Source: Researchers.


Fig. 5: Using Nettle's graphic from "Happiness: the science behind your smile" to define happiness. Source: Researchers.

5.1 Psychology of happiness

Multidisciplinary researchers split happiness into three phases, as shown in Figure 5: Level 1 of immediate happiness differs from Level 2 of satisfaction or contentment, but both are related. Contentment and joy are essential for a successful existence to reach Level 3, depending on one's potential or purpose in life.

5.1.1 Level 1 of happiness

Emotional happiness involves joy or pleasure. The pleasant sentiments are not permanent. These sentiments are detectable by equipment that recognises brain activity and questionnaires. These evaluations use pleasure centre activation and reduced stress and frustration as indications of happiness.

5.1.2 Level 2 of happiness

Subjective happiness and life satisfaction are studied. Level 1 and level 2 of happiness are related because someone with a high level of life satisfaction has likely experienced many joyous and restorative feelings. This is reflected in the World Happiness Index and related self-reported indicators. Subjective happiness (SH) includes emotional (level 1) and cognitive happiness (level 2) measurements.

5.1.3 Level 3 of happiness (Objective happiness (OH))

For a more complete perspective on happiness, researchers use indices that encompass numerous factors that impact "Objective Happiness" (level 3). which recognises the significance of location and environment, design of the urban environment, health, education, work, the local economy, socioeconomic development, safety, and politics in determining individual happiness. Subjective happiness (Levels 1 and 2) affects objective happiness (Level 3).

5.2 Influence of urban design on mental health and happiness

The Centre for Urban Design and Mental Health (UD/MH) aims to promote community mental health.

through happier and wiser urban design. They recognise the need for social capital and mental-health-friendly architecture to create a happier and healthier city (MH, 2018). The GAPS Framework, as shown in

Figure 6, highlights the link between social connections, security, and environmental aspects of happiness. Copenhagen, Denmark, has successfully developed a socially linked society to create a happy city. Traffic planners created a double-wide bike lane to encourage cycling and strengthen citizen connections.

6 DESIGN PRINCIPLES OF HAPPIER CITIES WITH POSITIVE HEALTH

Design and policy initiatives can enhance health and happiness in urban areas, e.g., Alexandria, as shown in Figure 7. The first theme (a) focuses on the physical and social fabric of the city, such as streets, piazzas, buildings, cycling routes, and parks that may be seen and touched. On the other hand, the second theme (b) highlights the conceptual aspects, such as city culture, community relationships, and services, which are symbolic and relational despite being concrete.

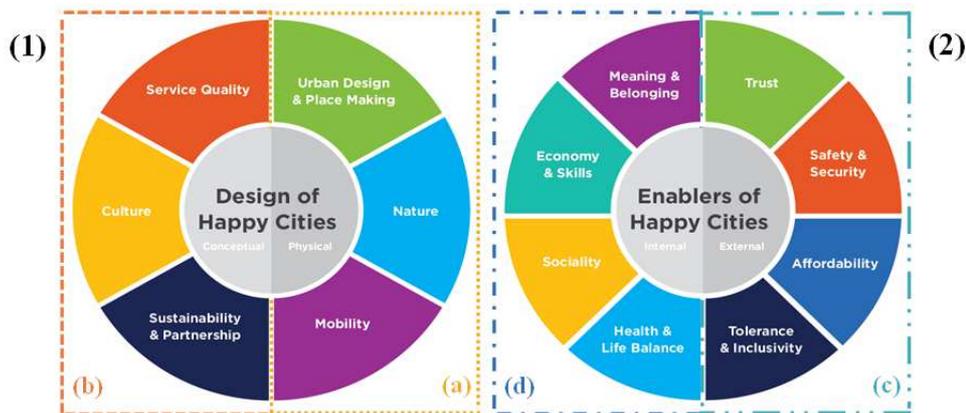
Fig. 6: MIND the GAPS Framework. Source: www.urbandesignmentalhealth.com


Fig. 7: This shows two sets of categories as a practical tool for city makers. Source: Aisha Bin Bishr, 2019
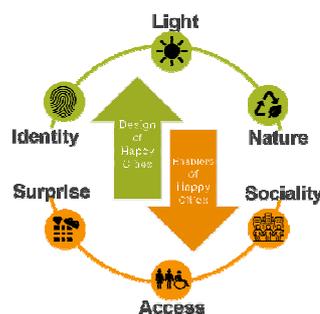

Fig. 8: Approach to happy and healthy cities. Source: Researchers.

7 APPROACH TO HAPPY AND HEALTHY CITIES

This research highlights that better-designed streets and public spaces are more important than a quicker path. In Alexandria, it is better to cancel highway projects and invest the money in cycle paths, gardens, and open spaces. Planners should also alter the car-centric design of the city, reducing hospital admissions by a third and reducing air pollution. So, nature, light, surprise, identity, access, and sociality positively affect people's happiness in Alexandria, so urban planners and policymakers should follow the suggestions for a happy city as in Table 1.

Environmental aspects	PRINCIPLES	DESCRIPTION
NATURE	Clean Cities of Blue and Green	Green parks and shoreland areas are crucial for creating a happier city with a clean atmosphere.
	Public Spaces	City prioritizes parks, natural landscapes, seashore, plazas, and accessible roads.
	Healthy And Security	Prioritize health and safety, focusing on air quality, freedom of fear, zero crime targets, mental and physical health, and natural light cycle.
LIGHT	Sustainability & Efficiency	Sustainable cities that use less energy and materials and incorporate green technologies
SOCIALITY & INTEGRATION	Community Spirit	A strong community-based home with friends, family, and neighbors is essential for outdoor activities and socializing.
	Integrated Neighborhoods	Living, working, and receiving essential services in one's area with mixed zoning.
SURPRISE	Humans Priority	Cities surprise with unexpected features, while machines detract from metropolis, blending into the backdrop when needed.
	Surprise Elements	happy and unexpected surprises, inclusive beauty to lessen class conflict
ACCESS	Walkable & Accessible	Cities with walkable, efficient transportation prioritize pedestrian and cycling, with excellent public transit and housing proximity.
	Compactness	Compact designs minimise distances. Wide roadways and parking lots have a lower passenger capacity than light rail.
	Regionalism	Cities and regions are integrated. Without regional connections, transportation is useless.
IDENTITY	Cultural & Civic Pride	Clean, distinct areas preserve identity and culture, engaging but not overwhelming the senses.
	Quality Of Life (QoL)	Urban design enhances self-reported quality of living, attracting economic activity and investment, enhancing overall well-being.

Table 1: Approach to happy and healthy Egyptian cities based yon 6 environmental aspects. Source: Researchers.

8 CASE STUDY: (DEVELOPMENT OF THE PHAROS PROMENADE (PP))

In 2001, the Ministry of Tourism and the Governorate of Alexandria developed a master plan for the PP and QC with the objective of establishing an integrated urban space with historical significance within six months (Asmaa Abdelrahman, 2018). Figure 9 depicts a pedestrian spine PP that respects human scale and provides visitors with a sense of place. Table 2 compares the physical and behavioural qualities of Pharos promenade before and after development. Currently, once a prominent tourist attraction, the Pharos Promenade has lost regional prominence due to poor design, a lack of entertainment amenities, and poor maintenance. As shown in Table 3, it also lacked comfort and safety for pedestrians and vehicles.

Fig. 9: Site plan for the development of Pharos Promenade in 2001. Source: https://www.binaomran.com/tnews_details.php?n=2

Before Development	After Development 2001
Two primary paths experienced pedestrian and vehicle interference, affecting comfort and safety; the former location deteriorated due to a lack of maintenance.	PP has three levels: two for pedestrians and one for vehicles, using an open-continuous staircase to preserve shoreline views and QC. The third trail is extended with a 42-m tongue.
In this region, limited landscaping and lighting units resulted in a lack of activities and engagement.	Landscape elements like planting, lighting, urban furniture, pavement materials, and public art create a unique experience in the study area, influencing people's interactions with PP.

Table 2: Comparison of development after and before. Source: Asmaa Abdelrahman, 2018, Ragheb, 2014.

	Problems Identification	Resources and Approaches
Cultur	1. The large-scale development of the urban waterfront is considered the start of a modern urban development aimed at encouraging investment. But it's difficult to revitalise historical waterfronts by generating a new design identity while retaining its overall character.	The heritage areas improvement strategy is based on three major pillars:
	2. No civilised entrance reflected the area's history. 3. Restoring the study area's design identity. This necessitates understanding the need of having a thorough waterfront plan in order to prevent future design blunders. 4. The absence of architectural identity of surrounding buildings as well as the usage of distracting materials and components. 5. Uses and activities in the area did not suit the region's culture.	**The first strategy** is to protect existing historic sites. For this strategy to work, all the built-up blocks' facades must be changed to match the local history and bring the design's spatial character together. **The second strategy** is to restore and redesign the surrounding buildings using the same architectural components and materials as the QC. **The third strategy** is to make existing buildings and open spaces more efficient and come up with creative designs to create more jobs and places for people to visit and bring more tourists to the area.
Social And Urban Environment	6. Insecurity from overlapping bikes, vehicles, and pedestrians' lanes.	Providing a safe passage from outside of the PP for bikes, vehicles, and pedestrians.
	7. Parking for vehicles and buses is limited.	Parking spots for all kinds of vehicles are a must, and the promenade should be designed in a way that reduce driving speed.
	8. The absence of recreational venues and green spaces 9. The inadequacy of landscape furniture, poor pavement materials, and public art. All of these elements do not contribute to a happy environment. 10. Few lights in the research area are insufficient. 11. Misuse and uncleanliness of the waterfront. 12. There are no well-designed selling units for street vendors. 13. Absence of a tourist and informative support facility. 14. Insufficient public services and locations for recreational and cultural activities (diving centres, yacht berths, restaurants, etc.) and constrained usage of private clubs.	Redesigning the place based on **sustainability**, **health**, and **happiness** principles

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

9   RESULTS

9.1 Measurements and Policies for the Happier City

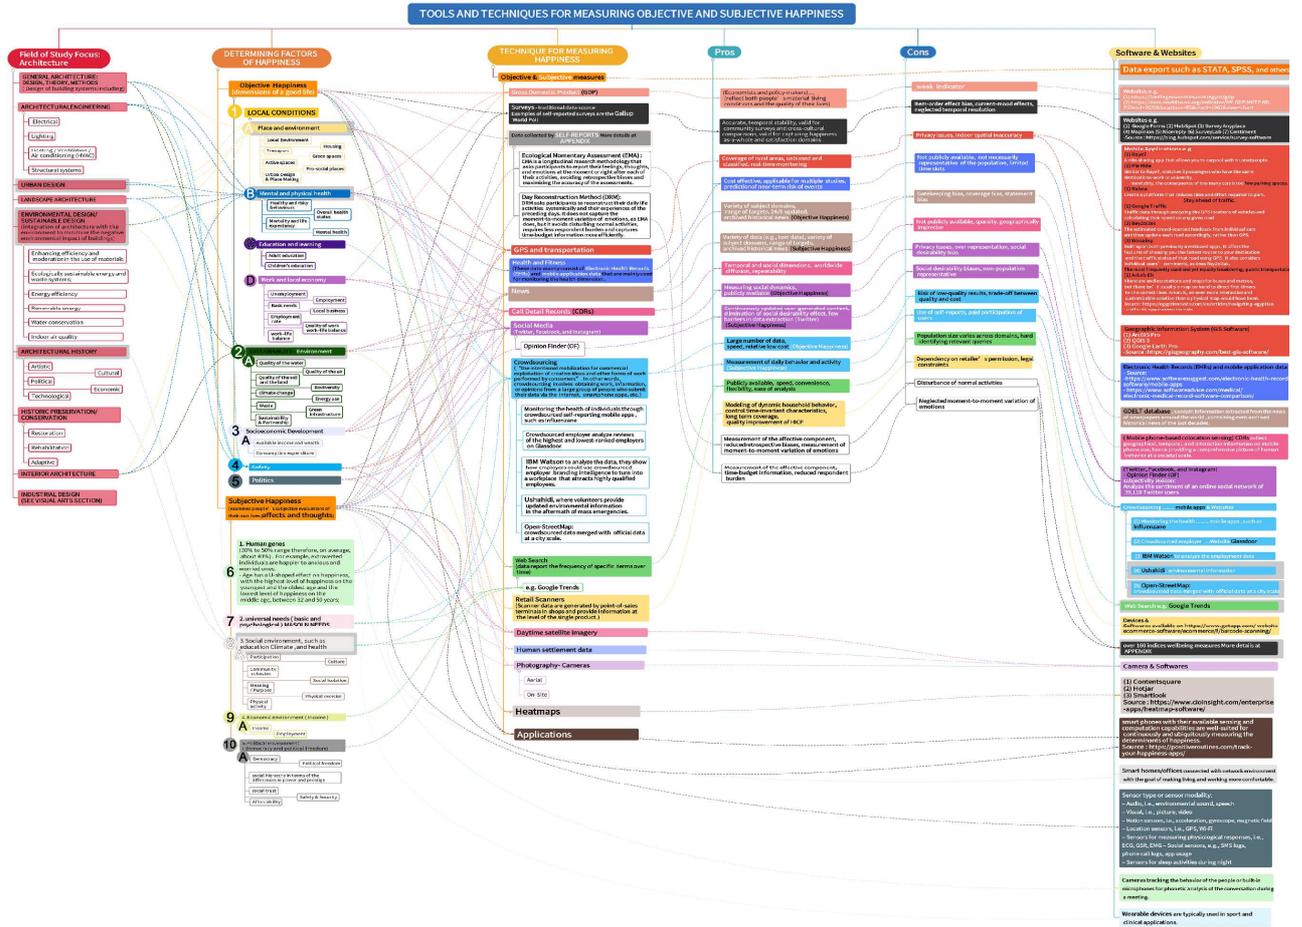
Experts are identifying factors that promote happiness and health in urban areas, with a focus on Egypt As depicted in Figure 10. Happy City, established in 2010, aims to combat the notion that economic development is the primary measure of human happiness. The organization creates measuring tools to recognize, analyze, and enhance happiness in people and places. Important instruments, such as the "Collection of Happiness Measure" in the World Database of Happiness (WDH), are analyzed in this section (Veenhoven, Ruut, 2017).


Fig. 10: Tools and techniques for measuring objective and subjective happiness are needed to assess happiness levels in the city. Source: Researchers.

9.2 Framework for a Healthy and Happier City

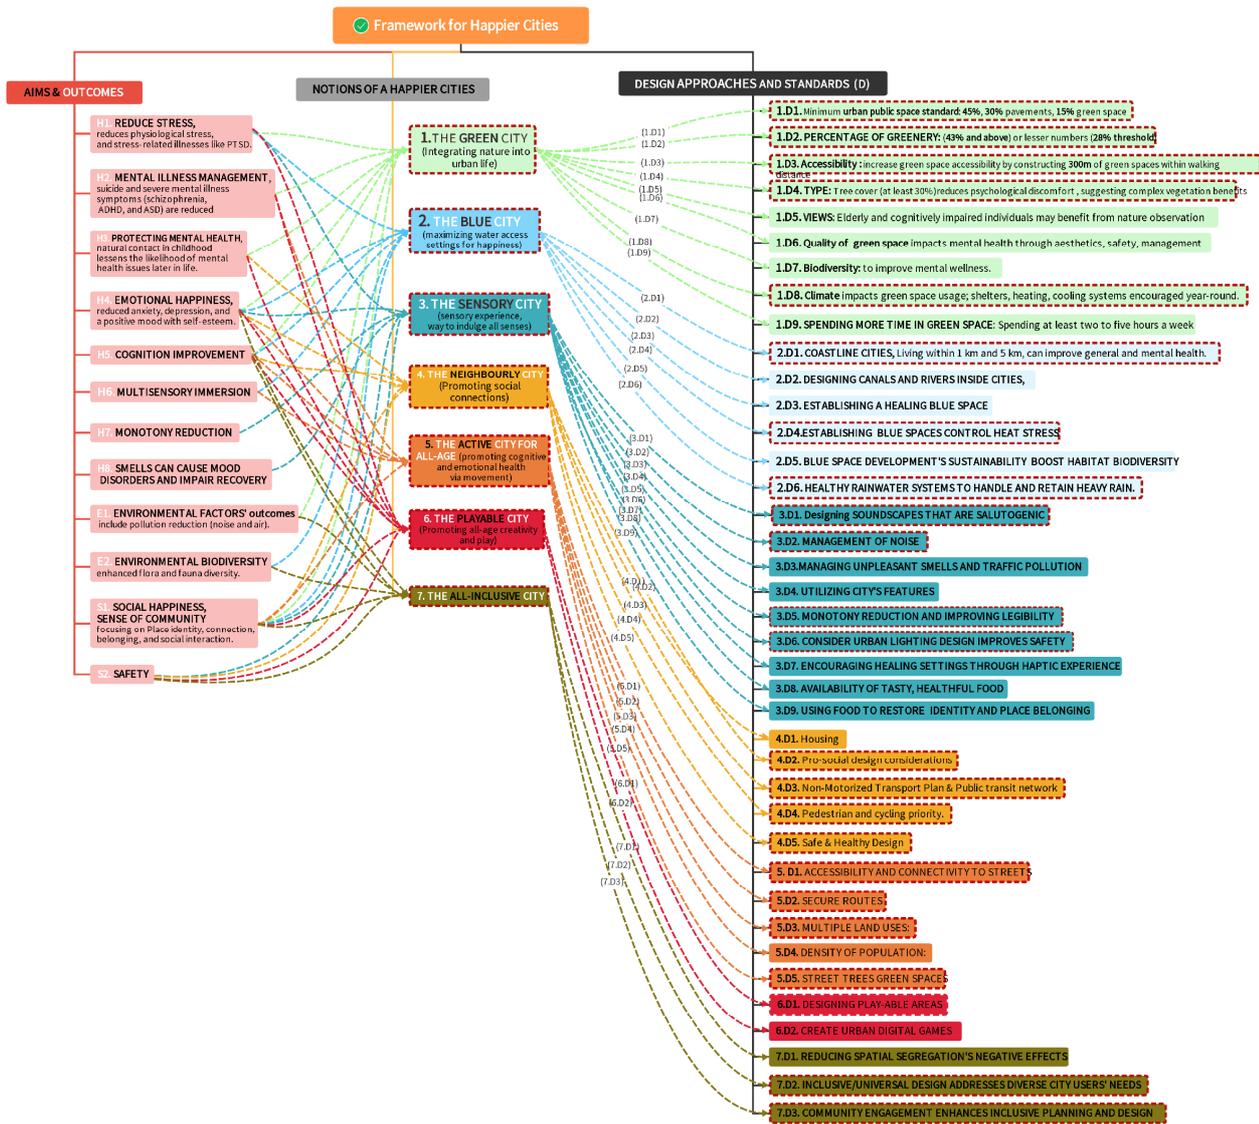
This study sets out a new framework for "happier urbanism" based on the "all-inclusive city" idea that examines how city and neighbourhood design may create happiness, focusing on mental health outcomes as:


Fig. 11: Framework for a healthy and happier city. Source: Researchers.

10 CONCLUSION

Few studies explore happier cities' design principles for architecture and urban design. To promote health and happiness, architects and planners should use the GAPS Framework to create Green spaces, Active spaces, Pro-social places, and Safe places based on sustainability principles.

To design or plan a happier city, there are three distinct factors that may be applicable:

(1) Urban Design for Health and sustainability

- Cities are hubs of creativity and innovation, but they also contribute to climate change and planetary health problems. Global sustainability involves more than treating urban woes; that requires rethinking urban systems.

- Citizen happiness is tied to city planning and design. So, architects and urban planners should create active designs with walking and cycling access, social contact, and a direct link between humans and the environment by putting activities in green areas in diverse neighbourhoods with health and sustainability in mind. Good urban design and reliable public transit allow individuals to conveniently travel and be active.

- Nature, light, accessibility, and identity are also keys to urban attractiveness. So, green landscapes, water, and natural light are restorative; a complicated spatial plan adds interest and encourages exploration; and visual markers aid direction and offer relaxation.

378

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

(2) Participation at work

The work-life balance contributes to national happiness. Example: flex time, working from home, and a year of maternity leave for both parents. This helps citizens enjoy life and be happy at work while maintaining strong family relationships.

(3) Reduce impediments

- Health care and education are provided. People can access these services effortlessly. Less stress increases their happiness.

- Although happiness cannot be quantified, the quantitative environmental elements influencing human happiness, such as fluctuating temperatures, wind speed, water and air pollution, and other factors, may be measured and compared. As a result, public places are created in accordance with agreed-upon sustainable environmental criteria.

- Based on the facilities, resources, and data that are available, the designer must figure out the best ways and tools to measure happiness.

- In Egypt, particularly in the city of Alexandria, there is a noticeable lack of open-access data and data repositories, which is regarded as a barrier to any improvement.

- The Thriving Places Index (TPI) is a modern compass. It helps decision-makers from all sectors evaluate and prioritise policies based on people's well-being and community sustainability. Businesses of any size can utilise the TPI and Happiness Pulse together. So that may be useful in Egyptian projects by analysing happiness elements and how individuals are doing.

Implementierung von Waldinseln im Bereich der gründerzeitlichen Innenhöfe von Graz

Petra Kubin, Aglaee Degros

(DI BSc. Ba. Petra Kubin, 145 Institut für Städtebau TU Graz, petra@kubinquadrat.at)
(Arch. Univ.-Prof. Aglaee Degros, 145 Institut für Städtebau TU Graz, a.degros@tugraz.at)

1 ABSTRACT

Viele Städte in Europa sind seit jeher von Platzproblemen betroffen. Die Etablierung von Grünflächen innerhalb urbaner Gebiete stellt eine komplexe Herausforderung dar, die oftmals einschneidende Veränderungen in dicht besiedelten Arealen erfordert. In diesem Kontext erweist sich die Stadt Graz als bemerkenswerte Ausnahme, da sie über eine beträchtliche Anzahl unbebauter Innenhöfe im Stadtzentrum verfügt. Nichtsdestotrotz ist Graz, wie viele andere städtische Zentren, den Auswirkungen extremer Wetterereignisse ausgesetzt. Insbesondere während der Sommermonate treten Extremhitze, intensiver Starkregen und ähnliche meteorologische Phänomene auf, die erhebliche Herausforderungen darstellen. Eine Möglichkeit diesen entgegen zu wirken stellen Waldinseln in den Innenhöfen der gründerzeitlichen Bebauung von Graz dar.

Keywords: Grünraum, Klimawandel, Wärmeinsel, Innenhof, Gründerzeit

2 GRÜNDERZEITLICHE INNENHÖFE VON GRAZ

Gründerzeitliche Innenhöfe stellen in einigen Bezirken von Graz eine große Grünraumressource dar. Sie befinden sich gut versteckt im Inneren der historistisch geprägten Baublöcke. Diese teils brachliegenden, teils bespielten Grünflächen sind vor allem in den Bezirken St. Leonhard, Geidorf und Jakomini zu finden – jedoch kommen sie auch in den Bezirken Innere Stadt, Lend und Gries vor. Aufgrund ihrer Begrenzung durch die umliegenden Baublöcke sind sie für Passanten meist uneinsehbar.

3 FORSCHUNG UND METHODE

Dieser Beitrag basiert auf den Forschungsergebnissen der Dissertation der Autorin, die derzeit in Form einer Monografie verfasst wird. Die Forschungsfrage hierzu lautet: „Wie können gründerzeitliche Innenhöfe in Graz in der Geschichte verortet werden, wie werden sie heute genutzt und welche Potenziale für die Zukunft stellen sie dar?"

Wie auch die Forschungsfrage schon andeutet, gliedert sich die Dissertation in drei Teile: Die Vergangenheit der gründerzeitlichen Innenhöfe, die Gegenwart und die Zukunft dieser. Diese Veröffentlichung beschäftigt sich vor allem mit dem dritten Teil der Zukunft und wie das Potenzial der Innenhöfe bestmöglichst genutzt werden kann. Hierbei werden die Ergebnisse der Forschung, die den zweiten Teil der Dissertation (Gegenwart) bildet, miteinfließen.

Um eine bessere Vergleichbarkeit zu gewährleisten und das Thema besser abgrenzen zu können, fokussiert sich diese Dissertation vor allem auf den Aspekt „Wohnen". Von den anfangs 246 in Betracht gezogenen Innenhöfen erfüllten 131 folgende von der Autorin festgelegten Kriterien:

Der Innenhof befindet sich in einem der Grazer Bezirke, der zu großen Teilen gründerzeitliche Bebauung aufweist.

Der Innenhof ist zum Großteil von gründerzeitlicher Bebauung umschlossen.

Abbildung 1: Mapping ausgewählter Innenhöfe.

Der Innenhof wird vor allem der Funktion „Wohnen" zugeschrieben oder ist zum Großteil von Wohnungen umgeben.

Der Innenhof ist ganz oder teilweise geschlossen.

Da keine Daten über alle den Kriterien entsprechenden Innenhöfen vorhanden waren, mussten diese mit unterschiedlichen Methoden selbst erhoben werden. Mittels den „Messtools", welche online über „GoogleMyMaps[1]" bereitgestellt werden, wurden Daten über Blockgröße, Innenhofgröße und Bebauung des Innenhofs generiert. In Zuge von Begehungen wurde eine Fotodokumentation mit über 4.000 Fotografien von Innenhöfen erstellt. Hierfür wurden alle infrage kommenden Innenhöfe von mindestens drei unterschiedlichen Blockseiten mehrmals fotografiert. Die Fotos wurden dann verortet und mittels Festlegung von rund 70 Merkmalen wie (Abgrenzung, Erschließung, Bodenbelag, Nutzung für Fahrzeuge...) analysiert. Im Zuge der Dissertation wurden mithilfe eines Katalogs der ausgewählten Innenhöfe die Entstehung dieser und der jetzige Zustand sowie deren Nutzung festgehalten. Die Daten der Evaluierung des Naturschutzbundes Steiermark aus dem Jahr 2004[2] wurden miteingearbeitet, um Veränderungen hinsichtlich der Innenhofbebauung sichtbar zu machen. Weiters war eine genaue Verortung (Kennzeichnung, Straßenbegrenzungen, Satellitenbild, grafische Darstellung im Bezirk) für die Wiederauffindbarkeit für spätere Arbeiten von großer Wichtigkeit. Grundlegende Informationen wie Block- und Innenhofgröße wurden in Zahlen dargestellt. Die wichtigsten Daten über Besitzverhältnisse, Mikroklima sowie Nutzung aus der Fotodokumentation[3] wurden grafisch auf Katalogblättern abgebildet. Die Nutzung durch die Bewohnerinnen und Bewohner wurde auf Basis der vorliegenden Daten geschätzt. Da die Begehung der Innenhöfe nicht immer zu 100 Prozent möglich war, wurde dies auf jedem Katalogblatt sichtbar gemacht. Um eine grobe Vorstellung der Flächenaufteilung zu bekommen wurde die Karte des Katasterauszuges des jeweiligen Innenhofes im Katalogblatt aufgenommen.

Um mehr über die Nutzung der Innenhöfe durch Bewohnerinnen und Bewohner zu erfahren, wurde über das Tool „Google Forms[4]" eine Umfrage erstellt, welche im Zeitraum Mai 2017 bis Juli 2018 durchgeführt und in Folge dessen statistisch ausgewertet wurde. Als Gesamtheit der Umfrageteilnehmer wurden alle Grazerinnen und Grazer, welche in einem Mehrparteienhaus mit Innenhof wohnen, ausgewählt. Die Umfrage wurde über Facebook in verschiedenen Gruppen, welche eine möglichst breite Erhebung gewährleisten, verbreitet. Da jedoch bestimmte Altersgruppen auf Facebook schwächer vertreten sind, wurde ein Aufruf zur Teilnahme an der Umfrage an „Schwarze Bretter" direkt in den Eingangsbereichen der Gebäude, welche für die Umfrage relevant waren, gehängt. Weiters wurden Personen, die zufällig während der Fotodokumentation getroffen wurden, gebeten an der Umfrage teilzunehmen. An ältere Personen, welche nicht an der Umfrage mittels Internet teilnehmen konnten/wollten, wurde die Umfrage in Papierform ausgegeben und nach dem Ausfüllen in die online Umfrage eingetragen. Die Stichprobe dieser Umfrage liegt bei 263 Personen.[5] Die Umfrage wurde grafisch in Abbildung 3 aufgearbeitet, um ein Meinungsbild der Teilnehmerinnen und Teilnehmer in den für dieses Paper relevanten Aspekten besser darzustellen.

Der Wohnungsmarkt wurde analysiert indem von Mitte Jänner 2017 bis Mitte Jänner 2018 insgesamt 2278 Wohnungsanzeigen auf ihre Angaben zu Innenhöfen bei historistischen Grazer Häusern evaluiert wurden.[6]

4 FUNKTION DER GRÜNDERZEITLICHEN INNENHÖFE VON GRAZ

Aus Archivunterlagen und der auch heute noch sichtbaren Parzellierung (Abbildung 2) wird klar, dass die Größe und Form der Grundstücke je nach Gegebenheiten gewählt wurden. Grundlagen hierfür sind Straßenverläufe, Bäche sowie die Lage der bereits bestehenden Gebäude. Weiters ist zu bemerken, dass der Innenhof bei Eckgebäuden meist deutlich kleiner ausfällt als bei mittig stehenden Gebäuden. Häufig wurde entlang der Hausgrenze, die an das benachbarte Haus angrenzt, eine Linie gezogen um den Innenhof zu

begrenzen. Die Begrenzung, die mittig des Hofes verläuft, wurde von Baublock zu Baublock und von Innenhof zu Innenhof unterschiedlich gezogen. Dies führt dazu, dass man nicht von einheitlichen Innenhofgrößen innerhalb eines Blocks ausgehen kann.

Abbildung 2: Parzellierung heute (Eigene Grafik nach Digitaler Atlas Steiermark[7])

Diese ungleichen Innenhofgrößen machen es schwierig eine einheitliche Funktion festzustellen. Vor allem gilt dies für die Innenhofbereiche im Zentrum des jeweiligen Gründerzeitblocks. Die Freibereiche, welche direkt an die Hausseite anschließen, werden auch Haushufen genannt. Sie hatten früher großteils einheitliche Funktionen. So dienten diese, zumeist mit Beton versiegelten Bereiche, den hauswirtschaftlichen Tätigkeiten. Sie waren in unmittelbarer Nähe zur Waschküche und den Hausbesorgerinnen- und Hausbesorgerwohnungen. Als Ausstattung sind die heute oft noch bestehenden Teppichklopfstangen und Wäscheleinen signifikant. Die Haushufen wurden meist mit einem Gartenzaun begrenzt, sodass man nur durch eine Gartentür in den weiteren Innenhof gelangte. Der vom Wohnhaus weiter entfernte Bereich des Innenhofes besticht heute mit seinen Grünflächen und Altbaumbeständen auf denen immer wieder auch alte Obstbäume zu finden sind. Diese Bereiche könnten durch ihre geschützte Lage auch früher schon der Eigenversorgung gedient haben.[8] Schriftlich konnten jedoch hierzu keine Anhaltspunkte gefunden werden.

4.1 Nutzung der Innenhöfe heute

Die Nutzung der Innenhöfe variiert. Durch die Befragung[9] wird deutlich, dass über ein Drittel der Bewohnerinnen und Bewohner besonders die Ruhe im Innenhof schätzen (Abbildung 3: Nutzung). Hier ist der Innenhof eine besonders wertvolle Ressource, da er durch die Häuserblöcke von der Straße abgeschirmt ist. Diese Ruhe kann man dank des Innenhofes jedoch nicht nur im Innenhof selbst sondern auch über innenhofseitige Fenster oder Balkone genießen. Ist der Innenhof zusätzlich noch begrünt und frei von Motorgeräuschen kommt ein besonders hoher Entspannungswert zu tragen. Im Gegensatz zum Wunsch nach einem ruhigen Innenhof steht das Bedürfnis vieler Bewohnerinnen und Bewohner den Innenhof in Gesellschaft zu erleben. Hier wird besonders oft das Spielen von oder mit Kindern oder geselliges Zusammensitzen genannt (Abbildung 3: Nutzung). Bei der Befragung konnte festgestellt werden, dass Bewohnerinnen und Bewohner, die eine Wohnung mit Innenhof in Graz besitzen, diesen oft nutzen, wenn sie Kinder haben (Abbildung 3: Nutzung nach Häufigkeit mit und ohne Kinder). Grünbereiche in sehr kurzer Distanz der Wohnung sind besonders attraktiv, da keine zusätzlichen Gegenstände mitgenommen werden müssen, und man schnell wieder in der eigenen Wohnung ist. Durch die Umfrage konnte ermittelt werden, dass der Personenkreis 51+ den Innenhof besonders stark nutzt (Abbildung 3: Nutzung nach Häufigkeit und Alter). Dies könnte mit der freigewordenen Zeit im Ruhestand, mit den kurzen Wegen im fortgeschrittenen Alter und mit der Nutzung mit Enkelkindern im Zusammenhang stehen. Da prozentuell nur ein kleiner Anteil der Innenhöfe Kinderspielgeräte besitzt dürften diese nur von sekundärer Bedeutung sein. Untersuchungen zeigen, dass Bewohnerinnen und Bewohner, die sich mit ihrem Wohnumfeld identifizieren, soziale Strukturen stärken. Die aktive Nutzung der Innenhöfe kann zu einer verstärkten Identifizierung mit diesem führen und somit die gesellschaftliche Teilhabe fördern und Verwahrlosung und Stigmatisierung

[9] Bewohnerinnen und Bewohnerbefragung, durchgeführt von Petra Kubin, Durchführungszeitraum Mai 2017 bis Juli 2018

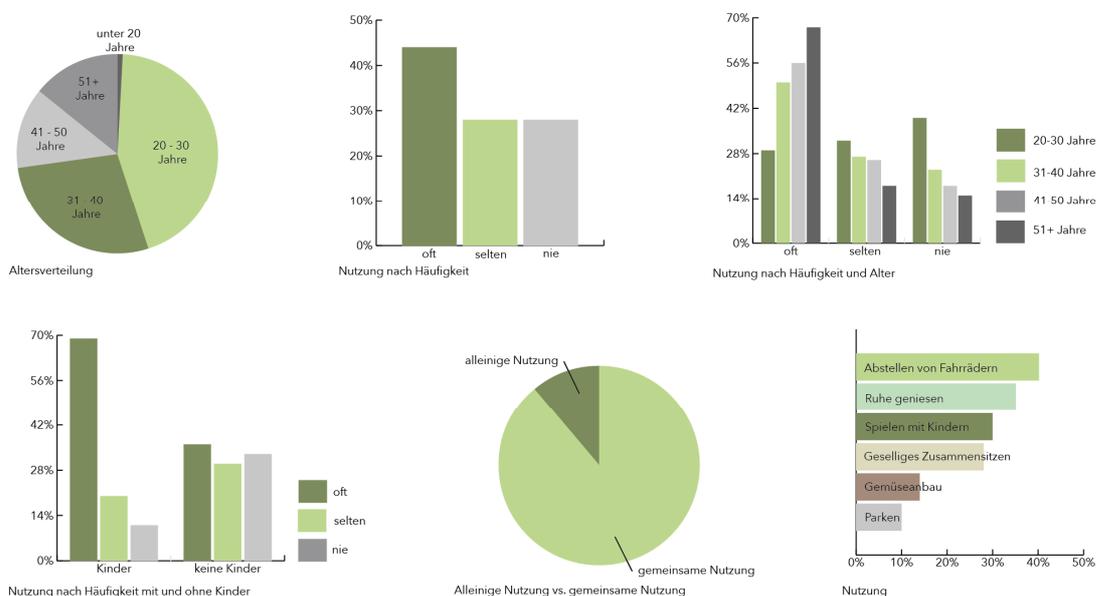
entgegenwirken.[10] Sitzmöglichkeiten sind in einigen Innenhöfen vorhanden. Hier können temporäre und langfristige Möglichkeiten, welche auch während der Wintermonate im Garten bleiben, unterschieden werden. Temporäre Sessel und kleinere Tische mit Klappmöglichkeiten werden oft von einzelnen Bewohnerinnen und Bewohnern in den Garten gebracht und wieder abgebaut nach der Benützung. Auch Grillmöglichkeiten sind in einigen Innenhöfen zu finden. Bei den Kinderspielmöglichkeiten sind vor allem Sandkästen und Schaukeln, die an den vorhandenen Teppichklopfstangen angebracht sind, vorherrschend. Laut eigener Umfrage wird der Innenhof von rund 40 Prozent der Befragten für das Abstellen von Fahrrädern genutzt (Abbildung 3: Nutzung). Von dieser Abstellmöglichkeit nehmen vor allem Bewohnerinnen und Bewohner in Ausbildung besonders starken Gebrauch. Die Nutzung als Autoabstellplatz wird hingegen nur bei 9,5 Prozent der Befragten angegeben (Abbildung 3: Nutzung). Durch die Auswertung der Begehungen der Innenhöfe wurde klar, dass Vermieterinnen und Vermieter Innenhöfe oft als Abstellmöglichkeit für Abfalltonnen nutzen. 28 Prozent der Bewohnerinnen und Bewohner geben an, den Innenhof überhaupt nicht zu nutzen (Abbildung 3: Nutzung nach Häufigkeit). Hier sind jedoch die unmittelbaren Nutzungen durch das Öffnen der Fenster und der Ausblick ins Grüne nicht zu unterschätzen. In vielen Wohnungsanzeigen werden genau diese Aspekte zur Bewerbung der Wohnung genutzt. [11,12,13]


Abbildung 3: Auswertungen aus der Bewohnerinnen und Bewohnerumfrage[14]

4.2 Private, semiprivate und öffentliche Nutzung der Grazer Innenhöfe

Grazer Innenhöfe können zum Großteil von ganzen Hausgemeinschaften genutzt werden. In der Umfrage geben 89 Prozent an, dass ihnen der Innenhof zur gemeinsamen Nutzung mit anderen Hausbewohnerinnen und Hausbewohnern zur Verfügung steht (Abbildung 3: Alleinige Nutzung vs. gemeinsame Nutzung). Nur in wenigen Höfen finden sich Hinweise, die davon ausgehen lassen, dass der Innenhof für andere Hausbewohnerinnen und Hausbewohner gesperrt ist. Direkte Ausgänge über Erdgeschoßwohnungen sind die Ausnahme. Der Zugang zum Innenhof erfolgt großteils über einen Ausgang, welcher vom Stiegenhaus aus für alle Bewohnerinnen und Bewohner gleich begangen werden kann. Öffentliche Nutzung und Begehbarkeit ist fast immer unerwünscht. Schilder auf Innenhoftüren weisen häufig klar darauf hin, dass darauf zu achten ist, dass die Türen verschlossen zu halten sind.

[14] Bewohnerinnen und Bewohnerbefragung, durchgeführt von Petra Kubin, Durchführungszeitraum Mai 2017 bis Juli 2018

In den einzelnen gründerzeitlichen Blocks in Graz gibt es eine unterschiedliche Anzahl von Innenhöfen. Meist sind die Innenhöfe klar einem Haus zugeordnet. Öffnungen zu anderen Innenhofbereichen sind nur in wenigen Fällen vorhanden. Viel mehr ist zu bemerken, dass die Abgrenzung gewünscht ist und durch Sichtschutz, Hecken und Bäume auch innerhalb des Blocks eine Intimität und Uneinsichtigkeit geschaffen wird. Abgrenzungen sind in allen Grazer Innenhöfe zu finden.

Die Vorstellung eines großen Innenhofs, der in Graz oft bis und über einen Hektar groß sein könnte, ist für viele Planerinnen und Planer eine schöne Vorstellung. Großräumige Grünflächen, die alle Möglichkeiten des Verweilens bieten und Kinder großer Wohnblöcke ohne störenden Verkehr miteinander spielen lassen könnten, wären theoretisch anzustreben. Hierfür gibt es in anderen Städten bereits Vorbilder. In Graz jedoch scheint diese Vorstellung aufgrund der Besitzverhältnisse (meist gehört jeder Wohnungsbesitzerin und jedem Wohnungsbesitzer ein ideeller Anteil der Innenhoffläche) und aufgrund der gewünschten Intimität nicht das Ziel zu sein. [15]

5 GEOGRAFISCHE UND KLIMATISCHE GEGEBENHEITEN IM ZUSAMMENHANG MIT GRÜNDERZEITLICHEN INNENHÖFEN

Die Stadtklimakarte von Graz entstand im Zuge der Stadtklimaanalyse. Diese wurde von der Stadt Graz in Auftrag gegeben und vom Institut für Geographie und Raumforschung an der Karl-Franzens-Universität Graz durchgeführt. Die gründerzeitlichen Gebiete der Stadt Graz befinden sich innerhalb der sehr stark bis stark von Überhitzung betroffenen Gebiete. Verantwortlich dafür sind die windarme Tallage von Graz sowie die stark eingeschränkte Durchlüftung aufgrund von dichter Bebauung. Infolgedessen bilden sich hier Wärmeinseln aus. Obwohl sich die Wohnungen der gründerzeitlichen Baublöcke innerhalb der am meisten von Hitze betroffenen Gebieten befinden, weisen diese, wenn sie begrünte Innenhöfe besitzen, laut Stadtklimaanalyse ein bioklimatisch behagliches Wohnklima auf.[16]

Der Begrünungsgrad der gründerzeitlichen Innenhöfe in Graz ist meist recht hoch. Viele der Innenhöfe weisen einen hohen Grad an Wiese und vereinzelten Bäumen auf. Die Nutzung des Innenhofes ist laut Bewohnerinnen und Bewohnerbefragung mit 44 Prozent die den Innenhof "oft" nutzen und 28 Prozent die diesen "selten" nutzen recht hoch. Weitere 28 Prozent geben an, den Innenhof nie zu nutzen. Somit verbleiben 72 Prozent der Befragten die den Innenhof nutzen (Abbildung 3: Nutzung nach Häufigkeit). Als häufigste Nutzung wird das Abstellen von Fahrrädern angegeben (Abbildung 3: Nutzung). Dies lässt sich auch sehr gut über die Begehung und die darauffolgenden Auswertung bestätigen. Fast in jedem Innenhof sind Fahrräder zu finden. Was sich aber durch die Begehung auch gezeigt hat, ist, dass meist ein kleiner Bereich des Innenhofes genutzt wird. So sind Sitzgelegenheiten meist im Bereich zu finden der nicht weiter als zehn Meter von der Blockrandbebauung entfernt ist. Die inneren Bereiche der Innenhöfe sind weitgehend unbenutzt.[17,18]

Abbildung 4,5,6: Eigene Fotografien von gründerzeitlichen Innenhöfen in Graz

So stellt sich unweigerlich die Frage, wie der Innenhof genutzt werden sollte? Wie oben schon eingehend erläutert, ist vor allem die Intimität der Innenhofbereiche eine wichtige Funktion, die diese in Graz erfüllen sollen. Mit Zäunen und Hecken wird innerhalb der Wohnblöcke eine Privatheit geschaffen. Das Verweilen im Innenhof und das Spielen mit Kindern sind weitere wichtige Punkte. Spielgeräte für Kinder findet man

---

[15] Daten von Begehung und Fotoauswertung, durchgeführt von Petra Kubin, Durchführungszeitraum Mai bis Juli 2017

[16] Lazar/Sulzer, S 169, 224-225.

[17] Daten von Begehung und Fotoauswertung, durchgeführt von Petra Kubin, Durchführungszeitraum Mai bis Juli 2017

[18] Bewohnerinnen und Bewohnerbefragung, durchgeführt von Petra Kubin, Durchführungszeitraum Mai 2017 bis Juli 2018

jedoch auch eher wenige. Hier ist der genutzte Bereich auch meist auf den Bereich beschränkt, der 10 Meter von der Hauskante entfernt ist. [19,20]

Grundsätzlich ist die Nutzung der Innenhöfe als Grünfläche ein sehr positives Beispiel für eine Nutzung von Flächen im innerstädtischen Bereich. Wie die Grafik „Ökosystemleistungen von Vegetationsstrukturen" von Grzimek aus dem Buch „Die Grüne Stadt" (Abbildung 7) veranschaulicht, ist das Potenzial an Ökosystemleistungen noch nicht ausgeschöpft. Vergleicht man eine Rasenfläche mit einem Laubwald, wäre der Nutzen für das Ökosystem deutlich höher einzustufen. Die Biomasse des Grünraums würde bei einem Laubwald um das 12-Fache und bei „Intensivem Grün" um das 16-Fache höher sein als bei einer Rasenfläche. Ähnlich sieht es bei der Temperaturminderung, der Schadstoffbindung sowie der Lärmminderung aus. Hieraus ergibt sich die Frage: Welche Möglichkeiten für eine Etablierung eines Waldes gibt es in den gründerzeitlichen Innenhöfen beziehungsweise welche Vorteile würden diese bieten?

		Biomasse Sommer	Biomasse Winter	Biomasse insgesamt	Temperaturminderung	Luftschadstoffbindung	Lärmminderung	Optische Kulissenwirkung
RASEN	häufig geschnitten immergrün hoher Pflegeaufwand	1	1	1	1	1	0	0
ZIER-PFLANZEN	Boden intensiv bearbeitet, keine geschlossene Fläche, im Winter offen	2	0	1	2	2	1	1
PARK	getrennter Wuchs in Bodendecke-, Busch und Baumzone, hoher Pflegeaufwand	13	3	8	12	10	8	6
LAUBWALD	je nach Dichte Strauch- und Bodendeckerschicht	18	6	12	16	14	14	14
INTENSIVES GRÜN	Intensiver Wuchs in drei Schichten, Biomasse Sommer	20	12	16	18	20	20	20

Abbildung 7: Ökosystemleistungen von Vegetationsstrukturen (gekürzt)[21]

5.1 Begriffsdefinitionen für urbane Flächen mit Baumbestand

Es gibt viele Arten und Bezeichnungen von urbanen Flächen mit Baumbestand. Unter „Urban Forest" versteht man urbane Baumbestände, die unabhängig von ihren Eigentümern als „Ressource" und insgesamt als Anbieter von Ökoleistungen agieren und von denen Stadtbewohner profitieren. Dies schließt alle urbanen Gehölzbestände und Wälder ebenso ein, wie alle Bäume im öffentlichen und privaten Besitz. Als „Urbane Wälder" hingegen bezeichnet man überwiegend Waldrelikte, die durch natürliche Sukzession und durch Pflanzung in Städten entstanden sind. Sie verfügen über ein eigenes Waldklima in dem spezielle Lebensraumbedingungen entstehen. Laut Leser 2008 und Dietrich 2013 müssen sie mindestens 0,5 Hektar groß sein. Burkhardt hingegen gib die Mindestgröße mit 0,3 Hektar an jedoch müssen sie einen Mindestdurchmesser von 50 Metern aufweisen. Sie können im öffentlichen oder auch privaten Eigentum sein und müssen in der Regel öffentlich zugänglich sein. Nach Kowarik sind Stadtwälder entweder angepflanzte oder ursprünglich natürlich entwickelte standortgerechte Gehölzkombinationen. [22]

Aus einem Projekt der Universität Potsdam, dem Bezirksverband Berlin –Süden der Kleingärten e.V., dem Freilandlabor Britz e.V und dem Umwelt- und Gartenamt der Stadt Kassel, das im April 2021 gestartet wurde, ist der Name „Urbane Waldgärten" hervorgegangen. Ein urbaner Waldgarten besteht vorwiegend aus essbaren Pflanzen wie Obst- und Nussbäumen, Beerensträucher sowie Gemüsen und Kräutern, die langfristig miteinander angebaut und geerntet werden können. Es soll die Bodenfruchtbarkeit aufbauen und erhalten und so ein klimaangepasstes Anbausystem mit hoher Artenvielfalt gewährleisten. [23]

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Eine besondere Art des „Urban Forest" stellt der „Tiny Forest" dar. Das Tiny Forest Konzept basiert auf der Restaurierungsarbeit für Brachflächen des japanischen Försters Akira Miyawaki aus den 1970er-Jahren.[24] Ein „Tiny Forest" kann schon ab einer Größe von 0,01 bis 0,04 Hektar Fläche entstehen. Das besondere am Konzept ist, dass auf kleinstem Raum eine Maximierung der Vegetationsstruktur und der Artenvielfalt geschaffen wird. Hierfür werden die Bodenverhältnisse durch gezieltes Zuführen von natürlichen Materialien verbessert. Durch eine extrem dichte Bepflanzung von verschiedenen heimischen Gehölzen wird das Wachstum so stark angeregt, dass schon in kurzer Zeit ein dichter Wald entsteht. So können vor allem auch Brachflächen in grüne Inseln verwandelt werden. Wichtig ist die Einbindung von Anwohnern in die Planung, Umsetzung und Pflege der Wälder, um sicherzustellen, dass auch alle Wünsche und Bedürfnisse für die Gestaltung und Funktionen der städtischen Grünfläche berücksichtigt werden. Der Wissenschaftsingenieur Shubhendu Scharma hat die Methode in seinem Öko – Unternehmen umgesetzt und weiter in die Öffentlichkeit gestellt. So kann man das Konzept der Umsetzung eines „Tiny Forest" über YouTube Videos in einem DIY-Kurs erlernen.[25] [26]

6 ANWENDUNG EINES „URBAN FOREST" KONZEPTES AUF DEN GRÜNDERZEITLICHEN INNENHOF VON GRAZ

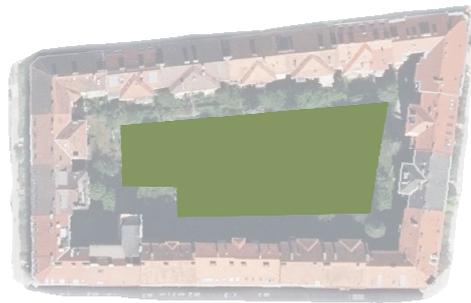
Die Innenhöfe der 131 gründerzeitlichen Baublöcke, welche im Zuge der oben genannten Dissertation bearbeitet wurden, stellen eine Gesamtfläche von etwa 80 Hektar dar. Einzelne Innenhöfe sind unterschiedlich groß, der kleinste Innenhof hat eine Größe von 0,073 Hektar und der größte ist 2,2 Hektar groß. Im Durchschnitt liegt die Größe der erfassten gründerzeitlichen Innenhöfe 0,6 Hektar. Durch die unterschiedlichen Gegebenheiten ist es natürlich schwierig ein gemeinsames Konzept für eine Innenhofbewaldung zu erstellen. Die Mindestgröße eines „Urbanen Waldes" von 0,5 Hektar wird nicht von allen Innenhöfen erreicht. Die Mindestfläche für einen „Tiny Forest" von 0,01 bis 0,04 Hektar jedoch ist bei jedem der bearbeiteten Innenhöfe gegeben.


Abbildung 8: Gründerzeitlicher Innenhof in Graz mit möglicher intensiv begrünter Fläche[27]

Hier kann jedoch nicht die gesamte Fläche, die den Innenhof definiert, mit Bäumen bepflanzt werden, da ein gewisser Abstand zu den Gebäuden bestehen bleiben muss. So könnte der Ansatz zwischen intensiv mit Bäumen begrünter Fläche und Gebäude in Anlehnung an die im steiermärkischen Baugesetz vorgeschriebenen Mindestabstände von Häusern liegen.[28,29] Bei den meist drei geschossigen Gründerzeitbebauungen sowie den 10 bis 20 Meter hohen Bäumen würde sich daraus ein ungefährer Abstand von 10 Metern ergeben. Dies ist auch in dem Bereich, der laut Begehung am intensivsten von den Bewohnerinnen und Bewohnern genutzt wird. Hier ergeben sich je nach Größe des Innenhofes unterschiedliche Flächen, welche bepflanzt werden könnten. Im vorliegenden Beispiel handelt es sich um einen Innenhof mit 0,66 Hektar Fläche, welcher mit 10 Metern Abstand zu den Gebäuden eine Fläche von

[28] (1) Gebäude sind entweder unmittelbar aneinander zu bauen oder müssen voneinander einen ausreichenden Abstand haben. Werden zwei Gebäude nicht unmittelbar aneinadergebaut, muß ihr Abstand mindestens so viele Meter betrgen, wie die Summe der beidseitigen Geschoßzahl, vermehr um 4, ergibt (Gebäudeabstand)

[29] RIS

0,3 Hektar erreicht. Innerhalb dieser 0,3 Hektar Fläche (Abbildung 8, grüne Fläche) könnte eine intensive Bepflanzung stattfinden.[30]

Da die Innenhofbereiche der Grazer gründerzeitlichen Innenhöfe meist sehr viele Besitzerinnen und Besitzer haben, und jeder Wohnungseignerin bzw. jedem Wohnungseigner gehört meistens ein Anteil des Haushofes, ist es von großer Bedeutung, die Wichtigkeit von intensiver Bepflanzung mit Bäumen für die Besitzerinnen und Besitzer sichtbar zu machen. Hierfür kann das dreistufige Verfahren, das von der TEEB DE 2016 entwickelt wurde, herangezogen werden, um ökonomische Perspektiven auf die Stadtnatur zu schaffen. Als erster Schritt wird die Identifizierung und Anerkennung genannt. Besitzerinnen und Besitzern die ihren Innenhof als Möglichkeit der Verbesserung des Stadtklimas akzeptieren und auch als dieses wertschätzen werden bei einem Projekt zur Umsetzung eines intensiv bewachsenen Waldes in ihrer unmittelbaren Wohnungsumgebung und in ihrem Besitzt eher zustimmen bzw. daran mitarbeiten als Bewohnerinnen und Bewohner die nicht im Projekt involviert sind. Dies stimmt auch mit den Grundsätzen des „Tiny Forest" überein, die auch die Einbindung der Anwohnerinnen und Anwohner als sehr wichtig ansehen. Als zweiter Punkt wird das Erfassen und das Bewerten von Stadtnatur hervorgehoben. Hier soll der Wert der neu geschaffenen Stadtnatur herausgestellt werden. Hierfür eignet sich die Grafik der Ökosystemleistungen (siehe Abbildung 7). „Urbane Ökosystemleistungen bezeichnen Leistungen, die von Stadtnatur erbracht und von Menschen genutzt werden. Sie basieren auf ökologischen Funktionen, von denen Menschen aktiv oder passiv einen direkten Nutzen für ihr Wohlbefinden haben."[31] Positive Aspekte wie Temperaturminderung, Luftschadstoffminderung, Lärmminderung und auch die optische Wirkung als Kulisse können als solch ein Wert definiert werden. Der dritte Punkt ist die Berücksichtigung von Werten in Entscheidungen. Demnach müssen Ökosystemleistungen als Wert betrachtet werden. Maßnahmen für die Entstehung einer Stadtnatur stehen somit in direktem Zusammenhang mit einem höheren Kapital und können so als Instrumente zur Generierung dieses Kapitals herangezogen werden. Hier wird ein wirtschaftlicher Zugang geschaffen, um durch Mehrwerte zu überzeugen.[32]

6.1 „Tiny Forest"

Der Vorteil des „Tiny Forest" liegt vor allem im schnellen Wachstum der Pflanzen und in der hohen Biodiversität, die dadurch erreicht werden kann. Die mehrschichtige Art der Begrünung gewährleistet einen sehr dichten, aber auch unbegehbaren Wald. Es können zwar Wege durch den Wald geschaffen werden, jedoch ist diese Durchwegung mit den vorherrschenden Besitzverhältnissen innerhalb der Baublöcke nur schwer zu realisieren. Ein weiterer Faktor, der berücksichtigt werden muss, ist der Aufwand, der für die Durchführung eines „Tiny Forest" entsteht. Bodenschichten müssen angereichert und somit umgegraben werden. Bestehende Zäune können oft nicht bestehen bleiben da, diese eine Anlegung erschweren würden. Die Privatheit, die von den meisten Grazer Bewohnerinnen und Bewohner so geschätzt wird, würde für bis zu drei Jahre gestört sein. Weiters ist eine Pflege der bepflanzten Fläche in den ersten Jahren notwendig. Hierfür müssten Freiwillige, die vor Ort sind, gefunden werden. Das Projekt, das durch die Entwicklung eines „Tiny Forest" entsteht, würde aber auch die Stärkung des sozialen Gefüges innerhalb der Blockgemeinschaft anstoßen. Alle können mitarbeiten und sind Teil eines Projektes das einen Mehrwert für ihre Wohnungsumgebung schafft.[33]

6.2 Waldinsel

„Urban Forest" hingegen ist nicht genau definiert und kann durch jeden zusätzlichen Baumbestand erreicht werden. Hierfür wurde in diesem Paper die Bezeichnung Waldinsel gewählt. Hiermit sind stark bepflanzte Bereiche innerhalb der Blockrandbebauung gemeint. Die Innenhofgemeinschaft, die sich aus allen Akteuren, die Teile des Innenhofes besitzen oder bewohnen, zusammensetzt, kann beschließen, ihren Teil des Innenhofblocks intensiv und mehrschichtig mit heimischen Gehölzern zu begrünen. Um daraus ein Projekt entstehen zu lassen, welches viele Innenhofbesitzer motiviert, sich anzuschließen, müsste ein Leitfaden mit Best-Pracis-Beispielen erstellt werden. Hierfür gibt es schon einige Anregungen, wie zum Beispiel das oben

erwähnte Projekt „Urbane Waldgärten".[34] Welche Baumarten sich besonders eignen, kann über verschiedene Informationsbroschüren ermittelt werden, die von der Bayrischen Landesanstalt für Wein und Gartenbau erarbeitet wurden und über deren Homepage öffentlich zugänglich sind. Im Zuge des Forschungsprojektes Stadtgrün 2021+ wurden klimafite Stadtbaumarten zusammengestellt und aufgelistet.[35] Diese strategisch durchdachte, intensive, mehrschichtige Begrünung durch heimische Gehölze und Laubbäume könnte im kleinen Maßstab, also in einzelnen Innenhofbereiche oder auch auf einen ganzen Block angewendet werden. So müssten die von den Grazer Bewohnerinnen und Bewohnern geschätzten Abgrenzungen zum gesamten Block nicht entfernt werden. Der Boden müsste meistens nicht aufgebessert werden, da eine nicht so dichte Bepflanzung wie beim „Tiny Forest" angestrebt wird. Wenn ausreichend große Flächen zur Verfügung stehen, könnten Waldinseln ebenfalls begehbar sein, ähnlich wie Wälder. Eine Waldinsel im Innenhof des Wohnhauses könnte auch Kindern als natürlicher Spielplatz dienen.

7 CONCLUSION

Um den städtischen Wärmeinseleffekt zu verringern, ist intensive Begrünung mit mehrschichtiger Bepflanzung von heimischem Gehölz und Laubbäumen in diesen Gebieten von besonderer Bedeutung. Solche Waldinseln könnten innerhalb der Grazer Blockrandbebauung entstehen. Sie hätten nicht nur einen wichtigen Effekt auf die Temperaturregulierung in den heißen Sommermonaten, sondern könnten auch anderen Problemen im städtischen Bereich entgegenwirken. Angesichts der zunehmenden Wetterextreme aufgrund der Klimaerwärmung ist die lokale Wasserversickerung von besonderer Bedeutung. Bei Starkregen ist es oft unmöglich für das städtische Kanalsystem, die Wassermassen aufzunehmen. Waldinseln könnten einen erheblichen Anteil des Wassers vor Ort aufnehmen. Eine weitere wichtige Funktion besteht darin, zur Luftreinigung beizutragen und den CO_2-Ausgleich zu unterstützen. Graz könnte weiters von einer Reduzierung der Feinstaubbelastung profitieren Die Lärmbelastung im Innenhof sollte ebenfalls nicht unterschätzt werden. Im Vergleich zu einer Wiese kann intensive Begrünung eine um das 20-fache reduzierte Lärmbelastung gewährleisten.[36]

Die gemeinsame Entscheidungsfindung und Nutzung einer Waldinsel kann einen neuen sozialen Wert schaffen. Gemeinsame Tierbeobachtungen, Spielen im Wald und Entspannen in bewaldeten Bereichen tragen zum physischen und psychischen Wohlbefinden bei.[37] Für ältere Bewohnerinnen und Bewohner wäre eine im Innenhof gelegene Waldinsel aufgrund der kurzen Erreichbarkeit und der angenehmeren Temperaturen besonders wertvoll.[38] All diese Aspekte können herangezogen werden, um die ökologischen Leistungen von vegetativen Strukturen zu bewerten und auch wirtschaftlich darzustellen, um die Bedeutung solcher Maßnahmen verständlich zu machen.[39]

1 ABSTRACT

Transport is responsible for 30% of Austria's CO_2 emissions. Of these, 17.13% are caused by passenger cars. Car traffic (kilometres driven) has increased significantly in recent years, while at the same time, the occupancy rate is continuously decreasing and is currently only 1.15 persons per car in Austria. Due to the traffic load and the associated negative environmental impacts, there is a great need to increase the occupancy rate in passenger cars. The shared mobility concept of carpooling offers starting points to counteract this trend. In this context, carpooling in particular shows great potential for reducing the volume of traffic. Carpooling reduces emissions and lowers the risk of accidents, and an improvement of occupancy rate of cars can reduce traffic by up to 10%. However, the "critical mass" of carpooling platforms is often not reached and there is a lack of adequate advertising and communication measures. Traditional advertising channels such as print rarely reach the entire target group in the shared mobility sector and digital advertising channels miss internet-averse target groups who hardly use social media.

This article is therefore dedicated to the evaluation of an advertising campaign that aims to increase awareness and acceptance of the accelerated use and market penetration of carpooling offers. By means of a digital display placed at the side of the road, attention was drawn to the degree of occupancy by means of various statements - with the aim of triggering a rethink in the direction of carpooling. Based on a preliminary survey, the perception and acceptance were surveyed using feedback from passers-by and app users. The main finding is that many car drivers noticed the display and rated it as positive. Ultimately, however, only a small number of people could be motivated to use carpooling or to give other people a ride. The main barriers to use carpooling are the lack of schedule flexibility, reliability of passengers and loss of time.

Keywords: signage, ridesharing, carpooling, awareness, Occupancy rate

2 BACKGROUND AND STATE-OF-THE-ART

The occupancy rate in Austrian vehicles is 1.15% (VCÖ 2017). In other words, most people drive predominantly alone, leading to resource consumption, increased traffic, environmental pollution, and an inefficient use of transport systems. At the same time, this low utilization represents a great potential (Mühlethaler et al 2011). Ridesharing and carpooling, as part of shared mobility, are promising concepts that can counteract the low utilization of passenger cars and the associated consequences. Both terms are often used synonymously, but important distinctions exist (see 2.1.). What they have in common is that by pooling routes, several people can share one vehicle. This is often based on mobile solutions that facilitate booking and payment for the drivers. Both concepts still have an awareness and image problem, for which there are various approaches to raising awareness.

2.1 Carpooling and ridesharing as sustainable transport modes

Carpooling and ridesharing are promising tools when it comes to sustainable mobility. Carpooling involves a group of individuals sharing a single vehicle to travel together, usually for a regular commute or a specific trip. Typically, the passengers and the driver know each other, are part of the same organization or community, or are matched through a digital platform (Shaheen 2018). Ridesharing involves connecting individuals seeking transportation with drivers through a digital platform or mobile application. The drivers provide transportation services in their own vehicles for a fee, and passengers are typically strangers to the driver. Uber is often mentioned as a Ridesharing service from the American perspective (Wallsten 2018). This primarily serves as an on-demand transportation service, allowing individuals to request rides as needed. In this article, ridesharing is referred to as a shared trip transportation option rather than an on-demand transportation service. In contrast to carpooling, ridesharing represents a transportation option for

spontaneous trips (Furuhata et. al. 2013). Especially in rural communities, carpooling and ridesharing offer great potentials and until now, it has been considered as a supplement to public transport, which is still insufficiently established. However, there are "many influencing factors to consider - local and temporal distributions of demand, specific trip requirements, and attitudes of potential participants toward car pooling" (Mühlethaler et al 2011).

2.2 Mobile Solutions

Ridesharing and carpooling depend predominantly on mobile solutions which organize the communication and connection between the users (someone offering a ride and someone requesting a ride). Today, numerous online platforms exist in Austria for the organized networking of unknown persons (e.g. BlaBlaCar, Mitfahrgelegenheit.at, mitfahrzentrale.at). It is striking that the ride offers on these intermediary platforms are primarily limited to longer distances (usually several hundred kilometres). Pave Commute for example, offers a white-label solution for employers to connect employees, using commuting time wisely and reducing CO_2 emissions. Pave Commute focuses on B2B use and is mainly used by employees of medium-sized and large companies (Pave Commute 2023).

2.3 Signage as a nudging mechanism?

There are different possible ways to motivate commuters toward a more sustainable behaviour. "Nudging" is one way to change behaviour and refers to influencing the behaviour of an individual without monetary incentives (Thaler & Sunstein 2008). In road traffic for example, nudging is well known in the form of visual speed feedback. A study showed that displays that communicated verbal feedback such as "thank you" or "slow down" were more effective than those with a pure speed display (Schulze & Gehlert 2010). In terms of occupancy levels, there are defined carpooling lanes in the US, which are reserved for the exclusive use of vehicles with a driver with one or more passengers (Javid at al 2018). In the field of mobility sharing, there are only very few empirical studies in the context of nudging and these tend to be applied in the "offline" world (Dörrzapf at al. 2019, Namazu et al., 2018).

In this project, nudging is thus understood as "soft" measures that influence people in their decision-making and behaviour, whereby it is crucial that freedom of choice is always enabled. Nudging in this case is linked with digital signage and positive reinforcement. This project is the first to apply this principle to the occupancy rate of cars. The combination of individual feedback from the roadside in combination with the promotion of alternative mobility solutions has not yet been scientifically evaluated in such a form. If it is effective enough, it can create a completely new communication channel for environmentally friendly mobility, which will bring new momentum to the transport transition.

3 METHODOLOGY

3.1 Goals and settings

The project aimed to foster ridesharing and carpooling through the app Pave Commute as an innovative, user-friendly solution. Furthermore, the awareness and acceptance of commuters for ridesharing and carpooling should be increased in the test area by implementing an "awareness campaign". The other component is the hardware: a digital display, which provides feedback on the occupancy rate of a passing car to the commuter themself.

3.1.1 Software

As part of this project, the app was opened up and made available to all citizens of Amstetten for free use. In the course of the technical onboarding the Amstetten ride-sharing platform was created in the app, which was accessible in just a few steps and gave app users the certainty that local carpools with people from the region were in the foreground. Data collection and processing of user requests during the awareness campaign were also prepared.

3.1.2 Hardware

In this research project, the prototype of an innovative street installation was used to carry out the awareness campaign. The survey of the respective occupancy rate of passing cars was carried out on site by a team using a manually operated input device (Windows tablet with specially programmed interface), as is still

392

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

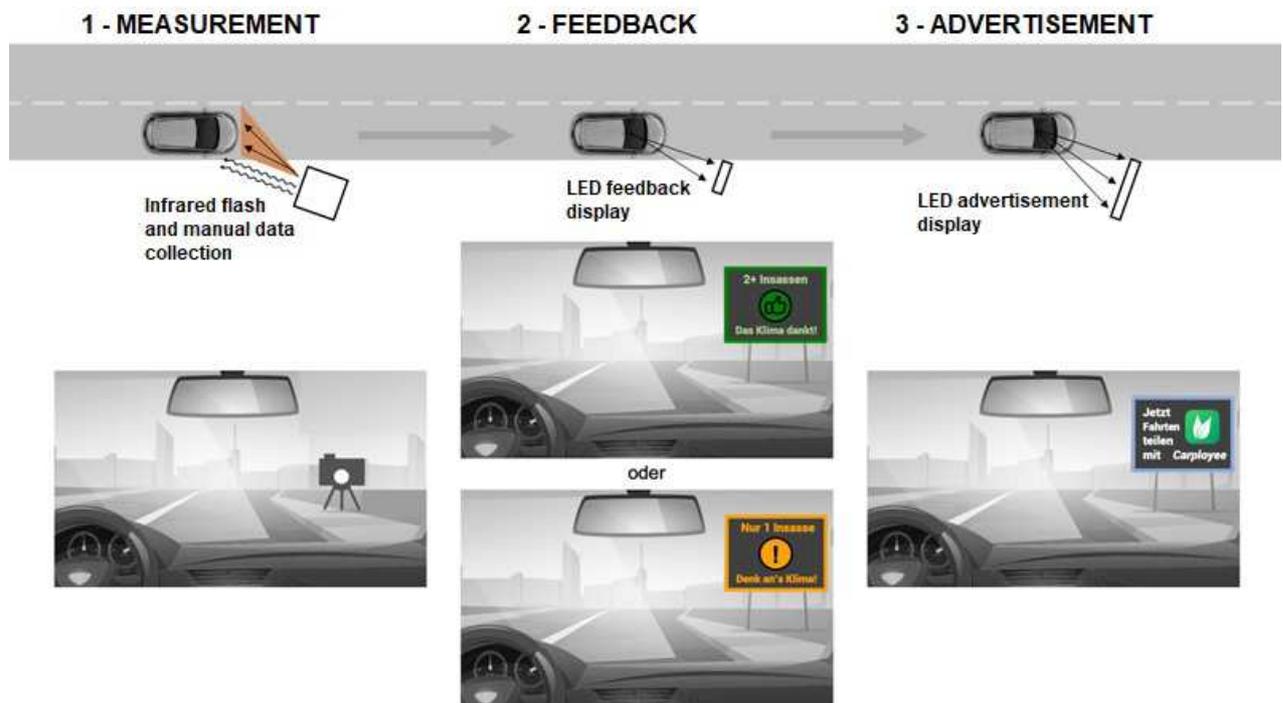
used in many places for occupancy rate surveys. This input device in combination with two specially assembled feedback displays resulted in the prototype of Carpacity. With the help of a streetscape installation, "praise" and "thanks" were presented to the drivers. However, gentle feedback should also encourage solo commuters to reconsider other means of transport (see Figure 1).


Fig. 1: Streetscape installation as digital signage (source project "Happy smileys for full cars")

3.2 Methods

3.2.1 Preliminary Questionnaire

	Group 1	Group 2	German average
Age			
0-20	2,4%	4%	18,8%
21-40	56%	55,9%	24,5%
41-60	35,2%	32,7%	27,3%
61-80	6,4%	7,1%	22,2%
81+	0%	0,3%	7,2%
Gender			
Male	60,8%	67,2%	49,3
Female	38,9%	32,8%	50,7
Other	0,3%	0%	n/a
Highest level of education			
Apprenticeship	14,9%	14%	46,6%
Middle school	8,8%	14,4%	23,5%
Matriculation/Secondary education	27,4%	26,8%	33,5%
Higher education	**46,9%**	**42,1%**	18,5%

Table 1: Comparison of the two sample groups to the German average. Source: Statistisches Bundesamt, 2019; 2022

Data collection throughout the project took place through four main channels. During the project, a preliminary online survey to generally assess perceptions and attitudes of individual occupancy level feedback LED displays were incorporated into the design of the experiment. The questionnaire collected socio-demographic characteristics, patterns of mobility behaviour, but most importantly participants were asked to imagine themselves experiencing the awareness campaign. This was "simulated" by a picture story. In the simulation, group one (N=296) was driving by a feedback display that slightly criticised their low rate of car occupancy before passing by the PAVE Commute ridesharing advertisement. Group two (N=299) did not pass by a feedback display at all before passing the advertisement. Subsequently, participants were asked

about their perception of the campaign, their attitudes towards carpooling in general and their openness to using the PAVE app.

A total of 595 Participants were recruited using the Clickworker platform. As 91,7% of the respondents currently reside in Germany, participant representativeness will be compared to the German average. Despite slight differences in middle school respondents, a certain degree of comparability is achieved between the two groups (see Table 1). Compared to the German average, the sample significantly overrepresents younger and highly educated men. The findings therefore represent a specific sub-group and cannot be generalised to the broader German population.

3.2.2 Awareness campaign

The main experiment revolved around the 6-week awareness campaign consisting of a station where oncoming traffic was manually analysed with regards to the rate of occupancy by trained staff, during peak hours in the morning (primarily from 6:00 to 9:00) and the afternoon (primarily from 14:30 to 17:00). All entries were made using a tablet, which stored the data in real time and forwarded it to the feedback displays 30 meters further down the street, thereby allowing for personalised feedback to be created.

Two LED displays were installed 150 meters apart on the busy B1 street entering Amstetten from the east (see Figure 2). The first display either provided positive feedback to vehicles occupied by two or more people or nudged vehicles with only one passenger with slightly negative feedback. All passing vehicles would see an advertisement for PAVE Commute, an app to organise carpooling and ridesharing on the second display.

Fig. 2: Location of the pilot project on the B1-Reichstraße at the eastern entrance of Amstetten and view of the green strip where the feedback displays would later be implemented (source project "Happy smileys for full cars")

The exact slogans of the feedback and advertising displays as well as other measures to further carpooling practices were discussed at a workshop and information event with local stakeholders. It was decided that displays with a local reference, for example "Amstetten says thank you" and emphasis on the cost-saving potential of carpooling were preferred.

Fig. 3: Two positive feedback signs, two negative feedback signs and two advertisements used during the awareness campaign (source project "Happy smileys for full cars")

Parallel to the implementation of the pilot project, an online survey recording the perception and impact of the installation was conducted with participants in Amstetten. A total of 77 responses were collected, 26 of which had passed the installation. Participants were recruited by means of social media, billboards, e-mails and personal contact. Due to the relatively small sample size, the main focus of the questionnaire lies in its

394

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

qualitative elements, where participants were able to write detailed accounts of their experience and perception regarding the installation.

3.2.3 Traffic counts

As part of the awareness campaign, the vehicles that passed the displays were also counted and classified by means of a visual inspection of the trained staff. This was done using a simplified classification tool allowing categorisation into the following: buses, larger and smaller trucks, vans, cars, cars with trailers, motorcycles, bicycles and non-classified vehicles. Likewise, the rate of occupancy for each vehicle was recorded. Each data entry also included a timestamp with the day of the week, date and time when the entry was made.

3.2.4 Smartphone app user data

Being able to utilise the project partner's data from the PAVE Commute app, further analysis could be conducted on the user-data in Amstetten. Most importantly, this included data such as the number of app downloads in the region, the number of completed onboardings, new carpooling groups created, tracked commutes. Utilising user data was a key parameter allowing to evaluate the success of the awareness campaign.

3.3 Data Analysis

A mixed-method approach was employed throughout the data analysis process. Statistical analysis of the two groups was used to analyse and compare findings in the preliminary questionnaire. Likewise, with the data regarding the number of vehicles, vehicle classification, rate of occupancy. The written replies within the awareness campaign survey highlighting participants' perception and impact of the feedback displays were assessed using qualitative content analysis.

To illustrate the potential for work-related carpooling beyond the app, 35 home and workplace locations collected in the awareness campaign questionnaire were utilised using georeferencing to create a network analysis of potential commuting routes in Amstetten. The commuting routes reflect the fastest connection between home and workplace and may therefore not reflect actual routes.

4 FINDINGS

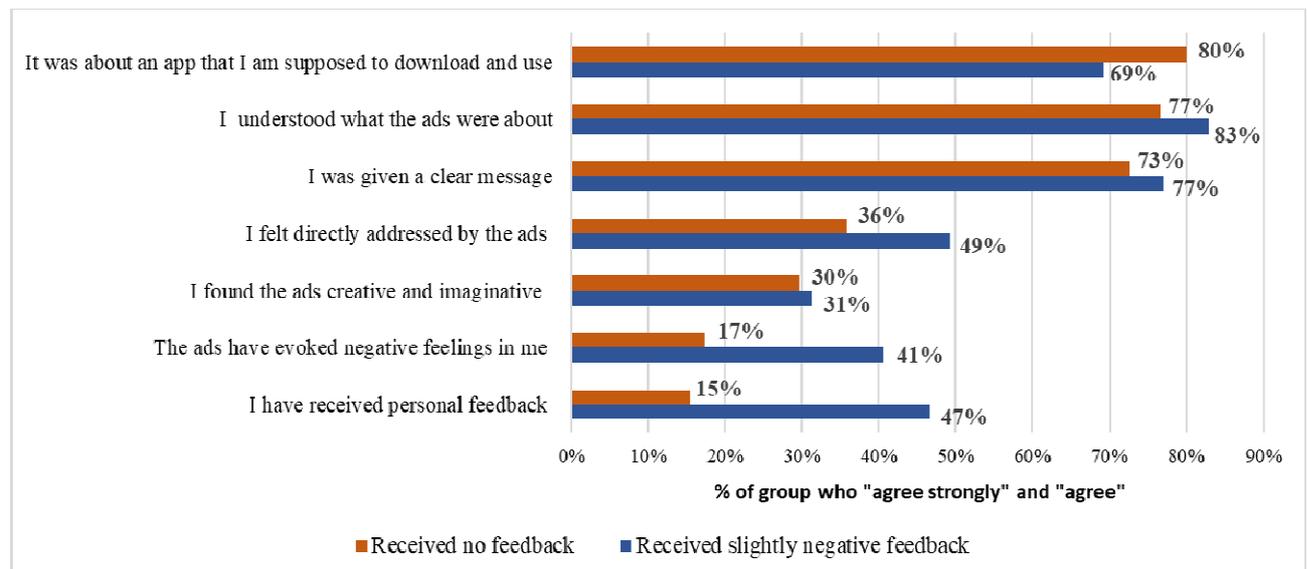
4.1 The role of individual feedback displays in shaping car-occupancy levels


Fig. 4: Experience of simulated feedback and advertisement displays (N=595)

As part of the preliminary questionnaire, 595 participants from outside of Amstetten underwent an image guided simulation of passing the LED feedback displays. Group 1 (N=296) received slightly negative feedback before passing the advertisement whilst group 2 (N=299) did not receive any feedback at all before passing the advertisement. Comparing different perceptions of the simulated experience (see Figure 4), both groups emphasised that they had understood the feedback and advertisement displays and characterised them

as providing a clear message about downloading and using a carpooling app. Many more participants who received feedback felt addressed more directly (49%) than those who just saw the advert (36%) and felt more personally addressed. At the same time, those who received slightly negative feedback were more often experiencing negative feelings (41%) compared to those who did not (17%). It can therefore be said that feedback displays provide an opportunity to directly and personally address drivers whilst also carrying the risk of evoking negative emotions.

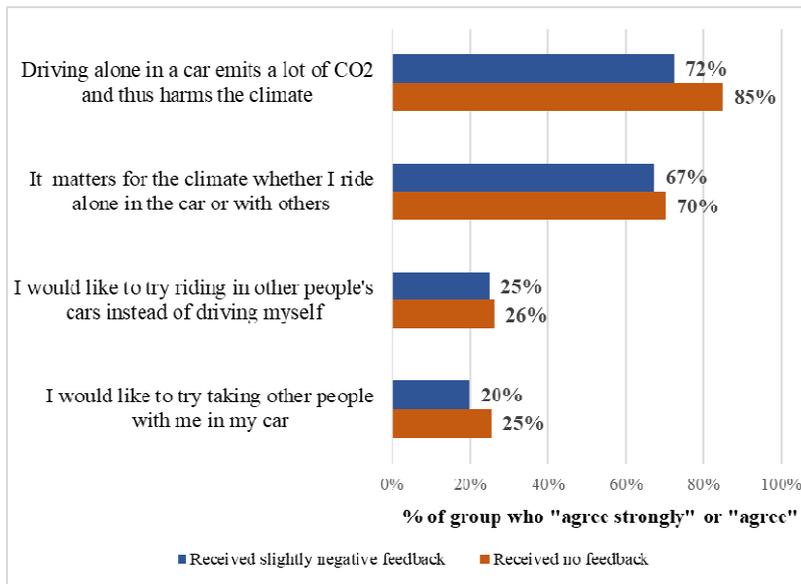
In addition, the survey aims to illuminate the potential of the simulated nudging experience on attitudes of carpooling and openness to utilise the advertised smartphone application. Regarding attitudes of carpooling (see Figure 5), participants who have received slightly negative feedback within their simulation showed more negative attitudes towards carpooling. Accordingly, whilst they were equally open to riding in other people's cars, they were less open to taking other people with them (20%) compared to those who have not received feedback (25%). Likewise, those who did not receive feedback agreed more strongly on the importance of not driving by themselves for environmental reasons (85%) than those who received slightly negative feedback (72%).


Fig. 5: Attitudes towards carpooling (N=595)

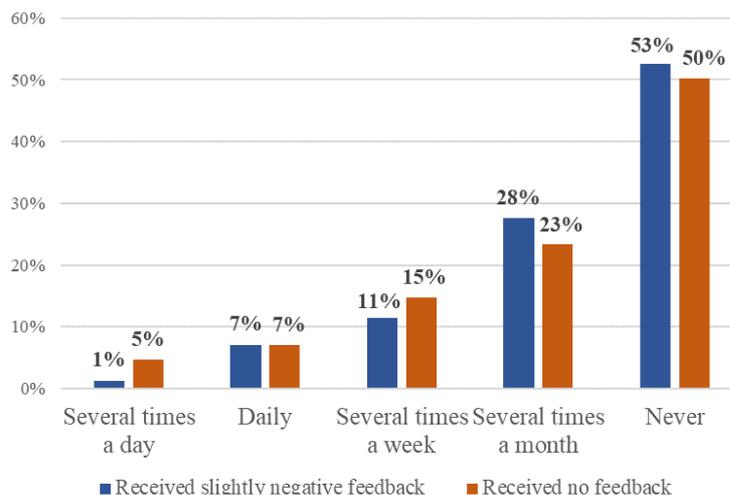
Similarly, with the openness to using the carpooling app, participants who have received slightly negative feedback in the simulation were generally less open to use the PAVE Commute app to organise carpooling both as a driver (see Figure 6) and as a passenger. Accordingly, only 19% of participants who had received feedback could imagine themselves commuting with the PAVE app several times a day, daily or several times a week as a driver compared to 27% of those who had not received feedback.


Fig. 6: Openness to using the PAVE Commute app to share car trips as a driver (N=595)

Likewise, only 20% of participants who had received feedback could imagine using the PAVE app to commute as a passenger several times a day, daily or several times a week compared to 24% of those who did not receive any feedback. Generally, willingness to commute as a passenger was higher than to be a driver. Whereas an average of 48,5% across both groups were open to driving others, an average of 52% could imagine themselves as carpooling passengers. This echoes data from the US, where the rate of people who wanted to be a passenger was generally higher, primarily for people who did not own a car themselves (Park et al., 2018). This pattern continues when it comes to expressed motivations of testing the carpooling app. Overall, only 18% of participants who had received feedback on their car occupancy expressed feeling strongly motivated or motivated compared to 29% of those who had not seen feedback.

4.2 Factors shaping vehicle occupancy rates in Amstetten

Throughout the process of the awareness campaign, the number and type of passing vehicle and the number of occupants within the vehicle were counted by trained personnel. The timeframe of data collection included workdays (Mondays to Fridays) from the 4.10.2022 to the 20.10.2022. In general, findings from the project indicate an average annual daily rate of traffic of 15.000 vehicles. This contrasts with earlier automated counts on Amstetten's B1 in 2019, which have arrived at an annual average daily rate of 13.000 vehicles (NOE, 2020). As emphasised in Figure 7, traffic peaks of up to 850 vehicles per hour occurred between 6:40 and 7:00 am. Isolated peaks may be explained in reference to shift changes in the surrounding industrial area

Throughout the recorded timeframe, the vast majority of recorded trips were made with cars occupied by only one occupant. Other modes of transportation such as bicycles, buses or motorcycles play a negligible role in the traffic volume. Considering the split of vehicle types recorded throughout the experimentation phase, cars made up 84% of the traffic. Amongst the cars recorded, 77,5% were occupied by a single person. Likewise, amongst the local participants from Amstetten who participated in the main questionnaire (N=77), 93,5% reported work as their primary reason to commute. This and the large share of single-occupancy rides reflects the continuing potential for carpooling as a means to reduce individual transport, especially for work trips.

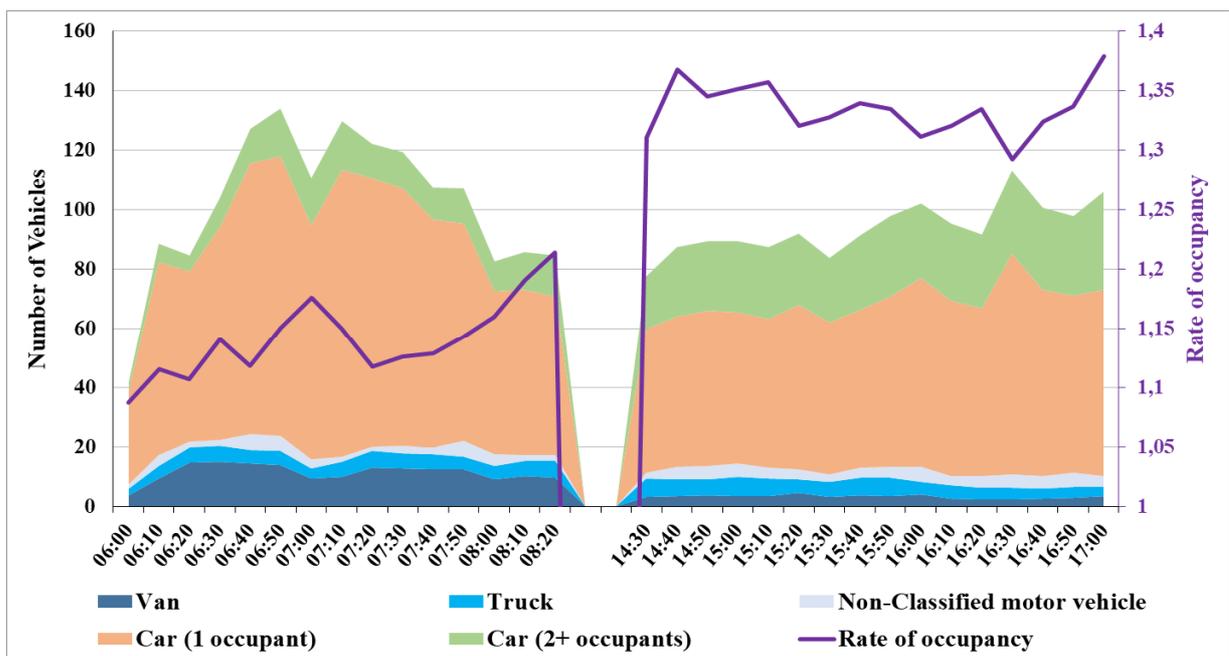
Whereas car trips with only one occupant were especially dominant throughout the morning hours, a clear increase in the number of car trips with two or more occupants can be observed in the afternoon, when cars were occupied by an average of 1,3 to 1,35 people. Especially in light of the high volume of morning traffic, car occupancy rates in these hours remained between 1,15 and 1,2 individuals per vehicle. Findings from Amstetten are thereby generally slightly below the Austrian average of 1,3 for all trips and especially for the rate of 1,7 for recreational traffic (Österreich Unterwegs, 2013/14).


Fig. 7: Average daily rate of traffic as per type of vehicle and rate of occupancy 4.10.2022 - 20.10.2022

The highest traffic flow of 120 cars per 10 minutes between 6:40 and 7:30 only shows a rate of occupancy of 1,1 to 1,17 people per car. This could be explained by the high volume of single-person workplace traffic in the morning in contrast to more recreational traffic in the late afternoon and evening. To illuminate other factors shaping the rate of occupancy, weekdays have been considered. In this context, the rate of occupancy has been examined during traffic peak hours. Only minor variations in vehicle occupancy from 1,12 on Tuesdays to 1,15 on Mondays can be observed at the first peak of the day from 07:00 to 08:00 in the morning. In contrast, occupancy rates during the second peak from 15:00 to 16:00 remain at stable levels between 1,32 and 1,34 from Monday to Thursday but rise significantly to 1,39 on Friday afternoons, thereby echoing existing findings highlighting the correlation between occupancy rates and recreational traffic on weekends (Rapp et al. 2001).

4.3 The impact and perception of Amstetten's nudging awareness campaign

Amongst the survey respondents in and near Amstetten (N=77), a general inquiry of carpooling perceptions has been conducted. Accordingly, most respondents had a positive (18,2%) or rather positive (26%) rather than negative (7,8%) or rather negative (16,9%) perception of carpooling. The largest group, however, has expressed neutral views (31,2%) towards carpooling. Elaborating on their response through an open question, participants have especially highlighted the financial and ecological benefits of carpooling. On the other hand, lack of flexibility, dependency on others as well as discomfort of travelling with strangers were amongst the key disadvantages that have been named. Potential drivers have highlighted the barrier of being responsible for their passengers. Potential passengers on the other hand occasionally referred to the lack of knowledge of the driver's driving style as a negative factor. Some participants have thus referred to carpooling as "saving money, stress free" but also negatively in terms of the "lack of punctuality of passengers" or "feeling not comfortable carpooling with strangers". Whereas the findings further illustrate the potential of carpooling as a means of contributing to more sustainable patterns of mobility, there is an ongoing need for social or technological innovation to overcome some of its inherent limitations.

Building on the rather positive perception of carpooling, the experiment has explored the potential of LED displays to improve car occupancy levels by nudging single occupant cars with slightly negative feedback whilst providing positive feedback to cars occupied by two or more people coupled with creating awareness for a carpooling app. Quantitative analysis of responses to the nudging signs is limited in terms of the low number of participants who have filled in the main survey and also passed the signs (N=26). Of those who have passed and read the nudging display, open text replies in the questionnaire have provided mixed feedback. Overall, 48% of the qualitative responses were positive, 26% negative and 26% neutral. This was partly based on the display being perceived as unnecessary and overly intrusive. Accordingly, participants emphasised how they "had a guilty conscience because I was driving alone, but at the same time were a bit annoyed, because I can't take anyone with me". Others have highlighted, that the displays were "prompting but not encroaching" has provided a thought-provoking impulse, since they "always go to work alone".

Feedback towards the advertisement display were much more negatively amongst the participants in Amstetten who had passed it (N=26). In total, 63% of the qualitative responses were negative, 31% positive and 6% neutral. Consequently, whilst some referred to the advertisement as evoking positive connotations of "carpooling is good", the majority experienced it as "one of many useless distractions on the road" or another advertisement for "just one more app on the phone".

Following the instalment of the field experiment in Amstetten, the app activity in the region was closely monitored. During the time of the experiment, a total of 66 new users have downloaded the app and registered for the Amstetten commuting platform. Of those, 48 have completed the onboarding process of getting familiarised with how PAVE functions leading to a total of 9 new commuting groups being established. Despite registration numbers in Amstetten growing much more significantly during the experiment in comparison to the time after the experiment, the goal of 250 downloads had not been reached. A total of 29 carpooling rides have been registered during the experimentation phase, connecting individuals with similar times and routes of travel.

Illustrating local potential of work-related carpooling in Amstetten, 35 home and workplace locations were utilised using georeferencing. Maps were created reflecting potential commuting routes in Amstetten (see Figure 8). As the routes reflect the fastest connection and route choice is generally subject to various factors

398

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

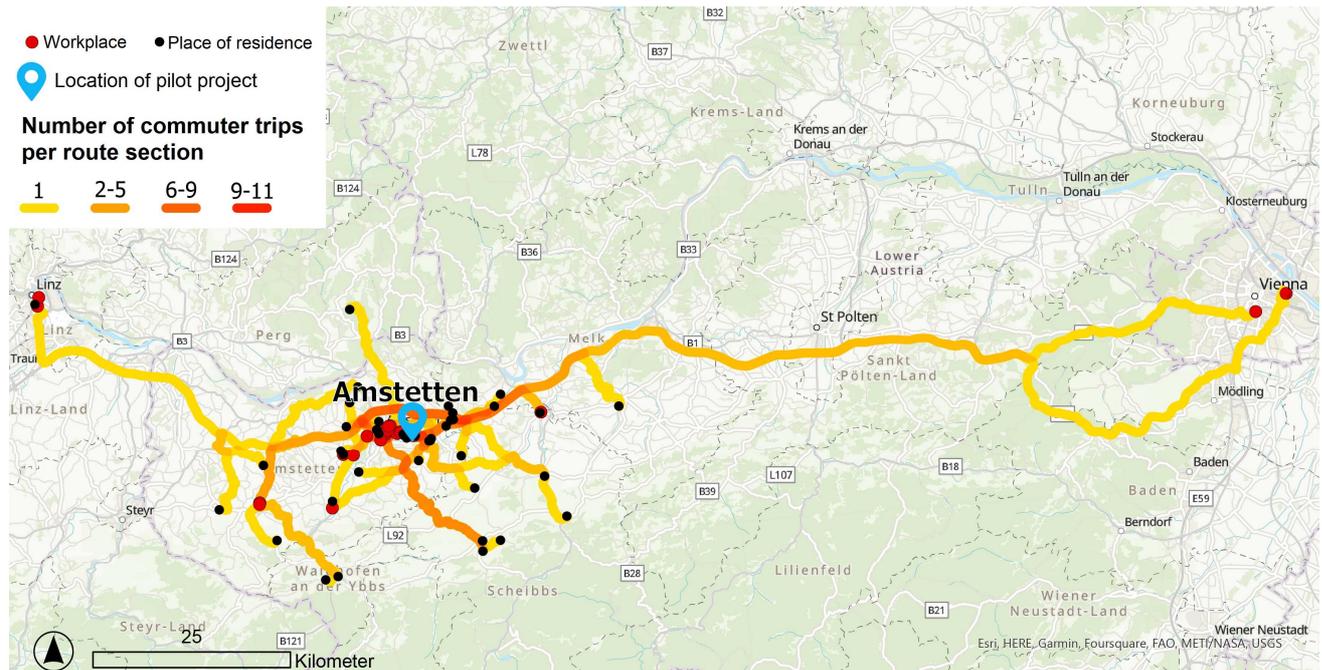
such as personal habits or potential stops along the way, it is important to highlight that actual routes may differ.


Fig. 8: Network analysis of potential commuting trips in Amstetten from 4:00 – 9:00 o'clock

As can be seen in the figure, there is a limited accumulation of commuting routes and thus a lower potential for shared car trips. Whereas workplaces are strongly concentrated in the city of Amstetten, the places of residence are dispersed across the region. This may be due to the low levels of elevation in the region, resulting in few clusters of roads. Carpooling may therefore hold more potential in mountainous areas where traffic is limited to fewer and more concentrated roads.

In addition to the spatial dimension of potential routes, the time of departure and arrival also plays a critical role. Potential routes were analysed in 60-minute increments. Whilst the highest potential for carpooling was identified between 5:00 and 7:00 in the morning, the differing temporal needs of commuters generally further limits the chances for carpooling.

5 CRITICAL REFLECTION

The following section involves the critical reflection of the methodology and other implications of the study like the challenge of the critical mass.

5.1 Methodological limitations in the preliminary questionnaire

Whereas it seems that the feedback displays might have negatively impacted the participants' perceptions and attitudes of carpooling and their openness to utilise carpooling apps, the differences between the two groups is not significant. It therefore remains questionable whether these differences result from the simulation or if they just reflect differences amongst the two sample groups. Other statistical methods like t-test or ANOVA could be considered. The findings do, however, highlight low levels of awareness and sense of relevance of increasing car occupancy levels as an important sustainability measure. Additionally, it has to be considered that the simulation on a display does not reflect real world conditions and social desirability might have played a role in the preliminary questionnaire.

5.2 The critical mass problem

The network analysis of potential carpooling illustrates the need for platforms to navigate both spatial and temporal differences in their matchmaking. This reflects the fundamental dependence of app providers on high numbers of users as a prerequisite for offering carpooling options. Especially in rural and less dense areas this aspect becomes even more of a challenge. Whereas the use of awareness campaigns using feedback displays and nudging can certainly contribute to establish this critical mass of users on carpooling

platforms, other measures such as the integration of multiple communication channels on different types of media or the inclusion of carpooling options in existing MaaS apps (Wright at al. 2020).

In addition, it can be assumed that longer detours and longer travel times tend to lead to a higher rejection rate. Which factors influence this refusal requires further research (König & Grippenkoven 2020).

6 CONCLUSION AND OUTLOOK

In the project a striking campaign was used to raise awareness for sustainable mobility in road traffic. It can be summarized that participants who received slightly negative feedback felt more directly addressed and experienced more negative feelings compared to those who did not receive feedback. Additionally, participants who received feedback showed more negative attitudes towards carpooling and were less open to utilizing carpooling apps compared to those who did not receive feedback. The majority of recorded trips in Amstetten were made with cars occupied by only one person, indicating the potential for carpooling to reduce individual transport. Car occupancy rates in Amstetten were generally below the Austrian average, with an increase in the number of car trips with two or more occupants observed in the afternoon. Participants in and near Amstetten had mixed perceptions of carpooling, with positive views emphasizing the financial and ecological benefits, and negative views highlighting the lack of flexibility and discomfort of traveling with strangers. The experiment with LED displays for nudging car occupancy levels received mixed feedback, with some participants perceiving it as unnecessary and intrusive, while others found it thought-provoking. Overall, the findings suggest that feedback displays and nudging interventions have the potential to shape car-occupancy levels and attitudes towards carpooling, but their effectiveness and acceptability can vary among individuals.

The findings from the research project can be used to increase awareness and acceptance of shared mobility services such as carpooling and ridesharing, and thus reduce the number of private cars on public roads. In addition to the promotion of carpooling, as was done in this project, a number of other mobility offers and modes such as on-demand transport (call buses, shared taxis, on-demand mobility, etc.) could be the focus of a further awareness campaign in road transport. In the course of follow-up projects, omni-channel communication campaigns should be taken as a basis to further increase the effectiveness of awareness campaign. All available channels can be used (posters, flyers, social media, etc.) to achieve a strong and repeated involvement of all stakeholders.

1 ABSTRACT

Rund ein Viertel der deutschen Bevölkerung wurde in den geburtenstarken Jahren zwischen 1955 und 1969 geboren und ist damit Teil der sogenannten Babyboomer-Generation.[1] Mit zunehmender Alterung ergibt sich für diese ein höherer Bedarf an medizinischer Versorgung – als künftig größte Patientengruppe haben die Babyboomer daher eine hohe Relevanz bei der Sicherung der medizinischen Versorgung. Entsprechend dem gesetzlichen Auftrag zur Sicherstellung einer jederzeit verfügbaren, wohnortnahen ambulanten Versorgung, ist ein bedarfsgerechtes Versorgungsangebot erforderlich.[2] Als Erreichbarkeitsstandard werden etwa 15 Minuten für die hausärztliche Versorgung und in der Regel 30 Minuten für die allgemeine fachärztliche Versorgung angesetzt.[3] Ebenso wenig wie zu dem Gesundheitsverhalten und Mobilitätsverhaltender Babyboomer besteht allerdings auch kaum Datenmaterial über deren Wohnstandortverhalten nach ihrer anstehenden Verrentung.

Aus Sicht der Nachfrage und künftig im wesentlichen aus Sicht der Babyboomer ergeben sich eine Reihe an planungsrelevanten Fragestellungen. Welche Rolle etwa spielen die hausärztliche, allgemein fachärztliche und zahnärztliche Versorgung im ambulanten Bereich sowie die stationäre Versorgung für das künftige Wohnstandortverhalten der Babyboomer-Generation? Welche Bedarfe und welche Nachfrage sind aktuell und in Zukunft gegeben? Wie kann die Qualität und Zugänglichkeit der medizinischen Versorgung im ländlich-suburbanen Raum durch Einbeziehung telemedizinischer Dienste verbessert werden? Welche Akzeptanz finden digitale, mobile sowie hybride Angebotsformen der medizinischen Versorgung bei der Babyboomer-Generation? Auch aus Sicht des Angebots (Kommunen, Ärzteschaft etc.) ergeben sich Fragen. Welche Relevanz hat die medizinische Versorgungsinfrastruktur für die kommunale Entwicklung? Welche Weichenstellungen und Entscheidungen der Ärztinnen und Ärzte sind für kommunale Entscheidungsträgerinnen und Entscheidungsträger relevant? Welche Möglichkeiten bestehen, auf die Standortwahl von medizinischen Versorgungsangeboten (MVZ, kommunale und private Kliniken) Einfluss zu nehmen? Welche Rückschlüsse lassen die Determinanten der Wohnstandortwahl der Babyboomer-Generation auf die Konzepte und Modelle der Siedlungsentwicklung (Wohnen) der Raumplanung (Fokus Raumordnung) zu?

Zur Untersuchung einiger dieser Fragestellungen wurde im Teilprojekt „Gesundheit" des von der Carl-Zeiss-Stiftung im Rahmen des Programms „Durchbrüche" mit 4,3 Millionen Euro geförderten Forschungsprojektes „Ageing Smart – Räume intelligent gestalten"[4] eine teilstandardisierte Befragung zur Gesundheitsversorgung in zwei ländlichen und zwei suburbanen Kommunen in Rheinland-Pfalz, Baden-Württemberg und Thüringendurchgeführt. Mit den gewonnenen Erkenntnissen über Nachfrageverhalten und Bedarfe bei der Gesundheitsversorgung, das (überörtliche) Wohnstandortverhalten, das Mobilitätsverhalten sowie Akzeptanz und Relevanz digitaler und mobiler medizinischer Angebotsformen, sollen sowohl für politische Entscheidungsträgerinnen und Entscheidungsträger als auch für Träger der Gesundheitsversorgung Handlungsbedarfe aufgezeigt und Handlungsoptionen zur Sicherung der Gesundheitsversorgung und Mobilität formuliert werden.

Perspektivisch dienen diese der Einspeisung in das angestrebte DSS (Decision-Support-System) des Gesamtprojektes „Ageing Smart" zur politischen Entscheidungsunterstützung in den Modellkommunen. Die Ergebnisse der Befragung sowie die daraus abgeleiteten Schlussfolgerungen zur Sicherung der Gesundheitsversorgung und Mobilität auf kommunaler Ebene werden in diesem Beitrag thematisiert.

2 EINLEITUNG

2.1 Forschungsansatz im Carl-Zeiss-Projekt „Ageing Smart – Räume intelligent gestalten"

Das von der Carl-Zeiss-Stiftung und der RPTU Kaiserslautern-Landau über einen Zeitraum von fünf Jahren geförderte Forschungsprojekt „Ageing Smart – Räume intelligent gestalten" adressiert die geburtenstarken Jahrgänge 1955 bis 1969 (nachfolgend „Babyboomer") und führt in einem integrierten Ansatz erstmals raumplanerische und versorgungsseitige Ansätze, Bedarfe der Babyboomer sowie Handlungserfordernisse und -optionen von Kommunen zusammen. Das interdisziplinäre, im universitären Potentialbereich „Region und Stadt" der RPTU angesiedelte, Forschungsvorhaben gliedert sich in zehn Teilprojekte der Disziplinen Raumplanung, Stadtsoziologie, Klimatologie, Informatik sowie Mathematik und wird federführend am Fachgebiet Stadtsoziologie unter Prof. Dr. Annette Spellerberg koordiniert.[5]

Als ein Aspekt der Daseinsvorsorge widmet sich das Teilprojekt „Gesundheitsversorgung", das am Lehrstuhl Regionalentwicklung und Raumordnung koordiniert wird, der hausärztlichen sowie der allgemein fach- und zahnärztlichen Versorgung in vier ländlich-suburbanen Kommunen – den beiden Verbandsgemeinden Kusel-Altenglan und Nieder-Olm, dem Geisaer Land und der Gemeinde Remshalden. Ein Fokus liegt einerseits auf der klassisch standortgebundenen und digital-mobilen Gesundheitsversorgung (Angebot und Nachfrage), andererseits auf den verkehrlichen Infrastrukturen zur Gewährleistung von individueller Mobilität und Erreichbarkeit der medizinischen Einrichtungen. Konkret gilt es, die Bedürfnisse der alternden Menschen, die Raumentwicklung und die Versorgungsmöglichkeiten vor Ort in Einklang zu bringen.[6] Ein Baustein zur Generierung neuer Daten ist dabei die teilstandardisierte Befragung zu der Gesundheitsversorgung in diesen Kommunen unter Babyboomern. Sowohl mit Blick auf den Alterungsprozess als auch auf unterschiedliche Lebenslagen, -formen und -stile handelt es sich bei den Babyboomern um eine überaus heterogene Gruppe, über die jedoch vergleichsweise wenig bekannt ist.[7] [8]

2.2 Zielsetzung

Ziel dieser Umfrage war es daher, Daten zur aktuellen Wohnsituation, dem künftigen Wohnstandortverhalten beim Eintreten in den Ruhestand und zum spezifischen Gesundheitsverhalten der Babyboomer sowie deren Anforderungen an Erreichbarkeit und Ausgestaltung der medizinischen Versorgung zu erheben. Die Analyse der Präferenzen und Bedarfe dient der Beantwortung relevanter Fragestellungen und der Ableitung von Handlungsbedarfen und -optionen bei der Gesundheitsversorgung in ländlich-suburbanen Kommunen. Diese dienen im späteren Verlauf des Projektes zur Einspeisung in das im Gesamtprojekt „Ageing Smart – Räume intelligent gestalten" projektierte Decision-Support-System, insbesondere mit Blick auf eine steigende Nachfrage bei gleichzeitig geringerem verfügbaren Angebot. Dieser Beitrag thematisiert Auszüge aus den Ergebnissen und Herausforderungen bei der (inter)kommunalen Sicherung der Gesundheitsversorgung.

3 METHODIK

Der standardisierte Fragebogen war in vier inhaltliche Themenblöcke mit insgesamt 43 Fragen gegliedert, teils mit ein bis mehreren Antwortkategorien, teils auch mit offener Antwortmöglichkeit:

(1) Fragen zur Gesundheit (Gesundheitszustand und Einschränkungen, Regelmäßigkeit und Anlass bei der Nutzung von Angeboten der Gesundheitsversorgung, Akzeptanz digitaler und mobiler Angebotsformen),

(2) Fragen zur aktuellen Wohnsituation (Wohnstandort, Wohnfläche und -form, Wohnstandortfaktoren, Bedeutung von Gesundheits- und Verkehrsangeboten, Ausstattung der örtlichen Gesundheitsversorgung, verfügbare/genutzte Verkehrsmittel),

(3) Fragen zur künftigen Wohnsituation(Überlegungen zum Leben und Wohnen im Alter, Wohnstandort, Wohnfläche und -form (antizipiert), Wohnstandortverhalten, künftige Bedeutung von Gesundheits- und Verkehrsangeboten) sowie

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

(4) Fragen zur Person (Geschlecht, Alter, Haushaltsgröße, familiäre Situation und soziale Einbindung, Bildung, Erwerbstätigkeit und Einkommen).

Die Befragung wurde von Oktober bis Dezember 2022 in digitaler Form über einen Zeitraum von je etwa vier Wochen in den zwei ländlichen (VG Kusel-Altenglan, Geisaer Land) und zwei suburbanen (VG Nieder-Olm, Remshalden) Modellkommunen des Forschungsprojektes durchgeführt. Die auf Basis der jeweiligen Melderegister ermittelten Babyboomer in den Kommunen wurden über eine Postkarte mit Kurztext, Link und QR-Code zur Befragung eingeladen. In den beiden Verbandsgemeinden wurde eine Stichprobe von 50% aller Personen in der einschlägigen Altersgruppe aus dem Melderegisterermittelt, in Remshalden und dem Geisaer Land erfolgte die Umfrage als Vollerhebung unter allen vor Ort ansässigen Babyboomern. Insgesamt wurden in den ländlichen Kommunen 4.737 und in den suburbanen Kommunen 7.204 Babyboomer zur freiwilligen Teilnahme an der Umfrage eingeladen. Durch die anonyme Beteiligung an der Umfrage per Link bzw. QR-Code war eine Zuordnung der Teilnehmenden zu den Adressen der postalisch eingeladenen Babyboomer nicht möglich.

Die um die nicht zustellbaren Postkarten bereinigte Rücklaufquote in den ländlichen Kommunen betrug rund6% (Stichprobenumfang n=281), in den suburbanen 7,1%(Stichprobenumfang n=506).Insgesamt haben 787 und damit 6,7% der angeschriebenen Personen an der Befragung teilgenommen. Dies entspricht in den ländlichen Kommunen 3,6% und in den suburbanen Kommunen 4,5% aller dortigen Babyboomer. Im Mittel benötigten die Befragten ca. 20 Minuten zur Beantwortung der Fragen. Da vereinzelt Fragenunbeantwortet blieben oder ungültig beantwortet wurden, wird bei der folgenden Darstellung der Ergebnisse jeweils der Stichprobenumfang je Frage (n) angegeben. Die Auswertung der Ergebnisse erfolgte überwiegend deskriptivdurch Häufigkeitsanalysen. Die teils recht umfangreichen Angaben bei der Beantwortung offener Fragen wurden im Sinne einer übersichtlicheren Darstellung kategorisiert. Die Ergebnisse der Umfragewerden im Folgenden dargestellt, gegliedert nach suburbanem und ländlichem Raum. Sofern Werte ohne weitere Erklärung in Klammern angegeben sind, bezieht sich der vordere Wert auf die ländlichen, der hintere Wert auf die suburbanen Kommunen (z.B. 3%/8%).

4 ÜBERBLICK ÜBER DIE ERGEBNISSE

4.1 Demografie

Tab. 1 zeigt das soziodemografische Profil der Befragten im Vergleich zwischen ländlichen und suburbanen Kommunen. Die Befragten sind im Mittel59,8 (ländlich) Jahre bzw. 59,5(suburban) alt. Der Großteilist den Jahrgängen 1960 bis 1964 (38%/37%) zuzuordnen, gefolgt von den Jahrgängen 1965 bis 1969 (32%/36%) und 1955 bis 1959 (30%/27%). Frauen haben sich geringfügig häufiger als Männer beteiligt.

Die meisten Befragten leben sowohl im ländlichen als auch im suburbanen Raum in Zwei-Personen-Haushalten. Während im ländlichen Raum die zweit- und dritthäufigste Nennung der Mehrpersonenhaushalt und der Zwei-Personen-Haushalt mit Kind(ern) ist, wird im suburbanen Raum als zweit- und dritthäufigste Form der Zwei-Personen-Haushalt mit Kind(ern) und der Ein-Personen-Haushalt genannt.

Über 80% der Befragten haben ein Kind bzw. Kinder, die wiederum überwiegend bereits ausgezogen sind (74% im ländlichen Raum, 65 % im suburbanen Raum). 25% (ländlicher Raum) bzw. 20% (suburbaner Raum) der Kinder leben im elterlichen Wohnort, die Entfernung der Befragten zum Wohnort ihres Kindes bzw. ihrer Kinder beträgt im Mittel 40km/60km. Knapp die Hälfte der Befragten aus dem ländlichen Raum hat bereits Enkelkinder (48%), im suburbanen Raum sind dies 32% der Befragten.

Mit Blick auf das Bildungsniveau zeigt sich eine höhere schulische Bildung bei den suburbanen Befragten, ebenso eine höhere berufliche Bildung. Gut die Hälfte der noch erwerbstätigen Befragten ist als (Fach-)Arbeiter oder im Angestelltenverhältnis (52% ländlich bzw.58% suburban) tätig, gleiches gilt auch für die überwiegende berufliche Stellung der Befragten im Ruhestand.

Das monatlich verfügbare Netto-Haushaltseinkommen liegt unter den Befragten aus dem ländlichen Raum im Mittel bei 2.500 bis 3.000 Euro, bei denjenigen aus dem suburbanen Raum bei 3.500 bis 4.000 Euro.

Jeder vierte bis fünfte Befragte (27%, n=281ländlicher Raum/20%, n=506 suburbaner Raum) ist bereits im Ruhestand, in den ländlichen Kommunen ist der Anteil der Befragten im Ruhestand größer. Ein Großteil (73%, n=281/80%, n=506) steht dagegen noch im Erwerbsleben. Letztere gehen nach eigener Aussage in durchschnittlich 7,5/7,0 Jahren in den Ruhestand (n=187/n=370).

Soziodemografisches Profil der Befragten im Überblick*   Angaben in %

		Angaben in %
Geschlecht (n=274 / n=503)	männlich	46,7 / 48,1
	weiblich	52,2 / 51,5

4.2 Gesundheitszustand und Nachfrageverhalten der Patientengruppe Babyboomer

Gemessen an der durchschnittlichen Lebenserwartung als Querschnittsindikator für den Gesundheitszustand sind die Babyboomer gesünder als deren Vorgänger-Generationen.[9] Als Folge des demografischen Wandels steigt jedoch die Anzahl älterer Menschen, was mittelfristig zu einer Erhöhung der Krankheitslast und einem steigenden Bedarf an medizinischer Versorgung führt.

---

[9] vgl. KÖRBER-STIFTUNG (2022): S.8.

Zur Beurteilung des Gesundheitszustands und der Multimorbidität innerhalb der Generation der Babyboomer wurden die Teilnehmenden nach dem subjektiven Gesundheitszustand und objektiven Kriterien (Tab. 2) wie körperlichen Einschränkungen, Krankheiten mit regelmäßigem Behandlungsbedarf, chronischen Erkrankungen und Risikofaktoren befragt. Die Frage „Wie bewerten Sie Ihren derzeitigen Gesundheitszustand?" (n=279/n=506) (1= sehr gut, 5 = sehr schlecht) wurde ländlich zu54% und suburban zu 71% mit sehr gut bis gut beantwortet. Der Teil, der den Gesundheitszustand mittel (36%/22%) und schlecht bis sehr schlecht (10%/7%) bewertet, ist unter den Befragten aus dem ländlichen Raum höher. Auffällig ist hier die relativ positive Einschätzung des allgemeinen Gesundheitszustands bei gleichzeitiger Angabe wegen einer bzw. mehreren Krankheiten in ständiger Behandlung zu sein (vgl. Tab. 2). Bei der Einnahme von Medikamenten nehmen 68%/50% diese ein bis zwei Mal täglich, 12%/7% auch öfter ein(n= 279/n=504).

Einschränkungen (n=275 / n=503) (stark oder mäßig; leicht)	Hören/Sehen,	23,8; 53,4 / 15,5; 51,1
	Herz-Kreislaufsystem	12,7; 37,0 / 5,4; 22,7
	Mobilität	11,3; 34,9 / 9,0; 23,4
	Gedächtnis	4,4; 29,8 / 3,6; 19,8
Krankheiten in ständiger Behandlung und / oder Kontrolle (n=275 / n=506)	Ja, eine	33,5 / 35,4
	Ja, mehrere	37,1 / 18,6
chronische Erkrankungen / Risikofaktoren (n=281 / n=506); Mehrfachnennung möglich	Bluthochdruck	46,6 / 31,4
	Gelenkerkrankung / Rheuma	24,6 / 18,6
	Herzkreislauferkrankungen	17,4 / 6,3
	chronische Bronchitis / Asthma	11,7 / 6,1
	Diabetes mellitus	8,5 / 6,3
	Durchblutungsstörungen / Schlaganfall	3,2 / 2,6
	Übergewicht	24,2 / 22,1
ländlich ▬ suburban ▬	Alkohol: gelegentlich; regelmäßig	34,2; 7,1 / 34,6; 10,3
	Raucher; Exraucher [in Jahren]	11,4; 15,7 [19,4] / 8,9; 13,2 [17,3]

Tab. 2: Einschränkungen, Krankheitslast und Risikofaktoren; Prozentwerte auf jeweilige Antwort bezogen (ländlich/suburban), Mehrfachnennungen möglich. Quelle: eigene Darstellung.

Hinsichtlich ihres Bedarfs bei der Gesundheitsversorgung wurden die Befragten nach der Inanspruchnahme, (Regelmäßigkeit und Anlass) verschiedener Ärzte und den hier akzeptierten Erreichbarkeiten (Tab. 3) bei unterschiedlichen Verkehrsträgern befragt. Hausärzte wurden in den letzten 12 Monaten zu 36%/35% zwei bis drei und zu 30%/24% vier bis sechs Mal in Anspruch genommen (n=273/n=494). Allgemeine Fachärzte (n variiert)wurden dagegen meist nur ein Mal oder gar nicht, Orthopäden und Frauenärzte hierbei am ehesten konsultiert. Zahnärzte (n=273/(n=493) wurden meist (48%/48%)zwei bis drei Mal aufgesucht. Gemeindeschwesteroder Pflegedienst wurden dagegen kaum (1%) genutzt.

	Hausarzt	Facharzt	Zahnarzt	Apotheke
zu Fuß	15 (n=111)/15 (n=344)	15(n=60)/15 (n=189)	15 (n=80)/15 (n=264)	15 (n=99)/10 (n=381)
Fahrrad	10(n=57)/ 10 (n=191)	15(n=37)/15 (n=150)	10(n=45)/15 (n=163)	10 (n=46)/10 (n=178)
E-Bike, Pedelec	15(n=56)/15 (n=173)	15(n=40)/20 (n=142)	15(n=43)/15 (n=148)	15(n=50)/10 (n=158)
Auto	15(n=246/15 (n=368)	30(n=251)/30 (n=436)	15(n=237)/20 (n=380)	15 (n=238)/10 (n=294)
Bus, Bahn	20(n=48/20 (n=149)	30(n=45)/30 (n=186)	30(n=47)/30 (n=152)	15(n=44)/15 (n=124)

Tab. 3: Tolerierte Distanz bei der Nutzung medizinischer Angebote:„Wie lange sind Sie bereit, zur nächsten Arztpraxis/Apotheke zurückzulegen? (einfache Strecke in Minuten)"; Median-Werte in Minuten(ländlich/suburban), Mehrfachnennungen möglich. Quelle: eigene Darstellung.

Als vorwiegende Gründe für Arztbesuche (n=277/n=503) werden mit 66%/73% die Inanspruchnahme ärztlicher Leistungen angeführt, zu 24%/15%die Ausstellung oder Abholung von Rezepten und zu 11%/13%

meist Vorsorge oder Impfungen. 81%/76% der Befragten sind gesetzlich krankenversichert, 11%/18% haben eine Zusatzversicherung und 17%/24% sind privat versichert (n=281/(n=506).

Weiterhin wurde nach der Akzeptanz digitaler und mobiler Angebotsformen als Alternative zur klassischen Gesundheitsversorgungvor Ort gefragt, Tab. 4 zeigt die entsprechenden Zustimmungswerte. Suburban liegt diese bei beiden Formen und besonders beider digitalen Beratung und Behandlung höher als im ländlichen Raum. Für jeweils ein Drittel der ländlichen Befragten sind digitale oder mobile Angebote weder für eine Behandlung noch Beratung eine Option. 18% lehnen beides ab, für 19% ist beides hingegen eine Option. Suburban ist die Akzeptanz größer, hier lehnt ein Drittel eine mobile und nur jeder Fünfte eine digitale Beratung oder Behandlung ab. 12% lehnen beides ab, für 25% ist beides eine Option Die größte Akzeptanz unter allen Befragten erfährt die mobile Beratung und Behandlung, gefolgt von der digitalen Beratung.

	digital Beratung und Behandlung	mobil Beratung und Behandlung	digital nur Beratung	mobil nur Beratung	digital weder Beratung noch Behandlung	mobil weder Beratung noch Behandlung
ländlich	23,3	53,8	43,4	14,7	33,3	32,1
suburban	31,4	59,2	45,8	12,1	22,7	28,7

Tab. 4: Akzeptanz digitaler und mobiler Angebotsformen: „Können Sie sich vorstellen, sich a. von einem Arzt bzw. einer Ärztin in einem Onlineformat (z.B. Videosprechstunde)(n=279/n=505)/b. in einer mobilen Arztpraxis (z.B. Medibus) (n=278/n=505): beraten/behandeln zu lassen?“; Prozentangaben auf jeweilige Antwort bezogen. Quelle: eigene Darstellung.

Hinsichtlich der psychischen Gesundheit spielen u.a ein unterstützendes Umfeld und die soziale Einbindung eine Rolle. 84%/82% der Befragten bewerten ihre nahen verwandtschaftlichen Beziehungen sowie80%/81% ihre nahen freundschaftlichen Beziehungen (n=276/(n=501) als sehr gut bis gut. 81% /77% haben üblicherweise zudem täglich bis wöchentlichen Kontakt zu einem Teil der Familie (n=276/(n=500).

4.3 Wohnsituation und Wohnwünsche antizipiert für den Eintritt in den Ruhestand

Insgesamt wurden Menschen aus 47Gemeinden erreicht. 34%/18% leben seit Geburt in der Kommune, ein Viertelist in den letzten 25/23 Jahren zugezogen (n=280/n=506).Die Mehrheit lebt im Ein-/Zweifamilien-haus, überwiegend im Eigentum (92%/82%) und nur zu einem geringen Teil (7%/18%) zur Miete (n=278/n=504). Keiner der Befragten wohnt bisher in einer Senioren-Wohngemeinschaft, einem -heim oder einer -residenz.50%/44% der Befragten stehen durchschnittlich über 100m² Wohnfläche, weiteren 27%/23% stehen 75 bis unter 100m²pro Person zur Verfügung (n=275/n=500). 43%/58% der Befragten bewerten ihre Wohnsituation damit mit sehr gut, weitere 45%/36% mit gut(n=278/(n=506).

Beim künftigen Wohnstandortverhalten ist relevant, ob die Babyboomer einen Wohnstandortwechsel sicher planen, perspektivisch planen oder sich diesen vorstellen können (n=281/n=506). 50%/64% der Befragten können sich diesen unter bestimmten Bedingungen vorstellen. Bei den Gründen für einen Umzug liegt das Eintreten körperlicher Einschränkungen im Alter (41%/50%) vorne, gefolgt von Änderungen des Familienstandes (Scheidung, Verwitwung etc.) (21%/36%) und dem Renteneintritt (10%/21%). Während 6%/5% ihre Wohnsituation bereits entsprechend altersgerecht verändert haben und 4%/5% schon konkret nach einer neuen Wohnung bzw. einem neuen Haus suchen, können sich 45%/31% einen Umzug dagegen nicht vorstellen.

Nach möglichen Veränderungen an der Wohnsituation gefragt möchten bis zu 67%/56% das derzeit eigene Haus bzw. die eigene Wohnung grundsätzlich (n=281/n=506) beibehalten, gegebenenfalls mit einem altersgerechten Umbau oder bedarfsgerechter Betreuung. Wohnen bei den (Enkel-)Kindern ist mit deren Unterstützung/Pflege für 20%/14% eine Option, mit professioneller Unterstützung/Pflege sogar für 50%/47%.

Bei den Befragten, die einen Umzug in Erwägung ziehen, möchten 27%/40% in derselben Gemeinde, 32%/28% im Landkreis und 21%/18% in der Region bleiben (n=281/n=329). Die Befragten, die bereits konkrete Überlegungen für einen Umzug anstellen (n=139/n=329), werden zu 14%/10% in ihrer Wohnung bzw. im Haus wohnen bleiben. Bei der künftigen Wohnfläche pro Person möchte sich die Mehrheit der Befragten verkleinern, zu 47%/38% auf 50 bis unter 75m², zu 28% auf 25 bis unter 50m² (n=127/n=314).

Insbesondere bei den Befragten, die einen Umzug nicht in Erwägung ziehen, stellt sich die Frage nach der Zufriedenheit mit der Gesundheitsversorgung, Mobilität und Infrastruktur im Umfeld ihres Wohnstandortes

(n variiert). Dabei lassen sich zwischen den Raumtypen Unterschiede erkennen. Weniger als die Hälfte der ländlichen Befragten ist mit der hausärztlichen (45%) und allgemein fachärztlichen (38%)Versorgung zufrieden, ebenso wenig mit der Anbindung mit öffentlichen Verkehrsmitteln und deren Haltepunkten (26%) Die zahnmedizinische Versorgung (72%), die stationäre Versorgung (57%) und die Ausstattung mit Apotheken (84%) sowie die Anbindung mit dem Pkw (93%) wird mehrheitlich mit sehr gut oder gut bewertet. Die Befragten in den suburbanen Kommunen sind mit der hausärztlichen (67%) und zahnärztlichen (69%) Versorgung und insbesondere mit der Pkw-Anbindung (97%), der Ausstattung mit Apotheken (94%) sowie der Anbindung mit öffentlichen Verkehrsmitteln und deren Haltepunkten (60%) zufrieden. Weniger zufrieden sind diese hingegen mit der stationären (42%) und der allgemein fachärztlichen Versorgung (33%). In allen vier Kommunen sind digitale und mobile medizinische Angebote überwiegend unbekannt. Die digitale Infrastruktur bewerten 50%/77% mit sehr gut oder gut.

Tab. 5 stellt die Bedeutung der Gesundheitsversorgung, der Anbindung und Infrastruktur sowie der Nähe zu Kindern und Familie als Standortwahlfaktor bei der Entscheidung für den aktuellen Wohnstandort der Priorität bei der künftigen Wohnstandortwahl gegenüber. Erkennbar wird ein erheblicher Bedeutungsgewinn in allen zur Auswahl gestellten Bereichen – ambulante und stationäre Gesundheitsversorgung, soziale Angebote für ältere Menschen, technische Infrastruktur sowie Nähe zu Kindern und Familie.

Standortfaktoren bei der Wahl des Wohnstandortes (Vergangenheit; antizipiert)
(n=281; 139/n=506; 329)

		ländlich	suburban
gute Gesundheitsversorgung	allgemeinmedizinische Versorgung	33,5; 87,1	35,6; 89,1
	allgemeine fachmedizinische Versorgung	17,4; 71,9	11,1; 64,1
	zahnmedizinische Versorgung	22,8;73,4	17,2; 71,7
	stationäre Versorgung (Krankenhäuser)	19,9; 57,6	5,1; 40,7

	Beratungsstellen für Ältere	1,1; 18,7	1,4; 19,5
	soziale Begegnungsstätten für Ältere	1,8; 47,5	2,2; 47,4
	stationäre Einrichtungen (Alten-/Pflegeheime)	5,0; 22,3	3,2; 19,5
	ambulantes Betreuungs- und Pflegeangebot	3,2; 41,0	3,8; 52,6
gute Anbindung/Infrastruktur	Verkehrsanbindung mit dem Pkw	42,3; 57,6	59,1; 65,7
	Verkehrsanbindung mit öffentlichen Verkehrsmitteln (Bus, Bahn), Haltepunkte des ÖPNV	17,1; 82,7	53,2; 89,1
	digitale Infrastruktur (Internet/DSL, mobiles Internet, Mobilfunk)	12,1; 68,3	23,3; 80,5
Nähe zu Kindern und Familie		33,1; 51,8	24,9; 51,7

Tab. 5: Wohnstandortwahl: „Welche Gründe waren Ihnen bei der Entscheidung für den aktuellen Wohnstandort wichtig?/Welche Faktoren sind Ihnen bei der Wahl des künftigen Wohnorts wichtig?"; Prozentwerteauf jeweilige Antwort bezogen (ländlich/suburban), Mehrfachnennungen möglich. Quelle: eigene Darstellung.

5 DISKUSSION UND FAZIT

5.1 Stärken und Limitationen der Umfrage

Eine der Stärken der Umfrage besteht in der Verschneidung der Themen Gesundheit, Wohnen und Mobilität bei der Untersuchung der Babyboomer sowie der damit einhergehenden Verbesserung der aktuell schlechten Datenlage zu dieser Generation. Durch die Befragung in mehreren Kommunen des Forschungsprojektes konnten zudem Teilnehmende aus ländlich wie auch aus suburban geprägten Räumen erreicht und bei der Auswertung der Ergebnisse entsprechend differenziert werden. Schwächen bestehen dagegen in der geringen Rücklaufquote von sechs bis sieben Prozent und einer damit nicht hinreichenden Belastbarkeit der zuvor dargestellten Ergebnisse. Diese sind daher nicht repräsentativ und methodisch lediglich als Hypothesen bzw. Schlaglichter zu verstehen. Gründe für den geringen Rücklauf werden zum einen im Zeitpunkt der Feldphase gesehen, um welchen bereits weitere Umfragen (Zensus 2022, Bürgerbeteiligung, Grundsteuererklärung im

Rahmen der Grundsteuerreform) in den Kommunen im Umlauf waren. Zum anderen wird die ausschließlich digitale Möglichkeit zur Teilnahme negativ beurteilt. Diese Einschätzung wird von den Ergebnissen einer weiteren Befragung im Forschungsprojekt „Ageing Smart" durch das Fachgebiet Stadtsoziologie gestützt. Diese konnte frei wählbar als Papierfragebogen oder online ausgefüllt werden. Nur ein kleiner Teil der Babyboomer (27%) nutzen hierbei die online-Variante, in den suburbanen Kommunen 32%, in den ländlichen 18%.[10] Ein Bias auf Grund einer stärkeren Teilnahme inhaltlich betroffener und so besonders motivierter Personen sowie digital affineren Personen kann zudem nicht ausgeschlossen werden.

5.2 Entwicklungen im Gesundheitswesen als Herausforderung für die Raumentwicklung

Als Folge des demografischen Wandels und einer unzureichenden Nettozuwanderung prognostiziert das Statistische Bundesamt eine Zunahme des Anteils der Menschen im Alter von 65 und mehr Jahren auf etwa 31% im Jahr 2060[11], wobei die Babyboomer bereits ab 2030 das Schwergewicht im Rentenalter bilden.[12]

Diese Entwicklung lässt sich auch bei der Ärzteschaft beobachten. Zwar ist die Zahl der berufstätigen Ärzte im Jahr 2022 geringfügig gestiegen,9% der Ärzte sind jedoch 65 Jahre oder älter und stehen dem Arbeitsmarkt auf absehbare Zeit nicht mehr voll zur Verfügung.[13] Drastischer stellt sich die Lage in der ländlichen geprägten Modellkommune Verbandsgemeinde (VG) Kusel-Altenglan dar. Im Jahr 2022 waren dort 74% der Hausärzte, 61% der Fachärzte und 54% der Psychotherapeuten über 54 Jahre alt, 37,8% der Hausärzte gar 65 Jahre und älter und somit im Durchschnitt 59,7 Jahre alt. Bei einem aktuellen Median-Abgangsalter von je 65, 59 und 63 Jahren bedeutet dies einen prognostizierten Nachbesetzungsbedarf von 50% der Hausärzte, 59% der Fachärzte und 30% der Psychotherapeuten bis 2027.[14] Die Gruppe der Ärzte im Alter von 50 bis 65 Jahren zeichnet sich dabei durch hohe Wochenarbeitsstunden aus, wird erfahrungsgemäß jedoch nach Erreichen des 65. Lebensjahres überwiegend in den Ruhestand eintreten oder nur noch in Teilzeit tätig sein.[15]

Zudem lässt sich eine doppelte Fehlverteilung innerhalb der ambulanten Gesundheitsversorgung feststellen.[16] Einerseits nimmt die Zahl der Hausärzte ab und die der Fachspezialisten stark zu, verbunden mit einem Trend zur Tätigkeit in einem Angestelltenverhältnis. Die Motivation zur Niederlassung in einer eigenen Praxis sinkt hingegen seit Jahren, ebenso der Teilnahmeumfang an der vertragsärztlichen Versorgung. Dieses in Vollzeitäquivalenten angegebene Verhältnis zwischen gearbeiteten Stunden und üblicher Arbeitszeit einer Vollzeittätigkeit lag 2009 bei durchschnittlich 0,98 und 2022 je nach KV-Region zwischen 0,8 und 0,9.[17] [18]

Die Zahl der niedergelassenen Ärzte als Rückgrat einer bedarfsgerechten flächenhaften Versorgung sank daher im Jahr 2022 zuletzt um 3,8%.[19]

Andererseits bestehen erhebliche regionale Allokationsprobleme, da Ärzte oftmals dort praktizieren, wo die Versorgung bereits gesichert ist – beginnend bei Stadtteilen mit vielen Privatpatienten und einem hohem sozioökonomischem Status bis hin zu ländlich-peripheren Gemeinden mit einer gefährdeten medizinischen Grundversorgung.[20] Nach Befragungen aus den Jahren 2014 und 2018 geben fast 50% der nachrückenden Ärztegeneration gar eine Aversion gegen das Arbeiten auf dem Land an.[21] Zusätzlich zur demografiebedingt steigenden Nachfrage an Nachfolgern haben daher besonders Ärzte im ländlichen Raum Schwierigkeiten bei der Nachbesetzung offener Sitze und Stellen.[22] Trotz angestrebter Gleichwertigkeit der Lebensverhältnisse

hinsichtlich der medizinischen Versorgung wird deutlich, dass mit Blick auf bestehende Disparitäten[23] und die skizzierten Entwicklungen Herausforderungen bei der Sicherung der Gesundheitsversorgung bestehen.

5.3 Einordnung und Schlussfolgerungen

Die Ergebnisse passen in das Bild, welches frühere Untersuchungen von der Generation zeichnen. Über die Hälfte der Babyboomer hat eine abgeschlossene Berufsausbildung, ein Drittel ein Studium hinter sich. Drei Viertel stehen im Erwerbsleben, der Rest ist bereits im Ruhestand oder nicht erwerbstätig. Das monatlich verfügbare Netto-Haushaltseinkommen lag 2017 bei 3.817 Euro und damit über dem Bundesdurchschnitt. Etwa 73% leben in einer Partnerschaft, wobei eventuell vorhandene Kinder meist schon ausgezogen sind. Der Anteil Alleinlebender liegt mit 21% dagegen höher als unter den Befragten.[24]

Die Befragung verdeutlicht bestehende Defizite der Gesundheitsversorgung in ländlich-suburbanen Räumen. Gemessen am subjektiven Gesundheitszustand und objektiven Kriterien zur Gesundheit sind die suburban Befragten gesünder, materiell besser aufgestellt und eher privatkrankenversichert. Verbunden damit ist die Nachfrage bei der Gesundheitsversorgungunter den Befragten im ländlichen Raumhöher. Gleichzeitig fällt die dortige Bewertung insbesondere des hausärztlichen und allgemein fachärztlichen Angebots sowie der Verkehrsanbindung mit öffentlichen Verkehrsmitteln mehrheitlich schlecht bis sehr schlecht und damit auch insgesamt schlechter aus als in den suburbanen Kommunen.

Mit Blick auf die akzeptierten Erreichbarkeiten ergibt sich teils eine Diskrepanz zwischen den Präferenzen der Befragten und den angebotsseitigen Standards bei der Bereitstellung der medizinischen Versorgung. Wie die Umfrage zeigt, können mobile und digitale Dienste aus Sicht der Babyboomer zumindest teilweise eine alternative Möglichkeit der Beratung bzw. Behandlung bieten und zur Sicherung der Versorgung, Entlastung der Ärzte und Verbesserung der Qualität im ländlich-suburbanen Raum beitragen. Grundsätzlich ist für zwei Drittel der Befragten eine digitale und/oder mobile Form der Beratung bzw. Behandlung eine Alternative zur klassischen Gesundheitsversorgung vor Ort. Unterstützt wird dies durch die digitale Kompetenz (n=699/n=1.185) und Offenheit gegenüber neuen Technologien (n=699/n=1.187). 38%/62% schätzen sich hier als (eher) kompetent ein, Smartphones sind für eine Mehrheit (85%/96%) der Befragten Standard.[25]

Mit Blick auf die Wohnsituation lebt die Mehrheit zu Hause im vertrauten Umfeld, deutlich mehr als die Hälfte bis fast zwei Drittel leben im Eigentum. Die meisten sind zufrieden mit ihrer Wohnsituation, über die Hälfte bewertet diese mit sehr gut, 40,5% mit gut und nur 2% mit schlecht oder sehr schlecht. Zufriedenheit mit der Wohnsituation gilt ebenso wie eine gute Gesundheit und ausreichende Mittel zur Unterstützung im Bedarfsfall als Grund die aktuelle Wohnsituation beizubehalten. Motivierend kann hingegen ein Angebot an Wohnformen sein, die an die sich wandelnden Bedürfnisse im Alter anpassbar sind.[26]

Auch eine Mehrheit der Befragten kann sich einen Umzug zumindest bei gleichbleibender Gesundheit nicht vorstellen, wodurch die Sicherung der Gesundheitsversorgung im Wohnumfeld in den Fokus rückt. Für die Mehrheit spielte die medizinische Versorgung bei der letzten Wohnstandortwahl keine Bedeutung. Bezogen auf einen künftigen Umzug hingegen ist diese mehrheitlich von Bedeutung, ebenso soziale Angebote für Ältere und eine gute Anbindung insbesondere an öffentliche Verkehrsmittel und digitale Infrastrukturen. Die Gesundheitsversorgung gewinnt damit zunehmend an Bedeutung für die kommunale Entwicklung.

6   AUSBLICK

Langfristiges Ziel des Forschungsvorhabens ist die Entwicklung eines daten-, IT- und KI-basierten Systems zur Entscheidungsunterstützung (Decision Support System = DSS), welches von öffentlichen Akteuren in ihrem Planungs- und Entscheidungsprozess herangezogen werden kann. Infrastrukturen, Angebote und Dienstleistungen sollen so nachfragegerecht, tragfähig und zukunftsorientiert entwickelt werden können, um die Lebensqualität der Babyboomer und perspektivisch der Gesamtbevölkerung zu sichern und zu fördern.[27]

[24] vgl. KÖRBER-STIFTUNG (2022): S.7, S.50.

[25] vgl. Befragung der Stadtsoziologie RPTU Kaiserslautern-Landau „Wohnen, Alltagsgestaltung und Lebensqualität von Babyboomern am Wohnort 2022", Auswertung Benjamin Stefan.

[26] vgl. KÖRBER-STIFTUNG (2022): S.9f.

[27] vgl. STIEWING, Marvin/WEBER, Tobias/MANGELS, Kirsten et al. (2022): S.132f.

Relevanz gewinnt neben der kommunalen Ausstattung mit medizinischen Einrichtungen die Erreichbarkeit der Standorte, weshalb die Erarbeitung eines intermodalen Erreichbarkeitsmodells als Querschnittsansatz aus Raumplanung und Mathematik einen vielversprechenden Forschungsansatz darstellt. Dieses bietet als ein Baustein des DSS ein Analysetool für Akteure der räumlich planenden Verwaltung (z.B. Stadt-, Verkehrs- und Sozialplanung), um verschiedene Entwicklungsvarianten bei unterschiedlichen Entscheidungsoptionen nachvollziehbar und verständlich für politische Entscheidungsträgerinnen, Entscheidungsträger und Akteure der medizinischen Versorgungsforschung und Bedarfsplanung (z.B. Kassenärztliche Vereinigungen) aufzubereiten. Dadurch wird eine sachgerechte und datengestützte Entscheidungsfindung unterstützt.[28]

Die im Zuge der Umfrage erhobenen Daten können hier u.a. Toleranzen und Präferenzen zur Erreichbarkeit der – künftig von den Babyboomern geprägten – Nachfrageseite einbringen und die weiteren Parameter bei der mathematischen Modellierung ergänzen. Neben frei verfügbaren Daten werden diese u.a. aus Experteninterviews und der Literaturrecherche abgeleitet, etwa hinsichtlich der Standorte medizinischer Einrichtungen unter Berücksichtigung unterschiedlicher Strukturmerkmale, verkehrsplanerischer Parameter oder angebotsseitigen Schwellenwerten und Standards zur Erreichbarkeit.[29] Die Analyse der Erreichbarkeit für den Status Quo und im zeitlichen Verlauf kann dadurch Handlungsbedarfe (lokal unterversorgte Bereiche etc.) bei der Sicherung der Gesundheitsversorgung aufzeigen und zur Bildung von Szenarien genutzt werden.

Ausgehend von den Ergebnissen der Umfrage und der weiteren Arbeit im Forschungsprojekt zeigen sich zudem Handlungsbedarfe bei der kommunalen Bereitstellung der Gesundheitsversorgung und Mobilität. Entsprechende Strategien und unterschiedliche Handlungsoptionen für Kommunen und Träger medizinischer Angebote (Einflussnahme auf Standorte neuer Praxen, altersgerechte Wohnangebote etc.) sollen im weiteren Verlauf des Projekts eruiert werden. Mit Blick auf die geringe Umzugsbereitschaft der Befragten gilt dies auch für Strategien für altersgerechtes Wohnen im ländlich-suburbanen Raum. In Zusammenarbeit mit den Modellkommunen im Projekt erfolgt zudem im Rahmen von Workshops die Definition spezifischer „Use Cases" im Bereich Gesundheit, die in die Konzeption des DSS einfließen.

Perspektivisch soll außerdem das antizipierte Wohnstandort-, Mobilitäts-und Versorgungsverhalten bei der Nutzung von Gesundheitsdienstleistungen den raumordnerischen Konzepten und Modellender Siedlungs-und Verkehrsentwicklung sowie zur Versorgung mit Gesundheitsdienstleistungen gegenübergestellt werden. Die Modelle der Raumordnung (z.B. Zentrale-Orte-Konzept) sollen so auf den Prüfstand gestellt werden um gegebenenfalls auch Handlungsbedarfe der Raumordnung identifizieren zu können.

7   ANMERKUNGEN

(1) In diesem Beitragverwenden wir an einigen Stellen das generische Maskulinum als geschlechtsneutrale Schreibweise. Selbstverständlich wenden wir uns damit ausdrücklich auch an alle Menschen, die sich nicht dem binären Geschlechtssystem zugehörig fühlen, haben uns aus Gründen der Lesbarkeit und Formatierung aber gegen eine gegenderte Schreibweise entschieden.

(2) Eine ausführliche Darstellung der Ergebnisse zu allen Fragen wird im Laufe des Forschungsvorhabens über www.ageing-smart.de zugänglich gemacht.

(3) Wir danken Benjamin Stefan für die Bereitstellung und Auswertung der Befragungsergebnisse des Fachgebiets Stadtsoziologie der RPTU.

Integrating Multi-Scalar Attributes in Assessing Urban Sustainability for the Built Environment in Heritage Sites: The SHAI Model

Dalia Abdel Fattah, Aida Nayer

(Assistant Professor Dalia Abdel Fattah, El Yamama University KSA)
(Associate Professor Aida Nayer, BHI-Egypt, aidanayer@gmail.com)

1 ABSTRACT

Sustainable development approaches are a widely used term, which has been increasingly essential in the Middle East, in general and, in Egypt in specific, for the purpose of planning and urban policies formulation specifically in heritage sites. The research was inspired by the significance of assets of historical areas which motivated the researchers to study and define their values, and find appropriate processes and mechanisms to measure, and evaluate their qualities.

A proposed model, for re-structuring planning processes and assessing information in regards of relative materials on sustainable, urban indicators is discoursed in order to develop a distinctive representation that integrates approaches of urban sustainability in the built environment, in terms of socio-culture and socio-economic aspects, environmental, and spatial dimensions, furthermore, various factors such as time, activities, space, interests, and quality of life.

This paper aims to reduce the complexity of multi-attribute criteria of sustainability, by adopting analytical representation for selected case study, based on a integral model to assess urban sustainability in the built environment for Heritage Sites. This approach investigates indicators of urban qualities relying on the integration of a BEQUEST framework implementing effective qualitative scales (quantifiable cities) and concludes with recommendations to develop an integrative, multi-scalar assessment method.

The paper present details for the proposed framework; Sustainable Historical Area Index (SHAI); model as an integrated tool used to evaluate the capacity of the multi-scaler attributes to assess the urban sustainability in the built environment for Heritage Sites. Results should provide assessment methods to be used in developing the model and provides sustainable evaluations for enhancing urban aspects.

Finally, the paper applies its findings on a case study assessment of the urban setting in El Fustat, Cairo, Egypt. The application comes to show the validity of the conceptual application of the proposed multi-scalar attributes of the Sustainable Historical Area Index upon evaluating values and principles within an existing Heritage Sites towards more sustainable built environment. This paper investigates the optimal corresponding values to be applied in evaluating the sustainability of urban development based on the analytical techniques of the empirical study.

Keywords: fustat old Cairo, assessment models, heritage sites, urban planning, sustainable design

2 INTRODUCTION

Over the past few decades, historical and heritage sites have gained a great priority, reflecting the new urban agenda goals. From this perspective, employing urban sustainability assessment frameworks for the built environment in historical and heritage sites, as key mechanisms for assessing the sustainability variables have become crucial instruments to follow sustainable urban development (UWH, 2015). Particularly during the last decade, sustainability assessment through indicators and indexing models has gained recognition. These assessment approaches based on reliable variables are highly considered as logical approaches in determining urban sustainability measurable values (Singh R. et al, 2009).

Although various urban sustainability assessment methodologies, models, and tools have been developed so far(Kalman H. , 2014), only a few have focused on the historical and heritage sites with a multi-scalar integral approach that takes into account all of the urban sustainability domains; environmental, economic, and social, ecological, and urban.

The importance of the Sustainable Historical Area Index (SHAI) Model as a variable-based urban sustainability assessment model is the quantifiability of the urban sustainability variable and parameters. In addition itaims to reduce the complexity of multi-attribute criteria of sustainability by simplifying, quantifying, and analysing complex and complicated information (A.Nayer, & Fattah, D. A., 2015).

3 HISTORICAL AND HERITAGE SITES

The interpetation of the term "heritage" is quite broad and encompasses various aspects. Part of the heritage are the historic buildings that not only refer to an inheritance from the past, but also carry a definite connotation of value or importance or frame: architectural, aesthetic, economic, and even political and symbolic values. (Nasreldin, R. 2019).

3.1 Defining Heritage sites

The term heritage has different meanings in different contexts. The World Heritage Convention classifies heritage into two categories: Cultural heritage: a monument, group of buildings or site of historical, aesthetic, archaeological, scientific, ethnological or anthropological value. Natural heritage: includes outstandingphysical, biological, and geographical features, different kind of plants or animals species and areas with significant scientific or aesthetic value; those could be best for conservation (UNESCO, 2002).

The Budapest Declaration on World Heritage Convention (UNESCO, 2002) made reference to"ensure an appropriate and equitable balance between conservation, sustainability and development, so that World Heritage properties can be protected through appropriate activities contributing to the social and economic development and the quality of life of our communities". Historical and Heritage are invaluable resources for cities and regions; they contribute to economic development, social cohesion, and citizens" sense of place.

In addition, to these arguments there might be other perspectives to approach historical and heritage values.Adding the word "sites" to the term "heritage" will reveal multiple dimensions of identity and emotional symbol of characteristics continuity in the sense that it has a physical existence (Embaby. M. ,2014).

Historical and Heritage sites, whatever their size and scale, are an essential resource to build identity and a sense of belonging and can serve social cohesion, pride and integration. As a diverse resource, it ranges from tangible valuesof buildings, landscapes, etc. to intangible values, such as traditions, language, knowledge, etc. An important characteristic of the built heritage is its presence in time and space(UWH, 2015). Great attention has been devoted to Historical and Heritage sites considered as request to save local identity(Singh R. et al, 2009). The idea of sustaining Historical and Heritage sites from the urban perspective can help to visualise the diversity of urban form and to explore the cultural, political and historical character of the urban areas, for more suatainable approaches (Singh R. et al, 2009).

3.2 Urban Sustainability for Historical and Heritage sites

The World Commission on Environment and Development (WCED) in 1987 proposed a definition of sustainability as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." The definition considered the balance across three interconnected domains: economic, environmental, and social dimensions(Guzmán PC, ,2017).

Urban sustainability for historical and heritage sites tackles the conservation of the urban context and heritage from deterioration.From this approach, heritage, which has long been absent from the platform of urban sustainability is nowadays recognised to have great potential in contributing to social, economic, and environmental development. Urban sustainability for historical and heritage sites can significantly maintain social capital and generate economic resources and can strengthen the sense of living place and sense of belonging. The new urban agenda also acknowledges historical and heritage sites as a crucial component of urban sustainable development (10,11), particularly in the sub-goal 11.4 that aims to "strengthen efforts to protect and safeguard the world's cultural and natural heritage" (Fletcher, R., 2007).

4 ASSESSMENT TOOLS: MULTI-SCALAR ATTRIBUTE

In recent years, various tools and methodologies have been developed, both at a strategic and operative level, for Assessing Urban Sustainability For the Built Environment in Heritage Sites (Murtiyoso, A., 2018). The research is adopting the multi-scalar approach as a tool for assessment. The multi-scalar approach works on the concept of variable and parameters that enables the exploration of the urban sustainability dynamics of interrelated key processes in the Historical and Heritage Sites.

4.1 Quantitative assessment method

The Multi- scalar attribute represents a family of methods that describes and models integral evaluations with respect to different interests, subsystems of the cases, or disciplinary perspectives. This method is a mean to analysing situations and creating an evaluation process. As a case evaluation method,the multi- scalar attribute tackles both the conceptual/qualitative and numerical/quantitative approaches. The objective of the multi- scalar attribute is to attain a conjoint measure of the urban sustainability variables in correspondence to the urban sustainability main domain (Guilherme C. et al., 2013).

4.2 Sustainable Historical Area Index (SHAI)

The literature highlights the shortcomings of the current evaluation models and the urgent need for more efficient assessment methods and tools as sustainable urban development demands rise rapidly (Vincenzo B., et al., 2002). Accordingly, the current study demonstratesthe multi- scalar attribute as an assessment tool. It discussses a proposed model for re-structuring planning processes and assessing information regarding sustainable, urban variables. The purpose is to develop a distinctive representation that integrates approaches of urban sustainability into the built environment, in terms of socio-cultural and socio-economic aspects, environmental, and spatial dimensions. Furthermore, it incorporates various factors such as time, activities, space, interests, and quality of life. This index is based on the bequest framework(Mark D. et al., 2014) and the quantifiable city theories (Rose, C., 1995), in addition to local community psychological aspects, and taking into consideration the decision making process among key actors representing governmental institutions, local communities and NGOs (A.Nayer, & Fattah, D. A., 2015). The model aims to provide a more effective sustainability assessment by taking all of the major aspects affecting sustainability into account.

5   RESEARCH METHODOLOGY: SHAI MODEL FOR ASSESSMENT

The paper is presenting a structured methodology to provide a coherent assessment of heritage beneficial implementation of sustainable development approaches. Based on the literature review and the qualitative and quantitative content analysis, with the integrated community involvement, the methodology is running accordingly:

Step 1: Building up the model: Integration between different approaches, based on the literature review, backgrounds and definitions.

Step 2: Discussion: Case study analysis (on site documentation for existing conditions, including investigations through observations and semi-structured interviews with multiple stakeholders (local-residents and visitors – NGOs – Local government and institutions)

Step 3: Model implementation and variable assessment (measurable verification), case study as an application.

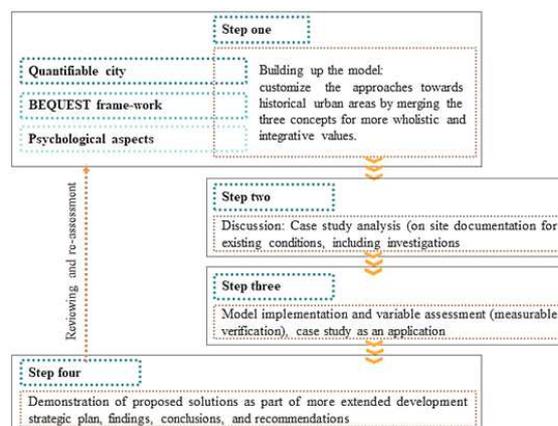
Step 4: Demonstration of proposed solutions as part of more extended development strategic plan, findings, conclusions, and recommendations.


Figure 1: Structured Methodology, by Authors.

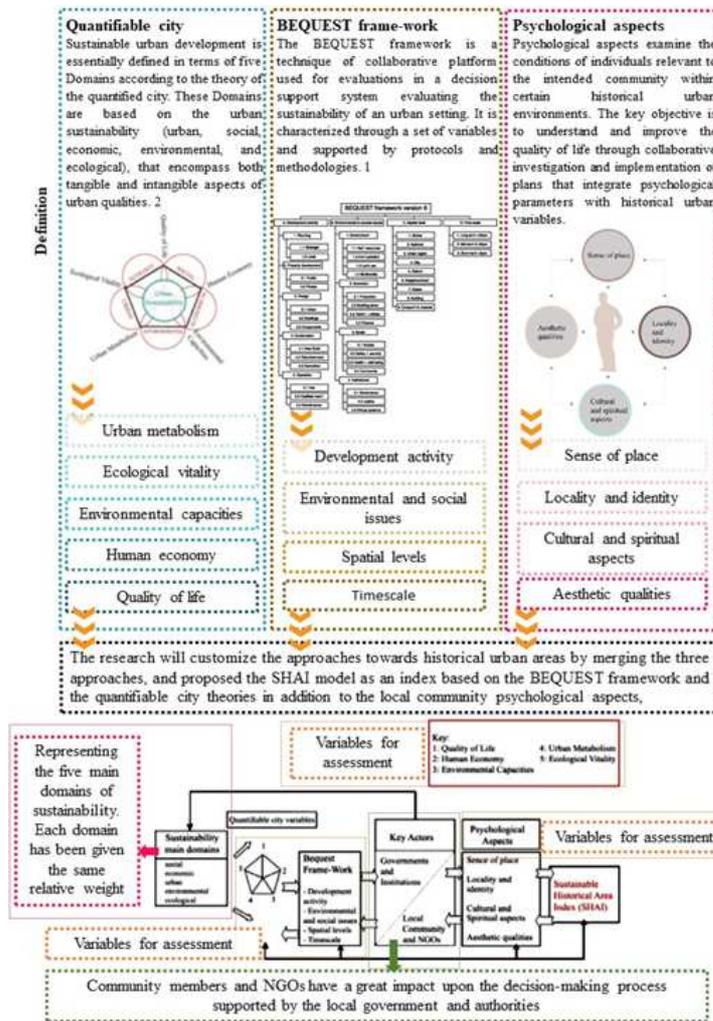
STEP 1: BUILDING UP THE MODEL: The integration of multiple approaches, each representing certain concept. The model introduces wholistic vision that accommodates various layers of informations, and tackles deep interpretation for the historical and heritage sites.


Figure 2: Sustainable historical areas index (SHAI) Diagram, by Authors.

Theories and approaches	Variables	Discussion
Quantifiable city	Quality of life	Giving a value and standards to the living environment.
	Urban metabolism	Reflects the deep relation between the urban physical features of street width, building heights, and theirrelationship with the environment, in terms of shades and shadow, air circulation, and landscaping.
	Ecological vitality	Analysing the impact of the environment and studying the interactions withinthe local community
	Environmental capacities	It is a process that involves, shifting societal attitudes, to pursue environmental development, strengthening individuals" capabilities.
	Human economy	The ability of the local community to be a part of the financial process of the sustainable urban development in the historical areas
BEQUEST frame-work	Development activity	Projects and strategies, in the approach to conservation and preservation, property development public and private interests.
	Environmental and social issues	It explains how the local community is capable of preserving its surrounding environment and re-using the resources of the local materials.
	Spatial levels	Various spatial levels ranging from the scale of the whole urban setting down to that of the individual historical building and its construction systems and material components.
	Timescale	Represents the normal scale used in economic and strategic planning, as time-scale phases of evaluation and re-assessment.
Psychological aspects	Sense of place	It is a place made up of a web of various buildings and streets, from different periods along history, which creates various cultural and urban strata.
	Locality and identity	The feeling of belonging to a certain urban context, as part of the self-conception and self-perception to local community within its urban settings.
	Cultural and spiritual aspects	Aspects represent the psychological values of the local communities related to their urban setting, and culture.
	Aesthetic qualities	The theory of beauty, providing luxury for human demands, feeling comfortable, safe and secure.

Table 1: Sustainable historical areas index (SHAI), by Authors.

The sustainability historical areas index (SHAI) Model is developed as an advanced variable-based urban sustainability indexing model.It is presented through thirteen variables, which will be evaluated based on statistical methodology according to their relative weights, depending on case study approach, applying data gathering based on observation,and semi-structured interview for the actual physical context for the designated site (A.Nayer, & Fattah, D. A., 2015). The idea of the direct weighting means that the evaluator is asked to simply specify the weights numerically. This is, of course, possible for only a small number of attributes. The weight can be specified in percentage (with all weights summing to 100%) (Vincenzo B., et al. , 2002).Appropriate values are expected to be assigned, each variable (X1,X2… Xn) gives a value to each domain of the (SHAI) = YN, (social, urban… etc.,) Scale as: Inconvenient: 0-5%, Moderate: 6-10%, Good: 11-15%, Convenient: 16-20%.

The five domains originally driven from the "Quantifiable city" approach are representing a pentagon with equal values, translated within the SHAI Model as 20% value for each domain. In addition, for more accurate calculations, and more reliable numerical values, the formula had to have one variable to be measured (the thirteen variables) while the other conditions on a constant state. Accordingly the five domains kept an equal relative weight to facilitate assessing the variables, and validate the idea of applying the model upon various historical sites (which might not by necessary have a domain with a privilege upon the others), dealing with all the domains on an equal distance approach.

Sustainability Historical Areas Index Variables / Urban Sustainability main Domain	Sustainability historical areas index variables													
	Human economy	Urban metabolism	Ecological vitalities	Quality of life	Environmental capacities	Development activities	Environmental and social issues	Spatial levels	Timescale	Sense of place	Locality and identity	Cultural and spiritual aspects	Aesthetic qualities	Total
Social20%														
Economic20%														
Ecology20%														
Environmental20%														
Urban20%														
Total100%														

Table 2: Assessment methodology sustainability historical areas index (SHAI), by Authors.

The paper methodology indicates the application on the SHAI Model by analysing a case study of a historical setting. The evaluation process followed the hierarchy of the site introduction, the documentation of the existing conditions, the observation and finally the application of the assessment tool.

6 STEP 2: DISCUSSION: CASE STUDY ANALYSIS ASSESSING URBAN SUSTAINABILITY IN HERITAGE SITES; FUSTAT, CAIRO EGYPT

6.1 Defining the Context of Fustat

Fustat's historical significance is rooted in the days of the Arab conquest in 21 AH/641 AD during the Byzantine era. Caliph „Umar ibn al-Khattab" gave his orders to establish a new capital for Egypt. Fustat was founded by "Amr Ibn al-Aas" becoming Egypt's first Islamic capital. The new capital, with its unique location in proximity to the Nile and the Fortress of Babylon, had quite distinguished values. Later, it became part of the Fatimid capital. References mention that the area was named Fustat, derived from the Arabic word for "tent", named after the camp set up by the army of "Amr ibn al-As" because its initial inhabitants lived in the army"s tents before they built the original Amr Ibn Al-Aas Mosque in the same location as the new one (which is also known as al-"Atiq" the Old Mosque). Fustat remained the capital of Egypt for around 500 years, on and off, until 1168(Feilden, B., 2007).

Today, Fustat is a part of the Old Cairo District, one of the historically significant spots in Cairo, famous for its important archaeological sites, such as the Mosque of „Amr ibn al-As", the seven old churches, the excavated ruins of the old city, the Nilometer, al-Manesterley palace, and Mohammad Ali Palace in al-Manyalm (Karim K., 2016). Fustat is considered one of the unique cultural heritage sites in the world, where

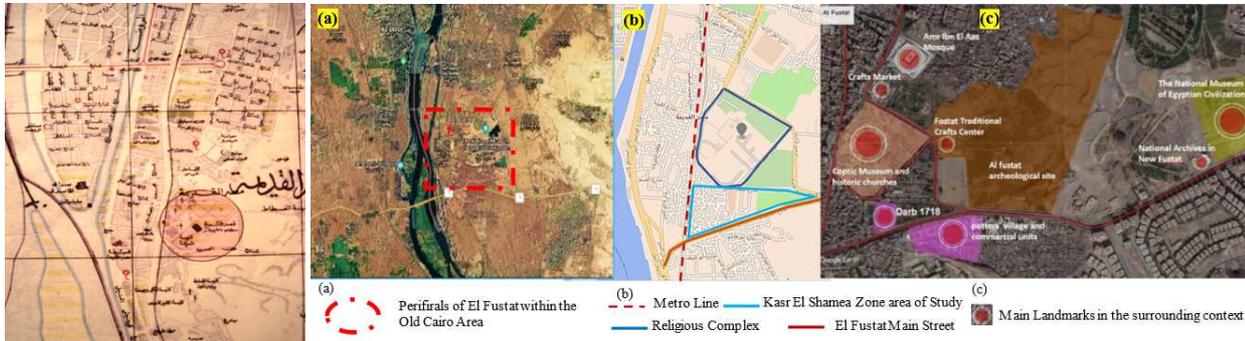
the integrated area of Fustat along with the area of Islamic Cairo and Khedivian Cairo is a world heritage site, in figure 3, (Wladyslaw B., 2016). Great dedication was attributed to site preservation and development, and projects have been implemented, tackling various aspects and domains (Aghakhan, 2001). The development project suggested a framework of integrated development policies, based on having the greatest variety of archaeological sites on a global scale. It aims to integrate historical and modern areas in order to ensure continuity and vitality while balancing the economic development of the site with environmental and aesthetic heritage as well as tourism potential (Feilden, B., 2007).


Figure 3: Fustat contextual map, Wladyslaw B. 2016. Figure 4: Case study Localisation: Old Cairo zone highlighting the study area of "Kasr El Shamea" in the core of "El Fustat" ,by Authors.

The selected localisation represents the three main aspects of architectural heritage, comprising the following integrated properties which promote the importance of urban sustainablility:

Firstly the integration of monuments: this refers to all the buildings and structures of conspicuous historical, archaeological, artistic, scientifc, social, or technical interest, including their fixtures and fitting presented in the existance of the "Religious Complex"as indicated in Figure 4.

Secondly the surrounding context containsa group of heritage buildings in addition to residential neighbourhouds at various densities which require interventions to assure the sustainable developmentof the area showcasing its historical, archaeological, artistic, scientifc, social, and technical interest.

Thirdly, the selected site of Kasr Elshamea incorporates combined contributions ofhumankind and nature.Some activities based on local products such as leather workshops and stone carving are supporting the tourism and visitors interest in the area. Their settingsare distinctive within the topography and, together with the inherited historical background rooted in cultural settings of the inhabitantsthey are built upon.

6.2 Landmarks in the surrounding context

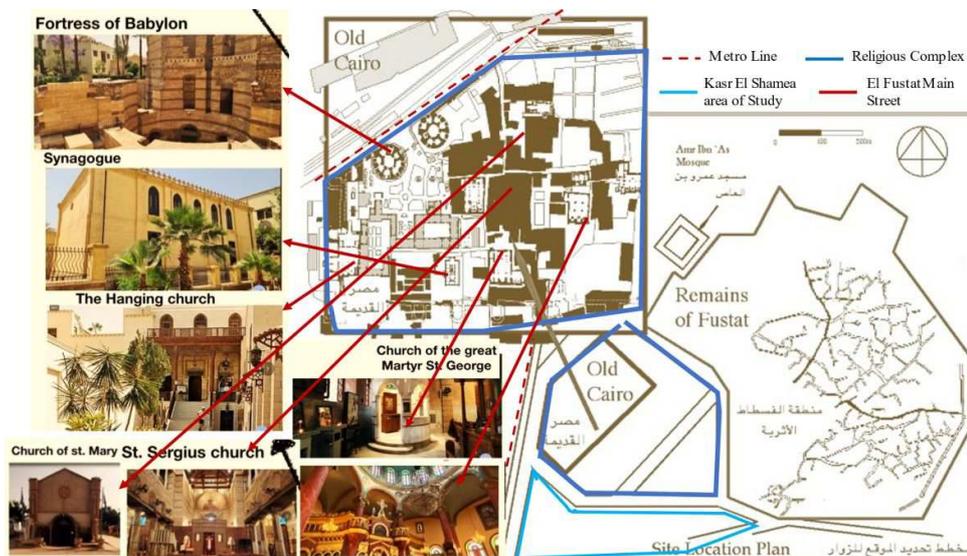
Several Projects have adopted the idea of restoring the existing historical buildings in Fustat, in particular the Religious Complex in "Babylon Fort" (Figure 5).


Figure 5: The Main Landmarks in the surrounding Context of "Kasr El Shamea", by Authors.

6.3 Defining the studying site

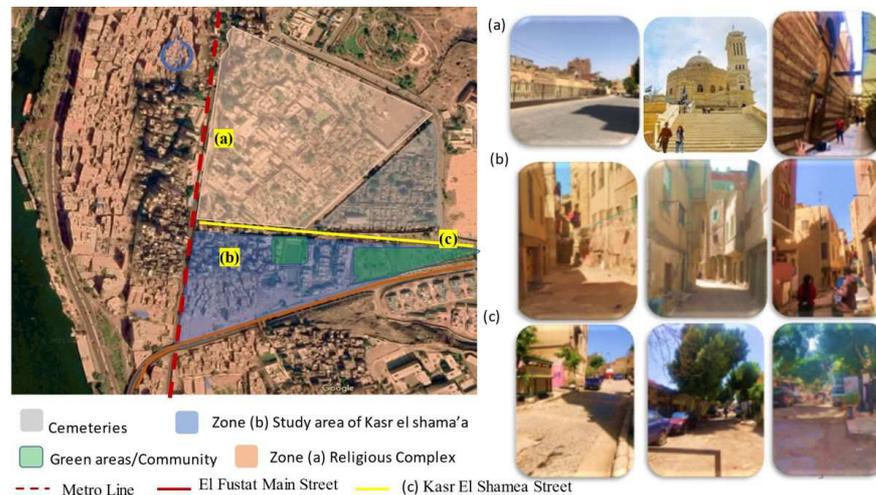
Figure 6 shows existing values to be assessed by the research team in the urban context of Kasr El Shamea regarding architectural features. Explain the architecture in terms of heritage building, and discuss their relevance in terms of heritage values related to the built environment add ref. to the cond. And regulations for future additions and renovations. This highlights the importance of elaborating urban management processes to support sustainable development of future city expansions and public spaces (Matero F., 2000). Urban heritage streets have some common characteristics that define their style and history. They can create a more liveable community by providing a setting for activities which are attractive for all people, including walkability to enhance the pedestrian experience (H. Elshimy& R. Ragheb, 2017).


Figure 6: Existing values to be assessed in the urban context in terms of architectural features, by Authors.

6.4 Discussion: Assessing Urban Sustainability Domains

Assessing urban sustainability domains plays a key role in defining sustainable measures of development in heritage-related sites (De la Torre M, 2002). Studies are provided continuously by local authorities and researchers with a set of demonstrations as their main target, that supports the recognition and expression of the values latent in the work asbeing of special importance in the conservation of architectural heritage (20). Analysing the urban context and the settings of activities of the inhabitants activity brings more value to the decision-making on treatment and intervention in such settings (Sama Badawi, A.Nayer, 2017).Nevertheless, the selected site shows a wide concentration of heritage buildings, sites, structures, and landscapes, as well as the consistency in visual elements throughout the district, including scale or built form, all give the impression of a distinct time period, and define the uniqueness of an area (A. Nayer, Samaa Badawi, 2016).

This section discusses the detailed aspects influencing the conservation policies in the Fustat area in an integrative approach while being inspired and aspiring local community anddecision makers like the case of Jameel Community in 2022, highlighting the role of participatory approches in sustainable urban development initiatives.

6.4.1 Demographic and Social Domain

A thorough investigation is done to define the social demographics of inhabitants of the study zone,to emphasis on the local residence capacities and potentials, (H.Rashed, 2013). The results in Figure 6 shows that the majority of inhabitants are elderly persons and families of 4 to 6 persons residing in the units allocated to the south of the Kasr El Shamea Street. Educational facilities do not exist on site. Nevertheless it comprises a medical complex and community centre including sport court.

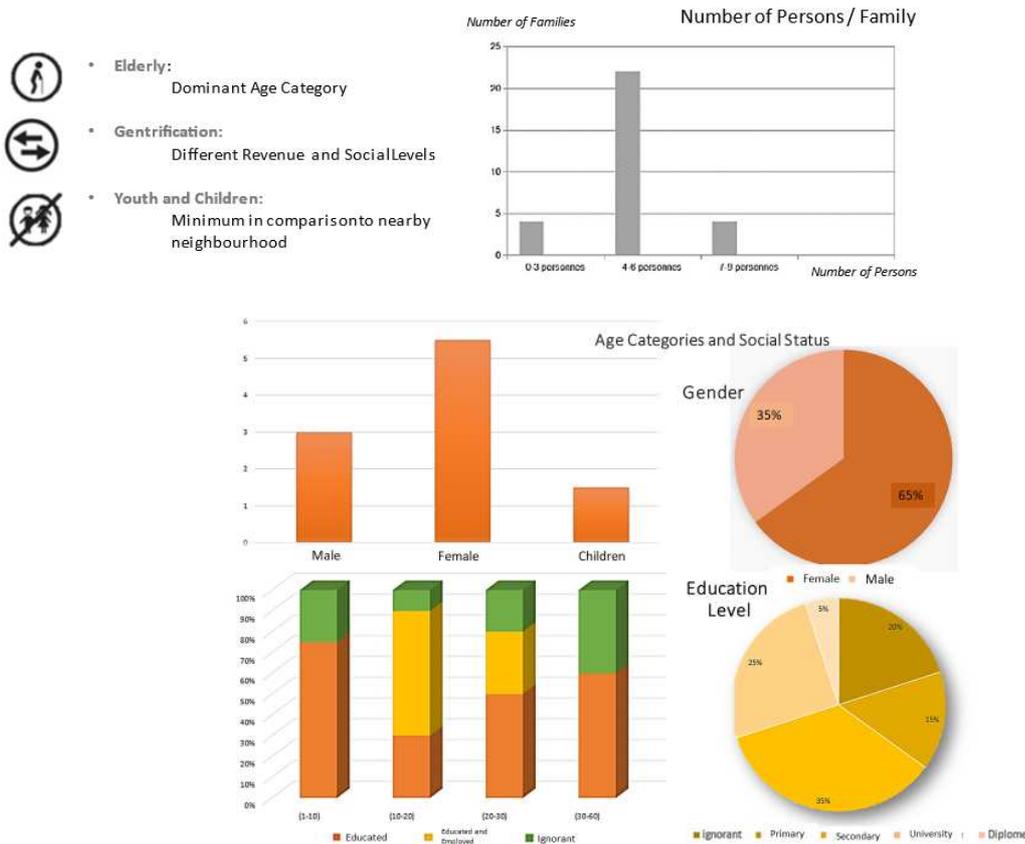
The majority of the residents are middle sized families of 4 to 6 persons and children are mostly attending schooling in the younger age while trying to find small jobs to support their parents. Most of the residents tend to learn the local crafts related to leather making or pottery enherited from elderly generations. It is recognised that number of females is up to 65% of the total population and they do participate in sustaining the local cgftsmenship by selling the products to small shops or for lower daily wages.


Figure 7: Demographic pattern for Kasr El Shamea residents, by Authors.

6.4.2 Economic Domain

The most relevant economic activities are supporting the tourism potential of the nearby existing heritage sites (Figure 7). The existence of local small shops for leather works and gifts are located on the ground level of the residential units, inhabited mostly by low-income families. Some local food stalls and cafes are more frequently active in the evenings and during weekends. The commercial activities on site have the purpose of preserving the historical and cultural built environment (Shaheen, P. 2010).

Figure 7: Exiting activities supporting the sustainable development in the area, by Authors.

6.4.3 Ecological Domain

Ecological values are driven by the role of the environment and the interactions among the local community. Fustat has a unique ecological footprint, and direct access to the Nile banks, in addition to the Ein-ElSira lake. There has been a large change in the surface water masses of the area where some have dried out while others have extended. since Ain al-Sira lies on lower land, sewage water runs down to the lake, creating both ecological and environmental damages (UNESCO, 2012).On the other hand, the natural topographical settings in the nearby area are due to archeological sites going back to the Greco Romain eras. The existence of natural stones also encouraged the settings of local human activities for artifacts and touristic products, as well as locally built units for workshops or residential units in an informal setting.

422

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

6.4.4 Environmental Domain

The natural environment supports and sustains human life in many different ways. It plays a critical role in delivering social, cultural, economic, and environmental outcomes for the local community. The Site is currently in the heart of the potential for developing Old Cairo, It provides opportunities to diversify and strengthen the economy in sectors like tourism and local art-crafts, yet the environmental conditions impose adaptation to the environmental settings of the capital with related densities and infrastructure demands, (URHC, 2012). As mentioned, The site suffers deeply from sewage complicationsand need for more support regarding waste management and garbage collection, in addition to lacking vegetation and air quality.

6.4.5 Urban Domain

The site has faced layers of development and showcases the typical sprawl impact on the existing urban fabric (Figure 8) showing densities and quality of the urban fabricof three different zones.

Figure 8: Existing densities and varity of urban fabric, by Authors. Figure 9: Demolished units on Fustat main street, by Authors.

The site has a unique organic urban fabric with layers of accumulated history and spirtual values. Due it its significance many project redevelopments have been proposed for the area (UNESCO, 2015). Of the most recent ones, thedevelopment project for informal areas in the heart of Cairo has resulted in the demolition of a number of residential buildings with deteriorated status (Figure 9 a) resulting in vacant land (Figure 9 b) where further solutions for sustainable development are proposed by the research project, in alignment with policies as well as considering local potentials resulting from the assessment of related values on the site.

Considerations for the displaced inhabitants forming less than 10% for actual residents of the site are alocated to new housing settelments at Al-Asmarat , the process is focusing on the upgrading of the economic conditions of existing site by ensuring the available infrastructure and the actual potentials of craftsmanship in the study area. Further studies by Saleh E., 2022, highlights the advantages and drawbacks of the upgrading project comprehensively of informal settlements in Cairo region.

Considerations for decision making regarding further develepment plans discusses the impact on the local art and craft activities which gain income from integrating the community and enhancing touristic values of the site.

6.5 Step 3: Model implementation and variable assessment

Sustainable Historical Area Index (shai):Model Assessment

Based on the documentation of the existing conditions, and the studies of the sustainability domains, the SHAI model proposes to analyse, measure, and assess the implemented sustainable development for the Fustat area. The model represents five domains: social, economic, ecology, environmental and urban, in addition to thirteen variables defining the sustainability historical area index. Each domain has a weight of 20% with a total of five domains of 100% total. Each cell represents a value of the variable in reference to the domain with a weight out of 20, with a final row with a total percentage of each variable, in addition to the vertical column indicating the percentage of each domain.

The assessment methodology of the Sustainability Historical Areas Index for the Fustat site presented in Table 3 indicates a set of measurable values and weights for each domain and variable. The values were attributed by the evaluators (Fattah, D. A., 2017), representing multiple categories. The community as the local residences, in addition to the historical sites" visitors, whether national or foreigners. As for the NGOs, number of non-governmental institutions offered support through cooperative representative from the local residences accommodated guided tour around the site, and facilitated group meetings with the families, women, and children. Those NGOs, one supported by Amr Ibn Alas Mosque, the other represented the Christian community, and finally the workmanship representing the craftsmen and the local art. Regarding

the local authorities, they acted as enabler, they supported the idea of community involvement and provided validation documents to allow the researcher to collect data, applying observation, taking photos, and produce visual maps.

Sustainability Historical Areas Index Variables / Urban Sustainability main Domains	Human economy	Urban metabolism	Ecological vitalities	Quality of life	Environmental capacities	Development activities	Environmental and social issues	Spatial levels	Timescale	Sense of place	Locality and identity	Cultural and spiritual aspects	Aesthetic qualities	Total	Percentage
V1,V2,V3……..Vn	V1	V2	V3	V4	V5	V6	V7	V8	V9	V10	V11	V12	V13		
Social 20%	13	17	15	15	13	18	13	18	16	17	19	19	17	210	**80%**
Economic 20%	12	14	13	13	13	17	13	15	16	17	17	17	17	194	75%
Ecology 20%	16	17	13	14	14	18	14	15	15	18	18	18	17	207	79%
Environmental 20%	14	14	13	13	11	18	14	16	16	18	18	18	18	201	77%
Urban 20%	16	14	12	13	12	19	14	18	18	18	18	20	18	210	**80%**
Total 100%	71%	76%	66%	**68%**	**63%**	**90%**	68%	82%	81%	88%	**90%**	**92%**	87%	Total percentages	

Table 3: Assessment methodology sustainability historical areas index (SHAI), by Authors.

The numerical values were extracted and translated by the researcher from huge amount of date collected through the semi-structed interview, and focus groups. The idea of the numerical assessment was to validate the qualitative data into quantitative values. From the table above, the relatively high values of three variables are noted (V6: Development activities – V11: Locality and identity – and V12: Cultural and spiritual aspects) scoring approximately 90 - 92%, affecting the values of both the social and urban domain, scoring an accumulative figure of approximately 80% from the thirteen variables. The emphasis of V6 (Development activities) represents all the previous projects, and the current ones, targeting sustainable developments. The values of V11, and V12 (Locality and identity, Cultural and spiritual aspects) are expressing the high sense of locality and place attachment of the local community, and the significant cultural and spiritual values within the Fustat sites. The readings are representing the sensitivity of the current status, with high values of the variables related to the development and local identity, while, on the other hand, the Environmental capacities (V5), and Quality of life (V4) show very low values. The results indicate that, despite the historical and heritage values of the Fustat site, and its significant character with all the proposed and implemented sustainable development projects, still suffers from lacking services, facilities, and environmental and ecological treatments. Measures are indicating a poor quality of life, which urges a more holistic vision that would tackleall the variables in a parallel pattern.

Step 4: Demonstration of proposed solutions

The SHAI model is offering the interrelation of the integrated variables in a graphical visualization as per the framework shown in figure 10. The arrows represent the flow of information and how the model works, how the variables are connected and affecting each other as an endless loop of enhancements and developments. Annotated on the model the values of the variables with a highlight on the highest (green) and lowest (red) values. Noted that both Environmental capacities and environmental and social issues scoring the lowest values 63% and 68% respectively. These numbers indicate the poor environmental quality, and its direct harmful impact on the historical site. It acquires an instant urban solution. Although, development projects are introduced, but the aim of the SHAI model is to highlight, focus and define the deficiencies.

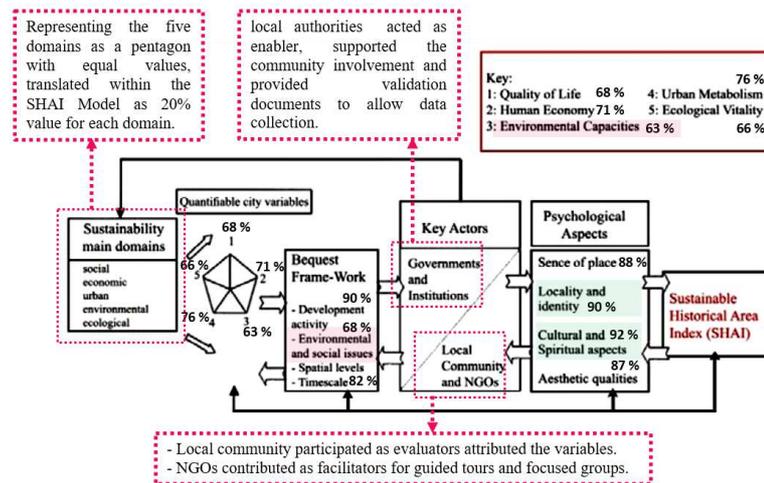
The implemented projects had focused on the urban development, in terns of building restoration and street networks, however, lacking the environmental approach with disregards to its importance and damageable effect. On the other hand, the SHAI model flourishes the variables with the highest scores as: locality and identity, and cultural and spiritual aspects, 90% and 92% respectively.


Figure 10: Framework demonstration of proposed solutions integration, by Authors.

The site is quite rich with sense of locality, that creates a strong identity and community solidity. These vibes were shown throughout the focus groups. The idea of having a strong identity and community connections, facilitating the residences participation and involvement. This promotes a stable platform of a motivated community to support the development projects and act together to enhance their local urban setting.

7 CONCLUSION

The paper applies its findings to show the validity of the conceptual application of the proposed multi-scalar attributes of the Sustainable Historical Area Index upon evaluating values and principles within existing Heritage Sites towards a more sustainable built environment.

The paper presented details of the proposed framework; the Sustainable Historical Area Index (SHAI); model as an integrated tool used to evaluate the capacity of the multi-scalar attributes to assess the urban sustainability of the built environment for heritage sites. The model has been applied to a case study based on a research project for assessing the urban sustainability of the Fustat site, focusing on Kasr El Shamea Street. Assessment results indicates promising results in the social and urban domains (as mentioned in the discussion) scoring relatively high values on the SHAI Model. The numerical values provide reliable readings, conveying valid figures with a clear vision of the site's existing conditions. Investigations, surveys and the analysis of gathered data demonstrate that detected points need specific remedies that should be mended in terms of spatial solutions and community involvement. Parallel investigations of people's responses, as well as physical surveys provide a complete image of howpublic involvement would work best to enhance the visitors' experience. Despite all the dedicated efforts and proposed projects, the site is still lacking essential needs, with major deficiencies of environmental issues such as waste management, freshwater supply, ecology of water level and sewage leaking into the lake water, and finally the economy, with poor communities and low-incomes.

Further suggestions are made towards resolving major points to urban enhancements. They include: encouraging safe pedestrian accessibility while preserving the built environment in the historical area of Kasr El Shamea; encouraging public services and enhancing the quality of spatial features and establishing connecting points with the adjacent heritage sites by including commercial purposes and while preserving the historical and cultural built environment.

Accordingly it can be concluded that there is a need for a regulatory model assessing the values of sustainable developemnet factors existing in the heritage sites to support the presence and conservation of development of today's societies taking in consideration the the architectural heritage. The research emphasises on the main purpose of attracting visitors, both local residents and tourists, sustaining the unique sources of income and improving the quality of life of the district's surrounding neighbourhoods while integrating existing community in the process of assessment and potential developement.

8   LIMITATIONS

Limitations of the study is due to the continuous alterations performed on the extentions of infrastructure development plans in the periferals of El Fustat zone. Instead, reflection on site potentials should consider more sustainable and effective developments for both residents' and visitors' interests in the zone of Kasr El Shamea.

9   SUGGESTIONS FOR FURTHER STUDIES

The main goal of the "SHAI Model" research project is to assess sustainable values for sites under study by means of weighted analysis to provide quantifiable measures towards setting priorities for planimplementation. Thus, other potential areas of study can be suggested to apply the model while adjusting the value settings according to related analytical investigations with the aimto simulate a heuristic responsive set of recommendations and guidelines for future sites under study.

Integrative Design Solutions for Connecting Street Trees to the Urban Water Cycle

Karl Grimm, Dagmar Grimm-Pretner

(Dipl.-Ing. Karl Grimm, Karl Grimm Landschaftsarchitekten, Mariengasse 13/2, 1170 Vienna, Austria, k.grimm@grimm.co.at)
(Dr. Dagmar Grimm-Pretner, University of Natural Resources and Life Sciences Vienna, Institute of Landscape Architecture, Peter-Jordan-Straße 82, 1190 Vienna, Austria, dgrimm@boku.ac.at)

1 ABSTRACT

Climate change adaptation and the need to improve micro-climates in cities bring urban forestry into focus. Street trees are important nature-based solutions (NBS) with multiple functions. But only large, well-developed trees that are at least a few decades old can provide the necessary range of ecosystem services and perform the tasks required. There are two essential criteria for trees to grow old: (1) the qualities of the site, in particular the adequate supply of water, air, and nutrients to the root zone, and (2) the choice of tree species. This links tree planting in the urban environment to the improvement of the urban water cycle, which is a goal of NBS in its own right.

In this paper, we explore how tree planting and the urban water cycle can be combined by means of integrated design solutions in different types of open spaces in cities. Based on a qualitative analysis of built design projects using NBS in Austria and scholarly literature, we explore the requirements for and the range and combinations of different design solutions for NBS.

In the design of urban rainwater management based on the "sponge city" principle, NBS can be used for the "collection of water", "retention of water", "purification of water", and "discharge of water to the atmosphere or water bodies". Three different design approaches for water management are possible: "concealment" (diverting rainwater rapidly from the surface to underground systems), "integration" (leaving the water visible, but unobtrusive, and integrating it into the overall design of the site), and „showcasing" (transforming stormwater measures into water-based amenities).

The analysis of 24 projects showed that implementing NBS by using the sponge city principle for trees has become an important element in stormwater management cascades and has been applied in a range of different types of urban open spaces. The sponge city principle for trees is primarily a NBS with low design impact: strategies of "concealment" and "integration" predominate. "Showcasing" has only occurred in conjunction with sunken planters for purification. Incorporating NBS into the overall design of an open space has untapped potential.

The projects under analysis also show that while the water conditions for trees are being improved, the choice of species is also changing. The focus now is on species that are able to cope with hotter and drier conditions. Native species are being replaced with trees from appropriate climatic regions.

The conclusion is that finding synergies between landscape design and engineering provides a rich source of innovation for new urban open spaces. The overall design goal is to achieve an integrative solution serving technical, ecological, social, and economic needs. Designing nature-based solutions means taking a site-specific, integrative approach and connecting with a citywide network of green infrastructure.

2 INTRODUCTION

2.1 NBS connecting stormwater management and street trees

Stormwater management in urban planning and site planning is increasingly becoming an issue (Kruse 2014). On the one hand, quantitative changes in the water cycle caused by surface sealing – in conjunction with a climate change-related increase in heavy rainfall events –have brought existing sewer systems to the limits of their capacity. On the other, urban heat islands created by enlarged structures and surfaces, increased waste heat, and reduced evaporative cooling in connection with the climate change–induced aggravation of heat periods are becoming a public health problem. This problem can be counteracted through shading by vegetation and adiabatic cooling caused by increased evaporation (Schmidt 2010). This requires many strong, healthy, and well-irrigated trees providing evapotranspiration in built-up areas.

Summarizing the two EU Commission strategies (EC Energy, Climate Change, Environment n.d.& European Research Executive Agency n.d.), green infrastructure is the strategically planned network of

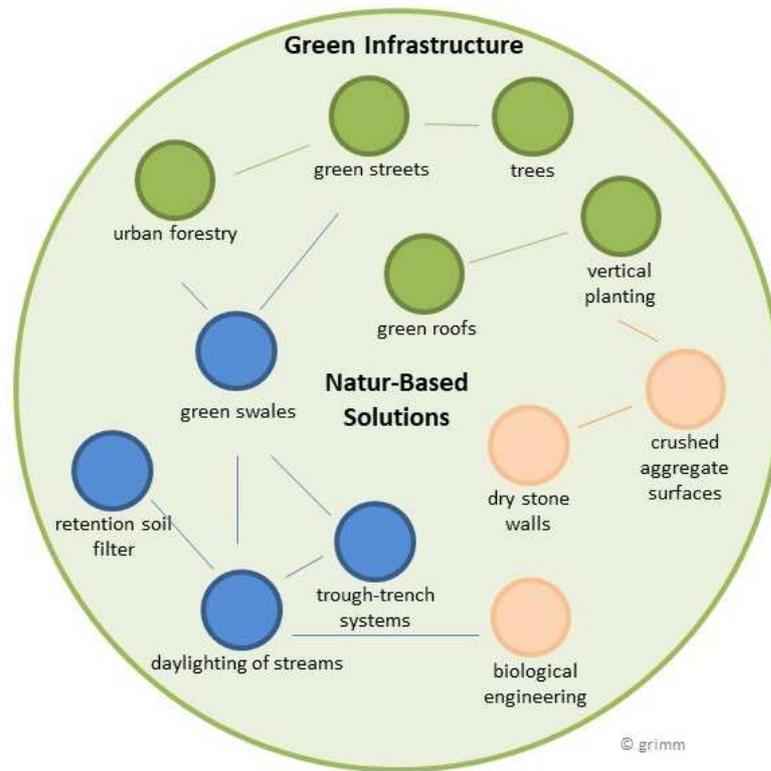
green structures, while nature-based solutions are the concrete measures to address specific challenges that can be integrated into a strategic network. NBS can thus be seen as modules of green infrastructure. Many of them address water management or at least have an influence on the water balance (Fig. 1).


Fig. 1: Nature-Based Solutions –Modules of Green Infrastructure (source: Karl Grimm)

Seen from a climate and water-management perspective, increasing the evaporation of stormwater has the highest priority, ahead of infiltration for groundwater recharge. Stormwater management in combination with urban greening measures can also support biodiversity, offer an experience of nature, and enhance recreational value in urban areas. Accordingly, stormwater management implemented on roofs and facades and in open space is increasingly interlinked with landscape architecture. The transformation of urban drainage systems includes opportunities to enhance the quality of open space in existing urban structures as well as in new urban developments in terms of a network of green infrastructure (Grimm 2018). The living elements of open-space design – trees, planting, permeable surfaces – are themselves NBS. To effectively deploy the multiple functions and services of NBS, a precise development and integration of NBS into high-quality designs is a major task for the future. This implies a paradigm shift in planning for infrastructure and in designing open space, moving towards integrative solutions that are also customized for specific sites.

2.2 Research question and aim of the paper

The focus of this paper is on NBS in the context of trees and water. We investigated which NBS have been implemented in public space in Austria and how water was integrated in the design of the open space.

It is the aim of the research to identify the status of NBS realizations in Austrian projects and to build a knowledge base on tree planting and the urban water cycle. It was important to identify the scope and trends of implementation.

3 MATERIAL AND METHODS

A literature analysis covered the topics urban rainwater management and design, the sponge city principle for trees, and the tree species suitable for urban environments, so-called climate-fit trees. The literature review set out to identify criteria for the analysis of the built projects taking into account the various functions of the realized NBS in connection with a design approach for rainwater.

Based on lists from AK Schwammstadt (the sponge city working group), we conducted a survey in May and June 2023 and identified 60 sponge city projects in Austria focusing on tree planting and the urban water cycle, which varied in terms of their stage of completion, size, and complexity. All the projects are either in a public space or publicly accessible. The list does not claim to be complete. We excluded projects that are still in preparation or planning or in which construction is not yet complete. We also excluded built projects where no information was available that could be analysed. We included projects focusing on rainwater management to cover a broader scope of NBS. This resulted in a list of 24 projects (Tab. 1) for further analyses. We conducted a qualitative analysis of the 24 cases aiming at complementary rather than comparable information (Yin 2010) to get an overview of the range and state of implementation.

Tab. 1: List of analysed projects

4 BACKGROUND

4.1 Urban rainwater management

Traditional urban drainage was developed in the 19th century (Brombach et al. 2011) and is based on end-of-pipe solutions (Geiger&Dreiseitl 1995). Water is primarily regarded as a problem and is rapidly removed into the sewers, into surface waters, or into the groundwater via dry wells. Green infrastructure seeks integrative solutions, and water is recognized as a resource. It aims to rehabilitate natural water cycles, harvest rainwater, protect against urban flooding caused by stormwater and cloudbursts, and reduce pollution. Furthermore, rainwater can also be regarded as an amenity (Grimm 2018). It is necessary to distinguish between these goals, as there is some conflict between them, and they require different solutions. As a result, water-sustainable urban design cannot be separated from open-space design.

4.1.1 Functions of NBS on site-level

When implementing NBS as design elements in an urban open-space context, the functioning of green infrastructure in more natural landscapes may serve as a model. The principles of hydrological systems are well researched. Surface runoff is determined by topology, geology, and land cover. The extent of tree canopies plays an important role. In the design of urban rainwater management based on the sponge city principle, NBS are used for various functions in different stages of the water cycle:

- Reduction of runoff
- Collection of runoff
- Retention of water
- Purification of water
- Discharge of the water to the atmosphere or water bodies (surface water or groundwater).

The systematic arrangement of these elements is referred to as a "management train" (Roehr&Fassmann-Beck 2015).

4.1.2 Design strategies for rainwater

Water features are a traditional topic in landscape architecture, but the creation of multifunctional systems based on green infrastructure principles requires a new taken design approaches, incorporating the various functions and benefits of NBS.

Following an analysis of literature and case studies in Europe and North America, three major design strategies for designing rainwater-based NBS were identified (Grimm 2017):

"Concealment" means that rainwater is removed from view as rapidly and unobtrusively as possible and diverted to underground systems, e.g. in downpipes and gutters.

"Integration" describes designs in which the water flow is open, but the system and its components are not highlighted. It is an unobtrusive integration of the infrastructure in the overall design of the site and everyday use of the open space. The elements involved can include green roofs, green swales, or sunken planters.

"Showcasing" means that the design not only addresses stormwater management but transforms these measures into stormwater-based amenities. Designs create site-specific features and interactions. The term "artful rainwater design" was coined by Stuart Echols and Eliza Pennypacker (2015) to describe this approach. A major consideration when designing for rainwater is that open space is used less when it rains, so showcasing rainwater should also make a feature of the system in dry weather. A planting design approach is called a "rain garden", when swales or sunken planters are designed as herbaceous or mixed borders. The planting design can be naturalistic or explicitly horticultural. It is a popular design approach in the USA that originated as a concept for making infiltration in front or back yards popular, but the term is now applied to any infiltration measure using specific planting.

On-site, a combination of "integration" and "concealment" is usually applied, and "showcasing" is the exception. The overall goal is to achieve an integrative solution serving social, technical, ecological, and economic needs by combining these three design approaches with functions of NBS.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4.2 From urban greenery to green infrastructure

4.2.1   Sponge city principle for trees

The use of structural soils (Bassuk et al. 2015) as root space for trees that are mostly under impermeable surfaces in combination with the infiltration of rainwater is referred to in Austria as a "sponge city principle for trees" (Grimm et al. 2022). This method has been developed and successfully applied in Sweden for about 15years. The pioneer was the city of Stockholm (Embrén et al., 2009). A defined grading of the mineral components of the soil ensures the long-term preservation of pores for the supply of soil air and soil water to the tree roots (Zeiser et al. 2023). A basic structure of uniformly sized crushed stones makes the substrate suitable for carrying traffic loads, so it can be used under public traffic areas. The Swedish recommendations have been further developed for application in Austria. The first results were published in 2021 (Grimm et al. 2021;Zeiser et al. 2021). Comparable systems have also been developed in Germany (Richter et al. 2021). However, the German solutions rely more on an impermeable trough in the subsoil for water storage and less on plant-available water retention in the substrate through field capacity. There are also current developments in Germany to realize the two infrastructural functions of the „improvement of the root space of trees" and "infiltration of rainwater", only in separate constructions (GALK 2023; Helmreich 2022).

In 2022 the Austrian Standards Institute published a revised national standard L 1112 "Requirements for the Irrigation of Vegetation Areas" (ÖNORM L 11122022), which includes a definition that reads "3.3 Sponge city principle for trees – Construction method of root spaces for trees that simultaneously functions as a base layer for vegetation, a water storage and distribution medium, and a subterranean infiltration system, and that can be installed under paved surfaces so that large-volume root space is made available."

The system is described as a storage medium for irrigation water as follows: "When the sponge city principle is applied to trees, the use of available surface water forms the basis of the water supply, with the substrate in the subsoil being the storage medium. A distribution system shall be provided under impermeable surfaces for the introduction of water and air. For surface water that cannot be absorbed directly by the storage medium, infiltration or drainage must be provided."

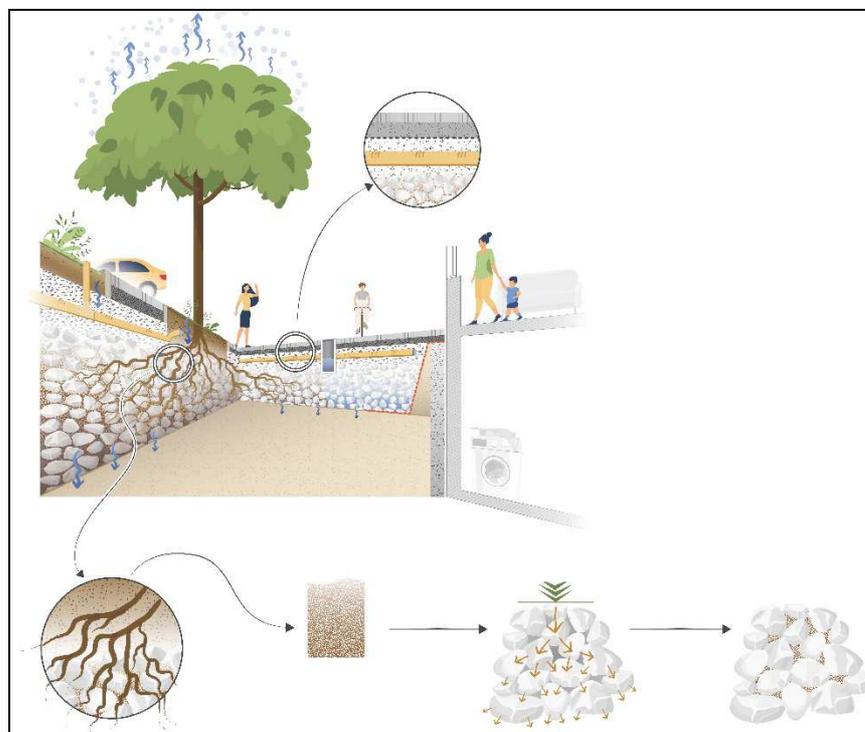
Our analysis of the projects is based on the description in standard L 1112.


Fig. 2:Sponge city principle for trees (source: Grimm, Murer, Schmidt 2021)

The method is disseminated in Austria through landscape architects and engineers to municipalities and in the larger cities to garden administrations, city planning, and environmental departments. Non-profit

organizations such as Climate Alliance and Soil & Land Alliance play an important role in informing smaller municipalities.

The number of design projects using the technique was estimated at 16 in 2021 (Grimm et al 2021). Currently there are about 60 projects that are completed, under construction, or planned.

4.2.2 Tree species

Moisture availability and temperature potentially have a significant effect on the growth, development, and fitness of plants in the urban public landscape (Alizadeh&Hitchmough 2020). Plants make species-specific demands on their environment. If these are not met, they will deteriorate, be more susceptible to diseases and pests, and ultimately die. Choosing the right plant for the site becomes more important the longer the life span, the greater the investment in the plant, and the more significant the functions assigned to it. Full ecosystem services are provided by large, well-developed trees that are at least a few decades old. A tree planted today will reach its full potential in about 50 years – if it reaches that age. It is a fact that in urban streetscapes our native trees struggle to cope with extreme radiation climates, drought, pollutant inputs, and mechanical damage (Moser et al. 2017). Few native tree species survive in these locations. In accordance with climate change scenarios, the choice of tree species and varieties is changing.

For several years, experts have been addressing the question of which tree species do well in urban environments. In 1976, the German Conference of Garden Officials (GALK) decided to support municipalities and planning offices in the selection of trees for streets and squares with a list based on experience and observation. This "GALK Street Tree List" has been available as an online tool since 2012 and has become a sound source of information (GALK-Straßenbaumliste n.d.). The varieties and their ratings are regularly discussed and published in professional journals. Since 2009, the Bavarian State Institute for Viticulture and Horticulture (LWG) in Veitshöchheim has investigated 30 tree species at three Bavarian sites in the "Stadtgrün 2021" project (Schönfeld 2022). In 2022, a "climate tree grove" was planted out for research purposes at the "Höhere Bundeslehr- und Forschungsanstalt für Gartenbau" in Schönbrunn, Vienna (Grimm et al. 2022). The aim is to identify so-called future trees. These are tree species and varieties that can not only cope with the current adverse conditions in urban areas but are also expected to be able to endure future conditions exacerbated by climate change.

New varieties of trees and species that have been rarely used in the past are in demand. The search is focused on deciduous tree species from climatic regions that are warmer and drier than we are currently experiencing but also have cold winters (Schönfeld 2022; Bund deutscher Baumschulen n.d.). In forestry, this approach relies on what are called "climate analogues" (Mette et al. 2021).Such comparable regions, characterized by a continental climate, can be found in South-eastern Europe and Anatolia, East Asia, and North America, for example. Another way is to breed new varieties. For example, Resista® elms are largely immune to Dutch elm disease and well suited as street trees in Central Europe.

The adaptation and diversification of tree species, together with the creation of suitable site conditions through larger root spaces with improved air and water supply, are the key to future-proof urban forests. Therefore, in addition to studying the design approaches, we also looked at whether the selection of tree species in projects applying the sponge city principle for trees was based on traditional urban trees or whether new tree species and varieties were used that are considered fit for the future.

5 RESULTS AND DISCUSSION

In the 24 projects selected for further investigation, three groups of projects were identified by using the criteria function of NBS, design approach and tree irrigation:

Group A: 7 projects – the sponge city tree principle is applied, but there is no integration in an overall design.

Group B: 4 projects – there is a focus on designing rainwater management without sponge city trees.

Group C: 13 projects – the sponge city tree principle is integrated in an overall design of the open space.

5.1 Group A: 7 projects – the sponge city tree principle is applied but there is no integration in an overall design.

The projects are realized in three different types of open space:

434

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4 streets

2 parking areas

1 urban plaza

The projects were constructed between 2018 and 2023. In all seven cases, the sponge city trees are a single infrastructure element. The effective part, the structural soil, lies underground and is invisible. The focus is on road infrastructure without any further creative claims. All seven projects investigated address the same NBS functions, which are the collection, retention, and discharge of rainwater. The same design approach – "concealment" – is applied in all the projects. The source of irrigation for trees is always rainwater collected on the surface. In group A, the "purification" function is mostly not applied. This keeps the design simple. The omission of purification is possible because only stormwater from areas without motorized traffic is collected, which is permissible for underground infiltration. Often trees were added into ongoing projects. The trees were either implemented separate from the open space design or there was no design at all: for example, when it involved the replacement of single trees, or new rows of trees were planted in a streetscape in the course of road reconstruction.

5.2 Group B: 4 projects – there is a focus on designing rainwater management without sponge city trees.

2 residential open spaces

1 urban plaza

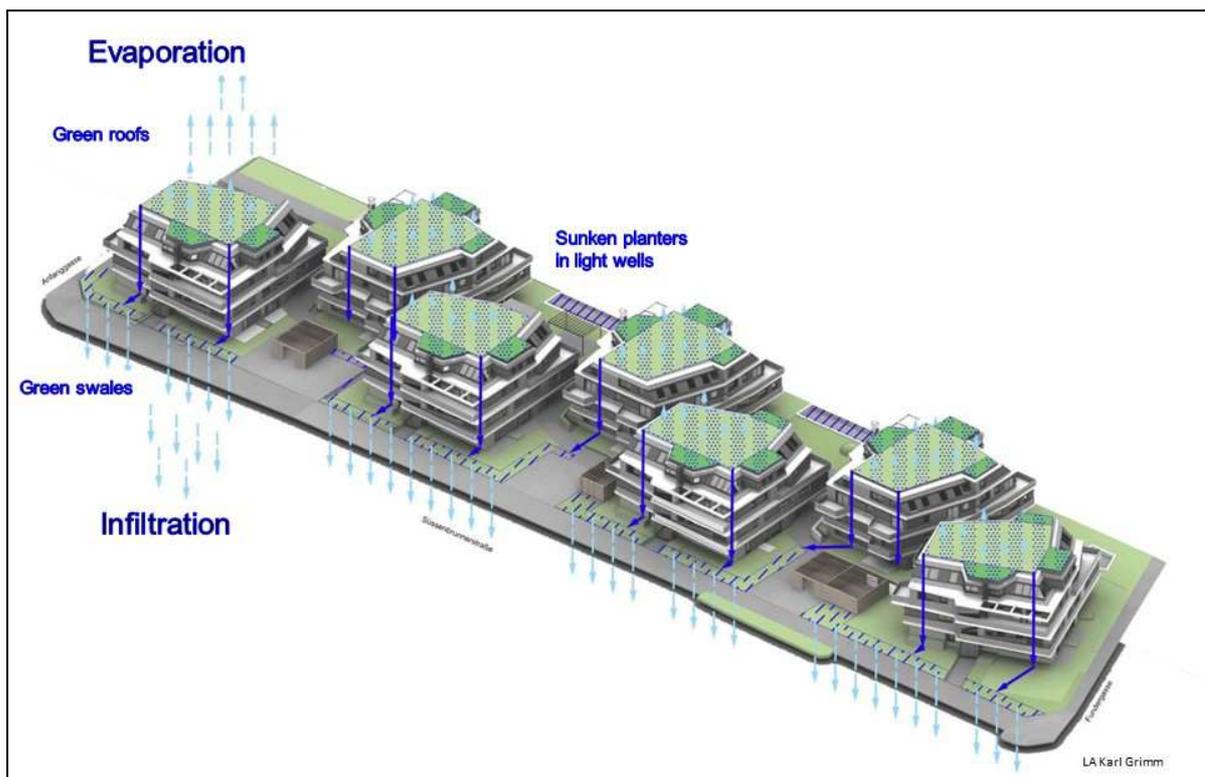
1 university campus


Fig. 3: Pilot project for rainwater management within the cost frame of affordable housing, Süßenbrunner Straße, Vienna, Austria. (Open-space planning: Jakob Fina; Rainwater management: Karl Grimm; Architecture: Thomas Moosmann).

In these projects, the function as a usable open space is in the foreground of design decisions, but the projects also focus on the water cycle and stormwater management. The time of realization spans from 2010 to 2019. These projects are older than the ones in group A and group C. The focus was on rainwater collection, retention, and discharge, and to some extent on purification too. In this group there are three different types of open spaces (residential open space, urban plaza, and campus). These open spaces have to cater to a wide range of uses and provide a variety of open-space qualities, like shade, light, protection from wind, ventilation, diversity of use and equipment, and communicative and aesthetic qualities. There are no streets in this group.

Owing to the size of the projects, several NBS were implemented, and they fulfil various functions, e.g. green swales for purification or green roofs for water retention. The aim in many cases is to develop "management trains" (Roehr&Fassmann-Beck 2015).

This approach can be best explained with the project Süßenbrunner Straße. It was a pilot project in Vienna for rainwater management within the cost frame of affordable housing.

The design combines NBS in a management train, and various functions and elements are integrated in the architecture and open-space design: retention of the runoff by green roofs, downpipes on the outside walls, retention in the planters, runoff in open flumes, retention and infiltration in infiltration trenches, and sunken planters in the light wells to provide daylighting in the garage. The project was the winner of the City of Vienna Environmental Prize 2017.

5.3 Group C: 13 projects –the sponge city tree principle is integrated in an overall design of the open space.

6 plazas

6 streets

1 residential open space

All 13 projects were constructed between 2018 and 2023. Two projects were in the course of urban expansion, but most of the projects were realized in the context of redevelopments in the existing city. All of them are design projects integrating diverse open-space needs and multiple functions. Trees are important design elements and NBS, and long-term tree health and the water supply of trees are key topics. During this period, climate-change adaptation became an important issue (BMNT 2017) and was considered in design projects. In one project, the financing was supported with an EU programme aimed at supporting the creation of micro open spaces, cooling measures, and tree planting to improve the quality of the open space.

Quality improvement of open space was achieved in almost all projects by redistributing the available space. The implementation of NBS is closely connected with the design of open spaces, although even in these projects the sponge city principle for trees is not necessarily a basic design approach but a subsequent functional addition.

The attitude towards the urban water cycle has changed from primarily integrating rainwater by infiltration to evaporation and the provision of water to urban trees. In all projects, the sponge city tree principle was applied. The water is collected from streets, plaza surfaces, and roofs. In five projects, water features were integrated as a new design element for play and for cooling the surroundings. The runoff is used for watering the trees.

Even in these projects, the design approaches regarding water are restrained. Purification of rainwater is often necessary in connection with street runoff. "Showcasing" and "integration" are only applied for sunken planters in connection with purification. Sponge city trees, whether they are fed by unpolluted stormwater or by a water feature, practically always follow the design approach "concealment" (Fig. 4).

The applied NBS are almost invisible, and the users of the open spaces cannot experience and comprehend the complex interplay of the NBS and the qualities of the open space.

436

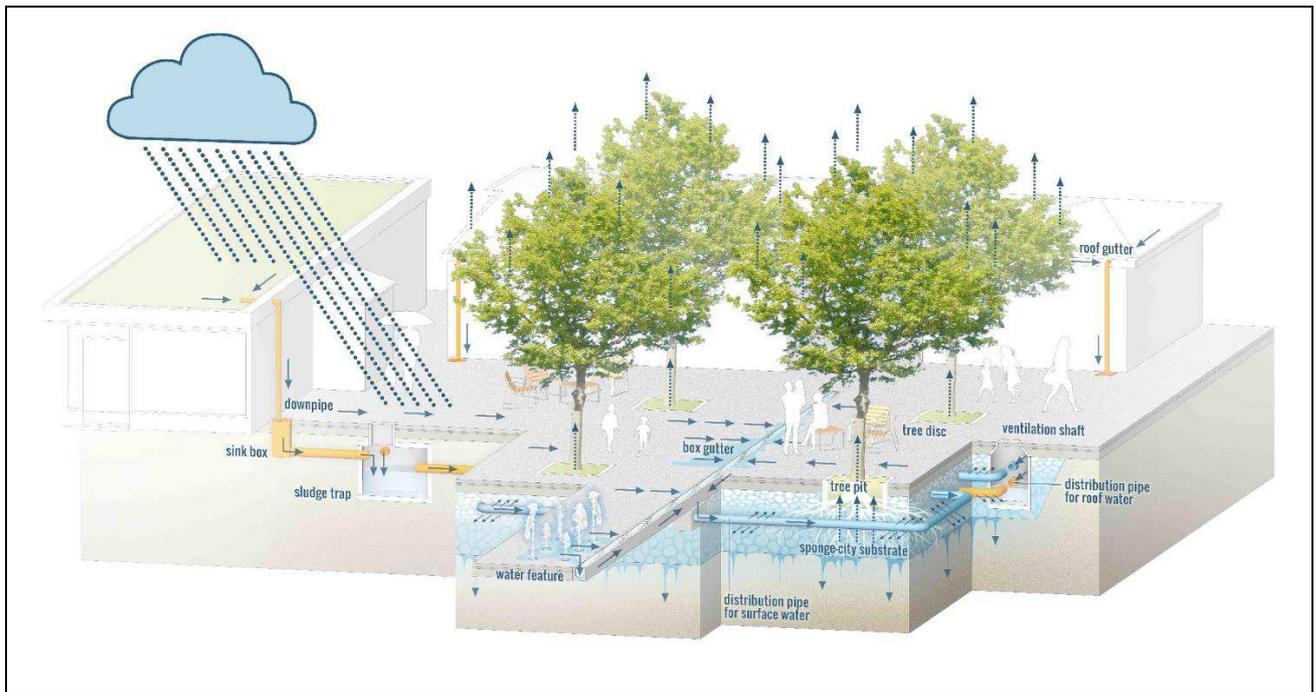
REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Fig. 4: Using rainwater and a water feature to improve the site conditions for urban trees and create an open space for the neighbourhood. Example: Johann-Nepomuk-Vogl-Platz, Vienna. Design: Karl Grimm Landscape Architects

The 13 projects in this group incorporate the findings of research on climate-fit trees. In some cases, use is made of traditional tree species (i.e. those already used in recent decades) whose suitability for urban climates has been confirmed. Alternatively, "new" tree species or varieties are planted that have been identified as climate-fit and have never or seldom been planted in the past. Classic street tree species that are not considered climate-fit were not used in these projects.

6   CONCLUSION

Until the mid-2010s, it was the aim of rainwater management to close the water cycle by infiltration and groundwater recharge. Subsequently transpiration through trees became important as part of urban heat island measures for improving the microclimate. Now the focus is moving to water retention in the soil for supplying water to vegetation in increasingly longer dry periods. Following the shift in targets the "sponge city principle for trees" emerged as a design solution. Its main characteristic is the use of structural soils to improve site conditions for urban trees, including water storage. It can reasonably be assumed that the sponge city principle for trees will play an important role in tapping and storing different on-site sources of water (stormwater, water features) for the irrigation of trees. This helps close the local water cycle with increased evapotranspiration and improve heat-affected microclimates through adiabatic cooling. Infiltration to the aquifer is also strengthened as a side effect, because surplus water from the supply of vegetation seeps into the groundwater.

The sponge city principle for trees has the potential to become an essential NBS in future urban green infrastructure systems and stormwater management cascades. The systems implemented so far have a certain experimental character and serve to gather experience. Two projects are being monitored.

Investigation shows that the sponge city principle for trees is a NBS with low design impact: "concealment" and "integration" strategies predominate. "Showcasing" has only occurred in conjunction with sunken planters for purification. This powerful NBS with development potential deserves to be made more visible in order to have a public presence. Although stormwater management is integrated in the design of several projects, incorporating NBS into the overall design of an open space has untapped potential, in particular for raising awareness of the connectedness of the urban water cycle and urban vegetation, especially trees.

Landscape architecture merges rainwater management, planting design, and irrigation planning. This means optimizing an NBS system for various functions, incorporating these in a design concept, and – usually – working within a tight cost frame. However, it is not a stand-alone challenge but rather a task for landscape architects, urban designers, architects and engineers, who can combine to mobilize the full potential of NBS.

1 ABSTRACT

Recently emerged social networks are gaining momentum and are becoming an integral part of modern life. The introduction of artificial intelligence methods, such as ChatGPT, show the importance of this field of science in computer technology, science and social life.

With more than 20 years of experience in the application of AI methods, we consider it appropriate to share ideas for their application in the interests of everyday human activities. Our main proposal concerns the creation of decision support systems based on social networks, localized in the interests of a particular person.

The main technologies that we apply are the following: Scenario Approach, which includes the Ontology System, Inference Machine, a Visual Integrated Development Environment, and a number of mathematical approaches that implement machine learning and DSS. First of all, these are: Singular Value Decomposition and Method of United Randomize Indices. Unlike neural networks, these methods have a clear mathematical interpretation and controlled accuracy. Also for their application there is no need for very large statistics.

Keywords: Intelligent Social Network, Artificial Intelligence, Inference Machine, Ontology, Scenario Approach

2 INTRODUCTION

The earliest online social networks appeared almost as soon as the technology could support them. E-mail and chat programs debuted in the early 1970s, but persistent communities did not surface until the creation of USENET in 1979 [17]. USENET began as a messaging system between Duke University and the University of North Carolina, but it rapidly expanded to other American universities and government agencies. USENET allowed users to post and receive messages within subject areas called newsgroups. Initially, there was no standard convention for the naming of newsgroups [17]. This led to confusion as the number of newsgroups grew throughout the 1980s. In 1987 USENET groups were reorganized into broad hierarchies such as news, talk, misc (for miscellaneous), and alt (for alternative; the last was created for newsgroups that dealt with taboo or niche topics, and it was the most populous category on USENET) [17].

The first companies to create social networks based on Web technology were Classmates.com and SixDegrees.com, Classmates.com, founded in 1995, used an aggressive pop-up advertising campaign to draw Web surfers to its site [17].

Others were quick to see the potential for such a site, and Friendster was launched in 2002 with the initial goal of competing with popular subscription-fee-based dating services such as Match.com. [17]. It deviated from this mission fairly early on, and it soon became a meeting place for post-"bubble" Internet tastemakers [17]. The site's servers proved incapable of handling the resulting spike in traffic, however, and members were faced with frequent shutdowns [17].

Overview of social networks. The statistics for 2023 show that there are 4.48 billion active social media users worldwide [18]. Let us note the most popular and well-known social networks and give them a brief description.

LinkedIn – more than 700 million active users per month. This professional networking site is great for B2B marketing. The audience on LinkedIn focuses on sharing professional content instead of personal. It is useful for professionals in various subject areas [18].

Facebook – around 3 billion active users per month. Easily the most popular platform on our list, Facebook is where you'll find most social media users actively engaging with brands [18].

It doesn't just allow you to connect with your peers; you can also use Facebook to sell your products through Facebook Shops and promote your brand through Facebook Ads. It's also a favorite among businesses, as reports show that approximately 70% of brands find new customers through Facebook [18].

Instagram – around 1 billion monthly active users.

Owned by Facebook, this app-based platform is a must for brands prioritizing Influencer Marketing. With features like Instagram Stories, IGTV, and Instagram Live, marketers can make the most of video content to engage with their audience [18].

Creating a business profile will let you integrate Instagram Shopping and Insights too [18].

YouTube – Monthly Active Users: 2.3 billion Currently the second-largest global search engine, YouTube is a pot of gold for content creators. If video marketing is your thing, don't miss out on this platform [18].

Brands can add YouTube advertising to their social strategy and share quality content easily across the globe. Stick to the community guidelines, and you'll not connect with your audience but also monetize your videos in no time [18].

TikTok – Monthly Active Users: 1 billion. Still new to the social scene, ByteDance's TikTok has garnered a huge user base since its inception in 2016. If your target demographic includes Gen Z, you have to master this application [18].

It's easy to go viral on TikTok, but that's also why the social platform is heavily saturated [18].

Telegram – Monthly Active Users: 500 million. A secure messaging application, Telegram can be used to create chatbots, broadcast messages to the audience, and provide customer support [18].

Brands can create large group chats (for around 200,000 members) to announce launches or simply interact with their audience [18].

Founder Pavel Durov has plans to introduce Telegram's ad platform soon [18].

Twitter – Monthly Active Users: 353 million Twitter has surprisingly lesser users when compared to other networks on this list. However, that doesn't mean that it isn't influential. In fact, 54% of users have taken action after seeing the brand mentioned on Twitter [18].

Using ads, integrating customer service, and growing an active customer following. You can do all of this with Twitter [18].

WhatsApp – Monthly Active Users: 2 billion. Originally created for connecting with family and friends, this platform now offers a WhatsApp Business application and WhatsApp Business API to create business profiles [18].

Brands can showcase their catalogs and offer quick customer service through this messaging application. That's not all. Unlike most messengers, WhatsApp is ad-free [18].

3 ADVANTAGES AND DISADVANTAGES OF SOCIAL NETWORKING

Just as the invention of the revolver (pistol) at one time created the illusion of human equality, so the widespread use of the Internet and social networks (SN) created the illusion of informational equality and freedom, social justice. Each person can become almost instantly widely known to the world audience without the need to wade through social steps, filters, often without wasting time on education and development of real creative principles in oneself. And this is a kind of "trap" of social networks, when the whole point is to collect likes from social pseudo-friends.

Social networking can affect individuals and corporations positively and negatively. That is why it is important to weigh the advantages and disadvantages of using these social media sites before getting too heavily involved. Various analysis variants can be found on the Internet. One of them is shown below.

3.1 Advantages [12]

- Social networking allows individuals to make and stay in contact with family and friends that distance and lost connections would otherwise prohibit.

Pietro Elisei, Darinka Golubovic-Matic, Pierre Laconte, Vasily Popovich, Tatiana Popovich, Manfred Schrenk, Vladimir Shutkov, Artem Zagvozdkin

- People can also connect with unknown individuals who share the same interests and develop new relationships.

- Social networking also allows companies to connect with new and existing clients.

- Companies can create, promote, and increase brand awareness through social media.

- Companies can capitalize on customer reviews and comments promoting products, services, and brands. The more customers post about a company, the more valuable the brand authority can become. This can lead to greater sales and a higher ranking by search engines.

- Social networking can help establish a brand as legitimate, credible, and trustworthy.

- Companies may use social networking to demonstrate the quality of their customer service and enrich their relationships with consumers. For example, if a customer complains about a product or service on Twitter, the company may address the issue immediately, apologize, and take action to make it right.

3.2 Disadvantages [12]

- Social networking can facilitate the spread of misinformation about individuals and companies.

- Due to its online nature, falsehoods can spread like wildfire. This became increasingly prevalent after 2012. One study found that misinformation is 70% more likely than factual information to be shared on Twitter.

- The detrimental impact of misinformation can create a virtual headache for a company's public relations (PR) department.

- The anonymous aspect of newfound personal relationships requires caution.

- Building and maintaining a company profile takes hours each week. Costs add up quickly.

- Businesses need many followers before a social media marketing campaign starts generating a positive return on investment (ROI). For example, submitting a post to 15 followers does not have the same effect as submitting the post to 15,000 followers.

3.3 Purpose of Social Networking

Social networking connects individuals and businesses by allowing them to share information, ideas, and messages. Companies also use social networks to create and strengthen brand recognition, promote products and services, and answer customer queries and concerns [13].

3.4 Benefits of Social Networks

The benefits of social networks include their ability to help people connect and stay in touch with family, friends, and new contacts; the opportunity they offer businesses to market their brands; their ability to spread useful, even vital, information instantly to individuals and institutions [13].

3.5 Importance of Social Networks

Social networks are important because they allow people to develop relationships that might not be possible due to distances of place and time. They also help boost business productivity when used for public relations, marketing, and advertising purposes [14].

4 ARTIFICIAL INTELLIGENCE FOR SOCIAL NETWORKS

Before moving on to our AI-related technologies, let us look at a typical algorithm for creating a social network, which can be easily found on the Internet:

a. Set your networking goals [15,16]

To help navigate through the networking process and to ensure you're using your time and resources wisely, set goals for yourself. Decide what you aim to accomplish by connecting with industry professionals. Potential reasons to build your network could be to gain job opportunities, enhance your industry knowledge or receive career advice.

b. Craft a compelling elevator pitch [15]

Before you meet with any professionals, have an elevator pitch prepared, which is a 30- to 60-second speech mentioning your strengths, value and background. If you're networking for potential job opportunities, emphasize your value and why you'd make a great fit for a company.

c. Reach out to current connections [15]

No matter where you are in your professional journey, you should already have a network. Contact people you know who could help you advance in your career. These can be friends, classmates, current or previous co-workers, family members or colleagues. Cultivate and grow these relationships by reaching out to them directly or connecting on social media.

d. Join local and national organizations [15]

Expand your network further by finding local and national organizations in your industry that interest you. Conduct research and make a list of potential organizations that appeal to you and align with the networking goals you set for yourself. Consider organizations targeted both toward where you currently are in your career and where you aim to be, such as groups for entrepreneurs, remote employees or business-to-business professionals.

f. Use social media to find new connections [15]

You can use social media to locate and reach out to potential connections. It's also a great solution to start out with if you're anxious to attend events and talk in person. Connect with industry professionals who hold similar values, aspirations and interests as you. Send a message to them that briefly outlines who you are and why you'd like to connect.

Continue your communication with them by commenting on posts or maintaining a casual conversation back and forth through social media. Once you establish a professional online relationship with them, you can feel more comfortable meeting them in person one day.

g. Attend industry events [15]

Many of the organizations you join may often host industry events. Attend these gatherings to meet some of your online connections in person. Some of these may be educational events or classes to help learn a new skill or develop your abilities. Try to meet new people regularly at these events and make as many connections as possible. You can also research industry events online to find those happening in your area, like conferences, conventions or seminars.

The algorithm for creating a social network recommended above (on the Internet) is focused primarily on business development. Meaning that the SN is created to support of an existing business, or to be exact the SN is created as a business itself. Here we consider the SN as a type of business aimed, first of all, at meeting the needs of the individual, and, in particular, to support the various kinds of decision-making in everyday life, including in business. At the current time, we do not consider ISN as a tool in the interests of business companies, but such an application is not excluded.

4.1 Main technologies of artificial intelligence

Our history of development and application of these technologies counts more than 20 years. Based on these technologies, maritime transport monitoring systems and decision support systems have been developed and are being successfully produced. The good example is the integration of DMSS in the Smart City project [1]. In our opinion, these technologies can be successfully applied in the intelligent social networks. In this case, their main focus is an ego-centric approach to a particular person, regarded as the main element of society. There is an obvious contradiction here, but we will not consider it in this article. Let us briefly review the technologies we offer.

4.1.1   Scenario Approach

The scenario approach has been described in detail in our previous publications. It has hardly changed, except for the development tools. The main difference is that instead of the Protege system, we have developed our own ontology system and a lower-level Scenario editor based on the Drools logic programming language built into the IntellIdea software development environment. The Scenario system is developed based on a client-server architecture, as a web-client. The Rete Inference Machine is part of the

Drools language. With the use of the scenario system, the main business analytics of the individual is described. Basic scenarios are created by experts and can be used as prototypes. Basic scenarios can also be generated automatically if there is a sufficiently complete source statistics.

4.1.2 Machine learning tool and a classifier

It is based on the Singular Value Decomposition (SVD) and the Method of United Randomized Indices (URI), which are also applied in almost all of our flagship products. The essence of these approaches is also described in detailed in our previous publications.

This toolkit can be used on the principle of neural networks application, processing huge amounts of data, and can be used on the basis of a repository formed by experts. Both options are possible, when at the first stage the experts' repository is used, and in the process of work the repository is corrected based on self-learning. This is one of the important advantages of SVD and URI over machine learning methods based on neural networks and similar approaches.

5 DECISION MAKING SUPPORT SYSTEM FOR SOCIAL NETWORKS

The most important element of ISN from the point of view of the user, or network member, is decision support in various situations. Any decision is made in case of availability of information. First of all, there are the following base classes: the decision maker itself, his goals, thoughts, ideas that should be maximallty clearly defined, the environment in a broad sense of the term, available resources and many different kinds of natural and artificial obstacles and restrictions.

The basis of any DMSS is the so-called. "management cycle", consisting of a number of fundamental stages:

- an intention (primary idea, desire or some challenge);

- suggestions (additional information that allows you to clarify the intention and form it as a task or a goal);

- a decision (a clearly formulated goal of actions, that takes into account various factors and restrictions, with various qualitative and quantitative assessments of various kinds);

- a plan (spatio-temporal assessment of achievement of a clearly formulated goal in the decision, the sequence of steps (actions) to achieve the goal;

- implementation of the plan (implementation of the plan, assessment of each stage regarding time, space, resources and trends directed towards achieving the goal, continuous assessment of the feasibility of the plan and its correction if necessary). If at the previous stages of the control cycle (CC) we can set some regulatory time requirements, then the last stage is, as a rule, already a real-time system. And for real systems, CC is the implementation of a situational control system. Definition of situational management or analysis of tactical situations can be found in the specialized literature, as well as in our previous works [2].

To implement the DMSS in the situational management (SM) variant, it is necessary to have an appropriate initial level of information and online access to the necessary information. All information and basic entities must be formalized. The first level of formalization is a system of ontologies, which describes non-overlapping sets of subject areas that interact with each other. The most complex ontology is the ontology of the individual using the ISN. This is due to an obvious contradiction: the need to formalize and enter personal data, on the one hand, and, on the other hand, ensure the confidentiality of personal data. Two groups of individual data are very important: static, or "a profile" of an individual [5], dynamic, or "a trace" of an individual [5]. This problem has a number of solutions and is not fatal, but depends on many factors. In this article, we will not consider this problem.

The second level is the development of business analytics for the selected abstractions of the ontology system. In fact, this is the implementation of the SM. The third level is the circulation of data, information and knowledge in the control loop. As the basis one can use the JDL model [12], which we also considered earlier in a number of papers regarding DMSS.

We expect that in our next paper a version of the working prototype will be presented.

6 CONCLUSIONS

The proposed version of ISN, in fact, can be an add-on over one of the versions of existing networks. For example, Telegram bot can used. In the proposed approach, it is not the SN itself that is important, but the ability to provide decision support using AI tools and methods. The Internet and a typical SN are used as an environment, an entourage in which the existence of an ISN add-on is possible.

At the moment, the development of a prototype of ISN is underway. Several subject areas have been selected, in which individual decision support will be provided. We also justify the localization of ISN data in order to solve the age-old problem of confidentiality with purpose to avoid "the Big Brother looking over one's shoulder". At the same time, this problem is solved not only and not so much by localization, but mostly by the development of a special technology that allows you to avoid external interference with individual data, information and knowledge without the knowledge of their owner.

We are also considering the involvement of general public, both organizations and individuals, in this venture project on a pro bono basis.

Investigating the Environmental and Economic Benefit of Waste to Energy Project: a Case Study of Methane Gas at the Thohoyandou Landfill Site

Mukona Kone, Trynos Gumbo

(Mukona Kone, University of Johannesburg, Dept. of Urban and Regional Planning, Johannesburg, South Africa, konemukona@gmail.com)
(Prof. Trynos Gumbo, University of Johannesburg, Smart and Sustainable Cities and Regions Research Groups, Urban and Regional Planning Department, Johannesburg, South Africa, tgumbo@uj.ac.za)

1 ABSTRACT

The increasing power outage in South Africa and other developing countries, coupled with the global challenge of fossil fuel depletion, highlights the need for urgent alternative energy sources. Despite various studies being conducted, there is minimal application of waste-to-energy projects. The waste-to-energy projects have emerged as a potential solution to address both waste management and energy provision challenges. This study aims to investigate the environmental and economic benefits of using methane gas from the Thohoyandou landfill site in the Thulamela local municipality as an alternative energy source to the coal-powered grid. The research methodology was a content analysis to examine the sustainability benefits. The results suggest that the technology is economically feasible, considering the sales of electricity generated and Certified Emission Reductions (CER) (carbon credits). In addition, the project has the potential to reduce greenhouse gases (GHGs) from coal-power stations, resulting in improved air quality in nearby communities. This paper recommends that the Thulamela Local Municipality should scale up the innovative waste-to-energy projects as they offer best practice solutions.

Keywords: Sustainable Benefit, Methane Gas, Landfill Site, Environment, Waste to Energy

2 INTRODUCTION

Municipality solid waste management challenge is experienced in both developed and developing countries. This challenge continues to grow with population growth, which is rapid, as a result of no proper stringent methods to divert the waste from the landfill so that it can be processed into other by-products or recycled. Despite that waste reclaimers and waste management services, either public or private are available at the disposal of the municipality, the challenge is still widely experienced. The lack of public-private partnerships hinders tons of waste from being diverted from the source. Referring to Jeff Delmon (2015) states that the solid waste sector is not naturally fit for public-private partnerships as compared to other sectors due to the fact that the fees for waste collection are relatively low. In some instances, in developing countries such as South Africa, residents do not pay service fees for waste collection, which results in the emergence of illegal dumping sites.

The concern when it comes to fast-growing illegal dumping sites is due to the population. It poses a lot of strain on the local government because of the lack of development, provision of energy, and waste management. Supported by Hoornweg and Bhada-Tata (2012), Municipal Solid Waste (MSW) production globally is currently over 1.3 billion tons per year, with projections of 2.2 billion tons per year by 2025. Therefore, there is an urgent need to properly manage and recycle waste. This cannot be overstated, because the increase in tonnages of waste annually causes the local government to encounter a crisis of airspace in the landfill site. Landfill site airspace, also known as landfill capacity is defined as the amount of volume a site has for disposal (J. Collins, 2020). The shortage of airspace makes it difficult for municipalities to render their waste management services. The difficulties in the management of landfills emerge from the lack of resources, and funds to sustain and manage the waste (Viljoen, et al., 2019). This results in the creation of backlogs which influence open dumping and burning of the waste by community members especially those that are residing in the informal settlements and rural areas.

In the Vhembe district municipality, 18470 tons of waste is left in open spaces, without any collection (District, 2021). This shows that there is a need for alternative solutions to the waste left in open places, which poses social and environmental threats such as contamination of soil and underground water. The contamination of the environment is also experienced in the landfill site, due to a lack of proper management and innovative strategies to utilize wastewater, methane, and waste by-products (Shareef & Abdelazim, 2019). In most small landfill sites, the facility for leachate collection and treatment is often not part of the design of landfill sites.

Relatively within the energy provision, there is a challenge of service delivery because innovative strategies are not implemented. The fossil fuels globally are decreasing due to a lack of management of the natural resources, lack of infrastructure, and development of alternative energy to supplement that which is already being supplied to the citizens. Thus Baraka Obama (2017) stated that the current generation is still utilizing the energy infrastructure that was developed to cater to the 19th-century population, which puts a strain on production The lack of improvement of the energy system especially in Africa has resulted in countries experiencing power outages or load-shedding over 24 hours per day (Agency, 2020). In the local concept of South Africa, the citizens experience six hours daily without electricity (Aljazeera, 2022), this is not applicable to those communities without electrification at all in remote areas. With this challenge expected to increase, it calls for urgent implementation of alternative energy such as waste-to-energy which will address both the waste and energy crisis that the country is currently experiencing daily. Wasteto-energy (WtE) projects are defined as projects that recycle substances and energy from solid waste through particular management methods and technical processes (UNECE, 2018).

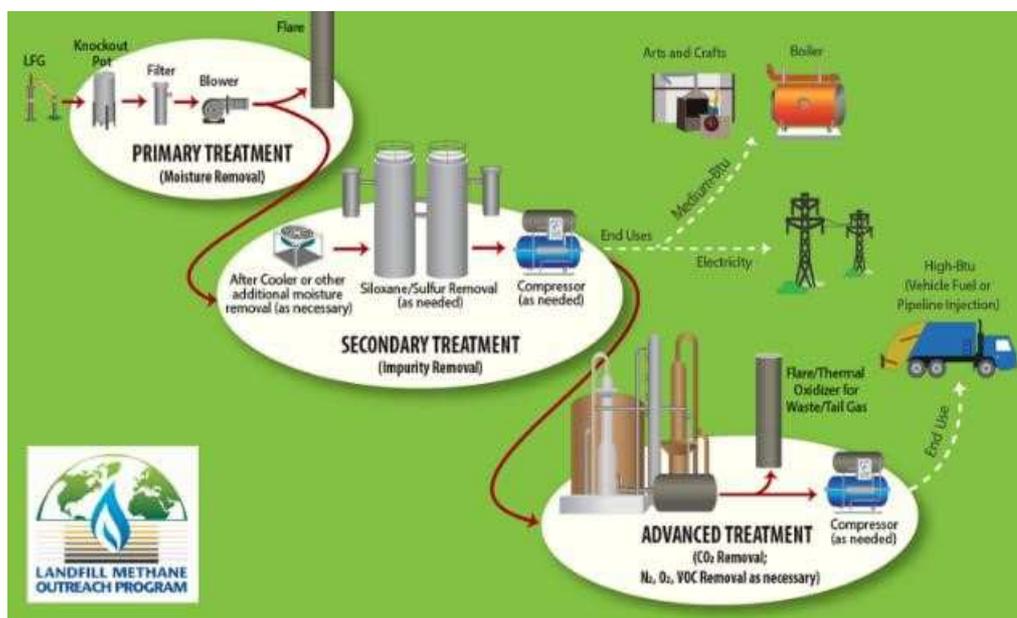
The waste-to-energy projects are an essential solution globally through addressing the challenge of waste. Despite that more research has been conducted but there is less implementation of this project. For instance, a feasibility study for the waste-to-energy project has been done across the 62 political territories in Africa. That mentioned only 7 territories have installed the technology and have the potential to advance their project whilst in South Africa the WtE project has been implemented in 3 metropolitan cities of the country: Cape Town, Durban, and Johannesburg (Chrtina, 2013). This raises concerns about why this technology is not being replicated in other cities of the country. The WtE project can be produced in a thermal or non-thermal way, where the thermal is used to heat or for the combustion to treat wastes such as incineration, whilst the non-thermal is a process whereby the methane and carbon dioxide are produced and then captured using anaerobic digestion (Purser.R., 2011). The diagram below illustrates the different stages of waste-to-energy projects and the area where the energy can be utilized. This shows how the municipality can implement this WtE project.


Figure 1 WTE potential usage by Landfill Methane Outreach Program

3 LOADSHEDDING IN SOUTH AFRICA

As the population in our township and industries continue to increase on a daily basis, the demand is increasing resulting in ESKOM not being able to cater to the energy demand. The Electricity Supply Commission (Eskom) is a state-owned company that was established in 1923. The company is responsible for supplying 90% of its electricity to South Africa and 30% to other African countries. It generates, transmits, and distributes electricity to industrial, mining, commercial, and agricultural sectors (BASE, 2023). This illustrates that this organization provides a vast amount of energy across the country, hence the challenge in providing electricity. In the past couple of years, South Africa has been facing a lot of challenges of power cuts, which are caused by various factors of corruption and lack of maintenance of

446

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

power plants. These power cuts are also referred to as load shedding. Load shedding is a deliberate shutdown of electric power in parts or parts of a power distribution system, generally to prevent the failure of the entire system when the demand strains the capacity of the system (Reporter, 2023).

This occurs because there is a shortage of coal to generate electricity or failure in power plants. For instance, in September 2022 South Africa had a bout of load shedding and this has continued till date resulting in 3.9 THw of energy being shed. This is double the electricity shed in 2021 (CSIR, 2022).

With all the different stages of load shedding experience, this is how communities are affected by the power cuts. Stage one load shedding means consumers will be deprived of electricity 3 times in 4 days at an interval of every 2 hours or 3 times in 8 days at an interval of every 4 hours. Stage two involves depriving consumers of electricity 6 times in 4 days at an interval of every 2 hours, or 6 times in 8 days at an interval of every 4 hours. Stage three involves depriving consumers of power supply 9 times in 4 days at an interval of every after 2 hours, or 9 times in 8 days at an interval of every after 4 hours. Stage four involves depriving consumers of electricity 12 times in 4 days at an interval of every 2 hours or 12 times in 8 days at an interval of every 4 hours. Stages five to eight indicate consumers not having electricity 12 times in four days at an interval of 4 hours. This is a clear depiction of how the electricity is shedding through the different stages.

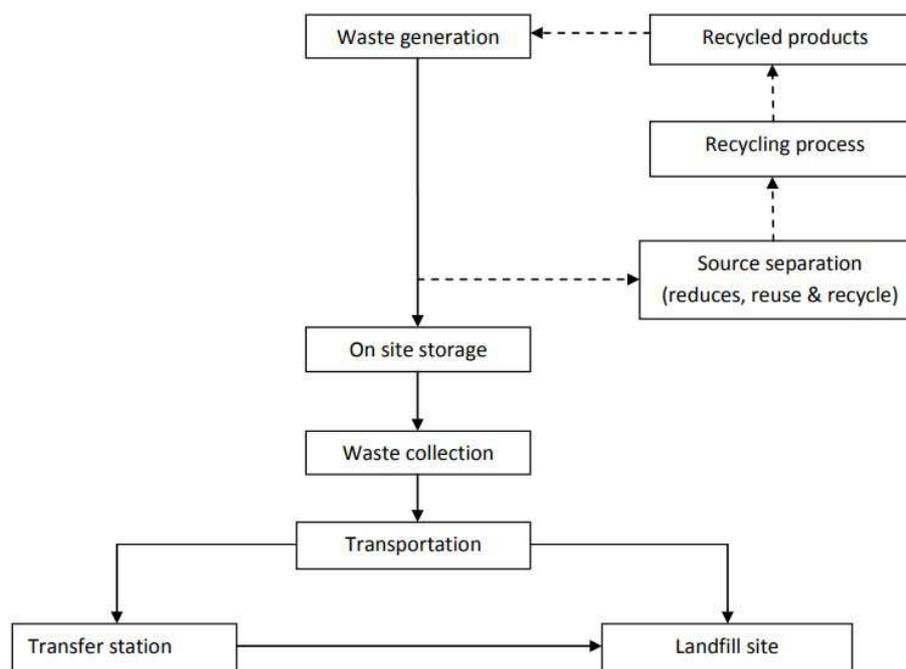
There are various factors that affect the production of energy, which are the electricity generation capacity storage, where the organization is not able to meet the demand required due to the high demand. This is also affected by the delay in the construction of new power plants and updating of old power plants (Omarjee, 2022), thus people are still dependent on the old plants which is no longer efficient to cater to the current generation. There is a cause of financial strains due to the fact that the operation cost is really high, whilst the revenue is low (Pueyo, 2018). The low revenue collection is a result of illegal connections by communities and the debts owed by local municipalities. Lastly, the other factor causing load shedding is environmental concern (Courses, 2023), as the plants rely heavily on coal for electricity generation leading to environmental concerns and climate change.


Figure 2 Flow Diagram of the Solid Waste Management In South Africa, Author University of Pretoria

4   MUNICIPAL SOLID WASTE MANAGEMENT

South African municipalities have the mandate to provide basic services to their community members as per the constitution of the republic. These services form part of the constitution of the country, which includes the right to clean water, sanitation, a clean environment, electrification, and waste management just to mention a few. The provision of services has a great potential to assist in the achievement of the National Development Plan 2030 as well as the Sustainable Development Goals related to the conservation of the environment, such as goal number 3 of clean energy (Nkosi, 2014). The Thulamela local municipality

provides waste management of collection, disposal and transportation of waste. Covering a surface area of 2 893.936 km² from 59097 households (Municipality, 2022). The Municipal Solid Waste Management (MSWM) performs activities related to the generation, storage, collection, transfer, transporting, processing, and disposal of solid waste which requires efficient and effective management (Bonolo, 2016). Below is a systematic flow chart of how the waste management service by municipalities is conducted in South Africa commencing from the collection till the last stage of disposing the waste at the landfill site.

One of the strategic objectives implemented by the municipality is to provide quality basic services and infrastructure to the citizen to enhance the quality of life of individuals residing in the community, which include solid waste management services (Tshwane, 2015). As of Schedule 5 Part 8 of the South African constitution, each municipality of the country has a mandate for refuse removal, refuse dumping, and solid waste management.

5 THOHOYANDOU LANDFILL SITE

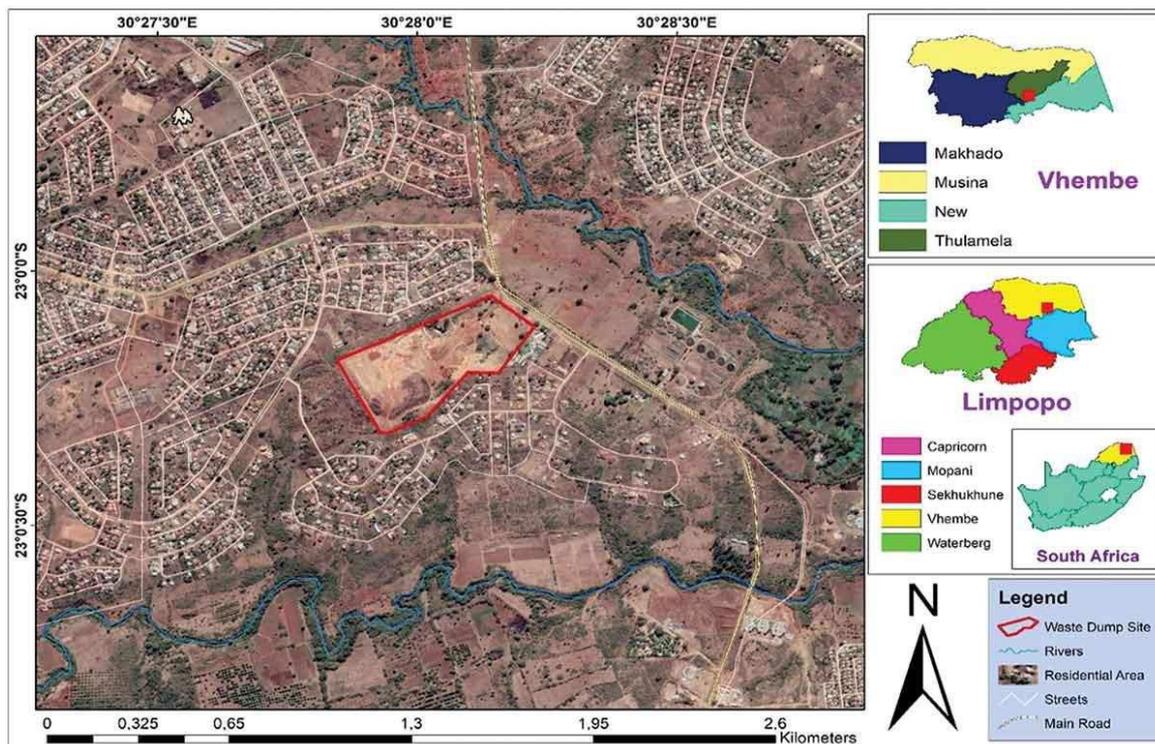
The use of renewable energy has been on a prominent rise since the 19th century by governments and organizations, thus in most countries globally there have been various experiments when it comes to the utilization of renewable energy such as wind, kinetic, nuclear, solar, and biogas energy. This aims to diversify the energy sectors through having various alternatives and to address the environmental problem (Panwar, et al., 2011). The urgent need to find sustainable solutions when it comes to energy is critical because the power outage is affecting the economy and infringing on the basic rights of South African citizens. As it infringes on the constitutional right the provide clean energy and stay in a clean environment so that they could be able to perform and develop effectively in their settlement (Mannak, 2015). As a way to find a solution to the issue of power outages, it is with this objective that the paper aims to investigate the potential environmental and economic benefits of using methane at the Thohoyandou Landfill Site.


Figure 3:Map of Thohoyandou Landfill Site, Author Google Maps

The Thohoyandou landfill site is situated within the Vhembe District municipality under the Thulamela local municipality. This landfill site has been in operation since 2004 and is located 180km from Polokwane and in the gateway to Kruger National Park (Njoku, et al., 2020) and it remains the main landfill for the local municipality. It lies on the geographic coordinates of 23°00'12.0" S longitude and 30°27'55.3" E. latitude (Edokpayi, 2018). Despite the municipality having four licensed landfill sites, the Thohoyandou Landfill Site, also known as Tswinga Mulendane landfill site is the one that carries the most capacity of waste because it caters to many urban and rural settlements and industrial areas (District, 2021). For instance, in

2014, the landfill site was able to receive 210000 tons of waste. This landfill site is located adjusted to the Thohoyandou wastewater treatment and residential areas just around the facility, which imposes environmental and health hazards to the community. This harm is also influenced by the fact that the Thohoyandou landfill site has 4 cells but currently only one is functional (Njoku, et al., 2020). Below is the map of the landfill sites, with legends the man-made and environmental elements found near the landfill site.

6 THE OBSTACLES OF WASTE TO ENERGY PROJECT IN THE MUNICIPALITY

The use of WtE possess so many advantages in terms of the economy and the environment, hence the need to shift into the utilization of the WtE in the different municipalities. WtE is defined as a technology that consists of any waste treatment process that creates energy in the form of electricity or heat from several types of waste (Change, 2020). This is waste such as organic waste, waste water, human excreta and landfill waste. Despite that the benefits of this have been illustrated from various decades and also from other countries implementing them such as Indian and Germany. The government has not been increasing its interest in the use of energy, despite that there is a desperate need to supplement electricity provision especially due to the power cuts. In the various municipalities despite that they owe ESKOM a lot of money, the policies and bylaws for using methane are not implemented (Victoria O'Regan, 2022). The other challenge obstacle in the implementation of the WtE projects is that there is a lot of substrate to utilize in the generation of the waste but unfortunately, the lack of separation at the sources hinders the local municipality from implementing the WtE (Wang, 2023).

New technology is emerging and has great potential to assist the municipality in reaching its service delivery. There is a need to further conduct studies on how it will assist in assist in reaching the mission and vision of the municipality when it comes to energy supply and waste management (S. Matos., 2013). Unfortunately, the local municipality has limited research when it comes to the WtE project, especially focusing on the landfill site, this lack of research in terms of the project makes it difficult for the municipality to venture into WtE as they are not much concrete data that would be used in supporting that the WtE benefits (P. Mukumba, et al., 2016). Furthermore, there is inadequate expertise for construction and maintenance, for instance, within the local municipality a lot of this WtE is mostly being monitored by the University of Venda. This illustrates that there is a gap of expertise within the WtE in the municipality. This is furthermore supported by the fact that there are no technical or vocational schools that provide such training so the market can be diverse (P. Mukumba, et al., 2016). New technology comes with a new design that needs to be procured by the local municipality. One of the obstacles that the Thulamela local municipality faces is the high initial cost required for the construction and installation of the WtE digester. This is a challenge as most departments are under-financed. This is mostly the challenge in developing countries which are struggling with waste management and lack of energy supply (A., et al., 2021).

7 THE ENVIRONMENTAL BENEFIT OF USING METHANE AT THOHOYANDOU LANDFILL

Landfill sites will remain the final destination for waste collected that is not being recycled, thus despite being supposed to be a solution to avoid waste being disposed of in open spaces, it also has a few challenges such as the contamination of the underground water and soil decay. To combat some of the reactions that are occurring at the landfill site with regards to greenhouse gases. it is best to utilise the resources effectively such as methane gas and carbon dioxide, which will have a benefit to the environment. Environmental benefit is defined as the economic appraisal of policies and projects concerned with the improvement in the provision of environmental services or actions that have a direct impact on the environment and community members (Atkinson & Mourato, 2008). When waste is disposed at the landfill site by the municipality, a process occurs whereby gases are emitted. The gas that is emitted is referred to as landfill gases (LFG), which is defined as a natural by-product of the decomposed organic material in the landfill, which compromises 50% methane, 50% carbon dioxide, and a small component of nonmethane compound (Agency, 2023). This LFG can be captured and used as renewable energy, because of the high potential of methane that is found. If the LFG is captured in the Thohoyandou landfill site, it will assist in reducing the odor especially because they are settlements located 80m away from the landfill site, which is not environmentally acceptable (Agency, 2023).

According to Dudek (2010), the LFG provided a lot of opportunities such as being used directly using it in the landfills for bowlers, generating electrical power, bio-methane production, and lastly for automobile fuel.

This opportunity contributes immensely towards the sustainable development goal and usage of natural resources in a sustainable manner. This is an agreement made during the Brundtland Commission conference. Another environmental benefit of using the methane gas from the Thohoyandou landfill site is that it will reduce the emission from the MSW landfill to achieve the near-term beneficial impact in the mitigation of global climate change, especially with the municipality vision for 2030 of achieving a City Status through urban regeneration and comprehensive rural development. As South Africa is facing the challenge of landfill sites reaching their airspace, the capturing of methane possesses the great benefit of extending its lifespan. especially because this is the main landfill site, the airspace has reached a capacity that a study conducted by Nelwomondo stated that by the year 2022, the airspace would be at 16391m³. Therefore, the use of methane could help in avoiding the construction or extending the landfill site, In terms of the Thulamela local municipality, the landfill site tender bid has been projected to be costing R16000000 (Municipality, 2022).

8 ECONOMIC BENEFITS OF USING METHANE GAS AT THOHOYANDOU LANDFILL

Economic benefits are defined as tangible benefits that can be measured in terms of the revenue generated or money saved through the implementation of policies or innovative strategies (Wells, 2021). The need to generate revenue through the utilization of wasteto-energy projects, especially with the economic state of the country and the Eskom crisis. Henceforth the utilization of methane gas in the Thohoyandou landfill site as will provide the economic benefit of providing a reliable energy source because landfill gas is generated 24 hours a day, every day of the year. This will be reliable energy because according to the LFG calculator done by (Njoku, et al., 2020), stipulated those simulations from Afvalzorg's model CH4 peak emissions for Thohoyandou landfill were 3336 Mg/year. Which is sufficient for providing energy. The world is facing the depletion of fossil fuel, which makes the buying prices high, thus using methane will reduce the demand and dependence on fossil fuel and nuclear energy. This when it comes to the municipality will be beneficial because according to Daily Maverick (2022), the Limpopo local municipalities already owe ESKOM R1062095. The reduction in the dependence can lead to the selling of greenhouse gas offsets, through the carbon credit method (Guy, 2016). Table 1 illustrates how to leverage the methane.

	REIPPP Feed in Tarriff (FIT) unit rate (2015)	Eskom Avg Mega flex unit rate (2016)	Units
Average output per MW installed	7 095 600	7 095 600	KWh/year
Average capacity/load factor experienced in SA projects	81	81	%
Anticipated/global average capacity factor	92	92	%
Tariff for landfill gas	1	0.85	ZAR/KWh
Annual income/MW installed	7 095 600	6 031 260	ZAR/MW
Annual income minus op costs	4 967 600	3 903 260	ZAR/MW
Revenue over 15 year lifespan (12 – 20 years avg lifespan)	106 434 000	90 468 900	ZAR/MW
Capital cost/MW (estimated avg. including wells)	19 300 000	19 300 000	ZAR/MW
Operational costs per year (figure indicative)	2 128 000	2 128 000	ZAR/MW
Operational costs (over 15 years)	31 920 000	31 920 000	ZAR/MW
Revenue minus costs (over 15 years)	55 214 000	39 248 900	ZAR/MW
Revenue minus costs (average annual)	3 680 933	2 616 593	ZAR/MW
Payback/break even – number of years	3.89	4.94	Years

Table 1 Simple payback analysis for LFG to electricity project by Ferry et al 2016.

The other economic benefits are available from the potential to use the methane from the landfill site. Making reference to Njoku's Study (2020) indicates that the engine generator set will generate an average electricity of approximately 9,366,635.263 KWh/year and will supply an average of approximately 4130 households every year. This will help to reduce the pressure on the coal-powered grid. In a municipality with a high number of unemployment, this equates to 47.7% (District, 2021). The use of the waste-to-energy project in the landfill site can assist with job creation in the municipality through having engineers, operators, maintenance officers, and various employment opportunities. This will be beneficial to the

municipality by making this project localized by employing local people procuring from local shops and working in partnership with the University of Venda and Makwarela Tvet College with their experts. This is because the WtE projects turn to source people from abroad to come and assist in design and assembling. The utilization of methane by the municipality can be used directly in the municipal vehicle fleet, as a way to have an alternative to the use of gasoline for their vehicle. The use of this gas possesses more benefits to the municipality as it solves environmental problems whilst generating revenue for the operation of the municipality which they have the opportunity to leverage on it.

9 CONCLUSION

At the rate the population is growing and the vision that Thulamela local municipality aims to achieve by 2030 will require stringent measures to be implemented. This will assist in addressing the issue of waste management and energy delivery within the landscape. Thus, this paper recommends that Thulamela local municipality should implement the waste-to-energy project at the Thohoyandou landfill sites, as it poses more environmental and economic benefits to the municipality and makes the municipality contribute towards the common goal set by the United Nations to achieve sustainable usage by the year 2030.

Investigating the Main Factors of Neighbourhood Morphology Affecting Social Cohesion: SEM-PLS Analysis Approach

Doaa Morsy, Khalid Al-Hagla, Mohamed Fikry

(Doaa Morsy, University of Alexandria, Department of Architecture, Egypt, do3a2_med7at@hotmail.com)
(Prof. Khalid Al-Hagla University of Alexandria, Department of Architecture, Egypt, khagla@hotmail.com)
(Prof. Mohamed Fikry, University of Alexandria, Department of Architecture, Egypt, mfikry2004@yahoo.com)

1 ABSTRACT

In a particular geographic location, a collection of individuals who share the same services and a certain amount of social cohesion is referred to as a neighbourhood. This research was conducted to present a model that examines several hypotheses regarding the impact of neighbourhood morphology and its main factors on the social cohesion of a neighbourhood and its subdimensions. To assess the extent of each factor of neighbourhood morphology affecting social cohesion and its subdimensions, a mixed research approach was followed. A structured questionnaire survey was undertaken on a random sample of residents of two neighbourhoods in New Borg Al-Arab City in Egypt with the involvement of 193 participants. After performing a measurement model analysis on the gathered information, the data were then subjected to a structural model analysis using Smart PLS 3.2.6. Internal consistency reliability, convergent validity, and discriminant validity are evaluated during the assessment of reflective measurement models in PLS-SEM. After proving the reliability and validity of the measurement models, the structural model is evaluated including examining the model's prediction ability and the links between its constructs. Regarding the main hypothesis, we concluded that neighbourhood morphology significantly affects social cohesion. Moreover, the subdimensions of neighbourhood morphology affect the subdimensions of social cohesion resulting in 22 hypotheses.

Keywords: New Borg Al-Arab City, SEM-PLS, Design Constraints, Social Cohesion, Neighbourhood Morphology

2 INTRODUCTION

Contemporary neighbourhoods are built for the sole purpose of housing and parking cars. Residents have to rely on their cars because they cannot conveniently get the necessities. Egypt's new cities are a great illustration of these kinds of contemporary neighbourhoods. Egypt's New Borg Al-Arab City is one example. In the 30 years between 1977 and 2006, the city was supposed to have 1,258,200 residents, but only 500,000 actually called it home. This is due to a lack of adequate infrastructure, including adequate housing, recreational facilities, public transportation, sidewalks, etc., as well as poor planning and design. The strength of the relationships within different networks is sometimes used as a proxy for the health of society as a whole. This causes cities to fall short in meeting the requirements of their residents, drives up the price of supporting infrastructure for parks, and boosts land values without improving community life in residential areas. (Mohamed et al., 2022)

By reviewing previous studies, this research finds that Dempsey (2009), examined the claim that there is an association between good-quality neighbourhoods and social cohesion. This is done through a mixed research approach starting by investigating the theoretical background of such claims and then providing empirical evidence on how the urban form and the built environment's features influence social cohesion in local neighbourhoods. The empirical stage is divided into two phases: physical site survey and household questionnaire. Statistical methods were used to examine the data, most extensively the SPSS statistical software for the social sciences (SPSS). Descriptive analyses, Spearman's rank-order correlation coefficient, multiple linear regression, binary logistic regression, factor analysis, and analyses of variance (both one-way and two-way ANOVA) were utilized.

On the other hand, this research developed a model to understand the effect of neighbourhood morphology (and its subdimensions) on social cohesion (and its subdimensions). The model was fabricated from a comprehensive analysis of the literature review of both the main neighbourhood design characteristics and the main dimensions and subdimensions of social cohesion. The model was analyzed using SPSS and the Partial Least Square analysis of SEM (PLS-SEM) technique. This technique combines factor analysis and multiple regression analysis to investigate the nature of the relationship between the empirically observable

and the more nebulous "latent" variables. Due to its ability to estimate various and interrelated dependencies in a single analysis, this technique is much more favoured.

3 NEIGHBOURHOOD MORPHOLOGY AND SOCIAL COHESION

The literature dealing with the relationship between the morphological composition of the residential neighbourhood and its social cohesion and how to measure this relationship has been numerous. This is evident in Table 1, which summarizes some of this literature and the usual measurement methods used.[1]

Research	Contribution
Are good-quality environments socially cohesive? Measuring quality and cohesion in urban neighbourhoods	Studying factors for both quality of the built environment and social cohesion For measuring: -Physical site survey -Household questionnaire survey
Built environment, urban vitality and social cohesion: Do vibrant neighbourhoods foster strong communities?	Tests a model in which urban vitality link between the built environment and social cohesion For measuring: -Survey and geospatial data
Urban Design, Public Spaces, and Social Cohesion: Evidence from a Virtual Reality Experiment	Investigates the impact of design alternatives on social cohesion through a virtual reality experiment
Social Cohesion in Cairo: Toward a Better Understanding Of The Potential Role Of Urban Design	The potential role of urban design in contributing to the social cohesion among the different components of the society in Cairo -Literature Review
Public Space Design and Social Cohesion: An International Comparison	Main concepts of public space, urban design and social cohesion the intersection of urban design and planning and social cohesion Explores how public behavior evidences ideas about social cohesion
European public space projects with social cohesion in mind: symbolic, programmatic and minimalist approaches	This paper characterizes three distinct open space design approaches – Symbolic, Programmatic and Minimalist – that governments and designers have put forward as best practices to enhance social cohesion
Urban planning, neighbourhoods and social cohesiveness: A socio-cultural study of expatriate residents in Dubai	Assess and analyze the role of the physical planning of the built forms, layout and design in creating socially cohesive neighbourhoods in the multicultural city of Dubai. For Measuring:- -Observation and Spatial Analysis using GIS -Surveys, and semi-structured interviews
Neighbourhood Form and Social Cohesion: What Can We Learn Before and During Social Distancing	This research identifies the importance of suburban neighbourhood form in promoting social cohesion. For Assessing socio-physical relationship for different patterns -Cross-sectional surveys and follow-up interviews
Neighbourhood open spaces for social cohesion	Measure and compare the open spaces in selected neighbourhoods in Europe and India according to Unitary Theory of Production For Measuring:- -On-site observation -Surveys

Table 1: Neighbourhood Morphology and Social Cohesion in Literature Review. Source: Researchers.

4 METHODS

4.1 Scales

Based on the previous analysis, The developed model in this research is comprised of two main variables which they are Neighbourhood Morphology and Social Cohesion.

Neighbourhood Morphology's main dimensions are Street System and Block System. The Street System is branched into the subdimensions of neighbourhood morphology which they are Street Network, Street Type, Pedestrian Network, and Access Points. The Block System is branched into Perceived Density, and Mixed-land Use.

The main dimensions of Social Cohesion are Participation/Solidarity, Safety/Trust, and Neighbourhood Attachment. Participation/Solidarity is branched into Community, Political, and Solidarity. The Safety/Trust is branched into General Trust and Institutional Trust. Finally, Neighbourhood Attachment is branched into Identity, Ownership and Memory, and Belonging.

4.2 Sample and Data Collection

For the purpose of this research, a structured questionnaire was conducted on a random sample of 193 participants (see Appendx). The participants are the residents of two selected neighbourhoods of New Borg Al-Arab City in Egypt, 95 participants from Neighbourhood Two and 98 participants from Neighbourhood Three. These neighbourhoods differ from each other in their structural composition as shown in Figure 1 and

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Figure 2. The structured questionnaire investigates the inhabitant's perception of both neighbourhood morphology and social cohesion's sub-dimensions. It's divided into thirteen sections: Street Network (6 items), Street Type (4 items), Pedestrian Network (2 items), Access Points (2 items), Perceived Density (2 items), Mixed-land Use (2 items), Community (2 items), Political (2 items), Solidarity (2 items), General Trust (2 items), Institutional Trust (2 items), Identity (2 items), Ownership and Memory (2 items), and Belonging (2 items). A five-level Likert scale with "Strongly Disagree" until "Strongly Agree", comprises the measurement level of the questionnaire. A Partial Least Square analysis of SEM (PLS-SEM) is followed in this study. Analyses are performed in two phases: first, a Measurement Model analysis (Reliability and Validity Test) is performed, and then, a Structural Model Analysis is performed (Hypothesis Testing).

Fig. 1: Neighbourhood Two. Source: Google Earth, Fig. 2: Neighbourhood Three. Source: Google Earth.

4.3 Research Hypothesis

According to the developed model, there are three scales of hypothesis testing which resulted in 55 hypotheses: Hypothesis Testing for the main Variables (1 hypothesis), Hypothesis Testing for the main Dimensions (6 hypotheses), and Hypothesis Testing for the main Sub-Dimensions (48 hypotheses).

4.3.1 Hypothesis Testing for the main Variables

H1: There is a significant relationship between Neighbourhood Morphology and Social Cohesion

4.3.2 Hypothesis Testing for the main Dimensions

H2: There is a significant relationship between Street System and Participation

H3: There is a significant relationship between Street System and Trust

H4: There is a significant relationship between Street System and Neighbourhood Attachment

H5: There is a significant relationship between Block System and Participation

H6: There is a significant relationship between Block System and Trust

H7: There is a significant relationship between Block System and Neighbourhood Attachment

4.3.3 Hypothesis Testing for the main Sub-Dimensions

H8: There is a significant relationship between Street Network and Community

H9: There is a significant relationship between Street Network and Political

H10: There is a significant relationship between Street Network and Solidarity

H11: There is a significant relationship between Street Network and General Trust

H12: There is a significant relationship between Street Network and Institutional Trust

H13: There is a significant relationship between Street Network and Identity

H14: There is a significant relationship between Street Network and Ownership and Memory

H15: There is a significant relationship between Street Network and Belonging

H16: There is a significant relationship between Street Type and Community

H17: There is a significant relationship between Street Type and Political

H18: There is a significant relationship between Street Type and Solidarity

H19: There is a significant relationship between Street Type and General Trust

H20: There is a significant relationship between Street Type and Institutional Trust

H21: There is a significant relationship between Street Type and Identity

H22: There is a significant relationship between Street Type and Ownership and Memory

H23: There is a significant relationship between Street Type and Belonging

H24: There is a significant relationship between Pedestrian Network and Community

H25: There is a significant relationship between Pedestrian Network and Political

H26: There is a significant relationship between Pedestrian Network and Solidarity

H27: There is a significant relationship between Pedestrian Network and General Trust

H28: There is a significant relationship between Pedestrian Network and Institutional Trust

H29: There is a significant relationship between Pedestrian Network and Identity

H30: There is a significant relationship between Pedestrian Network and Ownership and Memory

H31: There is a significant relationship between Pedestrian Network and Belonging

H32: There is a significant relationship between Access Points and Community

H33: There is a significant relationship between Access Points and Political

H34: There is a significant relationship between Access Points and Solidarity

H35: There is a significant relationship between Access Points and General Trust

H36: There is a significant relationship between Access Points and Institutional Trust

H37: There is a significant relationship between Access Points and Identity

H38: There is a significant relationship between Access Points and Ownership and Memory

H39: There is a significant relationship between Access Points and Belonging

H40: There is a significant relationship between Perceived Density and Community

H41: There is a significant relationship between Perceived Density and Political

H42: There is a significant relationship between Perceived Density and Solidarity

H43: There is a significant relationship between Perceived Density and General Trust

H44: There is a significant relationship between Perceived Density and Institutional Trust

H45: There is a significant relationship between Perceived Density and Identity

H46: There is a significant relationship between Perceived Density and Ownership and Memory

H47: There is a significant relationship between Perceived Density and Belonging

H48: There is a significant relationship between Mixed-land Use and Community

H49: There is a significant relationship between Mixed-land Use and Political

H50: There is a significant relationship between Mixed-land Use and Solidarity

H51: There is a significant relationship between Mixed-land Use and General Trust

H52: There is a significant relationship between Mixed-land Use and Institutional Trust

H53: There is a significant relationship between Mixed-land Use and Identity

H54: There is a significant relationship between Mixed-land Use and Ownership and Memory

H55: There is a significant relationship between Mixed-land Use and Belonging

5 RESULTS

5.1 Data Examination

Missing data, outliers, normality, and Common Method Bias (CMB) are all things that should be checked in the gathered data, as suggested by the literature (Hair et al., 2017). The key data concerns were therefore examined using SPSS in this study. There were no issues discovered after looking at the missing data and the outliers. Researchers can identify the CMB using Harman's single-factor test; the percentage of factors explaining the variance in the data determines the presence or absence of the bias. Common method bias is not an issue if the overall variance attributable to the factor is less than 50%. To our dismay, we found that the first component explained only 17.601% of the total variance. Given that the number was under 50%, it's possible that the CMB issue was overlooked. As displayed in Table.2, Skewness levels between -2 and +2 and kurtosis values between -7 and +7 are regarded as acceptable in displaying normal distribution (Hair et al. 2014; Bryne 2016).

Construct	Notation	N	Skewness	Kurtosis
Street Network	SN	193	-0.463	1.907
Street Type	ST	193	0.354	-1.178
Pedestrian Network	PN	193	-0.574	-1.023

5.2 Measurement Model Assessment

PLS-SEM calls for assessing internal consistency reliability, convergent validity, and discriminant validity to validate reflective measurement models.

The Internal Consistency and Reliability of the measurement model evaluate a construct to determine whether or not all of the indicators connected with it are truly measuring the construct. Despite its widespread use, Cronbach's alpha has been called into question due to its implicit assumption of equal outer loadings among all indicators (Hair et al., 2017), and because the number of indicators affects the calculation of Cronbach's alpha, with a smaller value being obtained for scales with fewer than 10 items (Pallant, 2010, Hair et al., 2017). Hence, additional methods of internal consistency assessment, including composite reliability (CR), are recommended. Values above 0.6 are also considered acceptable for CR, but 0.7 is the established norm (Fornell and Larcker, 1981; Hair et al., 2017; Taber, 2018). Values for internal consistency are shown in Figure 3 as composite reliability (CR). While evaluating internal consistency, the composite reliability takes into consideration the fact that each indicator has a unique external loading.

The Convergent Validity assesses the degree to which the variables used to measure one construct are correlated with one another. The Convergent Validity was assessed using AVE and Item Loadings. The AVE, also known as the grand mean of the squared loadings of the indicators measuring a construct, is a standard measure that is used to show convergent validity. Values for average variance (AVE) are shown in Figure 3. Although values of AVE greater than 0.5 are preferred, those greater than 0.4 are also acceptable so long as CR values are greater than 0.6. (Fornell and Larcker, 1981). Another measure of Convergent Validity is the item loading, and the minimum outer loading that must be met is 0.70. (Hair et al., 2014, Hair et al., 2017). When an item's outer loading is 0.70, it means that the construct can explain approximately 50% of the item's variance (Hair et al., 2017). On the other hand, the authors proposed that if the outer loading is

between 0.4 and 0.7, the effect that indicator deletion has on the reliability of the internal consistency should be investigated. the reflective indication ought to be kept if the deletion does not result in an increase in a measure above the threshold. As a result of low factor loadings, three items were eliminated from the analysis (Q4, Q10, and Q11), but all of the remaining items in figure 4 satisfy the criterion.

Discriminant Validity is tested by looking at how the construct compares to other constructs. The fornell-Larcker criterion is commonly used to demonstrate discriminant validity, which guarantees that the indicator only loads highly on the construct it is linked with. Indicators sometimes load to many constructs; however, the loading on the target construct must be greater than any other correlations the indicator may have with other constructs. The Fornell-Larcker criterion compares the square root of AVE to the correlations of the construct. The AVE of the construct should be greater than any of the construct's correlations with other constructs, as measured by its square root. As the square root values of the AVE for the construct were greater than the construct's correlations with other constructs, as shown in table 3, the discriminant validity was developed using these principles as a basis.

5.3 Structural Model Assessment

The structural model was analyzed using path coefficients, collinearity diagnostics, the coefficient of determination (R2), effect size (f 2), predictive relevance (Q2), and goodness of fit criteria.

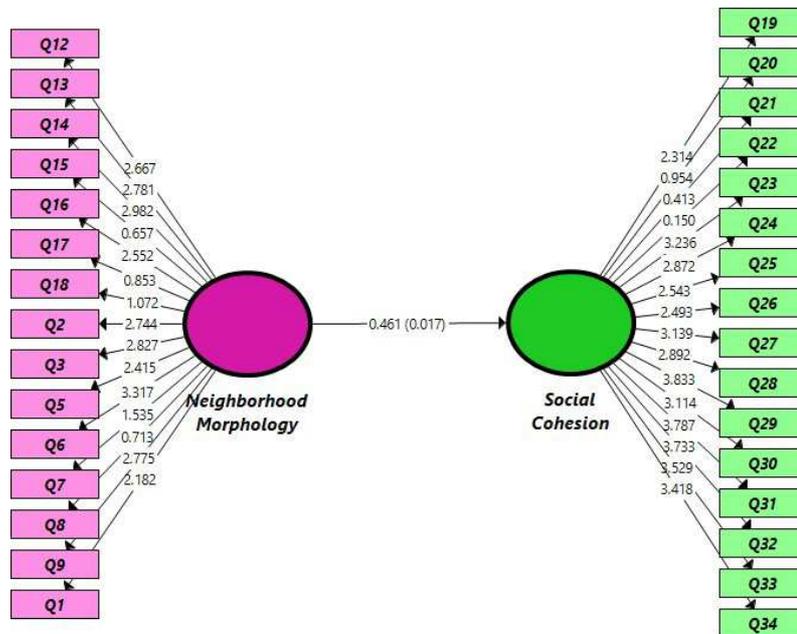
Estimates of the relationships between model constructs are referred to as "Path Coefficients" (Hair, Sarstedt, Hopkins, & Kuppelwieser, 2014). These coefficients lie on a scale from +1 to -1, with plus one indicating a highly positive relationship, zero indicating no relationship at all, and minus one indicating a highly negative relationship (Garson, 2016). Studies should also report the path coefficients alongside the significance level, t-value, and p-value when evaluating the PLS path (Hair, Sarstedt, Ringle, & Mena, 2012). It has been determined whether or not there is a statistically significant relationship between the two constructs by evaluating the hypotheses pertaining to the signs, sizes, and statistical significance of the calculated path coefficients. In general, bigger effects between a predictor and a predicted variable are indicated by higher path coefficients. It is possible to evaluate the reliability of the estimated path coefficients by comparing their p-values to two predetermined thresholds, set at 0.05 and 0.01. This procedure establishes the significance of the hypothesized relationships (Henseler et al., 2009; Hair et al., 2017). Conclusions were formed for each hypothesis later by comparing their p-values to the aforementioned traditional thresholds. The results of the hypothesis testing for the main hypothesis, main dimensions, and subdimensions are shown in Figures 5, 6, and 7, and in table 4.


Fig. 5: Structural model for the main hypothesis. Source: Researchers.
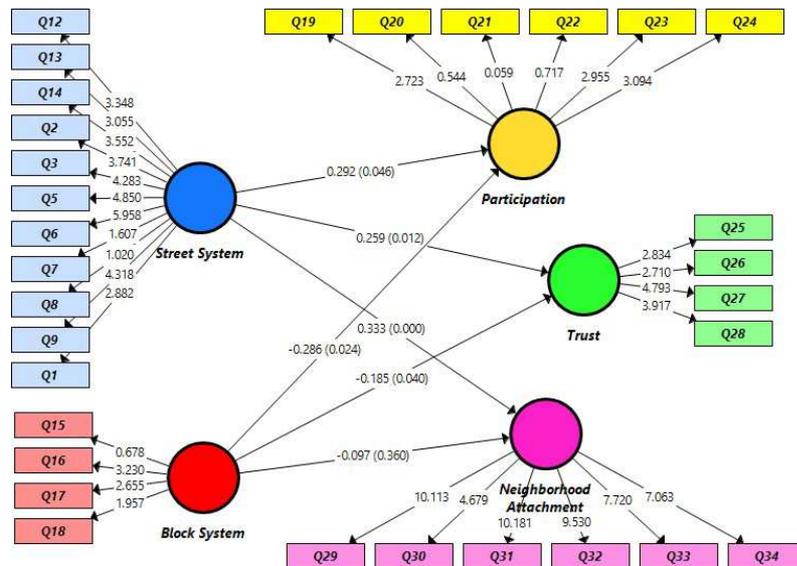

Fig. 6: Structural model for testing the hypotheses concerning the dimensions of the variables. Source: Researchers.

The effect of the subdimensions of neighbourhood morphology on social cohesion's subdimensions was the subject of 48 hypotheses. Therefore, another test was conducted as shown in figure 7, and disregard the non-significant association for the sake of clarity.

Hypothesis	B	t-value	P-value	Remark
H1: Neighbourhood Morphology -> Social Cohesion	0.461	2.389	0.017	Supported

There are interpretation problems caused by Collinearity when there is a high correlation between two constructs (Hair, Hult, Ringle, & Sarstedt, 2017). The variance inflation factor (VIF) is a measure of collinearity. High collinearity is indicated by a VIF value of 5 or higher (Hair, Ringle, & Sarstedt, 2011; Hair, Hult, Ringle, & Sarstedt, 2017). All VIF values in Table 5 are below the threshold, indicating that collinearity does not exist amongst the several independent constructs.

Path	VIF	Path	VIF
Neighbourhood Morphology -> Social Cohesion	1	Mixed Land Use -> Political	1.157
Block System -> Neighbourhood Attachment	1.015	Mixed Land Use -> Solidarity	1.02
Block System -> Participation	1.015	Pedestrian Network -> Identity	1.52
Block System -> Trust	1.015	Perceived Density -> Ownership & Memory	1.006
Street System -> Neighbourhood Attachment	1.015	Street Network -> Community	1.097
Street System -> Participation	1.015	Street Network -> General trust	1
Street System -> Trust	1.015	Street Network -> Solidarity	1.02
Access Points -> Community	1.097	Street Type -> Belonging	1.157
Access Points -> Identity	1.195	Street Type -> Identity	1.299
Mixed Land Use -> Belonging	1.157	Street Type -> Ownership & Memory	1.006
Mixed Land Use -> Institutional trust	1	Street Type -> Political	1.157

Coefficient of determination (R²) is a structural model quality measure that assesses the effect of independent factors on dependent latent variables (Hair, Sarstedt, Ringle, & Mena, 2012). (Hair, Sarstedt, Hopkins, & Kuppelwieser, 2014). From 0 to 1, coefficient of determination estimates range from low to high explained variance. Researchers used a different cutoff. Chin (1998) classified values below 0.19, 0.19-0.33, 0.33-0.67, or above 0.67 as very low, low, moderate, or high. Falk & Miller (1992) defined R² as negligible if R²<0.1 and adequate if R²>0.1. Table 6 shows that most R Square values were adequate. The R-Square of Social Cohesion was 0.213, indicating that Neighbourhood Morphology explained 21 % of its variation. Identity R Square was highest and Institutional trust lowest.

Dependent Variable	R Square	R Square Adjusted
Social Cohesion	0.213	0.209
Neighbourhood Attachment	0.128	0.119
Participation	0.187	0.178
Trust	0.113	0.104
Belonging	0.123	0.114
Community	0.154	0.145
General trust	0.099	0.094
Identity	0.225	0.212
Institutional trust	0.026	0.021
Ownership & Memory	0.144	0.135
Political	0.071	0.062
Solidarity	0.097	0.088

Table 6: R Square and Associated R Square Adjusted. Source: Researchers.

The effect size f² measures how much the endogenous construct will affect the model if an exogenous construct is eliminated. A construct has a small influence if its value is between 0.02 and 0.14, a medium effect between 0.15 and 0.34, and a high effect above 0.35. An endogenous construct with a value < 0.02 has no effect (Hair et al., 2017). Table 7 shows construct effect size f². Neighbourhood Morphology has moderate effect on Social Cohesion (f²=0.27). Street network affects community moderately (f²=0.157). Except for block system-neighbourhood attachment (f²=0.011), all other effect sizes were accepted since.

Path	F²	Path	F²
Neighbourhood Morphology -> Social Cohesion	0.27	Mixed Land Use -> Political	0.038
Block System -> Neighbourhood Attachment	0.011	Mixed Land Use -> Solidarity	0.04
Block System -> Participation	0.099	Pedestrian Network -> Identity	0.037
Block System -> Trust	0.038	Perceived Density -> Ownership & Memory	0.075
Street System -> Neighbourhood Attachment	0.125	Street Network -> Community	0.157
Street System -> Participation	0.103	Street Network -> General trust	0.11
Street System -> Trust	0.075	Street Network -> Solidarity	0.053
Access Points -> Community	0.072	Street Type -> Belonging	0.116
Access Points -> Identity	0.046	Street Type -> Identity	0.052
Mixed Land Use -> Belonging	0.072	Street Type -> Ownership & Memory	0.107
Mixed Land Use -> Institutional trust	0.026	Street Type -> Political	0.065

Table 7: f² Effect Size. Source: Researchers.

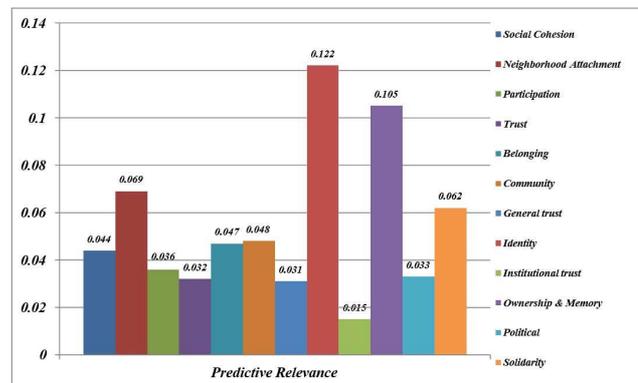
The out-of-sample prediction capability of the model is represented by the Predictive Relevance Q2 value. If a model is stated to have predictive power or predictive relevance, this indicates that it is able to reliably forecast data that was not used in the process of estimating the model. The Q2 values that were determined from the research are detailed in Figure 8. As the values of Q2 are more than 0, it is safe to say that the study model has a good predictive relevance.


Fig. 8: Predictive Relevance. Source: Researchers.

The geometric mean of the average and average variance retrieved from endogenous variables is the Goodness of Fit (GoF), a global fit indicator established by Tenenhaus et al. (2005). GoFs consider the measurement and structural models throughout the research process, focusing on model performance (Henseler & Sarstedt, 2013). The criteria for determining whether GoF values are unacceptable, small, moderate, or large for a globally adequate PLS model are as follows: GoF less than 0.1, no fit; 0.1–0.25, small; 0.25–0.36, medium; and 0.36+, large. These criteria and the GoF value (0.306) indicate that the GoF model is moderate to sufficient viable global PLS model.

6 DISCUSSION AND CONCLUSION

The main goal of this research was to investigate the influence of Neighbourhood Morphology and its subdimensions on Social Cohesion and its subdimensions and which subdimensions affects the other. Depending on extensive literature review, a structured questionnaire was conducted on a random sample consists of 193 participants of two neighbourhoods in New Borg Al-Arab City in Egypt. The questionnaire was divided into 3 scales which they are: the main variables, the main dimensions, and the subdimensions.

After that the data collected were analyzed using SEM-PLS model which is comprised of two phases. Phase 1 the measurement model assessment and phase 2 the structural model assessment. The model developed resulted in 55 hypothesis, only 21 of them are supported which are demonstrated in table 8.

Hypothesis	Remark
H1: Neighbourhood Morphology has a statistically significant effect on Social Cohesion	Supported
H2: Street System has a statistically significant effect on Participation	Supported
H3: Street System has a statistically significant effect on Trust	Supported
H4: Street System has a statistically significant effect on Neighbourhood Attachment	Supported
H5: Block System has a statistically significant effect on Participation	Supported
H6: Block System has a statistically significant effect on Trust	Supported
H8: Street Network has a statistically significant effect on Community	Supported
H10: Street Network has a statistically significant effect on Solidarity	Supported
H11: Street Network has a statistically significant effect on General trust	Supported
H17: Street Type has a statistically significant effect on Political	Supported
H21: Street Type has a statistically significant effect on Identity	Supported
H22: Street Type has a statistically significant effect on Ownership & Memory	Supported
H23: Street Type has a statistically significant effect on Belonging	Supported
H29: Pedestrian Network has a statistically significant effect on Identity	Supported
H32: Access Points has a statistically significant effect on Community	Supported
H37: Access Points has a statistically significant effect on Identity	Supported
H46: Perceived Density has a statistically significant effect on Ownership & Memory	Supported
H49: Mixed Land Use has a statistically significant effect on Political	Supported
H50: Mixed Land Use has a statistically significant effect on Solidarity	Supported
H52: Mixed Land Use has a statistically significant effect on Institutional trust	Supported
H55: Mixed Land Use has a statistically significant effect on Belonging	Supported

9 APPENDIX

Domain		Subdomain	Questions (Qs)
Neighbourhood Morphology (by researchers)	Street System	Street Network	The Visual Permeability in the street network is high The Physical Permeability in the Street network is high I can remember the streets that I have passed through before There are many junctions in the neighbourhood where I live There are many landmarks in the neighbourhood where I live I feel that the streets and open spaces are well defined by the buildings
		Street Type	The street where I live is Narrow The street where I live has shopping services The street where I live is a Cul de sac The street where I live is pedestrian only
		Pedestrian Network	There are enough crossings in the neighbourhood I live I am satisfied with the quality of the pavements in my neighbourhood
		Access Points	The access points are well distributed in the neighbourhood The access points are clear and well defined
	Block System	Perceived Density	I feel that my neighbourhood is overcrowded There is lack of parks in my neighbourhood
		Mixed Land Use	There is a mix of land uses where I live The neighbourhood center isn't so far from my home/work
Social Cohesion (Aliaa, Yuki et al., Gianmaria)	Participation/ Solidarity	Community	I take part in social activities in my district (Greetings in holidays, weddings, new practice openings …) I participate in cultural events in my district (concerts, exhibitions, festivals…)
		Political	Vote in the elections of community organizations such as neighbourhood committees and village committees I volunteer in charitable associations
		Solidarity	I contact my neighbours constantly I participate with neighbours in solving the building/ street problems
	Safety/ Trust	General trust	I spend much time in public places (parks, squares, etc.) I witness crimes against myself or others in public spaces
		Institutional trust	When I witness an accident, I report to the police When I witness a domestic problem, I report to family/ child services
	Neighbourhood Attachment	Identity	I feel attached to where I live\ work My place is well identified
		Ownership & Memory	I have the feeling of ownership due to the long stay The place around reminds me of good old times
		Belonging	I feel an urge to move out of this neighbourhood I feel isolated in this neighbourhood

1 ABSTRACT

The World Cities Report (2016) states that cities are the drivers of economic growth and development, but they also face numerous challenges such as urban decay which can hinder growth and negatively impact the quality of life for residents. Urban decay refers to the deterioration and decay of buildings and older areas due to various factors such as neglect, crime, and lack of economic support. Gordon (2003), as cited in Ndlebe (2017), highlights the same challenge in the city of Pietermaritzburg. The research aims to identify means of regenerating the Pietermaritzburg Central Business District while incorporating the concepts and principles of smart and sustainable cities development. The objectives include analyzing the conceptualization of smart cities, sustainable development, urban decay, and urban regeneration concepts and evaluating their impact on the urban environment, assessing the current state of the Pietermaritzburg Central Business District through urban decay and regeneration, determining the potential of community and public participation in planning for urban regeneration, and establishing a smart and sustainable regeneration strategy. The research methodology used in investigating the regeneration of the Pietermaritzburg Central Business District (CBD) is a qualitative descriptive case study approach, which enables multiple perspectives on the issue of urban decay and regeneration in the city to be incorporated. The research findings suggest that successful urban regeneration requires a planned, team-based strategy that includes community engagement and stresses social inclusion, open space, and environmentally friendly transportation. The case studies of successful regeneration programs in Singapore and Kwa-Zulu Natal highlight the importance of having a clear goal and being adaptable to changing circumstances. The study's results show that 30 municipal officials who were interviewed in October 2022 in Pietermaritzburg are aware of urban decay in the city center and suggest enforcing council ordinances, carrying out ongoing clean-up projects, raising public awareness, fostering local economic development, and coordinating between various municipal agencies as potential solutions. The officials believe that smart and sustainable city growth is necessary for urban regeneration in Pietermaritzburg, but it requires a concerted effort from multiple stakeholders. In conclusion, this study highlights the feasibility of urban regeneration in Msunduzi but underscores the need for a concerted effort from multiple stakeholders to achieve sustainable and smart city growth.

Keywords: Urban decay, Urban Regeneration, Smart City, Sustainable Development, Spatial Planning

2 INTRODUCTION

This paper focuses on the topic of urban regeneration in the context of smart and sustainable city development. The Integrated Urban Development Framework predicts a significant increase in urban migration by 2050, posing challenges for governments in supporting the growing population. To address this, industries are being decentralized from inner cities, leading to urban decay and hindered economic growth. Urban regeneration initiatives are being implemented to tackle these issues. The purpose of this research is to develop a strategy and alternatives for implementing smart and sustainable city development through urban regeneration within the Msunduzi Municipality, with a specific focus on regenerating the Pietermaritzburg Central Business District. The objectives of the study include analyzing the concepts of smart cities, sustainable development, urban decay, and urban regeneration, evaluating their impact on the urban environment through international and local case studies, assessing the current state of the Pietermaritzburg Central Business District in terms of urban decay and regeneration, determining the potential of community and public participation in urban regeneration planning using the concept of smart cities and sustainable development, and establishing a comprehensive strategy for smart and sustainable regeneration. The paper discusses various concepts related to urban decay, smart cities, and sustainable development, providing definitions and highlighting their significance. It also presents case studies of smart city initiatives in urban

regeneration, examining the efforts made by cities like Toronto and Korea to use advanced technologies and innovative strategies to improve various urban aspects. The paper concludes by focusing on the city of Pietermaritzburg in Kwa-Zulu Natal and presenting discussions on urban regeneration in the Msunduzi Municipality, incorporating insights from interviews with municipal officials regarding the existence of urban decay, its causes, and potential solutions. The concept of smart city development is also explored as a means to improve the urban decay situation in the area.

3 LITERATURE REVIEW

3.1 Refining the concept or urban decay and smart cities

Urban decay encompasses various aspects of persistent disorder within urban areas, including abandoned buildings, deteriorating infrastructure, and compromised living conditions (White, Sepe, & Masconale, 2014). This phenomenon is closely linked to social, economic, and physical changes in cities (Alias, Zyed, & Chai, 2016). It manifests through ill-kept properties, vandalism, social unrest, and economic decline, ultimately driving decentralization as people and businesses relocate to more functional areas (Clark, 2013; Alias et al., 2016). The concept of a smart city, as defined by multiple sources, involves leveraging information and communication technologies to enhance livability, sustainability, and efficiency (Roy, 2016; World cities report, 2016; British Standards Institute, 2014). Smart city development incorporates resource efficiency, innovative economies, sustainable mobility, intelligent urban planning, and improved citizen governance (Galati, 2018). The overarching goal is to create technologically advanced, inclusive urban environments that address urban challenges and promote community well-being (Moura & Silva, 2019).

3.2 Smart city initiatives in urban regeneration

The research that follows provides a comprehensive review of urban regeneration programs that have been put in place in West Don Lands project in Toronto, Dubai and Singapore as best examples for smart city initiatives in urban regeneration.

3.2.1 The West Don Lands Project in Toronto

Urban decay refers to the deterioration of urban areas due to a combination of social, economic, and environmental factors. In Toronto's case, the rapid growth of the city coupled with inadequate urban planning and development strategies has contributed to pockets of urban decay. As the largest city in Canada with a population of around 6 million, the challenges of providing sufficient housing, transportation, and infrastructure have become increasingly complex (Statistics Canada, 2016). The West Don Lands area, despite its prime waterfront location, fell victim to neglect, underutilization, and deteriorating infrastructure, reflecting broader issues in urban management.

The West Don Lands Urban Regeneration project aims to revitalize the 32-hectare area by creating residential units, mixed land uses, and job opportunities while prioritizing sustainable and smart development. One of the fundamental strategies employed is the adoption of smart growth policies, aligning with the city's commitment to sustainable development goals (OECD, 2015). Smart growth emphasizes efficient land use, transportation options, and community engagement to combat urban decay. One of the notable successes of the West Don Lands project lies in its community-wide approach to planning. The city invested two years in the initial planning stage, focusing on extensive community participation, transparency, and sustainability audits (Toronto, 2021). This inclusive approach ensured that the project addressed both opportunities and challenges, garnering support from stakeholders and minimizing potential conflicts. The project's design phase involved detailed block plans that facilitated resolution to building properties, street patterns, stormwater management, and utility services (Toronto, 2021). This comprehensive approach helped lay the groundwork for a functional and aesthetically pleasing urban environment. Furthermore, the integration of transit systems along Cherry Street highlights the emphasis on accessible and efficient transportation, a crucial aspect of smart cities.

466

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3.2.2 Aligning with Smart City Concept

City Strategies	Alignment with Smart City Concepts	Importance and Benefits
Sustainability	Sustainable designs, stormwater management, and efficient infrastructure minimize environmental impact and optimize resource use.	Reduced carbon footprint. Enhanced urban resilience. Improved quality of life
Community Engagement	Extensive community participation and transparency align with smart city's citizen-centric approach.	Greater social cohesion. Informed decision-making. Reduced conflicts and opposition.
Transportation	Integration of transit systems addresses mobility challenges and aligns with smart city's intelligent transportation solutions.	Reduced congestion. Improved accessibility. Enhanced economic activity
Mixed Land Uses	Creation of mixed land uses supports diverse and inclusive communities, a key aspect of smart cities.	Vibrant and resilient neighborhoods. Economic diversification. Enhanced cultural exchange.
Gaps	**Considerations and Mitigation**	**Implications and Risks**
Digital Inclusion	Equitable distribution of smart technology benefits to bridge the digital divide.	Preventing socio-economic disparities. Ensuring access for marginalized communities. Fostering digital literacy

3.2.3 Korea: a case study of Seoul and Pohang cities

The phenomenon of urban decline in Korean cities, including Seoul and Pohang, can be attributed to a combination of population decline, shifts in industries, and deindustrialization. According to Lee (2019), Seoul's new town development project was a response to the failure of previous redevelopment policies and aimed to address housing decline and inadequate infrastructure. Pohang, on the other hand, witnessed a decline in its city center, necessitating revitalization efforts led by the local government and public firms (Oh, 2020; Smart City Korea, 2021). Collaborating with public firms, the local government aims to introduce information and communication technologies in the central area, alongside establishing an industry hub for young entrepreneurs and redeveloping old housing to attract more visitors. The project includes a comprehensive platform incorporating smart city technologies, such as IoT in transportation, environment, and energy sectors, as well as AI-based solutions. These efforts target improving citizen security, disaster response, and enhancing existing public facilities. Despite these ambitions, resident preferences for tourism facilities and lower evaluations of energy-related amenities indicate potential disparities in policy goals and directions between public and private entities (Oh, 2020; Smart City Korea, 2021). Both cities recognized the potential of smart technology to address urban decay and foster sustainable development. The Korean government's enactment of the "Special Act on the Promotion of and Support for Urban Regeneration Act" in 2013 marked a significant step toward urban revitalization (Kim et al., 2020). This led to a slew of urban regeneration projects, aimed at integrating technology and smart solutions to create vibrant and efficient urban areas (Kim et al., 2020). Pohang's case is particularly noteworthy, as it showcases the city's endeavor to transform into a smart city by integrating information and communication technologies into various sectors (Oh, 2020; Smart City Korea, 2021).

3.2.4 Alignment with Smart City Concepts

Strategies	Alignment with Smart City Concepts	Importance and Benefits
Sustainability and Efficiency	Integration of smart technologies and infrastructure in projects for optimized resource use, enhanced urban efficiency, and sustainable growth.	Reduced resource consumption. Improved urban efficiency. Fosters sustainable development.
Community Engagement	Use of smart solutions to encourage citizen participation and engagement, promoting inclusivity and informed decision-making.	Empowered citizenry. Increased civic participation. Nurtures community cohesion.
Innovation and Economic Growth	Embrace of technology to attract businesses, entrepreneurs, and tourists, stimulating economic growth and fostering innovation.	Enhanced local economy. Expanded entrepreneurial opportunities. Catalyses innovation.
Infrastructure Enhancement	Implementation of IoT and AI technologies to enhance city services, bolster public safety, and fortify disaster response capabilities.	Improved service delivery. Strengthened public safety. Enhanced disaster management.

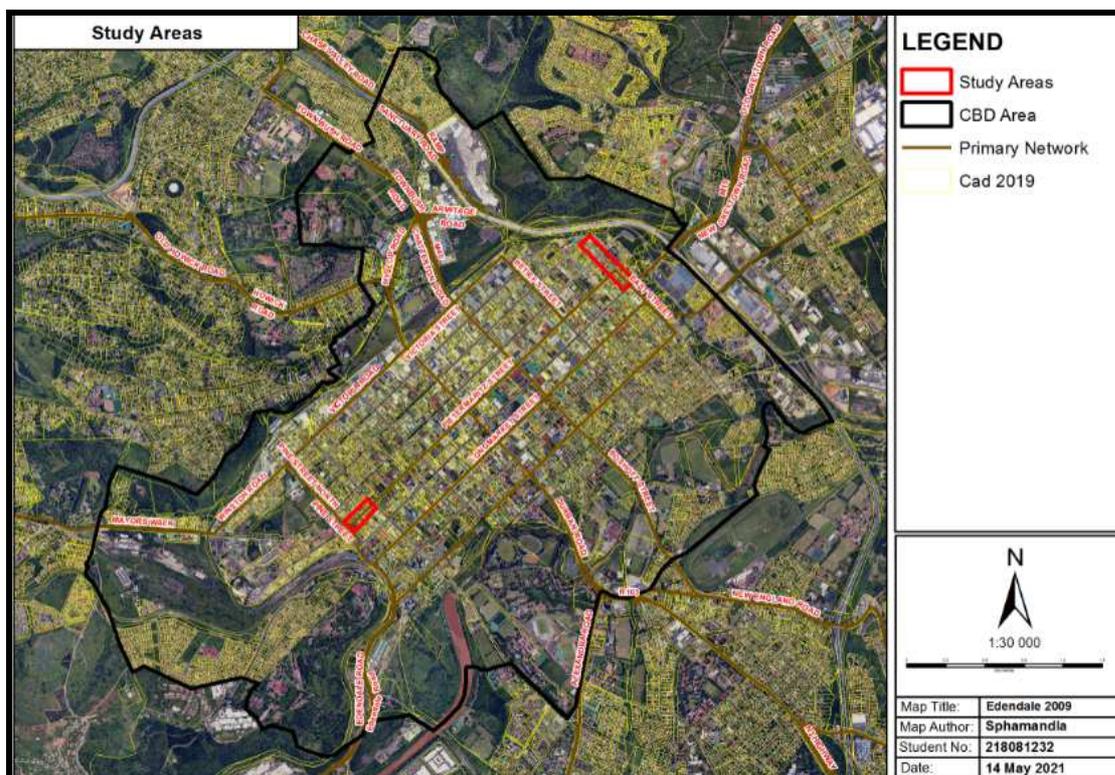
Gaps	Considerations and Mitigation	Implications and Risks
Public-Private Alignment	Addressing discrepancies between public and private entities' goals through improved alignment and communication.	Misaligned priorities may hinder project success.
Equitable Development	Ensuring the equitable distribution of benefits, especially to marginalized communities, through policy interventions.	Unequal distribution could exacerbate disparities.

3.3 Theoretical framework

The theoretical framework underlying this study encompasses four theories: Communicative Theory, Just City Theory, Modernization Theory, and New Urbanism Theory. Grant and Osanloo (2014) define theoretical frameworks as essential components relying on formal theory and philosophical thinking. Urban regeneration, often referred to as a theory, seeks to address urban decay and changes in the urban form, influenced by planning discussions and community involvement (Roberts, 2000). Communicative Theory emphasizes communication processes in urban development, with a focus on public participation (van Ruler, 2018). Just City Theory promotes equity in spatial relations and advocates for marginalized voices (Fainstein, 2000, 2005), while Modernization Theory examines societal development and can lead to gentrification (Goorha, 2017; Yeh, 1989; Ghertner, 2013). New Urbanism Theory, emerging in the 1980s, aims to combat urban sprawl and enhance community cohesion (Dwamena, 2015), but faces challenges related to spatial disparities and private development (Fainstein, 2000). These theories shape the study's exploration of urban regeneration's impact on social inclusion, spatial disparities, and the balance between private interests and societal benefits. Below is a table indicating the theoretical framework to assess the study area:

Theoretical Framework	Key Concepts	Implications for Study Area
Communicative Theory	Public participation, democracy	Investigate community engagement in planning and decision-making processes to ensure equitable urban regeneration.
Just City Theory	Equity, spatial relations	Analyze how urban regeneration initiatives address spatial inequalities and promote social inclusion.
Modernization Theory	Social evolution, development	Examine the effects of economic growth-focused urban regeneration on social issues and property ownership patterns.
New Urbanism Theory	Community, mixed uses	Evaluate the success of new urbanism-inspired plans in creating livable, cohesive communities in the study area.

4 STUDY AREA

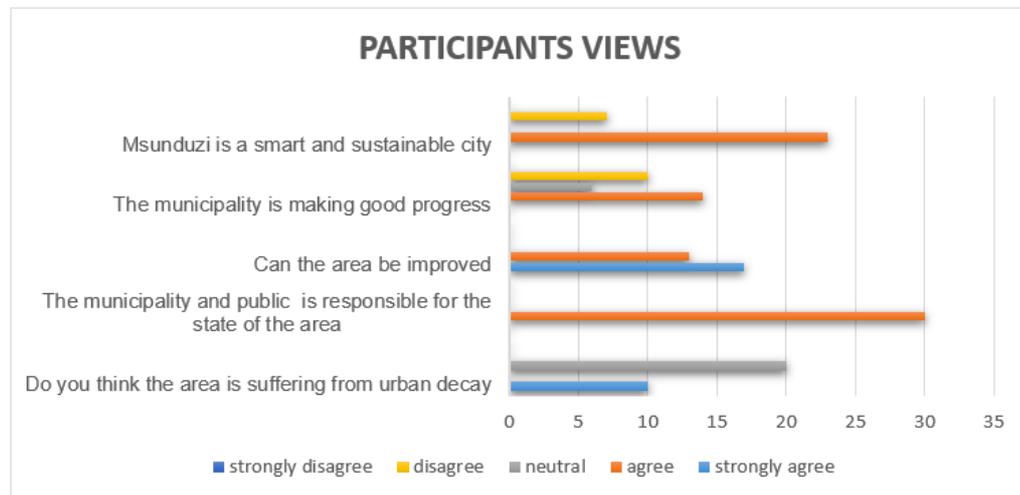
The city of Pietermaritzburg is located within the province of Kwa-Zulu Natal, along the N3 national road. The study area serves as the capital city in the province and sits within u-Msunduzi Municipality. Furthermore, the study area is located within the CBD of Msunduzi municipality known as the CACEN plan. The inner city of Msunduzi is dealing with challenges such as incompatible land uses regarding economic and social development (Msunduzi Spatial Development Framework, 2015). map 1 showing location of the study area within the inner city which is Pietermaritz and Downtown Street identified as experiencing high levels of urban decay.


Map 1 Location of study area within Inner city of Msunduzi

5 RESEARCH METHODOLOGY

The researchers have adopted a research methodology that encompasses both exploratory and descriptive elements. This choice is driven by the scarcity of studies on urban regeneration in the city of PMB, coupled with a specific emphasis on integrating smart city and sustainability concepts. To address these gaps, the study employs a descriptive qualitative case study approach, which involves comparing how other international and local cities have tackled similar challenges. To gather relevant information and perspectives on urban regeneration in Msunduzi Municipality, the researchers employ qualitative primary data collection instruments. These include making observations and conducting open-ended interview questionnaires with 30 municipal officials during October 2022. Through these methods, the researchers have gathered valuable insights and data on the subject matter.

6 DISCUSSIONS ON URBAN REGENERATION IN MSUNDUZI MUNICIPALITY

Based on the data gathered from 30 interview questionnaires conducted in October 2022, the study collected information from various municipal departments within Msunduzi Municipality. The participants were asked about their perceptions regarding urban decay in the area, the factors contributing to this problem, and their recommendations for the municipality to address it. The participants' views were sought on whether they believed that smart city development could help improve the state of urban decay in the area.


Out of the 30 officials who responded to the questionnaires, a significant portion of 10 officials strongly agreed that the area is indeed experiencing urban decay. Their agreement indicates that they perceive several underlying problems in the area, including the violation of municipal bylaws, an alarming rise in poverty and crime rates, the presence of drug addicts residing within the city, and inadequate management of buildings. This consensus among the officials highlights their recognition of the multifaceted nature of urban decay and the various factors contributing to it. All 30 authorities unanimously acknowledged that both the municipality and the public share responsibility for the current state of the area. This collective acknowledgment emphasizes the officials' awareness of the importance of involving the general population in concerted efforts to address and resolve the concerns related to urban deterioration. It signifies their understanding that effective solutions require collaborative actions and engagement from multiple stakeholders.

Regarding the potential for improvement, 13 respondents expressed agreement, while 17 of them strongly agreed that the area has the capacity for positive change. This consensus among policymakers indicates their belief that with appropriate strategies and interventions, the situation can be improved. It highlights their optimism and confidence in the possibility of implementing effective measures to reverse the urban decay trends in the area. However, opinions among the officials were not entirely unanimous. While 14 officials expressed that the municipality is progressing well in addressing urban decay, 10 others disagreed. This discrepancy suggests the existence of divergent perspectives and varying assessments regarding the advancements being made. It also implies that there may be room for improvement in certain areas or aspects of the municipality's efforts to combat urban decay. While 7 respondents disagreed, a significant majority of 23 officials stated that Msunduzi is a wise and sustainable city. This collective viewpoint reflects the

prevailing sentiment among most elected officials who believe that Msunduzi possesses the potential to evolve into a smart and sustainable city. However, the acknowledgment of some dissenting opinions suggests that there may be specific challenges or issues that need to be addressed to translate this potential into a tangible reality.

The responses from the officials indicate their recognition of the existence of urban decay in the area, with an understanding of the underlying problems contributing to it. The unanimous agreement on shared responsibility emphasizes the importance of inclusive approaches to address urban deterioration. The varying perspectives on the municipality's progress and the majority's belief in Msunduzi potential as a wise and sustainable city highlight the need for continuous efforts, collaborative actions, and targeted resolutions to overcome the challenges of urban decay and achieve a thriving and sustainable urban environment.

The officials identified several factors that contribute to the urban deterioration in Msunduzi. These include the disregard for local ordinances, an increase in poverty and crime rates, the presence of drug users in the city, and the mismanagement of structures. Additionally, breaking ordinances can result in environmental damage, health risks, and hazardous situations. The presence of drug users exacerbates the deterioration and leads to further detrimental circumstances, while poverty and crime contribute to a pervasive sense of fear and neglect. The officials also highlighted that poorly maintained buildings, due to a lack of care and upkeep, eventually lead to deterioration and disintegration. To address these problems, the officials proposed potential solutions. One approach is the enforcement of council ordinances to ensure cleanliness, safety, and proper maintenance of the city. By strictly adhering to these regulations, the city can be kept in better condition and prevent further deterioration. Another option is the implementation of ongoing clean-up projects aimed at alleviating environmental deterioration and enhancing the overall image of the city. These projects can contribute to a cleaner and more appealing urban environment.

The officials stressed the importance of working closely with the public to promote awareness about the value of city upkeep and adherence to legislation. By fostering a sense of responsibility and involvement among the citizens, the city can experience positive changes. The officials also recommended regularly monitoring property owners and conducting annual visits to assess whether they are adequately maintaining their properties. This proactive approach ensures accountability and encourages property owners to take proper care of their buildings. According to the officials, urban regeneration in Msunduzi can be enhanced through smart and sustainable city development. However, this requires the municipality to undertake ongoing, creative infrastructure-maintenance initiatives. By embracing innovative approaches, the municipality can effectively address the challenges of urban decay and facilitate positive change.

In order to carry out urban renewal in Msunduzi, the officials provided several suggestions. One recommendation is to educate the general population about urban planning and the importance of maintaining a sustainable city. This entails raising awareness about the value of abiding by the law, taking care of one's property, and actively participating in clean-up initiatives. Additionally, promoting local economic development was highlighted as a strategy to address urban decay. This can be achieved by encouraging investment, boosting tourism, and providing support to small enterprises, ultimately leading to job creation and city expansion. The officials also emphasized the need for collaboration among different agencies to overcome the challenges of urban development in Msunduzi. This underscores the importance of coordination and cooperation between various municipal entities to ensure the effective and efficient utilization of resources. By working together, these agencies can provide comprehensive solutions to the multifaceted problems faced by the city.

7 FINDINGS AND LESSONS LEARNT

The findings from the study conducted in Msunduzi Municipality reveal that:

(1) Urban Decay Existence: The study confirms the presence of urban decay in the area, as indicated by the consensus among officials, with a significant number strongly agreeing with this assessment. This finding highlights the urgent need for interventions to address the deteriorating state of the city.

(2) Multiple Factors Contributing to Urban Decay: The officials identified several factors contributing to urban decay, including violations of municipal bylaws, increasing poverty and crime rates, the presence of drug users, and poorly managed buildings. These findings underscore the complex and interconnected nature of urban decay, emphasizing the importance of addressing multiple challenges simultaneously.

(3) Shared Responsibility: All officials unanimously recognized that both the municipality and the public share responsibility for the current state of urban decay. This finding emphasizes the need for collaboration and engagement between the local government and the community to effectively tackle the problem. It highlights the importance of inclusive approaches that involve multiple stakeholders in finding and implementing solutions.

(4) Belief in Potential for Improvement: The majority of officials expressed their belief in the potential for positive change in the area. This optimism suggests that officials are hopeful and motivated to implement effective strategies and interventions to reverse the urban decay trends. It underscores the importance of maintaining a positive outlook and actively seeking solutions to address urban decay challenges.

(5) Divergent Perspectives on Progress: While some officials expressed confidence in the municipality's progress in addressing urban decay, others disagreed. This finding reveals the existence of differing opinions and assessments regarding the advancements being made. It highlights the importance of ongoing evaluation, transparency, and continuous improvement in the municipality's efforts to combat urban decay.

(6) Potential for Smart and Sustainable City Development: The officials recognized the potential of smart and sustainable city development to improve the urban decay situation. This finding emphasizes the significance of adopting innovative approaches, incorporating technology, and ensuring long-term sustainability in urban planning and development initiatives.

8   ASSESSMENT OF THE STUDY AREA THROUGH THEORETICAL LENS

Theory	Key Concepts	Implications for Study Area
Communicative Theory	Community engagement, participatory planning, collaboration	The officials' unanimous agreement on shared responsibility for urban decay highlights the significance of involving the public in addressing urban deterioration. Collaborative approaches that consider citizens' voices and perspectives can lead to more effective and sustainable solutions.
Just City Theory	Equity, social inclusion, spatial relations	The officials' recognition of factors contributing to urban decay, such as poverty, crime, and mismanagement, resonates with the principles of the Just City Theory. Addressing spatial inequalities and promoting social inclusion through urban regeneration initiatives can foster a more equitable and thriving city environment.
Modernization Theory	Social evolution, economic growth, development, property ownership	The officials' identification of factors like poverty, crime, and mismanagement as contributors to urban decay reflects the complexities described by Modernization Theory. The theory's critique of economic growth-focused policies and their potential effects on social issues is relevant to the study area, where addressing urban decay requires a balance between development and social well-being.
New Urbanism Theory	Community, mixed uses, sustainable development, social cohesion	The officials' recommendations for collaborative actions, public involvement, and integration of local economic development align with New Urbanism Theory. This theory emphasizes creating cohesive, mixed-use communities through sustainable development approaches. Implementing mixed-use areas, promoting local businesses, and fostering community cohesion can contribute to urban regeneration in the study area.

9   ASSESSMENT OF THE STUDY THROUGH THE LENS OF CASE STUDIES

As per the case studies explored regrading smart technology for urban regeneration to combat the issue of urban decay, an implementation plan for Msunduzi Municipality has been established:

Urban Decay	Smart Technology	How It Addresses Urban Decay
Deteriorating Infrastructure	Smart Infrastructure Monitoring	Utilize IoT sensors and data analytics to monitor the condition of roads, bridges, and public facilities. Detect issues early, enabling prompt maintenance and reducing urban decay.
Inadequate Security	Smart Surveillance Systems	Install smart cameras with AI-powered anomaly detection for real-time security monitoring. Enhance public safety, deter crime, and create a safer urban environment.
Lack of Community Engagement	Smart Citizen Engagement Platforms	Develop mobile apps and online platforms for citizens to report issues, provide feedback, and participate in urban planning. Increase community involvement and empowerment.
Economic Decline and Unemployment	Innovation and Entrepreneurship Promotion	Create innovation hubs and incubators to support local entrepreneurs. Foster economic growth, create jobs, and attract investments to revitalize urban economy.
Poor Waste Management	Smart Waste Management Solutions	Implement IoT-enabled bins for efficient waste collection. Monitor fill levels and optimize routes, reducing litter, environmental hazards, and overall urban decay. (This should be communicated between spatial planning and waste management departments).
Neglected Public Spaces	Smart Public Space Management	Deploy sensors and smart lighting to enhance public space usability and safety. Create vibrant, well-maintained spaces that encourage community gatherings and activities.

10 CONCLUSIONS AND RECOMMENDATIONS

Urban decay is a pervasive issue plaguing Pietermaritzburg and other cities, manifesting in the deterioration of buildings and spaces within the city center. The study conducted in Msunduzi Municipality has provided valuable insights into the presence of urban decay in the area, as officials have identified a range of contributing factors. Neglect, high crime rates, and limited economic assistance are among the key drivers of

this decay. The findings emphasize the shared responsibility that both the municipality and the public bear in addressing and mitigating urban decay, emphasizing the necessity of collaborative approaches. Despite variations in opinions regarding the progress made thus far, officials exhibit a sense of optimism and hold firm belief in the potential for improvement. This research holds promise in shaping the future of urban regeneration in Pietermaritzburg and beyond. The insights gleaned provide a solid basis for informed decision-making, policy formulation, and strategic planning. In Pietermaritzburg's journey towards becoming a smart, sustainable city, the lessons learned and recommendations provided in this study serve as a roadmap for policymakers, urban planners, and community stakeholders to collaborate effectively. The officials involved in the study have put forth several recommendations to address the urban decay situation in Msunduzi Municipality. These recommendations aim to tackle the identified factors contributing to the decay and pave the way for a more sustainable and thriving urban environment.

(1) Enforce Council Ordinances: One of the recommendations is to strengthen the enforcement of council ordinances. By ensuring strict compliance with local regulations, the municipality can promote cleanliness, safety, and proper maintenance throughout the city. This step is essential in curbing activities that contribute to urban decay, such as violations of bylaws and disregard for regulations.

(2) Implement Ongoing Clean-up Projects: The officials suggest the implementation of ongoing clean-up projects aimed at addressing environmental deterioration. These projects can help improve the overall image of the city and alleviate the negative impact of decay. By actively engaging in initiatives that promote cleanliness and environmental stewardship, the municipality can create a more appealing and vibrant urban landscape.

(3) Promote Public Awareness and Participation: The officials emphasize the importance of working closely with the public to promote awareness of the value of city upkeep and adherence to legislation. By fostering a sense of responsibility and involvement among residents, the municipality can enhance community ownership and engagement in maintaining the city's well-being. This recommendation highlights the significance of education campaigns, public outreach programs, and community-based initiatives.

(4) Monitor Property Owners and Maintenance: The officials recommend regular monitoring of property owners and conducting annual visits to assess the maintenance of their properties. This proactive approach ensures accountability and encourages property owners to take proper care of their buildings. By holding property owners accountable for maintaining their properties, the municipality can prevent further decay and deterioration.

(5) Embrace Smart and Sustainable City Development: The officials recognize the potential of smart and sustainable city development in addressing urban decay. They suggest that the municipality should embrace innovative approaches and creative infrastructure-maintenance initiatives. By incorporating technology, sustainable practices, and long-term planning, the municipality can foster positive change and improve the overall urban environment.

(6) Collaborate with Multiple Agencies: To overcome the challenges associated with urban development and regeneration, the officials recommend fostering collaboration among different municipal agencies. This emphasizes the need for coordination and cooperation between various entities responsible for urban planning, infrastructure, public safety, and social services. By working together, these agencies can pool their resources, expertise, and efforts to provide comprehensive solutions to the complex issues of urban decay.

1 ABSTRACT

Die Digitalisierung ist einer der globalen Megatrends des laufenden Jahrhunderts. Deutschland hat im europäischen Vergleich einen großen Nachholbedarf hinsichtlich der Digitalisierung des öffentlichen Sektors, der Wirtschaft und der Gesellschaft. Im Jahr 2022 lag der Digitalisierungsgrad in Deutschland laut DESI-Index bei 52,88 und damit knapp über dem EU-Durchschnitt von 52,28. Führende Länder wie Finnland oder Dänemark sind mit Werten von fast 70 weit voraus[1]. Nicht zuletzt aus diesem Grund fördert das Bundes-ministerium für Wohnen, Stadtentwicklung und Bau (BMWSB) sog. "Modellprojekte Smart Cities (MPSC)". Gefördert werden kommunale, interdisziplinäre, räumliche Smart-City-Strategien und deren Umsetzung sowie die notwendigen Kapazitäten in den Kommunen. Die Kommunen werden dabei unterstützt, sich auf die digitale Transformation einzustellen und die damit verbundenen Chancen zu nutzen. Der größte Anteil der geförderten "Smart Cities" sind Groß- und Mittelstädte. "Smart Regions" in Form von interkommunalen Verbünden oder Landkreisen, die in ländlichen Regionen liegen, werden von dem Förderprogramm kaum erfasst. Dabei kann gerade für Kommunen in ländlichen Regionen die Digitalisierung ein wichtiger Ansatzpunkt zur Verbesserung der Lebensqualität sein.[2] Dennoch ist die Digitalisierung im ländlichen Raum mit anderen Herausforderungen verbunden als in Städten: Neben der nach wie vor bestehenden Herausforderung der Verfügbarkeit von leistungsfähigen Internetzugängen im ländlichen Raum, stellen die begrenzten Kapazitäten bzw. die Fragmentierung der öffentlichen Verwaltungen und eine im Vergleich zur städtischen Bevölkerung verbreitete skeptischere Haltung der Bevölkerung gegenüber digitalen Angeboten weitere Herausforderungen im ländlichen Raum dar.

Der vorliegende Beitrag konzentriert sich daher auf die bisherigen Fortschritte des Landkreises Kusel als eines der wenigen ausgewählten Modellprojekte für eine Smart Region im Rahmen des Programms. Mit nur 69.949 Einwohnerinnen und Einwohnern ist er einer der kleinsten und mit 122 Einwohnerinnen und Einwohnern pro km² auch einer der am dünnsten besiedelten Landkreise in Deutschland. Mit seinen 98 Ortsgemeinden ist er sehr ländlich geprägt, in den meisten Ortsgemeinden leben weniger als 500 Einwohner.[3] Mit der Teilnahme am Förderprogramm verfolgt der Landkreis Kusel das Ziel, durch die Digitalisierung eine positive und nachhaltige Entwicklung in der Region zum Wohle der dort lebenden und arbeitenden Menschen zu bewirken. Das Förderprogramm gliedert sich in zwei Phasen: die Strategie- und die Umsetzungsphase, wobei sich Kusel derzeit in der Übergangsphase zwischen beiden Phasen befindet.Die Digitalisierung soll in mehrfacher Hinsicht genutzt werden: (1) zur Digitalisierung der Beteiligung aller relevanten Akteurinnen und Akteuren und der Bevölkerung am Strategie-entwicklungsprozess, (2) zur laufenden Kommunikation und zum Austausch über Vorhaben und Projekte der öffentlichen Hand mit Akteurinnen, Akteuren, Bürgerinnen und Bürgern, (3) zur Verbesserung der Verfügbarkeit, der Erfassung, des Austauschs und der Visualisierung von Daten in der öffentlichen Verwaltung, (4) zur Vereinfachung des Verwaltungshandelns und (5) zur Digitalisierung von Dienstleistungen zur Sicherung der Daseinsvorsorge.

Im Mittelpunkt dieses Beitrags steht die Analyse des Strategieprozesses auf dem Weg zur „Smart City Kusel" im Hinblick auf

- die Herausforderungen der Gestaltung des Digitalisierungsprozesses in einem ländlichen Landkreis in allen Handlungsfeldern,

- die Ansätze zur Gestaltung des Prozesses hin zu einer smarten Region und

- erste Ansätze für smarte Maßnahmen zur nachhaltigen Entwicklung des Landkreises.

Keywords: digitaler Wandel, Digitalisierung im ländlichen Raum, smart region, Daseinsvorsorge, Raumplanung

2 DIGITALISIERUNG UND SMART CITY IN DEUTSCHLAND

Die Digitalisierung ist allgegenwärtig – Smart-City-Konzepte sind längst fester Bestandteil im Kontext von Stadt- und Raumentwicklung. Doch gehen mit dem digitalen Wandel nicht nur Entwicklungspotenziale, sondern auch strukturelle wie gesellschaftliche Herausforderungen einher. Das Konzept der Smart City versucht die mit diesem Trend verbundenen Chancen aufzugreifen. Im Hinblick darauf bewegt sich die Smart City im Spannungsfeld zwischen Chancen zum Lösen von Herausforderungen (z.B. im Bereich der Daseins-vorsorge) und Risiken durch das Aufkommen digitaler Kluften oder im Bereich der Datennutzung und Kontrollierbarkeit.[4] Im nächsten Schritt werden die Dimensionen, Chancen und Risiken des digitalen Wandels sowie die Initiierung und Etablierung von Smart-City-Konzepten in Deutschland aufgezeigt.

2.1 Digitaler Wandel

Der digitale Wandel bezieht sich auf die Veränderungen, die durch den Einsatz digitaler Technologien in verschiedenen Bereichen der Gesellschaft, der Wirtschaft und des täglichen Lebens hervorgerufen werden. Er umfasst die Transformation von analogen oder traditionellen Prozessen, Methoden und Strukturen in digitale Formen. Die Digitalisierung hat dabei einen tiefgreifenden Einfluss auf viele Bereiche, darunter Kom-munikation, Bildung, Gesundheitswesen, Handel, Industrie, Unterhaltung und vieles mehr. Durch den Einsatz digitaler Technologien wie Computer, Internet, Mobilgeräte, künstliche Intelligenz, Big Data, Cloud Computing oder das Internet der Dinge („Internet oft hings" - IoT) werden neue Möglichkeiten geschaffen, um Informationen zu erfassen, zu verarbeiten, zu speichern und zu teilen.[5]

Die Digitalisierung und der digitale Wandel sind daher auch mit erheblichen Auswirkungen auf die Raumentwicklung verbunden. Im Kontext der Raumentwicklung beziehen sich diese Begriffe auf den Einsatz digitaler Technologien, die mögliche Veränderung räumlicher Bewegungsmuster und den damit verbundenen Auswirkungen auf die Art und Weise, wie Städte und Regionen geplant, entwickelt und verwaltet werden.[6] Hinsichtlich der Kompetenzen und Tätigkeitsfeldern von Stadt- und Regionalplanerinnen sowie Stadt- und Regionalplanern sind durch den digitalen Wandel Veränderungen zu erwarten: Das Zentrale-Orte-Konzept bedarf einer digital-angepassten Neuinterpretation, Abläufe und Verfahren formeller Instrumente gilt es weiterzu-entwickeln und nicht zuletzt ist ein zusätzlicher Kompetenzaufbau für den Umgang mit Daten und den Einsatz digitaler Medien erforderlich.[7]

Ein wichtiger Aspekt der Digitalisierung in der Raumentwicklung ist die Erfassung und Analyse großer Datenmengen. Durch den Einsatz von Sensoren, Geoinformationssystemen und anderen digitalen Technologien können umfangreiche Daten über den Zustand eines Raumes, seine Nutzungund viele andere Faktoren gesammelt werden. Durch Analyse dieser Daten können Erkenntnisse und Informationen gewonnen werden, die in die Planungs- und Entscheidungsprozesse einfließen und Entscheidungsträgerinnen und Entscheidungsträger unterstützen können.Dabei müssen die Wirkungen auf die einzelnen Phasen solcher Prozess differenziert betrachtet werden, um ein angemessenes Verhältnis zwischen Chancennutzen und Risikobegrenzung zu erreichen.[8] Denn ein „[...] Mehr an Daten und Informationen führt nicht ohne Weiteres zu ‚besseren' Planungsergebnissen [...]"[9].

Darüber hinaus ermöglichen digitale Technologien neue Formen der Bürgerbeteiligung und des Engagements. Durch Online-Plattformen, soziale Medien und andere digitale Werkzeuge können Bürgerinnen und Bürger aktiv in die Planung und Entwicklung von Projekten einbezogen werden. Dies fördert eine breitere Partizipation und ermöglicht eine stärkere Berücksichtigung verschiedener Interessen und Bedürfnisse. Dabei ist jedoch zu beachten, dass eine rein digitale Beteiligung auch zum Ausschluss einzelner Bevölkerungsgruppen führen kann – unabhängig ihres Ausschlussgrunds (z.B. fehlende Affinität

aufgrund von Alter, sozialer Ausschluss oder Gegenkulturder sog. „Offliner"[10]). Gleichzeitig ist ein Anstieg der Ansprüche an Planungsprozesse in Bezug auf Mitwirkung und Transparenz verbunden.[11]

Insgesamt bieten die Digitalisierung und der digitale Wandel in der Raumentwicklung viele Chancen, um Städte und Räume effizienter, nachhaltiger und lebenswerter zu gestalten. Gleichzeitig sind jedoch auch Herausforderungen zu bewältigen, wie der Schutz der Privatsphäre und die Sicherheit digitaler Infrastrukturen. Die erfolgreiche Integration digitaler Technologien erfordert daher eine ganzheitliche und abgestimmte Herangehensweise, bei der verschiedene Akteurinnen und Akteuren aus dem Bereich der Stadt- und Regionalentwicklung, der Technologie und der Bürgerschaft zusammenarbeiten.

2.2 Smart-City-Konzept und Förderung in Deutschland

Die Idee der Smart City geht mit der Nutzbarmachung digitaler Technologien einher und stellt zugleich eine Reaktion auf die wirtschaftlichen, sozialen und politischen Herausforderungen (u.a. Nachhaltigkeits-bewegung) dar, mit denen postindustrielle Gesellschaften um die Jahrtausendwende konfrontiert sind. Das Konzept hat seine Ursprünge in den 1990er Jahren und wurde von verschiedenen Akteurinnen und Akteuren und Entwicklungen geprägt.Diese verschiedenen Einflüsse haben dazu beigetragen, das Konzept der Smart City zu formen und die Vision einer vernetzten, technologisch fortschrittlichen und nachhaltigen Stadt zu entwickeln. Es ist wichtig anzumerken, dass das Konzept der Smart City weiterhin wächst und sich weiterentwickelt, da neue Technologien und innovative Ansätze eingeführt werden.Als konzeptionelle Leitvorstellungen der Smart City können

- die Verbesserung der Innovationskraft und Wettbewerbsfähigkeit von Städten als Produktions- und Dienstleistungsstandorte,

- die Verbesserung der Energie- und Ressourceneffizienz von Gebäuden, Infrastrukturen, städtischer Mobilität oder Produktionsprozessen,

- die Optimierung der Verträglichkeit von Funktionen sowie der Anpassungs- und Reaktionsfähigkeiten urbaner Systeme (insbesondere Infrastrukturen),

- die Sicherung der sozialen Versorgung der Bevölkerung (Ausbildung, Bildung, Gesundheit, Sicher-heit) und Verbesserung der sozialen Teilhabe sowie

- die Verbesserung von Steuerungs- und Koordinationsprozessen in und zwischen Politik, Verwaltung und Dienstleistungen (Smart Governance und Smart Government)identifiziert werden.[12]

In der deutschen Smart-City-Charta wird folgende Zielstellung formuliert: „Smarte Technologien sollen dazu beitragen, Ressourcen zu schonen, Mobilität umweltverträglicher zu machen, für mehr Inklusion und Mitwirkung zu sorgen oder neue Geschäftsmodelle zu ermöglichen. Digitalisierung ist […] kein Selbstzweck, sondern ein Instrument, um kommunale Ziele zum Wohle der Gemeinschaft zu erreichen."[13] Die Handlungs-felder umfassen dabei je nach Verständnis und Interpretation zahlreiche Themenbereiche. Im deutschen Sprachraum häufig zitiert sind die sechs von der TU Wien identifizierten Dimensionen einer Smart City: smart economy, smart mobility, smart environment, smart people, smart living sowie smart governance.[14]

Es bestehen international und national zahlreiche finanzielle Fördermittel zur Umsetzung von Smart-City-Konzepten – häufig angestoßen, durchgeführt oder unterstützt durch private IT-Unternehmen.[15] Die hohe Anzahl unterschiedlicher Fördermittelprogramme resultiert u.a. daraus, dass Städte in zahlreichen Ländern in ihrer Stadtentwicklung über ein hohes Maß an Selbstbestimmung verfügen. In Deutschland manifestiert die Selbstverwaltungsgarantie (Art. 28 Abs. 2 GG) die kommunaleSelbstverwaltung von Kommunen. Föderale Ebenen (bspw. der Bund) können daher nur Anreize schaffen, um auf eine Stadt- oder Regionalentwicklung im Sinne einer Smart City/Region hinzuwirken bzw. durch Förderungen deren Handlungsfähigkeit stärken.Im Sinne einer nachhaltig-integrierten Entwicklung fördert die Bundesregierung seit dem Jahr 2019

[12]vgl. LIBBE (2018), S. 431
[13]BBSR/BMI (2021), S. 5
[14]vgl. LIBEE (2018), S. 432
[15]vgl. DAMM/SPELLERBERG (2021), S. 63

insgesamt 73 Modellprojekte mit 820 Millionen Euro in drei Staffeln. Die jüngste Förderrunde mit einem Fördervolumen von 300 Millionen Euro für 28 Modellprojekte bei94 Bewerbungen startete im Jahr 2021.Hinsichtlich der Größe und administrativen Zuordnung werden bislang 27 Großstädte, zwölf mittlere Städte, zehn Kleinstädte und Landgemeinden sowie 24 interkommunale Kooperationen und Landkreise als Modellprojekte gefördert – ein Großteil dieser ist im städtischen oder im erweiterten städtischen Raum zu verorten.[16]

Die Förderung eines Modellprojekts umfasst dabei kommunale, fachübergreifende und raumbezogene Smart-City-Strategien, deren Umsetzung und den dafür notwendigen Kompetenzaufbau in den Modellkommunen. Ziel des Förderprogramms ist es, „die im Rahmen der Modellprojekte entwickelten Lösungen sicher, interoperabel und übertragbar zu gestalten und dabei die finanziellen und personellen IT Ressourcen in den Kommunen möglichst effizient zu nutzen"[17]. Die eingerichtete „Koordinierungs- und Transferstelle/Modell-projekte Smart Cities" ist mit der fachlichen Begleitung und dem Wissenstransfer zur Digitalisierung und Stadtentwicklung beauftragt. Mit der entwickelten Nationalen Dialogplattform Smart Cities wurde zudem ein Vernetzungs- und Austauschformat für die Modellprojekte sowie Expertinnen und Experten aus Gemeinden, Städten und Kreisen, Politik, Wissenschaft, Wirtschaft sowie der Zivilgesellschaft geschaffen.[18]

2.3 Herausforderungen der Digitalisierung im ländlichen Raum

Der digitale Wandel und die Digitalisierung bringen speziell im ländlichen Raum (häufig in Verbindung mit Strukturschwäche, geringerer Siedlungsdichte, Bevölkerungsrückgang) eine Reihe von Herausforderungen mit sich, die sich von denen urbaner Räume unterscheiden.[19] Als für diesen Beitrag relevant aufzuführen sind an dieser Stelle…

- die unzureichende Infrastruktur für Breitband-Internetzugang: Viele ländliche Gebiete verfügen immer noch nicht über eine schnelle und zuverlässige Internetverbindung, was die Umsetzung digitaler Technologien und Dienstleistungen erschwert.

- der Mangel an Fachkräften im Bereich der Informationstechnologie: Es fehlt oft an qualifizierten Arbeitskräften, die über die erforderlichen Fähigkeiten verfügen, um digitale Technologien zu implementieren und zu nutzen.

- die digitale Kluft zwischen Stadt und Land: Viele Menschen im ländlichen Raum haben keinen Zugang zu digitalen Geräten oder fehlende digitale Kompetenzen, um von den Vorteilen der Digitalisierung zu profitieren. Dies kann zu einer sozialen Ausgrenzung führen und den Zugang zu Bildung, Gesundheitsversorgung und anderen wichtigen Dienstleistungen einschränken.

- wirtschaftliche Herausforderungen: Traditionelle Branchen wie Landwirtschaft und Handwerk können durch Automatisierung und digitale Technologien beeinflusst werden, was zu Strukturveränderungen und dem Verlust von Arbeitsplätzen führen kann. Es ist wichtig, Strategien zu entwickeln, um die ländliche Wirtschaft zu diversifizieren und neue digitale Geschäftsmöglichkeiten zu schaffen.

- Fragen der Datensicherheit und des Datenschutzes: Es ist wichtig, angemessene Sicherheits-vorkehrungen zu treffen, um persönliche Daten zu schützen und Cyberkriminalität zu verhindern. Im ländlichen Raum kann dies aufgrund begrenzter Ressourcen und mangelnder technischer Expertise eine besondere Herausforderung darstellen.

Diese Herausforderungen zeigen, dass der digitale Wandel im ländlichen Raum sorgfältig geplant und um-gesetzt werden muss, um sicherzustellen, dass niemand zurückgelassen wird und dass die Vorteile der Digi-talisierung gerecht verteilt werden. Trotz dieser und weiterer Herausforderungen besteht eine unabdingbare Notwendigkeit der Digitalisierung auch im ländlichen Raum. Zunächst soll dadurch das Auseinandertriften zwischen ländlichen und urbanen Räumen abgemildert werden. Diese Aufgabe wird nicht zuletzt durch das Postulat gleichwertiger Lebensverhältnisse in allen Teilräumen in Deutschland deutlich, das im Grundgesetz

---

[16] BMWSB (o.J.)
[17] BMWSB (2023)
[18] vgl. BMWSB (2023)
[19] vgl. DAMM/SPELLERBERG (2021), S. 74

in Art. 72 Abs. 2 verankert ist. Die Digitalisierung wird in diesem Zusammenhang (der Diskussion um Werte- und Normenkontexte) als ein vielversprechender Ansatz zur Herstellung gleichwertiger Lebensverhältnisse angesehen.[20]Eine digitale Anbindung ist dabei nicht nur als Grundvoraussetzung Teil der Daseinsvorsorge, sondern bietet auch großes Potenzial zur Gewährleistung bzw. Sicherstellung der Erreichbarkeit andere Bereiche der Daseinsvorsorge. So kann beispielsweise das Zurücklegen großer physischer Entfernungen, die im ländlichen Raum häufig nur mit Hilfe des Individualverkehrs überwunden werden können, durch digitale Alternativen abdingbar werden.[21] Die Herausforderung, Angebote der Daseinsvorsorge für alle Menschen physisch erreichbar zu machen oder diese Angebote zu allen Menschen "nach Hause" bringen zu müssen, wird durch digitale Lösungsansätze abgemildert. So kann durch die Digitalisierung und der Nutzung damit verbundener Chancen gerade im ländlichen Raum ein wichtiger Beitrag zur Gewährleistung der Daseinsvorsorge und Steigerung der Lebensqualität geleistet werden.[22] Oder anders ausgedrückt: Durch die gezielte Steuerung und Nutzung der Digitalisierung auch im ländlichen Raum ist es möglich und erforderlich, „keine Unterschiede in der Smartness zwischen städtischen und ländlichen Regionen zuzulassen"[23].

3 DER LANDKREIS KUSEL AUF DEM WEG ZUR SMART CITY

Zur Verdeutlichung der mit Smart City verbundenen Herausforderungen und Chancen im ländlichen Raum, wird in diesem Beitrag exemplarisch die aktuelle Entwicklung des – als eines der wenigen Modellprojekte für eine Smart Region ausgewählten – Landkreises Kusel dargestellt.

3.1 Rahmenbedingungen, raumstrukturelle Ausgangssituation und Herausforderungen[24]

Der Landkreis Kusel liegt im westlichen Teil des Bundeslandes Rheinland-Pfalz und gehört zur Region Westpfalz. Mit nur 69.949 Einwohnerinnen und Einwohnern ist er einer der kleinsten und mit 122 Einwohnerinnen und Einwohnern pro km² auch einer der am dünnsten besiedelten Landkreise in Deutschland. Im Regionalen Raumordnungsplan Westpfalz IV ist er als ländlicher Raum mit disperser Siedlungsstruktur eingestuft.[25]Mit seinen 98 Ortsgemeinden in drei Verbandsgemeinden ist er sehr ländlich geprägt – in den meisten Ortsgemeinden leben weniger als 500 Einwohnerinnenund Einwohnern. Die Landschaft des Kreises ist geprägt durch das Nordpfälzer Bergland. Hier finden sich ausgedehnte Waldgebiete sowie zahlreiche Wiesen, Felder und landwirtschaftlich genutzte Flächen.Im Zentrum des Landkreises, angebunden an die Bundesautobahn A62 und eine regionale Bahnstrecke, liegt die Kreisstadt Kusel, die zugleich die größte Stadt des Kreises ist. Gemeinsam mit der Stadt Lauterecken bildet sie einen mittelzentralen Verbund kooperierender Zentren. Als Grundzentren ausgewiesen sind die Gemeinden Wolfstein (VG Lauterecken-Wolfstein) sowie Glan-Münchweiler, Schönenberg-Kübelberg und Waldmohr (VG Oberes Glantal).[26]Zahlreiche Herausforderungen ergeben sich bereits durch die räumliche Ausprägung der Siedlungsstruktur: Durch die disperse, kleinteilige Verteilung der Einwohnerinnen und Einwohner auf viele kleinere, dünn besiedelte Ortsgemeinden bestehen zum einen geringe „Nutzerzahlen" für beispielsweise Versorgungsangebote, wodurch die Tragfähigkeit gefährdet wird und zum anderen große Entfernungen zwischen den verschiedenen Standorten der Daseinsgrundfunktionen.

In den vergangenen zehn Jahren entwickelte sich die Bevölkerung des Landkreises insgesamt rückläufig (-3,4%)– teilweise um mehr als 5% in einzelnen Ortsgemeinden. Im selben Zeitraum weisen lediglich 6 von 98 Gemeinden Bevölkerungswachstum auf. Die rückläufige Bevölkerungsentwicklung ist in ca. zwei Drittel der Ortsgemeinden auf Wanderungsverluste, insbesondere durch Abwanderung junger und qualifizierter Bevölkerungsgruppen (Bildungswanderung) sowie Abwanderung älterer Bevölkerungsgruppen (Alters-wanderung), zurückzuführen. Damit einhergehend ist eine Zunahme der über 65-Jährigen und ein Rückgang

---

[20] vgl. WEITH (2020), S. 420
[21]vgl. DAMM/SPELLERBERG (2021), S. 63
[22] vgl. THAPA et. al. (2020), S. 5
[23]WEITH (2020), S. 421
[24]vgl. KREISVERWALTUNG KUSEL (2023), S. 52-87
[25]PGW (2012), S. 5
[26]PGW (2012), S. 14 ff.

der unter 20-Jährigen zu beobachten, was insgesamt das Bild einer alternden Bevölkerung mit diesbezüglichen Herausforderungen verdeutlicht.[27]

Die regionale Wirtschaft im Landkreis Kusel ist geprägt von kleinen und mittelständischen Unternehmen, insbesondere im Handwerk, in der Landwirtschaft und im Tourismus. Zwar ist die wirtschaftliche Leistungsfähigkeit gemessen am Bruttoinlandsprodukt in den letzten zehn Jahren angestiegen (ca. 24 %), jedoch wird die Diskrepanz zum rheinland-pfälzischen Durchschnittswert stets größer[28], was ein geringeres wirtschaftliches Wachstum kennzeichnet. Über alle Branchen erkennbar sind zum aktuellen Zeitpunkt erste Anzeichen des drohenden Fachkräftemangels, beispielsweise durch eine Vielzahl nicht besetzter Ausbildungsstellen im Handwerk. Zudem liegt der Anteil der Beschäftigten mit akademischem Abschluss deutlich unter dem Landesschnitt. Herausforderungen im Hinblick auf eine potenzielle Chance durch Digitalisierungsprojekte sind u.a.:

- das Aufzeigen von Berufswegen etc. für Schülerinnen und Schüler zur Nachwuchsförderung,
- die Etablierung multifunktionaler Arbeits- und Begegnungsorte (im Sinne von Co-Working-Spaces) zur Schaffung neuer Arbeitsorte und -möglichkeiten,
- die Einführung von Förderungsmöglichkeiten zur Qualifizierung von Unternehmen als attraktive Arbeitgeberzur Bindung bestehender und Gewinnung neuer Fachkräfte im Landkreis sowie
- die Attraktivierung des öffentlichen Verkehrs (u.a. durch Bündelung und Verknüpfung).

Die Verteilung der Bildungseinrichtungen im Landkreis Kusel verdeutlicht die von Norden nach Süden abnehmende Einwohnerdichte. Während in einigen Ortsgemeinden keine Kindertagesstätten zur Verfügung stehen und Grundschulen bereits deutliche Konzentrationseffekte zeigen, weist die Verteilung im zentralen Bereich des Landkreises eine dispersere Verteilung dieser Einrichtungen auf. Hinsichtlich der digitalen Ausstattung verfügen nicht alle Bildungseinrichtungen innerhalb des Landkreises über eine ausreichende Versorgung mit WLAN. Zentrale Herausforderungen sind in diesem Feld:

- die Etablierung außerschulischer Lernorte für alle Altersstufen bis hin zur Erwachsenenbildung,
- die Vernetzung von Schülerinnen und Schülern bzw. Schulabgängerinnen und Schulabgängern mit Unternehmen zur frühzeitigen Bindung junger Fachkräfte an den Landkreis sowie
- der Aufbau einer digitalen Ausbildungsmesse sowie eines digitalen Ausbildungs- und Stellenportals.

Eine wohnortnahe Versorgung mit Dingen des täglichen Bedarfs (Nahversorgung) ist vor allem für alternde und mobil eingeschränkte Bevölkerungsteile ein wichtiger Standortfaktor und entsprechend wichtig für lebenswerte Kommunen. Kurze Wege zur Versorgung mit Gütern des täglichen Bedarfs sind dabei ressourceneffizient, bilden jedoch gerade im ländlichen Raum – so auch im Landkreis Kusel – nicht das tatsächliche Bild ab, welches geprägt von weiten Wegen ohne ÖPNV-Nutzungsmöglichkeit und einer Konzentration weniger Versorgungseinrichtungen ist. Herausforderungen im Smart-City-Kontext sind u.a.:

- der Aufbau von personalfreien Angeboten (Automatenläden, Selbstbedienungsläden, click&collect) zur Erweiterung des Angebots (bei geringem personellem und finanziellem Einsatz),
- die Ermöglichung lokaler Online-Bestellungen (in Kooperation mit lokalen Einzelhandelsbetrieben)
- sowie die Einrichtung einer digital unterstützen Nachbarschaftshilfe (Mitbring-App).

Die Versorgung mit Gesundheits- und Pflegeangeboten rückt durch die Sicherstellung der Erreichbarkeiten von Standorten dieser in das Aufgabengebiet politischer wie auch planerischer Entscheidungsträgerinnenund Entscheidungsträger .Im Landkreis Kusel gibt es ein Klinikum in der Kreisstadt, Hausarztpraxen sowie Praxen von Fachärztinnen und Fachärzten sind über das Kreisgebiet verteilt, sodass sich eine durchschnittliche Versorgungslage von 723 Einwohnerinnen und Einwohnern pro Ärztin oder Arzt ergibt – ein Verhältniswert der weit über dem rheinland-pfälzischen Durchschnittswert von 569 liegt und sich durch einen errechneten altersbedingten Nachbesetzungsbedarf von 50 Prozent bis zum Jahr 2027 noch weiter verschärft.[29]Herausforderungen mit Potenzial zur Verbesserung durch digitale Angebote sind:

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

- die digitale Vernetzung aller Akteurinnen und Akteure der Gesundheitsvor- und -versorgung,

- Etablierung der Digitalisierung in der privaten und ambulanten Pflege und die entsprechende Ausstattung von betreuten Wohnangeboten (z.B. Wearables und Überwachung von Vitaldaten, ambient assistedliving Angebote) sowie

- die Einführung telemedizinischer Angebote und Möglichkeiten (Telemonitoring, Online-Videosprechstunden, Telediagnostik) in Kooperation mit medizinischen Angebotsträgern.

Ein zentrale Rolle im Hinblick auf die skizzierten Angebote der Daseinsvorsorge bzw. im Speziellen die Angebote der Versorgung nimmt die Erreichbarkeit dieser (ausgehend vom Wohn- und/oder Arbeitsort) ein. Dem öffentlichen Verkehr kommt dabei im Hinblick auf die Attraktivität des Wohnstandorts für alle Bevölkerungsgruppen sowie dem Umwelt- und Klimaschutz eine stets bedeutsamere Rolle zu. Innerhalb des Landkreises bestehen wenige Bahnanbindungen – der öffentliche Verkehr wird über Busverbindungen abgewickelt. Dieses stellt zwar in jeder Ortsgemeinde mindestens einen Haltepunkt bereit, allerdings ist die Attraktivität aufgrund geringer Anzahl der Abfahrten, schlechter Taktung und mangelnder Linien bzw. Zielauswahl teilräumlich stark begrenzt. In großen Teilen des Landkreises ist die Bevölkerung auf den Individualverkehr in Form des Pkw angewiesen.[30] Durch den Einsatz digitaler Tools bestehen insbesondere Entwicklungspotenziale durch die Verknüpfung verschiedener Mobilitätsformen (Intermodalität).

Die umfassende Digitalisierung erfordert hochleistungsfähige Netze, die Geschwindigkeiten im Gigabit-pro-Sekunde-Bereich (im Down-/Upload), zuverlässige echtzeitfähige Übertragungen und sichere Internetdienste in hoher Qualität ermöglichen.[31] Die Verfügbarkeit von leistungsfähigen Breitbandanschlüssen mit einer Geschwindigkeit von mindestens 100 Mbit/s ist im Landkreis Kusel nur in wenigen Gemeinden gegeben.[32] Neben der infrastrukturellen Verfügbarkeit spielen die Offenheit und Akzeptanz digitaler Möglichkeiten in Alltag und Berufsleben eine wegweisende Rolle im digitalen Wandel. Eine in der Kreisverwaltung Kusel durchgeführte Befragung zur digitalen Affinität, zum E-Government und zur Verwaltungsdigitalisierung zeigt bisher einen hohen Nachholbedarf diesbezüglich, mit Blick auf die Zukunft jedoch eine insgesamt hohe Bereitschaft (ca. zwei Drittel) zur Nutzung digitaler Infrastrukturen verbunden mit bei der überwiegenden Mehrzahl der Beschäftigten bereits vorhandenen hohen digitalen Kenntnissen.[33]

3.2 Prozess zur Smart Region

Mit der Teilnahme am Förderprogramm Smart City verfolgt der Landkreis Kusel das Ziel, durch die Digitalisierung eine positive und nachhaltige Entwicklung in der Region zum Wohle der dort lebenden und arbeitenden Menschen zu bewirken. Das Förderprogramm gliedert sich in zwei Phasen: die Strategie- und Umsetzungsphase, wobei sich der Landkreis Kusel derzeit in einer Übergangsphase zwischen beiden Phasen befindet. Die Gewinnung von Fachkräften startete sofort nach Bewilligung der Fördermittel und formte schließlich die Stabstelle der Kreisverwaltung mit folgenden Rollen: Chief Digital Officer (CDO), Sachbearbeitung, Partizipation und Teilhabe, Öffentlichkeitsarbeit sowie Datenanalyse und Digitallotsen.[34]Besonders zu Beginn bedarf der Konzeption und Koordination des Prozesses ein großer Stellenwert, wozu eine Kerngruppe aus internen und begleitenden externen Akteurinnen und Akteuren eingerichtet wurde. In Ergänzung des Teams der Stabstelle Smart City waren darin Mitarbeiterinnen und Mitarbeiter der Kreisverwaltung aus zentralen Abteilungen eingebunden. Externe wissenschaftliche Unterstützung lieferten u.a. Expertinnen und Experten des Deutschen Instituts für Künstliche Intelligenz (DFKI), des Lehrstuhls Regionalentwicklung und Raumordnung der Rheinland-Pfälzischen Technischen Universität Kaiserslautern-Landau (RPTU) sowie der Hochschule Worms.

Die Smart-City-Strategie im Landkreis Kusel wurde in einem offenen und partizipativen Verfahren vor Ort entwickelt. Die Beteiligung der Bevölkerung zur Erstellung einer Entwicklungsstrategie in einem Landkreis mit insgesamt 98 Ortsgemeinden ist eine Herausforderung, die im Falle der Smart-City-Strategie zusätzlich durch Einschränkungen, die aufgrund der Covid-19-Pandemie zu berücksichtigen waren, überlagert wurde. Der Prozess startete mit einer Auftaktveranstaltung in rein digitaler Form.Während der Phase der Erstellung

---

[30]vgl. STABSTELLE „LAND L(I)EBEN" LANDKREIS KUSEL (2022)
[31] BMWK (2023)
[32]BNetzA(2022)
[33]STABSTELLE „LAND L(I)EBEN" LANDKREIS KUSEL (2022)
[34]vgl. STABSTELLE „LAND L(I)EBEN" LANDKREIS KUSEL (2022)

der Bestandsaufnahme im Rahmen der Strategie wurden verschiedene Zielgruppen durch online-gestützte Befragungen beteiligt: Bürgerinnen und Bürger, Beschäftigte der Kreisverwaltung, Vereine, Bildungseinrichtungen, Museen sowie Orts- und Stadtbürgermeisterinnen sowie Orts- und Stadtbürgermeister. Ziel der Befragungen war es einerseits niederschwellig Informationen, die nicht statistisch aufbereitet vorliegen, zu generieren und andererseits Einschätzungen durch zentrale Akteurinnen und Akteure zu erhalten. Begleitender Effekt war hier auch die weitere Bekanntmachung des Projekts sowie die Erregung von Aufmerksamkeit für das Projekt bei Multiplikatorinnen und Multiplikatoren. Insgesamt konnten die Ergebnisse der Befragungen in Kombination zu statistischen Analysen einen wichtigen Beitrag in der Informationssammlung leisten. Zudem konnten die Ergebnisse im Rahmen der sieben hybrid durchgeführten Workshops mit Bürgerinnen, Bürgern und anderen Akteurinnen und Akteuren rückgekoppelt bzw. vertieft diskutiert werden.Im Anschluss an die Strategie-Workshops haben sich Arbeitsgruppen gebildet, um die Handlungsoptionen und Ideen, die im Rahmen der Workshops diskutiert wurden, weiter auszuarbeiten.[35]

Als eines der ersten Projekte, die bereits während der Strategiephase umgesetzt werden, wurde die Etablierung einer digitalen Partizipationsplattform für Bürgerinnen und Bürger festgelegt. Diese ist seit Juli 2022 unter dem Leitsatz „MITMACHEN – Landkreis Kusel im Bürgerdialog" freigeschaltet und wird seitdem zunehmend genutzt und bespielt. Die Partizipationsplattform bietet derzeit die Möglichkeiten (1) sich über das Gesamtvorhaben oder einzelne Themenfelder zu informieren, (2) Projekt-/Maßnahmenideen in den Themenfeldern der Strategie-Workshops zu formulieren sowie (3) bereits formulierte Projekt- bzw. Maßnahmenideen zu diskutieren.[36]

Unter Berücksichtigung aller eingebrachten Belange der beteiligten Akteurinnen und Akteure entwickelte die Stabstelle des Landkreises schließlich die Smart-City-Strategie. Diese befindet sich zum aktuellen Zeitpunkt in der Endphase des Aufstellungsprozesses und wurde im Juni 2023 durch den Kreistag beschlossen und beim Fördermittelgeber eingereicht.

3.3 Herausforderungen der Gestaltung des Digitalisierungsprozesses

Die Rahmenbedingungen zur Erstellung einer tragfähigen und innovativen Smart-City-Strategie in einem Landkreis mit 98 Ortsgemeinden (und 98 ehrenamtlichen Ortsbürgermeisterinnen und Ortsbürgermeister), die in drei Verbandsgemeinden organisiert sind und dementsprechend neben dem Kreistag und der Kreisverwaltung zwei weitere politisch-administrative Ebenen "vereinen muss", sind andere als in einer kreisfreien (Groß-) Stadt. Generell bedarf es eines größeren Abstimmungsbedarfs, was zum einen den Organisationsaufwand, zum anderen jedoch auch die notwendige inhaltliche Diskussion einer großen Zahl an Einzelinteressen („Kirchturmdenken") erhöht – häufig fehlt es bei kleinteiligen administrativen Strukturen an gemeinsamen Visionen und der Bereitschaft den interkommunalen bzw. regionalen Erfolg über den eigenen zu stellen; kommunale Einzelinteressen und interkommunale Konkurrenz prägen das Bild.[37]

Parallel dazu unterscheiden sich auch die raumstrukturellen Ausgangslagen einzelner Teilräume innerhalb eines Landkreisgebiets mit einer höheren Varianz. Gerade in ländlich geprägten Landkreisen kann dabei die Divergenz zwischen einem städtischen Zentrum und peripheren Teilen mit geringer Bevölkerungszahl und -dichte von großer Bedeutung für die zukünftige räumliche Entwicklung sein. Im Landkreis Kusel müssen entsprechend raumstrukturelle Unterschiede von 5.594 Einwohnerinnen und Einwohnern in der Kreisstadt Kusel bis hin zu 54 Ortsgemeinden mit unter 500 Einwohnerinnen und Einwohnern vereint werden. Die Aufstellung einer Strategie und vor allem die Definition von konkreten Projekten und Maßnahmen, die die Breite der Handlungsbedarfe in (möglichst) allen Teilräumen aufgreifen, auf Akzeptanz in der Bevölkerung und Zustimmung in den politischen Gremien treffen, sind daher eine große Herausforderung.

Zudem sind die kleinteiligen Verwaltungsstrukturen der Kommunen in ihrem personellen und finanziellen Handlungsspielraum noch eingeschränkter als der Verwaltungsapparat einer Großstadt. Die durch die Förder-ung zur Verfügung stehenden Mittel zum Personal- und Kompetenzaufbau müssen entsprechend aufwändig in die Kreisverwaltung integriert werden. Die eingerichtete Stabstelle der Kreisverwaltung ist zwar mit Abschluss der Strategiephase in voller Stärke besetzt, allerdings gestaltete sich die Gewinnung von

---

[35]vgl. KREISVERWALTUNG KUSEL (2023), S. 26-51
[36]vgl. STABSTELLE „LAND L(I)EBEN" LANDKREIS KUSEL (2022)
[37]vgl. STIEWING/WEBER/FASTNER/BERCHTOLD (2022), S. 379

Fachkräften in einem relativ neuen Handlungsfeld im ländlichen Raum – bei ohnehin anhaltendem Fachkräfte-mangel in nahezu allen Branchen – als große Herausforderung, die zu Beginn durchaus unterschätzt wurde. Bzgl. der Hemmnisse der Verwaltung kommt erschwerend die bisher über weite Teile fehlende Digitalisierung dieser hinzu. Zeitintensive analoge Prozesse und Abläufe innerhalb der Verwaltung oder im Austausch mit Bürgerinnen und Bürgern bedürfen einer aufwändigen Digitalisierung zur Vereinfachung, Entlastung und Entbürokratisierung.[38]

Als generelle Hürde bzw. Herausforderung stellte sich zudem der Begriff „Smart City“ heraus. Viele Bürgerinnen und Bürger des ländlich geprägten Landkreises, die im Durchschnitt weniger digital affin (u.a. aufgrund der Altersstruktur) als in städtisch geprägten Räumen sind, können sich mit der Begrifflichkeit nicht identifizieren. Smart City ist ein Label, das „[…] von einem primär technischen und weniger von einem sozialen Innovationsverständnis ausgeht“[39] und in erster Linie mit negativen Auswirkungen (z.B. Überwachung, mangelnder Datenschutz) in Verbindung gebracht wird. Internationale, utopische Smart Cities, wie New Songdo City in Südkorea, prägen das Bild der Smart-City-Idee, lassen sich jedochvonNicht-Expertinnen und Nicht-Experten nur schwierig auf den Landkreis Kusel übertragen. Nicht zuletzt dadurch sind auch Partizipationsverfahren im ländlichen Raum eine größere Herausforderung. Die Strategiephase des Landkreises Kusel verdeutlichte, dass einerseits aufgrund der geringeren digitalen Affinität der Bevölkerung ein erhöhter Bedarf an analoger Beteiligung erforderlich ist – allerdings andererseits auch, dass aufgrund der großen räumlichen Distanzen innerhalb des Landkreises, analoge Beteiligungsformate mit einem großen Verkehrsaufwand einhergehend mit einem zeitlichen und finanziellen Mehraufwand der Bevölkerung verbunden sind. Das Risiko, dass aus diesen Gründen selbst bei hybriden Beteiligungsformaten bestimmte Personengruppen (z.B. Ältere) ausgeschlossen sind, ist entsprechend hoch.

Der Landkreis Kusel hat aufgrund dieser Herausforderungen und Hindernisse eine Verlängerungvon sechs Monaten für die Strategiephase beantragt und von Seiten des Fördermittelgebers bewilligt bekommen.

3.4 Smart-City-Strategie und Ansätze für smarte Maßnahmen zur nachhaltigen Entwicklung des Landkreises

Im zuvor skizzierten kooperativen Prozess wurde schließlich die Smart-City-Strategie als Rahmen für die Umsetzungsphase und die zukünftige Entwicklung des Landkreises erarbeitet. Als gemeinsames Verständnis fungiert die bereits in Rahmen der Antragsphase entwickelte Vision "Land l(i)eben – digital. gemeinsam. vor Ort.". In der Strategie wurden sechs integrierte Zielbilder formuliert, die die Stoßrichtungen der zukünftigen Entwicklung vorgeben:

(1) Beteiligung und Teilhabe aller Menschen an den Vorhaben von Land l(i)eben ermöglichen

(2) Testen, inwiefern digitale Möglichkeiten das Leben im Landkreis Kusel erleichtern, zukunftsfähig und attraktiv gestalten

(3) Sicherung der Daseinsvorsorge mit Hilfe neuer Technologien

(4) Förderung bedarfsgerechter Mobilitätsangebote im Landkreis

(5) Förderung des Miteinanders, das Austesten von Innovationen und das Entdecken der Region

(6) Kompetenzgewinn, Generierung und souveräner Umgang mit Daten

Bereits während der Strategiephase gingen die drei Starterprojekte „E-Partizipationsplattform“, „Kulturelle Teilhabe in Wohneinrichtungen“ sowie „Digitalwerkstatt für Kinder und Jugend“ in die Umsetzung. Insbesondere die entwickelte Partizipationsplattform ist dabei als wegweisende Querschnittsmaßnahme des gesamten Smart-City-Prozesses zu bewerten. Inhaltlich wurden die gesammelten Projektideen in fünf sogenannte integrierte Maßnahmen geclustert: „Gemeinschaft l(i)eben“, „Liebenswertes Kuselerland“, „Medi-KUS“, „Mobilität im FoKUS“ sowie „Schlauer Landkreis“, die alle zahlreiche Chancen für eine digitale, nachhaltige und gesunde Kommunal- und Regionalentwicklung bieten. Auf die vollständige Darstellung der Maßnahmen wird aufgrund des für dieses Paper gewählten Fokus' an dieser Stelle verzichtet.

Abb. 1: Überblick über Maßnahmen und Projekte der Smart-City-Strategie des Landkreises Kusel. Quelle: KREISVERWALTUNG KUSEL (2023), S. 234-235

Exemplarisch für die Chancen einer nachhaltig-digitalen Kreisentwicklung werden die Projektvorschläge der integrierten Maßnahme „Schlauer Landkreis" aufgegriffen, die unter Beachtung des Querschnittsgedankens u.a. auf die Digitalisierung von Informationen und Prozessen sowie den notwendigen Kompetenzaufbau reagiert. Als erste Teilmaßnahme ist der Aufbau einer zentralen Datenplattform zur Bündelung und Katalogisierung aller relevanten Daten (Open Data, Verwaltungsdaten, Daten aus IoT-Infrastrukturen, Geodaten, Strukturdaten usw.) an einer zentralen Stelle („Hub"), die sowohl verwaltungsintern als auch externen Akteurinnen und Akteuren zur Verfügung steht. Die Entwicklung der Datenplattform erfolgt in interkommunaler Kooperation mit anderen Smart-City-Modellprojekten aus dem Südwesten Deutschlands. Neben direkten Mehrwerten, z.B. der einfacheren Handhabung von Daten oder der Möglichkeit zur Verknüpfung von Datensätzen, dient die Datenplattform zusätzlich als Grundlage für alle weiteren Schritte des landkreisweiten Dateninfrastrukturaufbaus. Durch diese Teilmaßnahme besteht für die Landkreisentwicklung der Zukunft eine stark positiv veränderte Ausgangssituation: Der Einbezug zahlreicher Daten stellt sich vor allem in der Verknüpfung und Interpretation dieser als bedeutsame Grundlage zielgerichteter Kommunal- und Regional-entwicklung dar. Ein weiteres Teilprojekt, um vor allem der Bevölkerung die Handhabung des digitalen Wandels zu erleichtern, ist die Entwicklung einer Landkreis-App. Hierin wird ein Teil der gesammelten Daten visuell aufbereitet und den Nutzerinnen und Nutzern in unterschiedlichen App-Modulen zugänglich gemacht, um insbesondere im Landkreis vorhandene Angebote abzubilden.Ziel der Maßnahme ist es, mit der App einen zentralen digitalen Anlaufpunkt im Sinne einer „all in one"-Lösung zu schaffen. Darin inbegriffen sind u.a. Module in den Bereichen Mobilität, Kultur und Tourismus, verwaltungsbezogener Bürgerservice, Gesundheit und Pflege sowie Ausbildung und Arbeitsmarkt. Das dritte Teilprojekt umfasst die Entwicklung eines flächendeckenden Frühwarnsystems für Hochwasser und Vegetationsbrände im Bereich Katastrophenschutz. Hierzu gilt es ausreichend Sensoren in der Fläche einzusetzen, die kontinuierlich im Hinblick auf bestimmte Schwellenwerte analysiert werden und im Notfall frühzeitige Warnungen an den Katastrophenschutz absenden. Angedacht ist die Verknüpfung der Sensorik mit der Landkreis-App zur direkten Information der Bevölkerung.[40]

4 FAZIT UND AUSBLICK

Der Prozess der Digitalisierung ist allgegenwärtig, bestimmt maßgeblich die zukünftige räumliche Entwicklung und muss in allen Teilräumen – unabhängig der jeweiligen Ausgangssituation – mitgedacht

---

[40]vgl. KREISVERWALTUNG KUSEL (2023), S. 119-141

werden. Er eröffnet dabei neue, vielfältige Möglichkeiten zur Gewährleistung der Erreichbarkeit von Angeboten der Daseinsvorsorge und trägt einen wichtigen Teil zur Schaffung gleichwertiger Lebensverhältnisse bei. Für die jeweilige räumliche Ebene werden eine Verbesserung der Standortfaktoren, ein Imagegewinn und eine vereinfachte und verbesserte Versorgung mit öffentlichen Dienstleistungen erwartet.[41] Insbesondere im ländlichen Raum bieten innovative, digitale Angebote in verschiedenen Bereichen große Chancen, beispielsweise zur Überwindung von physischen Wegen und großen Entfernungen. Einfach gesagt: Wenn Patientinnen und Patienten nicht zu Ärztinnen und Ärzten und wiederum Ärztinnen und Ärzte nicht zu Patientinnen und Patienten kommen können, dann kann eine digitale Möglichkeit die Lösung sein. Dies gilt gleichermaßen für die weiteren in diesem Beitrag aufgezeigten Strukturbereiche. Durch den verstärkten Einsatz digitaler Tools in allen gesellschaftlichen Bereichen besteht jedoch auch das Risiko einer entstehenden bzw. sich verstärkenden „digitalen Kluft" hinsichtlich Nutzbarkeit und Akzeptanz zwischen unterschiedlichen Bevölkerungsgruppen, insbesondere für ältere Teile der Bevölkerung. Entsprechend bieten digitale Beteiligungsformate zwar exorbitante Möglichkeiten zur Erweiterung der klassischen Partizipationsmethoden, allerdings besteht immer die Gefahr eines Ausschlusses von Personengruppen.

Die (digitale) Beeinflussung der zukünftigen Entwicklung von ländlichen Räumen ist dabei nicht nur an die digitale (infrastrukturelle) Ausstattung gekoppelt. Diese stellt die Grundvoraussetzung für die Initiierung digitaler Projekte, aber noch nicht die finale Lösung, dar – entscheidend für das Gelingen ist jedoch in erster Linie der Mensch vor Ort. Es braucht Strategien, Konzepte, Angebotsträger und vor allem Nutzerinnen und Nutzer für den Erfolg eines (digitalen) Projekts.

Die Umsetzung des im Rahmen der Smart-City-Förderung notwendigen Strategieaufstellungsprozesses gestaltet sich in interkommunalen – im Besonderen im ländlichen Raum – Modellprojekten durchaus schwierig und bedarf eines zeitintensiveren Prozesses als in (groß-) städtischen Einzelkommunen. Die Herausforder-ungen bestehen insbesondere durch vielfältige Interessenslagen der unterschiedlichen administrativen Ein-heiten sowie zusätzlichen Abstimmungsbedarfen mehrerer administrativer Ebenen. Dabei gilt die Priorisierung eigenerer (lokaler) Interessen gegenüber gemeinsamer (interkommunaler/regionaler) Interessen gleicher-maßen als Problem politischer Entscheidungsträgerinnen und Entscheidungsträger wie auch der Bürgerinnen und Bürger. Gerade in Bezug auf die Projektinitiierung ist das bekannte „Kirchturmdenken" einzelner Gemeinden prägend. Dies muss berücksichtigt werden, um die Digitalisierung als Chance für Innovation in ländlichen Räumen zu sehen und nicht als zusätzlichen Faktor des Auseinanderdriftens von städtischen und ländlichen Räumen.

Trotz der vielfältigen Herausforderungen ist es dem Landkreis Kusel gelungen auf Basis umfassender Analysen und eines breit angelegten Partizipationsprozesses eine innovative Smart-City-Strategie als Leitplanke der zukünftigen räumlich-digitalen Entwicklung aufzustellen. Ob die identifizierten integrierten Maßnahmen in der Umsetzung erfolgreich sind und dadurch eine zukunftsfähige Regionalentwicklung gelingt, wird die nun fünf Jahre laufende Strategiephase zeigen. Klar ist, die potenziellen und tatsächlichen Wirkungen der zunehmenden Digitalisierung auf die Stadt- und Raumentwicklung sind bei Weitem noch nicht ausgelotet. Insgesamt stehen dem Landkreis durch das Programm jedoch verhältnismäßig große finanzielle und personelle Ressourcen zur Verfügung, um die digitale Transformation voranzutreiben und diese für eine langfristig nachhaltige Kreisentwicklung zu nutzen.

1 ABSTRACT

People's daily living environment has an important influence on their physical and mental health. That living environment consists of many different components, as it is both a spatial or physical environment, and the result of many other processes (socio-cultural, economic context and individual characteristics and lifestyles). Overall, the pressure on the physical environment is very high, especially in densely populated and highly urbanised area's such as Flanders, the northern part of Belgium. In urban environments, for instance, many spatial demands come together (space for housing, economy, mobility, green and blue infrastructures, etc.). The spatial layout of our cities can influence our health (e.g. whether or not we live nearby green spaces or in an environment that promotes active mobility, social contacts, if there are sources that impact the air quality, etc.), and of course our behaviour.

The relation between health, living and working environment and spatial planning is complex. Therefore, the Flemish Department of Environment & Spatial Development has prepared a framework in 2019 to better capture that complex relationship, which we will briefly discuss in this paper. Broadly speaking, a policy committed to healthy environments may choose to make interventions that protect people's health from certain external factors (e.g. air pollution or environmental noise) or that enable and promote healthy lifestyles (e.g. physical activity, food,…). Next to that, providing citizens with up to date information is an important task of the government.

In this paper, we discuss the research that the Environment and Health research team at the Flemish Department of Environment & Spatial Development conducts in order to measure human exposure to certain factors via sensors. Those particular factors were chosen mainly because they are part of themes around which the Flemish Department can make policy. We will consider three ongoing cases: measuring the quality of the indoor environment in different types of semi-public locations (such as schools, residential care centres, cultural centres,…), measuring radiofrequency radiation from fixed transmitting antennas in urban environments and measuring noise pollution. Partnering with international research & development organizations such as IMEC (Interuniversity Microelectronics Centre) and VITO (Flemish Institute for Technological Research), they supplied us with innovative and high-quality sensor technology. The sensors can transmit their measurement data in real time and participating parties can track the data on dashboards allowing immediate feedback and action when necessary. The results are intended to feed further research. Although not all case studies are equally advanced, we will conclude each one with possible policy actions.

Keywords: exposure, sensor network, living and working environment, real time data, health

---

2 WHY DOES A HEALTHY LIVING ENVIRONMENT MATTER AND HOW DOES IT RELATE TO SPATIAL PLANNING?

Health goes beyond the absence of disease: it is a state of physical, mental and social well-being. Health is an interplay of various personal factors such as genetics, age, lifestyle, as well as circumstances such as family and social network, working and living conditions and general socio-economic and cultural context. Health in All Policies (WHO, 2014) ensured that attention to health – in the broad sense of the word – in spatial policy and research is gradually increasing. In the Netherlands for example, the National Institute for Public Health and the Environment (RIVM) has contributed to the National Spatial Agenda (NOA) by describing the relationship between the living environment and health and by identifying future challenges and opportunities for healthy living environments (Rijksinstituut voor Volksgezondheid en Milieu, 2017).

The SARS-CoV-2 period made certain aspects of the healthy living and working environment all the more obvious: the need for high-quality green space, for social contacts, the need for good indoor air quality, etc. The way we organise and also use our available space (where we live, work, preserve nature, provide agricultural land, or deal with the built environment and density, transport, etc.) has an impact on our health. "Land use affects mobility, nature, green space, the quality of water, air and soil" (Teughels et al., 2022). But how can we grasp this more precisely?[1] In 2019 the Flemish Department of Environment & Spatial Development has prepared a framework to capture the complex relationship between health and factors that spatial planning can influence (Gommers et al, 2019). Figure 1 shows this relationship by using the intermediate step of healthy living and working environments. In those environments, the pressure on health by certain stressors (chemical, physical, biological) is minimised, physical safety is ensured as much as possible (from e.g. dangerous traffic situations, or natural disasters) and stress prevention plays an important role. In addition, people have access to healthy food, are invited to move actively and social interaction is made possible.

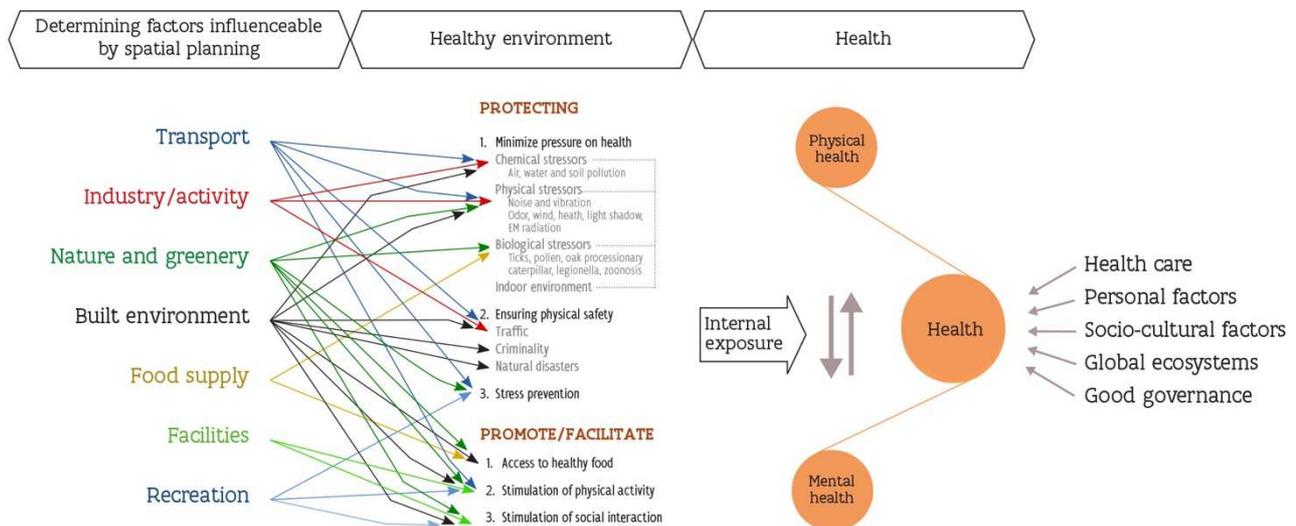
In terms of heath, the role of (spatial) policy might be seen as a combination of two themes: protecting or minimising health risks as much as possible and promoting healthy lifestyles and behaviour by providing the means to do so (e.g. active mobility, healthier nutrition).


Fig. 1: the complex relation between health, healthy living and working environments and factors that spatial planning can influence (Teughels et al., 2022)

In line with the first theme around protection, the Environment and Health research team at the Flemish Department of Environment & Spatial Development has been working for years to measure human exposure to certain factors, mainly concerning the exposure to certain substances and poluents in the indoor air and in the ground (in the context of gardening) and exposure to sources of non-ionising radiation (radiofrequency

---

[1] Some caution about measurable impact between health and spatial impact is in order. It would seem that the scientific literature is far from unanimous on cause-and-effect relationships between spatial interventions and health effects. Links are demonstrated in cross-sectional studies where observations are made at a single point in time (e.g. between the walkability of a neighbourhood and activity levels of that neighbourhood). However, few longitudinal studies exist examining the effect of a measure on behaviour and health. (Gommers et al, p. 17)

Sophie De Mulder, Michel Goethals, Mart Verlaek, Liesbeth Gommé, Niels De Kempeneer, Tine Van Hoof, Maja Mampaey, Philippe Van Haver, Caroline Teughels, Geert Van Haute, Karen Van Campenhout

(RF) and electromagnetic fields (EMF)). Next to this, the team is working around green infrastructure (types, proximity, perception,...) and human biomonitoring (including in the context of European Human Biomonitoring Network HBM4EU). Over the years, the team has accumulated a lot of knowledge on these various topics. However, this paper will focus on a few recent studies, which have a policy and societal question behind them. We will consider three ongoing cases. The first one is measuring the quality of the indoor environment in different types of semi-public locations (such as schools, residential care centres, cultural centres,…), which required rapid policy action in SARS-CoV-2 times. The second is measuring radiofrequency radiation from fixed transmitting antennas in urban environments, an important topic to follow up on, partly because oft he recent technological evolutions in telecommunications. And last is noise exposure, which is gaining importance internationally, as an factor with health impacts (e.g. Elmenhorst et al, 2019).

The finality of the different measurement campaigns varies: it is intended both to feed further research and legislative trajectories (e.g. in terms of standardisations, evaluation of standards), but also to provide very practical advice to participating partners (e.g. in terms of behaviour). Last but not least, in addition to raising awareness, it is also intended to provide correct information to people about certain important exposures, and so, reducing possible concerns.

3 RESEARCH ON HOW TO MEASURE EXPOSURE TO CERTAIN FACTORS

For the past 5 years, there was an accelerated technological development, which led to, among other things, the development of new types of sensors. Also in terms of data transmission, there were developments that allow instantaneous transmission of very large quantities of of data. This enables a different kind of measurement: where previously measurements were made with certain devices at a certain place and time, it is now possible to monitor a certain place for much longer, and collect more measurement data. In partnership with international research & development organizations such as IMEC (Interuniversity Microelectronics Centre) and VITO (Flemish Institute for Technological Research), we have started to develop different types of innovative and high-quality sensors. Depending on the factor we need to measure, the sensors can be placed outside or inside a building, or even on the human body. All sensors have in common that they can transmit their measurement data in real time and we collect the data in-house with the dataplatform Thingsboard. Interested parties can — in line with GDPR —track the data on dashboards allowing immediate feedback and action when necessary. For further global analysis, the data are anonymised. It is important to note that each sensor is calibrated at regular intervals, and updated when new technologies are available.

3.1 Indoor air quality & environment: the importance of people's behaviour and general knowledge at the start of building projects or reconversions

3.1.1 Introduction

In Figure 1, indoor air environment is a combination of chemical, physical and biological stressors, that can affect the health and well-being of its occupants or the people present in the room or building. It comes from three main sources: (1) the outside air (derived from how we organise our spatial lay-out, where we organise certain activities etc.), (2) the building materials of the built environment, especially when they consist of new building materials and at last (3) the sources inside the building envelope (people as a source of bio-effluents, including exhaled CO_2 and moisture but also bio-aerosols such as viruses and bacteria, furniture, smoking, use of ventilation when cooking, use of certain detergents or cleaning products etc). The building envelope functions between indoor and outdoor air quality. It can block certain pollutants from outside, but also keep certain pollutants from indoor sources inside, depending on the use of ventilation or aeration. Ventilation means that the air inside the builing is continuously refreshed, whereas aeration is briefly letting in a large amout of air by opening the doors or windows during a short amount of time. There exists four kinds of ventilalion types: (1) system A with natural supply and extraction, (2) system B — which is very rarely used in Flanders — with mechanical air supply and natural air extraction, (3) system C with natural air supply and mechanical air extraction and at last (4) system D with mechanical air supply and extraction.

In Flanders, people spend on average 85% of the day indoors. Because indoor air quality can affect the overall personal exposure of the building occupants, it is an important environmental determinant of health

(High Health Council Belgium, 2017). Since 2007, the Flemish Department of Environment & Spatial Development has been conducting research regarding indoor air quality in homes and schools to inform policy. One of the main conclusions of the research regarding the relation between the outdoor and indoor air quality is that the indoor air contains a number of pollutants, usually with greater diversity, and for certain pollutants in higher concentrations than outdoors. In addition, the research shows that ventilation is important: rooms that are mechanically ventilated often have better air quality, than non-mechanically ventilated rooms.

3.1.2   Why indoor air quality matters: research and measuring campaigns with the sensor boxes

The main research question regarding indoor environement quality is the following: when is the indoor environment healthy, and what measures help to achieve a healthy situation? To answer this, the Flemish Department of Environment & Spatial Development, together with VITO, developed 15 sensor boxes to continuously measure a number of pollutants and other parameters (Lazarov et al., 2019). The sensor box measures particulate matter (PM), carbon dioxide (CO_2), carbon monoxide (CO), nitrogen dioxide (NO_2), volatile organic compounds (VOC), temperature and relative humidity.

Indoor air quality contains many different substances and parameters. With the corona pandemic between 2020 and 2022, a big focus in Belgium and in Flanders has been on CO2 values[2] and how efficiently ventilation is carried out. CO_2 values are considered a good proxy to monitor the quality of the ventilation and aeration, and an important preventive measure to limit potential contamination via airborne transmission of viruses. The higher the CO_2 concentration, the higher the concentration of aerosols (microdroplets produced by breathing) that can contain micro-organisms, bacteria and viruses. In the absence of ventilation in enclosed spaces, these micro-organisms accumulate in the room. Effective ventilation and aeration reduces the concentration of micro-organisms in a room, and so limiting their spread through the air. In addition, the concentration of all other chemical and biological agents with indoor sources also decreases with effective ventilation; this is beneficial for good indoor air quality – needed for general health and well-being.

During the corona period, public indoor locations, where many people congregated, needed quick insight into the situation of CO_2 levels, how ventilation was happening and whether it could also be improved. Locations with vulnerable populations and/or that bring many people together, such as schools, residential care centres for elder people, sport halls and concert or cultural event halls were particularly targeted. Therefore, the Department of the Environment & Spatial Development, together with other government partners (from several government departments, such as health, education and sports & culture), started several measurement campaigns from 2020, and the last one planned in schools in autumn 2023. The measurement campaigns varied between 2 weeks (for sports halls) to 4 months (for residential care centres), and continued in both summer and winter. The hypothesis is that people tend to ventilate and aerate less during cold winter days, as there are colder outdoor temperatures, and residents want to keep the draughts out (and reduce energy bills). On hot summer days too, people tend to keep the heat out, and so, doors and windows are kept closed.

We processed the results from the measurements in several final products: (1) each participant (school, residential care centre, cultural house) received a report with results that also contained concrete advice, (2) we made an (anonymised) overview report per sector, (3) we made a website for schools where they can get targeted advice via questions and (4) we gave direct input to our partner governments to make policy frameworks on ventilation. The Departement of Health adopted a policy regarding ventilation in residential care centres.

3.1.3   Results: giving pratical advise and input to policy makers

About the different measurement campaigns in the different sectors, we can draw some overarching conclusions. As Figure 2 illustrates, it is clear that people's behaviour has an impact on air quality: keeping windows and doors closed increases CO_2 levels in a classroom, opening them almost immediately has a

---

[2] The general guideline values were: if the CO_2 concentration is below 900 ppm (or 500 ppm above outdoor concentration), we consider the room well ventilated. In practice, 900 ppm for an adult engaged in standard light activity corresponds to a ventilation flow rate of 40 m³.h.person of fresh outdoor air. This means that an amount of fresh air of 40m³ should be provided per person present in the room per hour. For values between 900 and 1.200 ppm, measures are needed to fall back below 900 ppm. Exceedances above 1.200 ppm are in principle not allowed.

decreasing effect. This knowledge was very useful during the corona pandemic: we were able to provide immediate practical advice to e.g. schools, depending on their situation (e.g. new building, type of windows) and whether or not they had a mechanical ventilation system. It is also possible to link actions to certain trends from the graphs: e.g. for rooms without mechanical ventilation, one could match room occupancy to the surface of the open or tilted windows. The results gave direct input to the policy makers during the corona pandemic, e.g. wether or not the different sectors could implement certain measures regarding CO_2 levels.

Next to behaviour, there are the technical aspects of the ventilation or aeration. When installing the sensor boxes in the field, we noticed that people on site – regardless of the type of sector – often have little knowledge about the presence of a ventilation system or the way it works, and when was the last maintenance. Inspection, maintenance and correct settings of ventilation systems are necessary for it to function correctly. It seems essential to sensitise and inform various target groups, in particular architects, technical staff, school teachers, residents of care centres etc., about possible interventions that help improve indoor air quality. Attention to possible complaints from the occupants of the room (e.g. draught, heat, noise...) and obstacles for the staff (e.g. extra workload, possibility of safely opening windows) is recommended, as ventilation and aeration should not be at the expense of well-being. Architects are an important target group as well, as ventilation systems are usually installed when renovation or new construction takes place. It is therefore essential to attach importance to the implementation of ventilation from the start of the (re)construction project.

Based on our findings, we conclude that investing in demand-controlled (mechanical) ventilation ¬ a system that measures and monitors CO_2 values — contributes to improved air quality and consistently lowers CO_2 concentrations in the indoor environment, and so helps reduce airborne viral transmission. Generally, regardless of the outside temperature and the saison, we noticed that rooms that are equipped CO_2 ventilation systems of type D (mechanical air supply and extraction) are more effective at keeping the CO2 levels low, in comparison to the other types of ventilation systems. However, we have little insight into the reasons for the potential reduced performance of other ventilation types. This aspect will be included in upcoming studies in 2023, by conducting a technical screening of the ventilation systems.

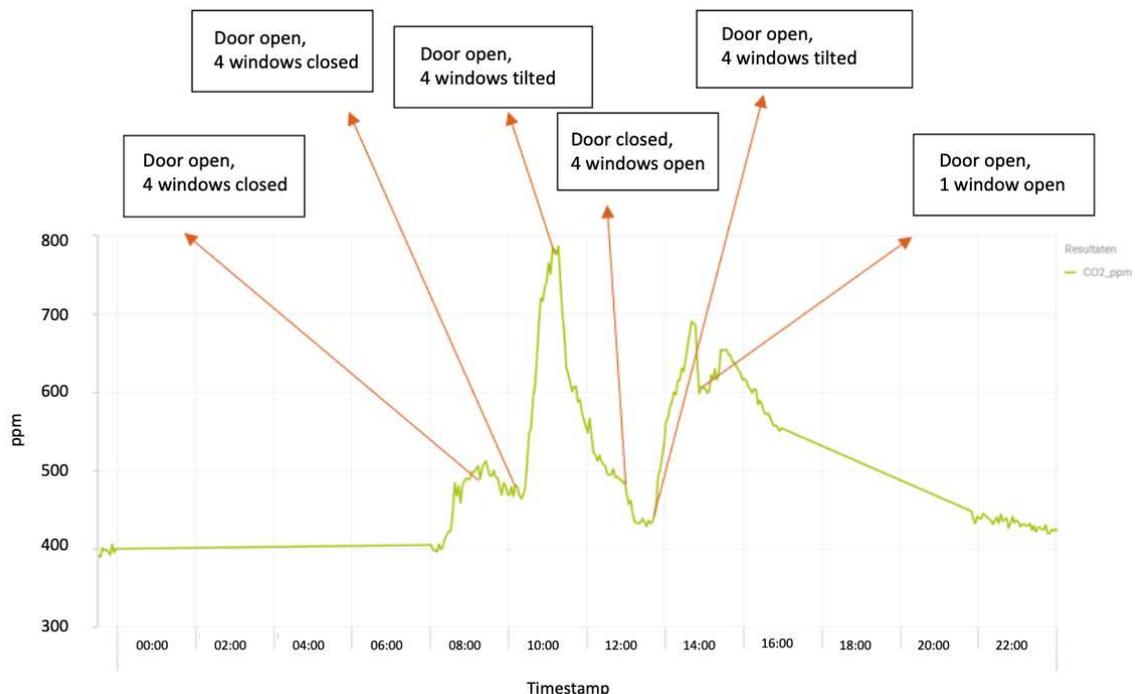

Fig. 2: the relation between CO_2 values (ppm) and measures to ventilate and aerate a classroom during a schoolday (own translation to English of the source: Taskforce Ventilation, 2021)

3.2 Exposure to radiofrequency radiation from fixed transmitting antennas: more accurate exposure maps to better inform the general public

3.2.1   Introduction

Transmitting antennas, equipped with the latest techonology, make it possible to transmit more and faster data, stimulating the development of interconnectivity, digital services, smart meters, etc. Several studies (e.g. the SmartSantander use-case in Spain (Diez et al, 2017) and the ongoing GOLIAT-5G project in Swisterland) addresses the health impact, by mapping exposure. In turn, we would also like to get a better idea of this in Flanders.

In Belgium, legislation around transmitting antennas is a regional competence. This means that in Flanders, operators of transmitting antennas apply for conformity certificates from the Flemish Department of Environment & Spatial Development before a transmitting antenna is put into service or modified . With these certificates, the Flemish government ensures that the requested condition complies with the standard for exposure to non-ionising radiation from fixed transmitting antennas. Referring to Figure 1, this theme relates to protecting from physical stressors.

In 2010, Flanders drafted its first legislation to limit exposure to electromagnetic fields from transmitting antennas (=radiofrequency or RF radiation). Since mobile telecommunications technology evolved significantly over the past 10 years, an adaptation of the legislation in 2022 was needed. Both times, the choice of the standards were based on international guidelines (ICNIRP), scientific research and on the precautionary principle. To test the impact of the new standards for the 2022 legislation, the Flemish Department of Environment & Spatial Development has simulated the virtual roll out of 5G in 2019 (Gommé et al, 2023). As input data we used the information from the confirmity certificates. These simulations resulted in exposure maps, which do not necessarily correspond to what actually happens in the field: the simulations are based on worst-case exposure. From the perspective of precautionary principle, this is a good approach. However, we still do not know what is happening in the field. By carrying out site measurements, we can get a better picture of what is happening in the field, e.g. peaks or fluctuations in exposure during the day etc. And so, with the sensor measurements we can create more accurate real time exposure maps. The subject of non-ionising radiation can raise concerns in society, and through more accurate and accessible information, we want to reduce concerns.

3.2.2   Spatial analysis of the transmitting antennas and the 5G roll out

Generally speaking, the location of the transmitting antennas follows the population pattern. About half of the sites for transmitting antennas are located in urban (core) area's, and almost one in 4 sites is located on an industrial/business/office parks.[3] In 2019, urban area's made up about 11% of the total area in Flanders and 72% of the population lived there (Pisman et al, 2021). Antennas are more closely spaced together in urban environments, while outside these area's, in more sparsely populated areas, less antennas transmit higher powers. Today, 5G technology is present in about half of the sites for transmitting antennas, but there are spatial differences. When comparing sites with or without 5G technology per type of area, there is a larger share of sites that contain 5G in large urban (core) area's (57%), than outside urban environments (46%).

Figure 3 illustrates these findings. It is a zoom map of the eastern part of Flanders, with Antwerp as the major urban area on the north-west of the map and Mechelen on the south-west (pink urban cores on Figure 3), surrounded by the port of Antwerp industrial zone to the northeast (purple area on Figure 3). The rest of the map consists of smaller urban areas or cores (dark grey areas). The business parks or industrial areas often connect to those cores of (smaller) urban areas, or they are located near major infrastructures, such as highways and canals. Compared to the rest of the map, there is a clear concentration of sites for transmitting antennas in the urban area of Antwerp. In addition, it is noticeable that there is a large mix of sites with both 5G technology (blue dots) and with other technologies (yellow dots), with a slight overweight of sites with 5G technology. In some other, smaller cores, the sites with other technologies are more prevalent, especially in the north-eastern part of the map.

---

[3] The legislation regulates that certain types of transmitting antennes do not need a comformity certificate, when they operate under a certain Effective Isotropic Radiated Power (EIRP, as a measurement of radiated output power from an ideal isotropic antenna in a single direction) and less than a certain amount of days. However, these antenna's still need to conform to the legal standard to limit exposure to electromagnetic fields.

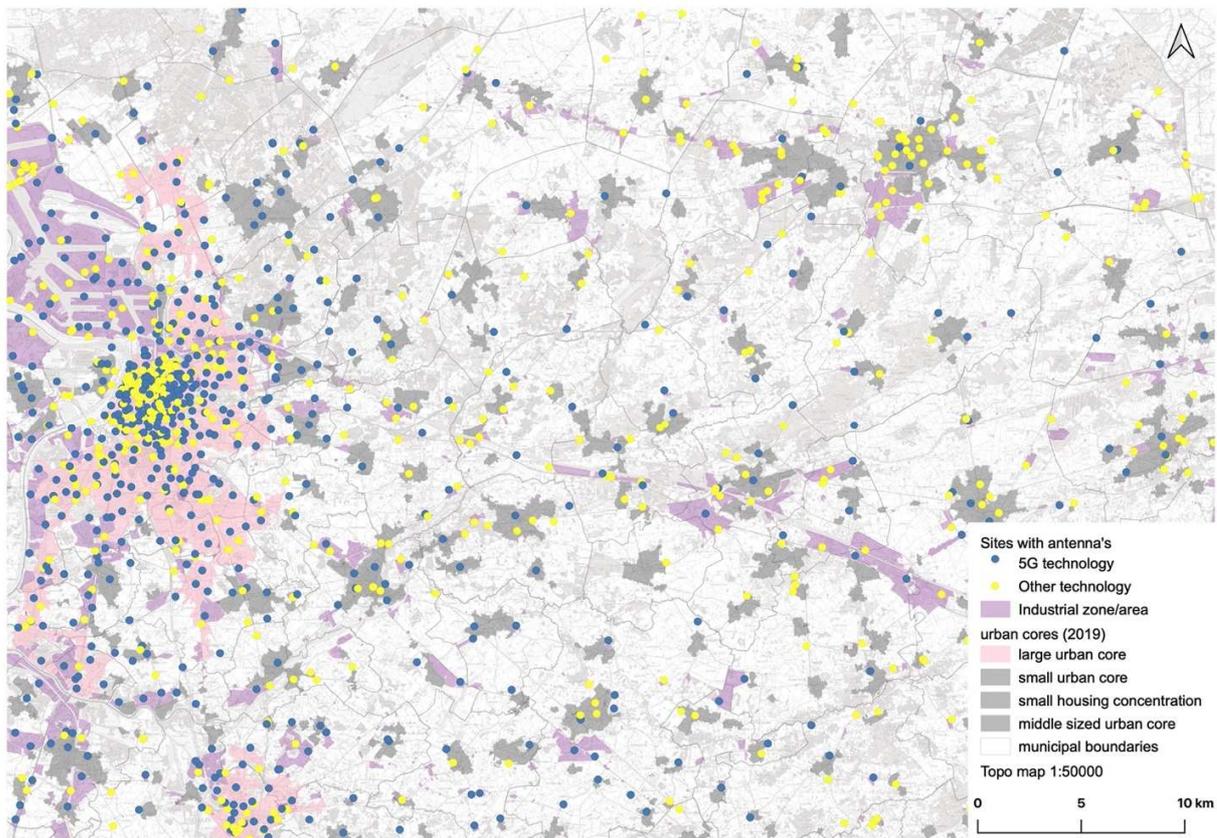
Sophie De Mulder, Michel Goethals, Mart Verlaek, Liesbeth Gommé, Niels De Kempeneer, Tine Van Hoof, Maja Mampaey, Philippe Van Haver, Caroline Teughels, Geert Van Haute, Karen Van Campenhout


Fig. 3: distribution of sites with 5G and other technologies in Flanders, according to a classification into urban areas/cores and industrial/business areas (own data from conformity certificates)

3.2.3 Research and results

As mentionned in the previous paragraph, the impact of the new legislation, adopting the precautionary principle, was investigated by means of simulations before it came into effect. Now we want to put into practise an exposure monitoring network in Flanders. The ultimate goal of the monitoring network is to map time-dependent exposure to RF radiation based on measurement data collected by sensor boxes and interpolating in zones located between the sensor boxes.

The Flemish Department of Environment & Spatial Development has 27 RF sensor boxes — developed in cooperation with IMEC — that continuously measure exposure to RF radiation from transmitting antennas (Aerts et al, 2022). There is also a data capture platform for receiving the sensor data from the 27 RF sensor boxes. The RF sensor boxes were designed to measure the electric field strength on following four telecom frequency bands: 800 MHz, 900 MHz, 1800 MHz and 3600 MHz.

The research in cooperation with IMEC on the best locations or buildings to place the RF boxes has started in February 2023. An urban environment, specifically the centre of the city of Ghent, was chosen to investigate in this pilot study. The city of Ghent is a suitable location as it reflects well the urban complexity: it is, after Antwerp, the second largest city in Flanders (circa 157 km2, 267.700 inhabitants, 1.695 inhabitants per km2 in 2023). The city centre has quite a dense street pattern, with several markets and squares, which for some parts can be traced back to the Middle Ages. Buildings have different heights, and streets have varying widths (the buildings will attenuate or reflect radiation to some extent). This is in other words a complex environment.

Using a modelled exposure, possible locations for the 27 boxes are proposed, taking into account a variogram analysis to estimate correlation distance and zones where exposure is potentially highest. The plan now is to place the boxes on the facades, roofs or balconies of buildings, mostly with view on the street. To this end, we have enlisted the cooperation of various public or government institutions (university buildings, Flemish government buildings, etc.). The deployment of the sensor boxes will start during the summer and the objective is to collect sensor data during a year, that will be further analysed.

3.2.4   Results

The finality of the study is to feed an interpolation model based on the measurements to come up with an exposure map. This will probably give a different picture than the previous exposure maps based on the conformity certificates. It allows us to take the first steps towards possible monitoring for the whole of Flanders. In addition, it can help us as a government to fulfil our role of monitoring standards[4], and to provide more precise information to citizens.

3.3 Noise exposure getting insight into the causal relationship between noise and health

3.3.1   Introduction: measurements and perception

Noise pollution is categorised in Figure 1 as another physical stressor. International research indicates that noise exposure can cause important health effects such as stress, sleep disturbance and cardiovascular effects (WHO, 2018). If we do not take into account endocrine disruptors, Flemish research cites noise pollution as the second most important factor in calculating DALY (or Disability Adjusted Life Years as a measure of years of life lost due to premature mortality combined with years of healthy life lost due to disability), after particulate matter.

In 2018, the Department of Environment & Spatial Development conducted a five-yearly written environment survey in order to estimate the proportion of inhabitants that are affected by noise, light and odour pollution. It was the fifth survey in a series of identical surveys conducted since 2001. The 2018 survey shows that noise is the main source of annoyance: 29% of Flemish people (or circa 3.299.060 inhabitants) said they felt bothered by noise in and around their homes (categories ranging from moderate (18%) to serious (10%) and extreme noise (2%) annoyance). Traffic and transport noise is the largest source of noise annoyance. More than a third of those with moderate to extreme noise annoyance related this to traffic and transport. People living in urban environments experience the most noise annoyance compared to more rural areas.

Modelled noise pollution maps exist for Flanders:[5] these mainly take into account the main traffic-related sources of noise (e.g. noise from traffic on motorways and other major roads, from high-frequency train connections or from air traffic from airports). However, they remain an estimate of actual noise exposure. To better map effective exposure, the Department of Environment & Spatial Development is collaborating with the University of Ghent, the Provincial Institute of Hygiene and Scivil (Flemish knowledge center for citizen science) on two 24-month projects of Public Procurement Innovation (PPI) with sound sensors, linking on-site outdoor nighttime noise measurements with health effects, sleep disturbance and human perception. The focus is on (1) better capturing personal and dynamic exposure, and relating this to health effects and sleep quality of the participants (PPI I) and (2) mapping environmental noise in Flanders on strategic locations and the appreciation of that environment by rolling out a measurement network of sensors in a citizen science project (PPI II).

3.3.2   Research with sensors: getting insight into the causal relationship between noise during the night and health

Both research projects are currently ongoing. In a first phase, the aim is to search for best-in-class sensors and establish measurement protocols through two pilot studies, so that this can be applied on a larger scale in Flanders in a citizen science project to be launched in a second phase.

The measurement protocols being developed for this is based on literature, but also on ongoing research. This will be done simultaneously with field testing in the form of two pilot studies, with 10 subjects each that live in several spatial environments (urban, suburban and more rural environments). The measurement protocols are designed to correlate noise exposure during the night with health impacts, sleep disturbance and noise pollution. The study allows the analysis of short-term effects on health and sleep and it allows to get insight into the causal relationship between noise and health, without taking confounding factors into account (e.g. air quality). To achieve this, biological response measurements are performed, thanks to an

---

[4] The sensors have a precision of measurement of more or less 5dB. They can indicate whether a standard has been exceeded. In that case, our enforcement services intervene and can measure with more accurate devices on site.

[5] These maps are based upon a weighted 24-hour annual average sound pressure level, with evening and night levels being relatively more heavily weighted (L_{den})

Sophie De Mulder, Michel Goethals, Mart Verlaek, Liesbeth Gommé, Niels De Kempeneer, Tine Van Hoof, Maja Mampaey, Philippe Van Haver, Caroline Teughels, Geert Van Haute, Karen Van Campenhout

ECG and actimetry device that the participants carry on their body (heart rate variability, motility,…). As mentioned in the introduction, perception is an important factor when we are dealing with annoyance. Therefore, the project uses a survey, in the form of self-reported noise annoyance and sleep disturbance among the pilot project participants.

In addition, noise at night is measured both inside and outside the home. That simultaneous measurement makes it possible to differentiate between indoor en outdoor noise (and to analyse the difference in impact on sleep), and also to identify the source of the ambient noise. The latter is important knowledge for policy: by knowing the sources, certain measures can be taken if necessary.

3.3.3   Results

Both PPI projects are ongoing. The first one that deals with health effects and sleep quality of the participants, is expected to be completed in December 2023. This project wants to monitor the impact of noise on health. A measurement protocol will be drawn up for later roll-out in a subsequent HBM (Human Biomonitoring) campaign. From this, the effect of noise on health (and quality of life) can then be monitored on a larger scale in Flanders. The second PPI project will end in March 2025. The result will be a proof of concept in order to map noise in Flanders more area-wide (in relation to the existing noise maps), classification of noise sources and their appreciation. A concrete plan of approach will be drawn up, to be used afterwards in a large-scale citizen science project. The data from the citizen science project will serve to create an area-wide map, which can also validate modelled noise maps.

So far, the results of the projects mainly focus on the technical aspects, regarding the the technology used, IT applications, problems encountered during the pilots, etc. This information will be processed in order to establish a concrete measurement protocol for later use.

4   OVERARCHING CONCLUSIONS AND REFLECTIONS ON SENSOR-BASED RESEARCH FOR LIVING IN A HEALTHY ENVIRONMENT

4.1 Reflections concerning spatial planning

This paper first and foremost highlighted the relationship between spatial planning and health by introducing the concept of healthy living and working environments. The physical environment has a major influence – both positive or negative — on our well-being and health. For instance, the beneficial effects of green space on physical and mental health are widely accepted and scientifically researched. Conversely, exposure to chemical pollutants present in air, water, soil, food or in certain products can lead to a broad spectrum of health effects that vary in severity and duration. The same applies to exposure to physical stressors such as noise, radiation, and biological stressors such as bio-effluents, including exhaled CO_2 and moisture but also bio-aerosols such as viruses and bacteria. Introducing more health aspects in spatial planning has several benefits. It takes into account the vulnerability of specific groups, such as the elderly, children and the chronically ill. Research shows that health differences exist between socioeconomic groups, and these differences also manifest themselves spatially (RIVM, 2017).

This paper mainly focused on protection, which is an important task of the government, by starting to measure the exposure of different stressors in the field. The underlying question is what measures help to achieve a healthy living environment. In the case of indoor environmental quality, where we focused on more vulnerable groups such as children and elder people, behaviour plays an important role, and sensitisation of different target groups (inhabitants, staff, architects, building contractors) is an important aspect. The measurements have also directly fed policy at other governmental agencies, e.g. the framework around ventilation and aeration in care centres. With non-ionising radiation from transmitting antennas, it is mainly about the legal standards, which must not be exceeded, and informing people correctly and removing any concerns. Finally, with noise exposure, we are only in the early stages of getting a grip on the state of affairs. These insights can give input to policy measures in the future, such as imposing noise standards in certain environments or specific measures to be included in noise action plans.

Flanders is not the only region dealing with measuring and tackling environmental impact on health. Of some factors, such as RF exposure, we know that other regions and countries are conducting studies to monitor this. Of other factors, we do not yet know about how the results of measurements are implemented in the policies of other countries, e.g. for the case of noise exposure. Presumably, our PPI studies on noise

could be relevant as it is conducted within a policy context and rolled out afterwards. In any case, it is interesting to follow up other countries and regions in the future.

Flanders is a densely populated region, and throughout the day everyone is exposed to certain stressors to a greater or lesser extent. Even though exposure partly depends on lifestyle and behaviour, a further exploration of spatial factors in relation to exposure seems interesting. Overall, we know that people living in urban environments are more likely to be exposed to certain environmental stressors, but there may be many differences between urban areas. For example, traffic density, proximity to certain industrial activities (and thus exposure to noise, among other things) play a role and may also occur outside urban areas (or cores) in Flanders. Agricultural activities outside cities, in turn, are a potential source of stressors. These constitute interesting starting points for further spatial research.

4.2 Refections about sensor-based research

Working closely with partners, we were able to develop innovative sensors, which we use in research that supports policy, as well as in policy preparation and standards evaluation. This way of working with sensors has the advantage of being cost-efficient, quick to set up and a step towards an independent and objective measurement network. It also has its challenges because it implies continuous monitoring of the latest technological innovations. The roll-out of different sensors in the field is also a process of learning by doing, that takes some time. It also requires a commitment to building in-house knowledge. Still, it remains worthwhile to enrich our knowledge and models with data in the field. Field measurements allow us to measure many more fluctuations and nuances, and we are closer to people's daily lives.

Local Climate Adaptation Governance and Planning: Challenges to Transformation

Carolin Schröder

(Dr.-Ing. Carolin Schröder, Zentrum Technik und Gesellschaft/ TU Berlin, Kaiserin-Augusta-Allee 104, 10553 Berlin, c.schroeder@ztg.tu-berlin.de)

1 ABSTRACT

Climate adaptation has so far been a voluntary topic for municipalities (in Germany), in consequence there is a fundamental challenge to establish the topic in everyday municipal life and to create suitable structures.

From sustainability and transformation research as well as from mainstreaming experiences with the topic of climate protection, a variety of insights can already be gained that are important for integrating the topic of climate adaptation in local governments. While there are many findings from research on sustainable development and climate protection, the introduction of a new produces some further challenges regarding the complexity of structures and processes.

In this contribution, it will be argued that there structural, procedural, and contextual barriers to local climate adaptation in governance and planning. Based on this assumption, experiences in transformation towards climate adaptation in a specific local administration will be analyzed and discussed. The case presented is part of the ReWanKa project in Berlin (Reallabore Regenwasser und Klimaanpassung) which focuses on experimenting with administrative structures.

Keywords: Local Governance, Local Planning, Climate Adaptation, Challenges Transformation, Germany

2 MAINSTREAMING CLIMATE ADAPTATION

Natural and anthropocentric climate change are major challenges affecting all global, national and local societies, economies, and individuals in various ways (EEU 2020). Over the last decades, many efforts have been made on the local, national and international levels already. Concepts and goals varied over time, starting with sustainable (local) development in the 1970s, the topic of climate (protection) in the 1980s, and followed by the topic of climate adaptation in the 1990s (Smithers, Smit 1997). This contribution explores the challenges of mainstreaming climate adaption in local governments.

2.1 State of the Art – Learnings from Research and Practice on sustainable development and climate protection

The first argument of this contribution is that in order to understand the challenges of introducing "climate adaptation" to local governments, a lot can be learned from empirical and practical findings from sustainable development and climate protection activities from different level. In the following, a very short overview of three aspects of transformation will be presented that one keeps coming across in the literature: Complexity, Paradigm Shift, and Place- or Context-Based solutions.

In the literature, it has been acknowledged that comprehensive sustainable development constitutes a multi-level challenge (Geels, Kemp 2012). Furthermore, that it needs to be understood as a long-term and sometimes resource-intensive process (Krellenberg 2016) which has to deal with "highly complex real problems" (Zscheischler/ Rogga/ Weith 2014). In order to deal with such complexity, large parts of the literature postulate that more cross-sectoral and flexible approaches are needed (Clune, Zehnder 2018). It is acknowledged that established silo thinking must be deconstructed (Chu 2016) in order to integrate (new) topics and structures. It is also ackowledged the importance of different forms knowledge as a basis for any successful sustainable development and climate protection (Walter et al. 2007; see also EU 2020).

In addition to acknowledging the complexity, a general shift in paradigms, framings and priorities can be observed: Initially, sustainable development and climate change were being conceived as a mainly environmental problem (Chu 2016) that can be solved with new technical solutions and new legal bindings (Ostrom 2012). But it became obvious that the complexity of the "problem" needs the cooperation and participation of large parts of society (Adger et al. 2013). In consequence, not only internal structures and foci were questioned but different paradigms promoted: This included a general shift from hierarchically organized approaches to participatory, co-creative or even cooperative approaches (Glass, Newig 2019) as well as a shift from the still prevailing approach of reactive to pro-active local governance and planning (Van der Berg 2022).

A third finding is that any approach to effective sustainable development and climate protection must be place- and context-based. In consequence, the concepts must be operationalized in different ways for different places (Elmquist et al. 2019) in order to have a chance to implemented successfully. This takes into account that effects of climate change are different in different places as well the finding that an abstract topic such as climate adaptation can be framed and operationalized differently, for example in the contexts of public health and life quality – or exclusivity and vulnerability.

2.2 Implications for Climate Adaptation Governance and Planning

These three characterics of sustainable development and climate protection embrace complexity, paradigm-shifts and local approaches. But they also highlight "a series of systemic pressures on urban public institutions [among others]" (Chu 2016: 2). Introducing the topic of climate adaptation may underlie similar pressures. First insights are already provided by cities all over the world embracing the topic of climate adaptation in governance and planning (Van der Berg 2022; Araos et al. 2016; EEA 2020).

According to the literature, Climate adaptation is similarly being conceived as a cross-sectoral, complex issue that needs different mindsets, flexible governance as well as context- and place-based solutions (Baker et al. 2012; Van der Berg 2022:18). These findings lead immediately to the question on how to integrate the topic of climate adaptation into existing processes and structures. Or whether it should be prioritized?

The second argument of this contribution is, in consequence, that there are fundamental practical challenges to establish the topic of climate adaptation in municipal governance and planning. This might also explain why local governments are more or less successful in dealing with these challenges. Existing concepts and plans usually stop short before explaining how to practically integrate topics and structures (Van Der Berg 2022:7). The following part of this contribution will explore reasons for such an "uneven uptake". In order to understand, a simple framework will be applied. The argumentation line of this framework is that local climate adaptation cannot be successful "without addressing structural, procedural, and contextual barriers" (Baker et al. 2012: 127). In a first step, I will illustrate a bit further these three aspects and relate them to what was written in chapter 2.1.

Structural aspects: First of all, there still seems to be a misunderstanding that climate adaptation is a separate topic that should best be dealt with with specific policies, objectives and plans. (institutional 'silos'). Another misunderstanding is that it is considered an environmental issue (Baker et al. 2012: 134; Van Der Berg 2022: 1). In consequence, suitable organizational structures are required to integrate climate adaptation in the long term (DIfU 2015). This would include to truly integrate awareness, capacity and resources for the issue of climate adaptation in administrations (Susskind & Kim 2022). But there are indications, that the topic can be pushed better either by strong leadership (with for example key actors and key events; Haupt, Kern 2020) and/or the formulation of explicit (and legitimate) goals (Um 2018; DIfU 2015). But given the complexity of the process, there often is a need for interim steps and solutions which might be contraproductive to the idea of climate adaptation on the long run (Baker et al. 2012).

Procedural aspects: With the understanding that climate adaptation must be supported by large parts of the society, adequate processes must also embrace different perspectives and population groups (Preston et al. 2011). In consequence, new forms of stakeholder engagement are implemented more and more often (Susskind, Kim 2022). But similar to the fact that there is not much empirical evidence regarding the structures and restructuration efforts of local administrations, there is neither much evidence for "the design of public participation efforts" (Uittenbroek et al. 2019).

As mentioned above, local consequences of climate change are rather unknown and suitable structures do not exist yet. One popular approach to deal with this uncertainty is experimentation (Bulkeley, Castán Broto, & Edwards, 2015; Chu 2016). It is said to allow for learning-by-doing (Susskind, Kim 2022), for generating new governance capacities (Healey, 2004), and more effective policy styles (Lesnikowski et al. 2021) - as a pre-stage to formal planning (Schmitt et al. 2019).

Contextual aspects: The integration of a new topic also asks to consider wider structural and content-related contexts. This ranges from the establishment of new internal structures and procedures to the integration of different levels and competing objectives. Which reinforces the argument that, even within an institution, new forms of aggregating and sharing knowledge are needed (DifU 2015). In addition, local adaptation governance and planning are never independent from higher levels (Brooks & Adger 2005) - their concepts,

498

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

plans, legal frameworks and timeframes. For example: One specific climate adaptation measure may be considered state-of-the-art in one administrative unit, but it may have negative consequences on specific natural elements, or people, or socio-economic trends. And one more aspect: While most local administrations have to deal with limited ressources in general, their ressources may be allocated differently between units and departments (Chu 2016), causing further imbalances in capacities. And all these aspects increase the degree of complexity.

3 THE REWANKA PROJECT

ReWanKa (Reallabore Klimaanpassung und Regenwasser – Living Labs Climate Adaptation and Rain Water) is a transdisciplinary project dedicated to introduce the topic of climate adaptation to a specific local government with a focus on developing governance and planning approaches regarding rain water.

The motivation for the project was that, in Berlin, almost all construction projects have so far been planned without using the synergies of decentralized rainwater utilization and climate adaptation measures. Adequate solutions to reduce the effects of droughts and heavy rain events on urban vegetation are well known, but so far these have only been insufficiently incorporated into official action. As a result, during the current construction boom in a growing city, opportunities are repeatedly missed to jointly develop rainwater utilization and climate adaptation measures and to integrate them into higher-level plans and projects.

3.1 Methodological approach

In order to get the process started, the method "constellation analysis" (Konstellationsanalyse) was introduced. It has been developed as a method of innovation research, as a so-called "bridging concept for [problem-oriented] technology, innovation and sustainability research" (Schön, Nölting & Meister 2004: 3). It can be used to depict and analyze relationships between technology and differently organized society - also across different levels. During the ReWanKa project, we used the method for facilitating communication between (science and) practice, structuring of different perspectives, and capturing complex problem constellations (Schön et al. 2007; Ohlhorst, Kröger 2015).

The methodological core of the method is a workshop where invited stakeholders jointly develop a visualisation (they map a constellation) of an actual problem. In the case of ReWanKa, the question was: "How can the ability to act regarding rainwater/climate adaptation be strengthened (within the local administration)?". In this workshops, the participants visualize the quality of a relation between actors, natural elements, signs and codes as well as technical artefacts. Such a visualisation helps to understand how aspects are (not) interrelated and which aspects are missing.

This methodological core can be added to by other formats. In the case of ReWanKa, we did five interviews beforehand with people responsible for specific topics within this sub-unit. The aim was to better understand how this unit is working, to start this discussion process and to identify shared points or terms of reference. Topics were structure, processes and context of their work, their content-related focus and specific challenges in relation to climate adaptation and rain water. The aggregated results of the interviews were discussed and validated during the actual constellation analysis workshop with a group of fourteen people (including some of the Interviewees). And later on, first ideas developed during the workshop have been implemented.

3.2 Intermediary Results

In the following, a short summary of the (intermediary) results of the projects, following the framework that has been presented in chapter 2.2.

Regarding structural aspects: The district administration has embraced the topic of climate change already with several resolutions) and the allocation of personal ressources (climate protection managers). The interviewees refered to a large variety of plans, guidelines and concepts on climate protection and sustainability that are relevant for their work – but not many named the same ones. Decision-making structures and processes, similar to the whole district administration, are well established, but linear in order to be efficient. The recent increase in personal ressources, rather unusual, has helped to attract some comparatively young staff.

The interviewees felt that climate adaptation is an important topic and that steps need to be taken to integrate it into their governance and planning processes. Rain water, in contrast, was a topic that was less well known. While conducting the interviews, it became obvious that introducing two topics at the same time is a rather complex challenge in itself. But in the end, this two-fold focus helped to better understand nuances in structure, process, context. Most of all, it turned out that different staff, units and departments have different perspectives and refer to different (legal) frameworks, content, scope and timeframes with differing data formats, and levels of detail. In addition, professional perspectives may be mixed with individual ones: For example, the interviewees were concerned to a different degree with the issues of climate adaptation and rainwater, they felt that specific aspects of climate change respectively measures were more relevant than others, and they would argue based on different guidelines and plans.

Regarding procedural aspects: Despite high individual motivation, the linear organisation of communication processes as well as the general workload do not allow for much discussion, knowledge sharing, or reflection. So far, to give a typical example, content-relation position statements are delivered according to a transparent but linear structure. Nonetheless, some of the staff already thought a lot about integrating climate adaptation in their work. They are aware that it would be a long-term, complex and ressourceful process – but felt that something needs to be done to promote the topic within the whole district administration.

An idea that was mentioned several times was that there should be more content-related exchange and reflection on the consequences of their linear structure. This idea has been implemented shortly after the workshop, leading to a lively internal discussion about formats and specific aspects of climate adaptation governance and planning – and a continuing demand for regular content-related meetings.

Regarding contextual aspects: As mentioned before, different departments relate differently to the topics of climate adaptation and rain water - even within this comparatively small unit of the local administration. During the workshop, it became obvious that the knowledge about factual climate adaptation/rain water measures is very limited. Which means that it is more difficult to integrate something if one does not have and idea what would be possible. In this specific case it was, most of all, lacking knowledge of the possibilities and synergies of coupling various decentralized rainwater management and climate adaptation measures such as facade and roof greening or evaporation with energy-efficient, intelligent rainwater collection. In addition, the informal discussions helped to better understand specific consequences of administrative decisions. Especially when it comes to understanding wider socio-economic effects of governance and planning decisions.

While these first steps were very promising, the question is what (further) challenges will emerge when trying to establish the topics in a wider institutional context? It became obvious that more personal resources would be needed (this goes not only for climate adaptation). But it remained unclear who should take on coordination respectively leadership for the process. Anyway, the participants of the workshops agreed to continue informal exchanges. But they also felt that the general term "climate adaptation" is – according to the findings - seldomly used successfully in work conversations.

4   DISCUSSION – MAINSTREAMING LOCAL CLIMATE ADAPTATION

The ReWanKa project deals with the transformation issue of structural, procedural and contextual barriers. This short exploration highlighted practical issues – and provides some insight in the complexity of further practical steps to take.

The approach taken in this specific unit of local administration is an informal, explorative approach. But they face a linear, well-established structure that does only little allow for knowledge exchange, experimentation and reflection. Nonetheless, a new generation of public administrators is determined to integrate the topic. And they are aware that it will and must be a long-term and complex process with many steps to take.

It has been agreed that there should be regular, informal meetings with content-related discussions. This might also happen with different departments and different people joining once in a while. At this stage, it is unclear what the most suitable format could be. But it was decided to organize project-based meetings before the actual process of approving a new building application in order to informally exchange professional opinions, ideas and concerns. This, so is the hope, might also help to discuss the integration of the concept of climate adaptation in general at the local level. This clearly shows how content and structure are interrelated.

There are some first steps towards a more reflective structure in this (part of the) local district administration. However climate adaptation, is still a voluntary task for local governments in Germany. In consequence, there will be a large variety of approaches in the future. Despite the assumption that the findings describe a rather typical example of German local administration, it became clear that local administrations are not at all homogenous institutions. And it must be assumed that not every governance or planning approach works in every local administration.

5 CONCLUSION

Reflecting these intermediary results, the project is still very far from jointly developping standard solutions and processes that have great potential for change – as formulated in the application for the project. I presented a short insight into practical problems of local administration, structural, procedural and contextual, as well as some aspects of their interplay. Some useful ideas regarding the transformation of structures and procedures were developped, now facing the challenge of stabilization and mainstreaming.

It also became obvious that members of staff need some (internal and external) inspiration in order to understand the variety of consequences of implementing specific measures. This turned out to be productive. But at the same time, the discourse on rain water in this project has mostly been limited to the interrelations between blue and green infrastructures. But it could also be framed in other ways, too: Local governments could create specif´n incentives to encourage the use and reuse of rainwater, or awareness campaigns on the benefits of rainwater harvesting and how to collect, store, and use it efficiently. But then again - there may be some other important topics too in local administrations. The search continues …

1 ABSTRACT

Climate change and rising temperatures particularly affect the built environment and intensify the Urban Heat Island (UHI) effect in cities. Nature-based solutions can have a balancing function and reduce overheating. However, greenery still receives too little attention in architecture and is added as an additional element at the end of the planning phase or even after the building has been constructed.

For a climate resilient urban development in the future, in addition to a change in processes, a change in real estate development and in the project management is necessary.

At least, three preconditions must be met for this to happen:

- Sound knowledge base: Many studies already exist proving the positive effects of nature-based solutions for densely built cities. However, the knowledge transfer to real estate companies is still insufficient as they require precise and site-specific information showing effectiveness of greenery on microclimate, building envelope and indoor temperature. At best, analyses apply a system view and consider interrelations with water and energy.

- Greenery-friendly planning framework: Real estate development takes place in compliance with local planning standards and procedures. Planning strategies and regulations, standards, urban development contracts and funding programmes strongly influence urban design and development and hereby have great potential to promote greening.

- Integrated mindset: In architecture and real estate development, it is still not standard to include greenery and nature-based solutions in design, planning and construction. Building optimization also includes greening. Thus, it needs an integrated mindset regarding greenery as natural part of architecture. This requires more awareness and knowledge about climate change and the benefits of nature-based solutions on quality of life and value of real estates in the long run.

The paper summarizes the experience of an interdisciplinary cooperation in the research project GreenDeal4Real and addresses all three aspects in detail. Analyses of the planning framework in Vienna and impacts of greening measures on the microclimate are described and general conclusions for more green in real estate development are drawn.

Keywords: 081

2 INTRODUCTION

The latest IPCC report confirms that worldwide cities are already affected by climate change with negative effects on human health, livelihood and key infrastructure (IPCC 2023). Thus, in order to sustain the liveability in cities, adaptation measures to climate change must be implemented today to proactively counteract negative developments in the future as climate change and its effects on cities in particular is expected to continue through the 21st century (Goodess 2012, Christidis et al. 2015, Qiu and Yan 2020).

Main issues in cities are the above-average warming known as Urban Heat Island (UHI) effect and the increase of heavy precipitation and its resulting runoff intensity (IPCC 2023). Causes are to be found in the

typcial urban structures with sealed surfaces and construction materials with different heat storage capacities than natural ones (Sharifi and Lehmann 2014, Singh et al. 2020), absorbing solar radiation during the day and releasing the energy surplus in the form of sensible heat flux and longwave radiation during the night. The UHI effect is further intensified by anthropogenic heat emissions, which are among others produced by traffic, households, industry and increasingly through air conditioning systems (Sham and Memon 2012).

Climate scenarios and projections show that the climatic situation in cities will even worsen in the future. Brown (2020) researched the present and future heatwave hazard for cities worldwide and found that temperatures are expected to rise during heatwaves by between 3.4 to 6.6 ∘C until 2099 (basis 2006). Although it is proved that more intense and frequent heatwaves result in excess deaths, this is still an "invisible risk" that is not given sufficient attention in policy and planning (Brimicombe et al. 2021).

Thus, it is high time that cities seriously address their vulnerability to climate change and start to transform towards climate resilient urban structures. More and more cities are becoming aware of the impending effects of rising temperature and extreme weather events and strategically plan and start to adapt the urban environment to the upcoming changing framework conditions. Green and blue infrastructure, i.e., a network of green spaces and water permeable surfaces as well as individual plants, green facades or green roofs, and corresponding rainwater management play an essential role for the urban microclimate and represent a possibility to significantly reduce the extent of the UHI effect (MA22 2015, Roehr and Laurenz 2008, Kleerekoper et al. 2012; Norton et al. 2015). Integrating nature-based solutions into urban structures helps to mitigate negative climate change impacts such as heat stress and flooding through natural cooling (evapotranspiration) and water absorption, storage and infiltration (Carter 2018; Everett et al. 2018; Li et al. 2019). Nevertheless, it is not even a matter of course for new buildings that optimal and most effective greening is implemented.

Exactly this issue is addressed in the research project "GreenDeal4Real - Improving the thermal comfort in mixed-use areas through cost-effective green infrastructure", which is funded by the BMK (Austrian Ministry for Climate Action, Environment, Energy, Mobility, Innovation and Technology) and implemented under the "City of Tomorrow" program. The project researches how positive effects of greening measures can be assessed, quantified, optimised and integrated into planning and construction processes. An actual real estate development project in the 22nd district of Vienna is taken as case study and demonstration site for testing the optimal integration of green measures into the design and construction process. The research project contributes to the construction process in an early planning stage when it is still possible to adapt static and design and to integrate greening into archtitecture. A systemic, integrative approach is pursued, which is also reflected in the composition of the interdisciplinary project consortium consisting of the AIT Austrian Institute of Technology GmbH, 6B47 Real Estate Investors AG, the landscape planning companies grünplan gmbh and Lindle+Bukor, the City of Vienna represented by the MA 18 - Stadtentwicklung und Stadtplanung, the greening company 90deGreen GmbH and the green innovation laboratory GRÜNSTATTGRAU. The exchange in the interdisplinary team allowed mutual learning and revealed regulatory barriers at the interface of private and public sectors that were discussed with city administration. Findings from the analysis for an efficient implementation of urban greening technologies, the microclimate simulations and the planning lab are presented in the following.

3   BENEFITS OF MICROCLIMATE SIMULATIONS IN THE EARLY PLANNING STAGE

In the last decades, microclimate simulation models became an important tool for the assessment of microclimatic performance of urban planning and building projects. While some models support the analysis of selected parameters (e.g. solar radiation, wind comfort), others aim at a holistic representation of physical processes in complex urban environments. In the project "GreenDeal4Real", two different microclimate simulation models were applied. While the Ladybug tool suite (module of the Grasshopper Plug-in of Rhino 3D) was used for evaluating radiation parameters (shading functions, mean radiant temperature in front of facades), ENVI-met as an example for a holistic microclimate model served to quantify the effects of greenery in an early planning stage of the real estate development project. ENVI-met is a three-dimensional model, locating buildings, vegetation and surfaces on a rectangular grid structure and simulating physical processes and interactions, such as radiation, wind dynamics, atmosphere-surface interactions, evapotranspiration and others. It is thus suitable to demonstrate the effects of greenery within this project.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Tanja Tötzer, Martin Schneider, Bosko Bozic, Raoul Bukor, Doris Enzersdorfer, Susanne Formanek, Valentin Gebhardt, Martin Jung, Andreas Lichtblau, Werner Sellinger

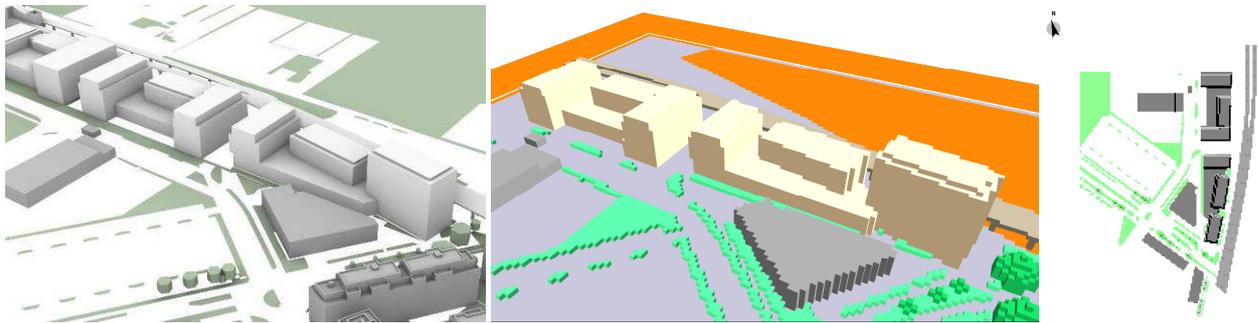
While the entire real estate development project is divided into seven construction sites, two of them have been used in the microclimate studies. The 3D model of the buildings and vegetation were designed in Rhino 3D based on the current planning status and directly exported to ENVI-met to guarantee a consistent simulation process in both models. For meteorological boundary conditions, June 10th 2010 was selected as a representative hot summer day from a typical meteorological year (data source: EnergyPlus Weather File).


Figure 1: left: Model domain designed in Rhino 3D, middle: Model domain imported to ENVI-Met, right Orientation of domain

Based on the simulation results of a draft version without greenery, the interdisciplinary project team discussed options for façade greening, green roofs (including water management and retention) as well as the economic viability and developed realistic versions of applicable NbS for the site. The close cooperation between real estate developers, landscape architects, greening experts, microclimate experts and local authorities in the project provided the possibility to highlight important aspects from different perspectives in an early planning stage, allowing for consideration of statics, architecture, rainwater management and for relevant adaptations. The consideration of microclimate simulations in an early planning stage proved to be essential for facilitating fruitful discussions about greening measures and adaptations to conventional building design. Such changes towards microclimatic effective NbS have to be taken in an early planning stage when costs of design changes are still low and the ability to impact design is high.

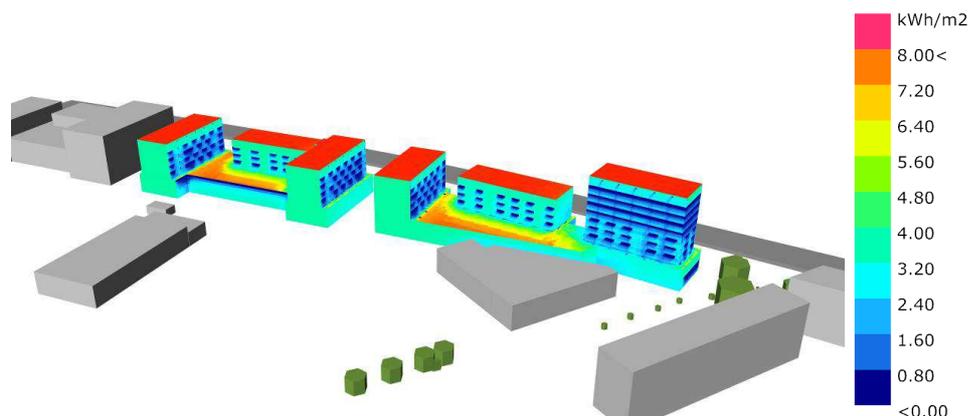
First conducted simulation results focused on the analysis of solar radiation with the Ladybug tool suite. It revealed the shading function of balconies on Southern oriented façades (Figure 2) and suggested to focus façade greening options on west- or east-facing façades. Besides, the roofs were identified as most exposed areas to solar radiation. To provide the necessary thermal comfort and make use of the roof areas at one high-rise and both low-rise parts of the buildings as gardens and recreational zones, NbS were required fulfilling the necessary shading function. Following this recommendation, intensive roof greening including trees and pergolas was included in subsequent simulations with ENVI-met. On the remaining roofs, extensive roof greening was applied (Figure 3).


Figure 2: Solar radiation analysis of June 10th, 2010.

With regards to façade greening, various types have been discussed in focus groups:

- Wall-mounted green façade with substrate layer (full and partial coverage)
- Ground-based green façade without substrate layer (full and partial coverage)
- Trough-based façade greening without substrate layer (full and partial coverage)

- Climber systems in front of balconies

In accordance with experts for façade greening, economic viability and fire protection considerations, partially covered wall-mounted and trough-based façade greenings were selected for further microclimate simulations. Sensitivity results focusing on the effects of façade greening on Western and Eastern oriented walls, showed the expected results of strongest effects for Eastern oriented facades during the morning hours and Western oriented facades during the afternoon and evening hours. Due to increased microclimatic effects during the times where cooling effects are desired by residents of the building (afternoon and evening hours), façade greening was focused on west-facing façade areas between balconies on the high-rise buildings in the middle of each construction site. For simulation purpose, each selected type of façade greening (wall-mounted, trough-based) was applied to one building (Figure 3).

To evaluate the effects of both types of façade greening on the outside and inside wall surface temperature, one grid point with applied greening was selected at each building and compared to the draft version without greening (Figure 4). The trough-based version only led to a reduction of the outside surface temperature during sun exposition of max. 2.2 °C. After sunset the surface temperature adjusted to the non-green draft example. However, the effect on the inside surface temperature remained throughout the day without any significant peaks, but an increasing difference to the non-green version during the simulation period. As the same is true for the wall-mounted type, it can be concluded, that the effect of façade greening on inside surface temperature and consequently inside air temperature (not shown) increases during heat wave periods. In contrast to the trough-based façade greening, the wall-mounted type led to reductions of outside façade temperature during the entire day with maximum differences during sun exposition of 17 °C. The larger differences can be explained by the substrate layer, acting as additional insulation layer in the wall construction. The experiments were calculated with a leaf area index (LAI) of 1 (wall-mounted) and 1.5 (trough-based) as they are the default values in ENVI-met. Further sensitivity experiments with higher LAI values suggested even stronger temperature reducing effects for the trough-based type, but similar results for the wall-mounted type of façade greening.

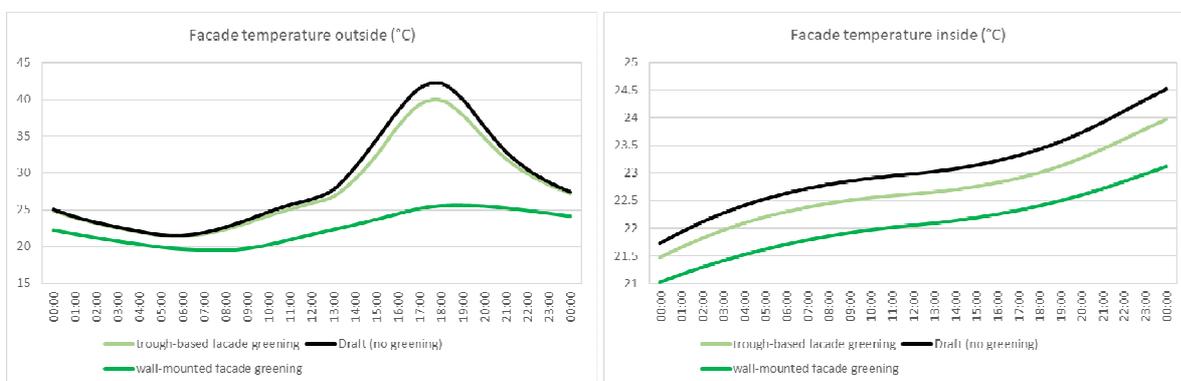
Figure 3: left: ENVI-Met model domain with applied NbS: extensive and intensive roof greening, wall-mounted (left building) and trough-based (right building) façade greening, trees in front of buildings; middle: trough-based greening implemented in ENVI-Met; right: wall-mounted greening implemented in ENVI-Met.


Figure 4: Comparison of façade temperature outside (left) and inside (right) with/without façade greening during one day

Evaluation results of different types, locations and intensities of NbS in the vicinity and directly at the buildings provided profound and decision-relevant information to the real estate developer of the building

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

project. Especially in early planning stages, where significant changes can be realised at low cost, compared to later planning stages, microclimate simulations provided an important source of information.

4 RELEVANCE OF THE PLANNING FRAMEWORK

Although microclimate simulations allow for assessing the effectiveness of different greening scenarios and for identifying optimal solutions from a microclimatic point of view, the actual implementation depends on additional framework conditions such as the planning framework. This is also the reason why a standard has been published in Austria in 2021, ÖNORM L1136, which includes the consideration of site conditions. Furthermore, the latest draft of the revision of the Energy performance of buildings directive (EPBD) already integrates green infrastructure. Member States must ensure that "new buildings…adapt to climate change through, inter alia, green infrastructure…" (Article 7 Paragraph 4). However, due to progressing climate change, further adaptations in the planning framework are needed to foster a transformation of cities towards more climate resilience. However, many existing regulations still act as a barrier for an easy and efficient implementation of nature-based solutions. For identifying the best greening solutions for the selected building project, the regulatory planning framework in the City of Vienna was evaluated. In a "planning lab" the project team exchanged with relevant stakeholders from city administration such as urban development, planning neighbourhoods and building inspection on potentials of guidelines, regulations, and urban development contracts.

In the City of Vienna, several guidelines for green roofs and green façades exist and since the amendment of the building code 2018 it is mandatory for new buildings that 20% of the façade oriented towards the street must be greened. However, the stakeholder interviews conducted during the project GreenDeal4Real showed that there are still several challenges in practice and potentials for further improving the planning framework to promote greenery.

In Vienna, the general definition of a mandatory 20% street-side façade greening in new buildings contributes to the promotion of green infrastructure and represents an essential step for greening in the city. However, in the case of street-facing façades that are exposed to the north, it is to be expected that the growth of plants will be impeded, and the microclimatic effect will be rather low. As a further development of the regulation, compliance with a green and open space factor in the construction of new buildings, which is planned to be implemented in the City of Salzburg (Stadt-Salzburg.at 2021) and combines built-up area, building volume, façade and roof greening, would be conceivable. It offers a system of parameters with a clear target but which can be achieved with several "levers" and takes the whole plot into account, which is more relevant for the microclimate than the single building, thus increases the positive effect on the microclimate and gives more flexibility to the design and planning processes.

Even though correct maintenance measures are essential for a well-functioning growth of green roofs and façades, controlling the compliance with required maintenance measures is a complex issue. At present, the current legal situation only requires a civil engineer to confirm the (correct) installation of greening measures. Although in the Austrian standard L1136 a care concept is integrated, a regular listing of maintenance checks in the building logbook could be a way to guarantee a continuous evaluation of the state of greening measures. Furthermore, the controlling bodies need relevant professional knowledge in landscape planning and greening as well as additional human resources.

Climate analyses are useful to assess the effects of building structure and greening measures on the microclimate. In the context of climate change and the resulting consequences for cities, it becomes more and more relevant to gain a deeper understanding of the effects of building projects on the microclimate. Conducting microclimate analyses can help to plan building projects in such a way that the climate resilience of new buildings is as high as possible. Particularly for large construction projects that not only affect the local microclimate but also the neighbouring urban areas and perhaps even wind circulation patterns for the entire city, mandatory microclimate analysis should be taken into consideration to identify the need for optimisation regarding building orientation and height and for greenery to maintain a microclimate at bearable level.

A rather specific but important topic is the fire protection. In the case of the GreenDeal4Real project, several challenges arose in order to comply with the newly issued requirements for fire protection of the City of Vienna. The building is located in a zone for mixed industrial-residential use and apartments are situated

above the ground storeys reserved for light industry and commerce. Thus, they fall into a higher building class which implied restrictions, especially on cost-efficient greening measures.

After several discussions in various committees with the City of Vienna, other consultants and representatives for the OIB 2 guideline (OIB = Austrian Institute of Construction Engineering), it became clear that a better consensus between greening and fire protection technology had to be found. The building inspection MA 39 from Vienna therefore carried out further fire tests with plants (meanwhile more than 90) and was able to revise the regulations. Since May 2023, a new requirement has been published and some of the examples mentioned in GreenDeal4Real have been included.

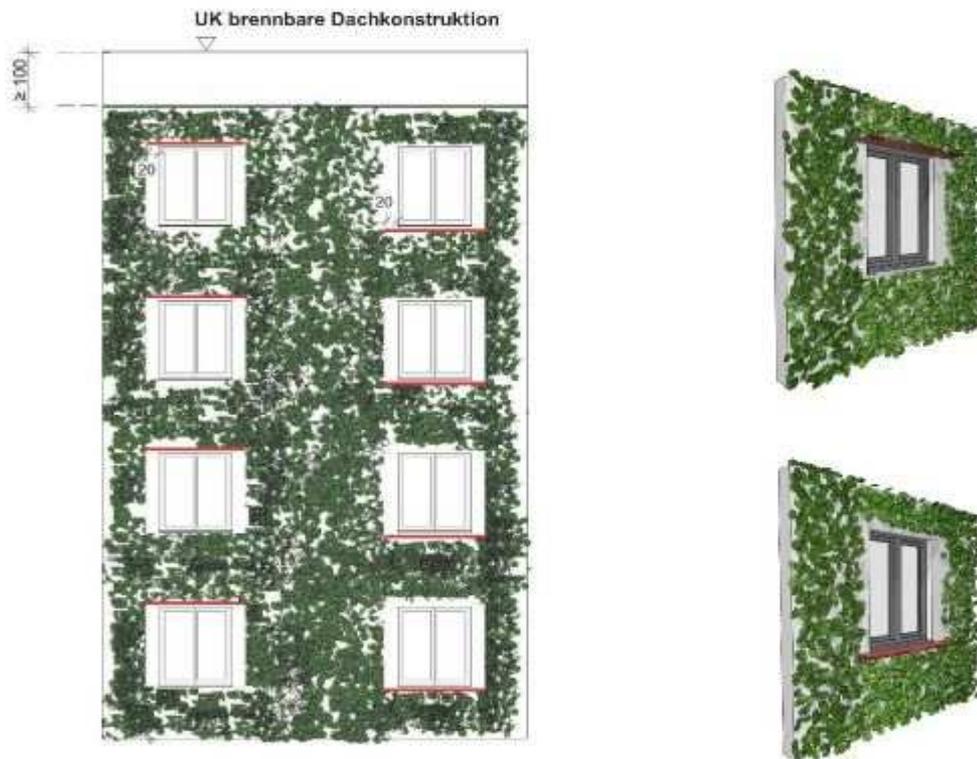
Now expanded greening options are given (see Figure 5), so that cost-effective ground-based systems can be used over several storeys for greening purposes. Through intensive exchanges with stakeholders misunderstandings and ambiguities could be eliminated and a compromise between safety and climate-resilient planning could be reached.


Figure 5: Expanded greening options in the new requirements for fire protection since February 2023; Source: Eder 2023, p.8 Chapter 2.2.6.

5 DISCUSSIONS AND LESSONS LEARNED

Many studies already exist proving the positive effects of nature-based solutions for densely built cities. However, the knowledge transfer to real estate companies is still insufficient as they require precise and site-specific information showing effectiveness of greenery on microclimate, building envelope and indoor temperature. Awareness of the interlinked parameters between built-up area and greening is often lacking, and additionally to the focus on the building itself, the effects on the neighbourhood I increasingly being taken into account. Thus, in the last years, microclimate analyses became an important tool for the assessment of different scenarios of urban planning projects on the local site and its neighbourhood. Even though the broader application of microclimate analysis is important and necessary, the simulation studies conducted in GreenDeal4Real have shown that there are still pitfalls and challenges which have to be considered.

Microclimate analyses are recommended to take place in an early planning stage and proved to be a good means to quantify the microclimatic effects of greening, raise awareness for the positive effects of vegetation for indoor, surface and outdoor temperature and foster a discussion among different disciplines of landscape

Tanja Tötzer, Martin Schneider, Bosko Bozic, Raoul Bukor, Doris Enzersdorfer, Susanne Formanek, Valentin Gebhardt, Martin Jung, Andreas Lichtblau, Werner Sellinger

planners, architects, greening experts, city administratives and microclimate experts. Roof greening and wall-mounted green façade with substrate layer were identified as most effective greening measures regarding cooling effects on the building surface. As such greening measures are not yet a natural part of architecture and can not simply be added to the existing planning design but have to be incorporated into the architecture and static of a building, it is crucial to consider them in an early planning stage. Only then, the potential for impacting the building design ist still high and the costs of design changes are reasonably low.

As the microclimate results from a complex interrelation of multiple parameters such as building height and structure, type of vegetation, water saturation of the soil, surface materials, etc., simplified averaged results are often misleading. Simple spatial and temporal averaging involves the risk to neglect important results and lose meaningful outcome of a study or project. At best, microclimate analyses can be an appropriate approach to apply a systemic view and reveal interrelations between buildings, vegetation, water and energy as well as bring together experts from multiple disciplines (urban, planning, meteorology, physics, statistics). Expertise from different fields is needed to holistically approach the improvement of the local microclimate and to allow suitable and feasible additional climate adaption measures to be recommended, added, and finally realized.

While this process led to several positive developments and best practice examples, the impact of a project on the microclimate of the surrounding areas or even the entire city is still neglected. Climate analyses are useful to assess the effects of building structure and greening measures on the microclimate. In the context of climate change and the resulting consequences for cities, it becomes more and more relevant to learn more about the effects of building projects on the urban climate. Conducting microclimate analyses can help to plan building projects in such a way that the climate resilience of new buildings is as high as possible. Particularly for large construction projects that not only affect the microclimate on-site but also the neighbouring urban areas and perhaps even wind circulation patterns for the entire city, mandatory microclimate analysis would be conceivable to identify the need for optimisation regarding building orientation, height and greenery to maintain a microclimate at bearable level. Depending on the size, location, extension, and execution of the project, it can negatively or positively affect its surroundings. Even positively assessed microclimate simulations on-site can have a negative effect on the urban climate of the surroundings, especially if formerly green areas are sealed, existing buildings are extended in height, cold-air production areas are sealed, or cold-air corridors are blocked. In this case, it is recommended to investigate and quantify the potential impact of construction projects on its surroundings. Further research is needed for identifying a suitable set of criteria that allows cities to decide whether an extended microclimate analysis is required.

Beside a sound knowledge base on the positive effects of green measures on the microclimate, a greenery-friendly planning framework is essential for promoting greenery in building projects. Real estate development is a highly regulated market based on local planning standards and procedures. From a business perspective it involves high initial investments with the potential of reasonable monetary returns. As nature-based solutions in their different forms are not per se cost-neutral, they need to be enhanced and demanded by authorities and regulations to come into effect on a large scale.

When it comes to nature-based solutions in real estate development, not only the initial construction, but also maintenance responsibility, costs and control measures need to be considered. While real estate developers may be held responsible for the proper implementation of greening measures, vegetation can only unfold its full positive microclimatic effects if properly cared for and maintained. Specifications on care and maintenance in the construction instructions ("Baubuch") or even a subsequent assessment of state and growth of plants could help to improve the long-term quality and actual effectiveness of greening measures.

Basically, taking into account the whole life-cycle of a building and the operating costs for heating and cooling as well as the increase in value, would be a significant motivation for real estate developers to implement more green. Our studies showed (see Chapter 3) that wall-mounted green façades lead to the biggest reduction on the wall surface temperature outside as well as inside. This is particularly true for glass façades. Experiments proved that double-glazed facades combined with modular vertical greening significantly reduce indoor temperature and energy consumption in summer (Bao et al. 2022).

Besides life-cycle and maintenance, also vegetation types are a relevant issue for climate resilient greening. With respect to predicted changes in temperature and water availability, plants with high cooling

performance nowadays may not survive future climate conditions without extensive maintenance and irrigation. Nevertheless, with regards to current strategies of biodiversity enhancement, it is also important not to limit greening to a small number of "high-performance plants". In contrast, replacement planting in case of cutting down trees or even deforestation for construction purpose needs strict and quantitative regulations. Large, long grown and climatically effective trees are often required to be compensated. However, small and young replacement trees need decades to reach the performance of the cut down tree. This vegetation performance gap is often neglected in current regulatory frameworks by only requiring a 1:1 replacement. To close this gap, an equivalent number of young trees with the same estimated performance could be enforced as replacement planting. This would not only account for the preservation of the current status, but also for an improvement in the future.

A greenery-friendly planning framework needs to be established to push nature-based solutions on the one side and still provide a flexible framework for real estate developers and architects to develop efficient and effective solutions embedded into the architectural design. Although strict specifications such as mandatory 20% façade greening are needed for monitoring and for implementation to take place, flexibility in the specific design or even additional microclimatic analysis help to find the most effective individual solution. As climate change is proceeding and hence the Urban Heat Island effect in cities, the cooling effect of greenery can be seen as necessary social measure for maintaining the quality of life. That is why greening is also being discussed to be included in urban development contracts. However, the legal basis asks for justifying the requirements in the contract by urban development reasons. Urban planning contracts have so far not been used as a control instrument for promoting greening. If uniform criteria existed that clearly give reasons for greening requirements under specific project conditions, this could change in the future and allow for an implementation in urban development contracts.

Furthermore, an integrated mindset in architecture and real estate development is needed. It is still not self-evident to include greenery and nature-based solutions in design, planning and construction, although there exists the L1131 standard for green roofs since more than 10 years and the ÖNORM L1136 for green walls since 2021. With regard to a transformation towards climate resilient urban patterns, building optimization has to include greening as well. Thus, it needs a new approach to perceive greenery as natural part of architecture. This requires more awareness and knowledge about climate change and the benefits of nature-based solutions on quality of life and value of real estates in the long run and under consideration of a changing climate. Applying microclimate simulations in an early planning stage helps investors, real estate developers and architects to quantify the effects of greenery on the surface temperature outdoor and indoor, as well as on the thermal comfort and air temperature. These aspects are becoming more and more important in the light of climate change and relevant regulations by the European Union such as its EU taxonomy, where climate adaptation is one out of 6 environmental objectives, which have to be met for green, sustainable investments. Consequently, nature-based solutions as effective measures for balancing the Urban Heat Island effect and the increase of heavy precipitation will find their way into architecture and real estate development.

6 CONCLUSION

The project GreenDeal4Real addressed the research question how greenery can be promoted in real estate development for realising climate resilient urban structures. An interdisciplinary team analysed the planning framework in Vienna and described the impacts of greening measures on the microclimate.

Findings from the research project show that although strategies, standards, guidelines and regulations are already in place to promote greenery in real estate development, there is still room for improvement regarding awareness and knowledge about the added value of green, the microclimatic effects, the benefits for outdoor and indoor temperature and for preserving the long-term quality of the property. The interdisciplinary cooperation between researchers, real estate developers, landscape planners, green planners and city authorities led to joint learning and a common understanding of microclimatic effects of greening. Furthermore, it was key that the research project contributed to planning at an early stage, so that adaptations in design, static and materials were still possible.

The research project made it possible to look more closely at microclimate simulations, carry out sensitivity analyses and thus created trust in the quality and reliability of the modelling results. At the same time, the effect of different greening measures for the outdoor and indoor space could be examined and proven based

on the microclimate simulations. This allowed to identify the most effective greening measures considering multiple parameters such as building orientation, sun exposure, material, architectural design, type of greening system, leaf area index and fire protection regulations. The cooling effects calculated by the microclimate simulations and the proven effectiveness of green convinced the property developer to plan further measures in addition to the subsidised façade greening. Thus, research projects like GreenDeal4Real can give important impulses for changing the mindset in the building industry and prepare real estate developers to comply with new regulations like the EU taxonomy.

The planning framework appeared to be another important driver for promoting greenery. The parallel planning laboratory allowed for an intensive exchange with stakeholders from the city administration. This also turned out to be very fruitful, as it made it possible to identify opportunities and hurdles in the planning framework. For example, severe constraints imposed by the fire safety regulation were uncovered and discussed constructively. This provided the impetus for further fire experiments to be conducted and the restrictions in the regulation to be withdrawn. The project helped to find a compromise between safety and climate-resilient planning and the new fire protection requirements will foster greening also in mixed industrial-residential areas.

In sum, the project underlines the relevance of interdisciplinary work. The exchange of knowledge between research, real estate developer and city administration is key for urban transformation directing to optimized climate protection and adaptation. Understanding both, the respective point of views and hurdles of each stakeholder is the starting point for essentials dialogues leading to the inevitable transformation.

1 ABSTRACT

Studying the impact of built urban environments on pedestrians' walking experience can improve our understanding of the environmental factors that influence perceived walkability. This can contribute to the design of pleasant urban environments that promote better health and well-being for city residents. However, evidence-based research on perceptions of walkability is still limited. Research has demonstrated that functional near-infrared spectroscopy (fNIRS), an optical brain imaging technique, can measure cortical neural activation. Some studies have employed fNIRS to investigate brain activation by contrasting built and natural environments; however, little research has used fNIRS to investigate the effect of built urban environments on brain activity. Therefore, the aim of this study was to apply fNIRS to measure the effect of different built urban environments on prefrontal cortex activation. The present article presents preliminary results from a pilot study involving five participants (one female, age 31.4 ± 5.1 years). While we measured their prefrontal cortex (PFC) oxyhemoglobin (HbO) and deoxyhemoglobin (HbR), participants watched nine 20-second videos of urban environments from a pedestrian's perspective in a laboratory setting. Viewing pleasant walking environments led to a significant decrease in HbO concentrations in the right and central regions of the PFC, indicating physiological relaxation. This study demonstrates the feasibility of using fNIRS to study the built environment and opens up promising opportunities to explore the relationship between urban environments and pedestrians' experiences.

Keywords: functional near-infrared spectroscopy , built environments, walkability, well-being, neuroscience

2 INTRODUCTION

Walking is considered a sustainable transport mode that benefits society in terms of supporting public health (Hanson & Jones, 2015), social well-being, and environmental sustainability (Silvennoinen et al., 2022).The beneficial effects of walking on physical and mental health have been extensively researched (Hanson & Jones, 2015), including in relation to public transport-related walking (Besser & Dannenberg, 2005; Saelens et al., 2014).As a moderate exercise, walking can help prevent chronic illnesses (McKinney et al., 2016)and promote mental health(Kelly et al., 2018). Walking in urban environments can be a stressful experience for pedestrians, with prolonged stress being linked to long-term mental health and well-being(Lederbogen et al., 2011). Although walking has a well-established positive impact, many streets, neighbourhoods and cities are not designed for pedestrians and do not provide a walkable environment that allows or encourages people to walk.

2.1 Walking and the built urban environment

The walking friendliness of a built environment is referred to as walkability (Frank et al. 2006).Walkability has been increasingly important in research andas a strategic goal in urban design and transportation practice(Forsyth, 2015). Residential density, street connectivity, and land use mix (also known as the 3 or 5 'Ds') are mesoscale environmental variables that have been found to support walking. Research into environmental characteristics on the micro-scale, such as sidewalk quality, street furniture, and the presence of trees and greenery, is relatively recent (De Vos et al., 2022; Otsuka et al., 2021; Silvennoinen et al., 2022; Talen et al., 2022).Of the four commonly identified walkability needs (convenience, safety, comfort, and attractiveness), most research has focused on convenience and safety, whereas comfort and attractiveness have received less attention (Nakamura, 2021; Silvennoinen et al., 2022).Thus, the factors of the built

environment that contribute to the walking experience are not yet well understood or quantified(De Vos et al., 2022; Silvennoinen et al., 2022).

Few studies have investigated the determinants and effects of the built urban environment on walkability, i.e. how pedestrians perceive and experience an environment (De Vos et al., 2022; Silvennoinen et al., 2022). For example, the character of the facades along the pavement is relevant to walking (Ameli et al., 2015; Ewing et al., 2016; Oreskovic et al., 2014; Park et al., 2016; Silvennoinen et al., 2022), the presence of windows on ground level(Ameli et al., 2015; Oreskovic et al., 2014), together with the design of the streetscape and street furniture (Ewing et al., 2016; Shi et al., 2020) and the available shops, services, and amenities (Ewing et al., 2016). Further, the dimensions of street blocks (Singh, 2016), the uniformity of the building pane, the presence of street focal points (Oreskovic et al., 2014), traffic volumes, speed limits, and the density of street and driveway intersections (Petritsch et al., 2006; Schneider, 2015)affect walking. Root et al., (2017)find the overall aesthetics of the environment (i.e. perceived presence of trees, interesting things to look at, attractive sights and buildings) to be associated with walkability.Urban greenery shows a largely positive effect on walking (Ameli et al., 2015; Sarkar et al., 2015; Tsai et al., 2019); however, the impact of greenery on the amount of walking in a particular street remains uncertain(Shuvo et al., 2021).

Nevertheless, there is still a lack of clarity about how walking environments are perceived and which features influence the walking experience. Walkability frameworks often fail to incorporate perceptions of comfort and attractiveness, resulting in a deprioritisation of the micro-level of walkability (Nakamura, 2021; Silvennoinen et al., 2022). Personal reactions, experiences, and interpretations play a crucial role in perceiving environments, making it challenging to assess them objectively (Dörrzapf et al., 2019). A growing number of researchers have proposed frameworks to combine quantitative objective data on the built environment with subjective preferences and perceptions (Dörrzapf et al., 2019; Talen et al., 2022). One approach involves using wearable sensors and other technologies to capture human perceptions and emotions, often through bio-physiological parameters such as skin temperature, heart rate variability (Dörrzapf et al., 2019)or brain activity (Chen et al., 2018; Neale et al., 2019). To this end, the aim of this study is to test a novel methodology for measuring brain activation to investigate the relationship between the built environment and walking experiences. In doing so, we demonstrate the feasibility and potential applications of functional near-infrared spectroscopy (fNIRS) for researching built environments.

2.2 Functional near-infrared spectroscopy (fNIRS)inurban research

Alongside other brain monitoring technologies, such as electroencephalography (EEG) and functional magnetic resonance imaging (fMRI), functional near-infrared spectroscopy (fNIRS) is used to measure brain activation. So far, EEG is the most commonly used method in urban research (Ancora et al., 2022). Functional near-infrared spectroscopy (fNIRS) is a non-invasive technique that uses near-infrared light to measure variations in the oxygen levels in the brain. Light absorption properties enable the assessment of changes in the concentration of oxyhaemoglobin (HbO) and deoxyhaemoglobin (HbR) in the superficial layers of the brain, revealing changes in neural activation through neurovascular coupling (Ferrari & Quaresima, 2012). The oxygen concentration provides information about the active areas of the brain during various cognitive tasks or experiences.fNIRSis a promising methodology for research in urban planning, especially for studying the effects of built environments. It is advantageous because it is safe, non-invasive, portable, and allows for research to be carried out in natural settings. Research in neuroscience and human brain imaging has confirmed fNIRS as a valid method for studying sensory processes, emotional responses, cognitive load and perception (Ferrari & Quaresima, 2012; Hoshi et al., 2011; Yanagisawa & Tsunashima, 2015; Yu et al., 2017).

In a recent study,Ancora et al., (2022) comprehensively reviewed all available research investigating the effect of urban and/or natural environments on brain activity using brain imaging technologies (fMRI, fNIRS, EEG, MEG, PET). A structured literature search identified ten fNIRS studies (see Ancora et al., (2022) for details), of which eight were conducted indoors and two outdoors. The research overview shows that all fNIRS studies so far have focused on the measurement of differences in the relaxation effects of nature (cf. Biophilia, Attention-Restoration Theory) (Horiuchi et al., 2014; Zhang et al., 2020) or the effects of nature in comparison to the more stressful urban environment(Joung et al., 2015; J. Lee, 2017; Ochiai et al., 2020; Song et al., 2018, 2020; Yamashita et al., 2021; Yu et al., 2017). The study design, therefore, often focuses on using stressful and unpleasant urban environments as experiment stimuli. For example,

Yamashita et al., (2021) investigated mood enhancement while participants viewed images of built and urban environments. The images showed a scene with monotonous and unattractive buildings compared to the natural stimuli.Similarly, Song et al., (2018) investigated the differences in physiological effects of forest and urban environments, with the urban scene represented by rather stimulating and stressful urban pictures. Yu et al., (2017) measured the PFC activation while watching urban and natural video scenes, with the urban stimuli recorded in typical Singapore environments. Joung et al., (2015) and Song et al., (2020)conducted in-situ studies, in which the participants were standing and observingurban and forest environments. Two studies focused on the sound-induced effects of forest and urban sounds on the PFC and autonomic nervous system activity. The natural sounds were a recording of a stream, and the urban sounds were traffic noise (Jo et al., 2019; Ochiai et al., 2020).However, the review paper outlines opportunities for future research, for example, in studying environmental complexity, aesthetics, and perception (Ancora et al., 2022).

To ensure awareness of more recent research on fNIRS since the review conducted by Ancora et al. (2022), we have carried out a structured literature search based on the search procedure and terms developed by Ancora et al. (2022). In this context, we repeated their literature search focusing only on fNIRS studies (see the paper for procedure and keywords). The search was performed in May 2023, dating back to May 2022, in PubMed, Scopus, WoS, and ProQuest. As a result, only one relevant article was identified, which examined the effects of walking in urban environments on women's health (Shaoming et al., 2023). The study found the transition between different urban environments to result in alterations of activity in the PFC. Further, spatial openness and mixed traffic flow factors were relevant to participants' perceptions of urban spaces(Shaoming et al., 2023).

3 METHOD

We designed a pilot experiment to investigate the effect of different walking environments on participants' brain activation in the prefrontal cortex using fNIRS. This pilot study aimed at testing the stimuli and selecting fewer stimuli for the full experiment. Data on the participants' subjective perceptions of urban environments and their perceived time was collected. This paper focuses only on the pilot fNIRS data.

3.1 Experiment procedure

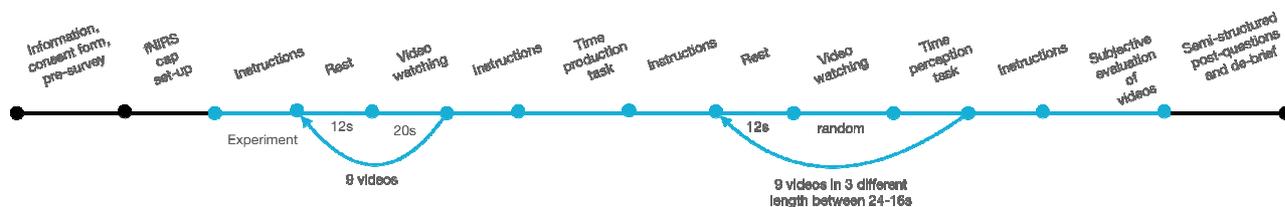
Upon arrival at the experimental room, participants were informed of the experimentalprocedure and asked to sign the consent form and complete a brief survey. Participants were then seated at a desk facing a screen and mouse, and the fNIRS cap was placed on their heads as per manufacturers' best practice. After the signal check, participants were instructed to sit still during the experiment and follow the instructions on the screen. PsychopPy software (Peirce et al., 2019) was used to present the stimuli and synchronize with the fNIRS and subjectively reported data. The experimental procedure of the entire pilot experiment is displayed in Figure 1.Notably, this study focuses only on the first part of the experiment (video watching). Following the initial instructions, participants watched nine 20-second videos in a randomized order. In between each video, there was a 12-second break. During the 12-second resting state, the participant views a grey screen with a centredwhite cross. The following procedures, which include time perception tasks and subjective evaluation of videos using Likert scales, were tested for the full experiment. The experiment was concluded with a subjective rating, after which the participants were disconnected from the sensors and debriefed. The experiment had a duration of around 30 minutes.


Figure 1: Experimental procedure of the pilot experiment.
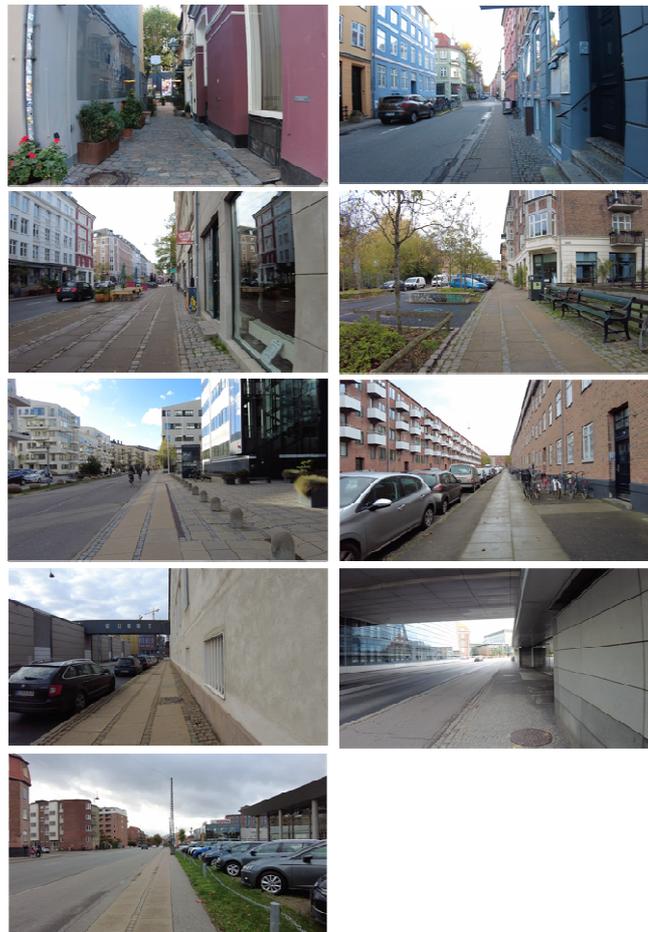

Figure 2: Screenshots of 20s videos recorded in different urban environments in Copenhagen (video 1 upper lect to video 9 bottom left)

3.2 Stimuli

Nine videos of 20 seconds each were used as experimental stimuli. The recordings were captured in 4k resolution using a gimbaled 3-axis stabilised camera (DJI Pocket 2) in the city of Copenhagen in November 2022. All videos underwent editing and stabilisation using Adobe Premiere Pro 2023. The video recordings were taken from a pedestrian's viewpoint and at a typical walking speed (4-5 km/h). For consistency between the videos, they were recorded under similar weather conditions (cloudy to sunny) and without direct encounters with pedestrians. Screenshots of the videos are presented in Figure 2. Considering this is an exploratory pilot study, a systematic overview of the video characteristics will not be provided.However, there are some differences to be noted. The character of the urban environments shown in the videos differs (to varying degrees) in terms of:

- Location (inner city, residential neighbourhood, industrial area)
- Functions (Mixed-use, single-use functions, ground-level use)
- Infrastructure (type of street, speed limit, traffic restrictions, parking, sidewalk, bicycle infrastructure)
- Moving and parked traffic (car and bicycle traffic, pedestrians)
- Urban design and spatial elements (seating, art, spatial elements, light elements, signs)
- Buildings (modern/historical, number, levels, view/lines of vision)
- Facades (openness/transparency, colours, materials, structures, windows, doors)
- Greening (planters, trees, façade greening, plant beds)

3.3 Participants

Five healthy participants (mean age 31.4 years; SD=5.1; 1 female) were recruited for the pilot study from the Faculty of Architecture and Design. Exclusion criteria included high caffeine consumption at the time of the experiment, awareness of atypical neurological conditions (such as autism or ADHD), or usage of medication affecting the nervous system. One participant was left-handed, and the others were right-handed. All participants gave their consent to take part in the study. The study was ethically approved according to local regulations.

3.4 fNIRS data collection and analysis

3.4.1   Data collection

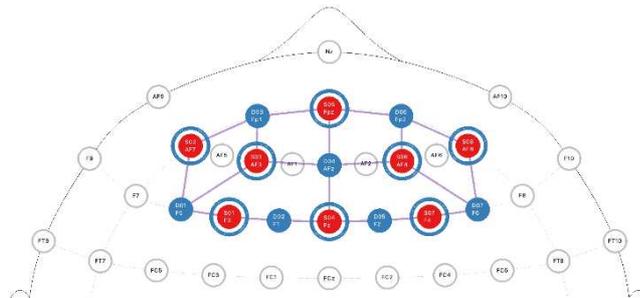
Brain activity was measured with acontinuous-wave system, theNIRSport 2 (NIRx Medical Technologies, Berlin, Germany),that had an 8x8 configuration and short channels. Data from two wavelengths (760 and 850 nm) was sampled at 10.17 Hz. Optodes were arranged in a montage placed on the PFC following the international10-20 system for EEG electrode placement (Oostenveld & Praamstra, 2001); seeFigure 3. The PFC, located in the frontal lobe of the human brain, is associated with higher cognitive processes such as problem-solving and decision-making (Song et al., 2020). Further,the orbitofrontal cortex, located in the PFC,has been identified to play an important role in emotional processes (Rolls & Grabenhorst, 2008).At this early stage of research, it remains unclear which constructs are suitable for studying urban environments. Further research is required to explore and identify the relevant brain regions and constructs for this purpose.


Figure 3: fNIRS montage with 8x8 configuration and short channels (NIRx Medical Technologies)

3.4.2   Data analysis

The fNIRS data wereanalysedwith the NIRS Brain AnalyzIR Toolbox(Santosa et al., 2018)in MATLAB Version: 9.11.0.1873467 (R2021b) Update 3 (The MathWorks Inc., Natick, Massachusetts). Raw light intensities were converted to optical densities. Thereafter, we applied the TDDR algorithm to correct for motion artifacts(Fishburn et al., 2019), before signal quality check. The signal quality was evaluated by computing the Scalp Coupling Index (SCI)(Pollonini et al., 2016)with QT-NIRS (Montero-Hernandez & Pollonini, 2020/2023). QT-NIRS uses a sliding time window of 5 seconds to calculate SCI over the entire time series, and automaticallymarks and rejects low-quality channels based on an overall threshold. We used the default threshold (0.75) for the overall quality threshold, which means that at a given SCI threshold, a channel is marked as good if it attains the SCI threshold at least 75% of the time. We evaluated signal quality at two SCI thresholds. For SCI = 0.8, 69.3% of the data were considered high quality. For SCI = 0.6, 75.7% of the data were considered high quality. Since these are pilot data, we selected the lower SCI threshold of 0.6. When considering that this is pilot data, theoverall channel quality is quite high.

After pruning channels, we converted motion-corrected optical density to hemoglobin concentration changes using the modified Beer-Lambert Law(Delpy et al., 1988)with a 0.1 partial path length factor of 0.1 and extinction coefficient from Jacques(Jaques et al., 2015). For subject-level statistics,the data was first resampled to 4 Hz. Thereafter, we ran ageneralised linear model with autoregressive-based prewhitening followed by iteratively reweighted least-squares(Barker et al., 2013, 2016) and short-channel regressors (Santosa et al., 2020), as this performs best in sensitivity-specificity analyses(Santosa et al., 2020).For group-level statistics,we ran a mixed-effects model includingthe main effect of the condition (i.e., video) andcontrolling for participants. The results presented are the main effects, i.e., the effects of watching videos on hemodynamic activation compared to baseline (i.e., baseline activation when not watching videos). The

Benjamini- Hochberg procedure(Benjamini & Hochberg, 1995)was used to control the false-discovery rate. The corrected p-value is denoted as q.

4 RESULTS

The results section presents the main findings from the fNIRS data collection while participants watched the nine videos. To test the videos in this pilot study, we selected the most interesting findings based on visual inspection of the main findings and contrasting the different videos. As this was a pilot study, we compared all the contrasts. Figure 2 shows the results of the main effects of watching the videos compared to the baseline (resting state). We have chosen to highlight some of the results for illustration.

Some significant HbO and HbR level changes were observed as participants watched the videos. When watching video 2, participants showed a significant decrease in blood oxygen (HbO) in one channel, with the other channels also showing a decrease in HbO. The decrease in HbO levels suggests a reduction in cognitive demand among participants while watching video 2. This finding could be interpreted cautiously as a pleasant response and physiological relaxation.We did not find significant results for videos 3 and 4. However, both videos resulted in a decrease in HbO levels in several channels. In particular, video 4 demonstrated a general decrease in HbO levels in almost all channels. In video 6, a slight increase in HbO is observed in ten channels and a larger increase in one channel. Video 8 shows negligible increases in HbO. In comparing the effects of watching different videos, a significant difference in HbO was found in one channel. Figure 3 presents two examples of contrasts. When comparing video 2 to video 8 and video 2 to video 6, a significant decrease in HbO in one channel is observed in the anterior medial superior frontal gyrus (SFG).

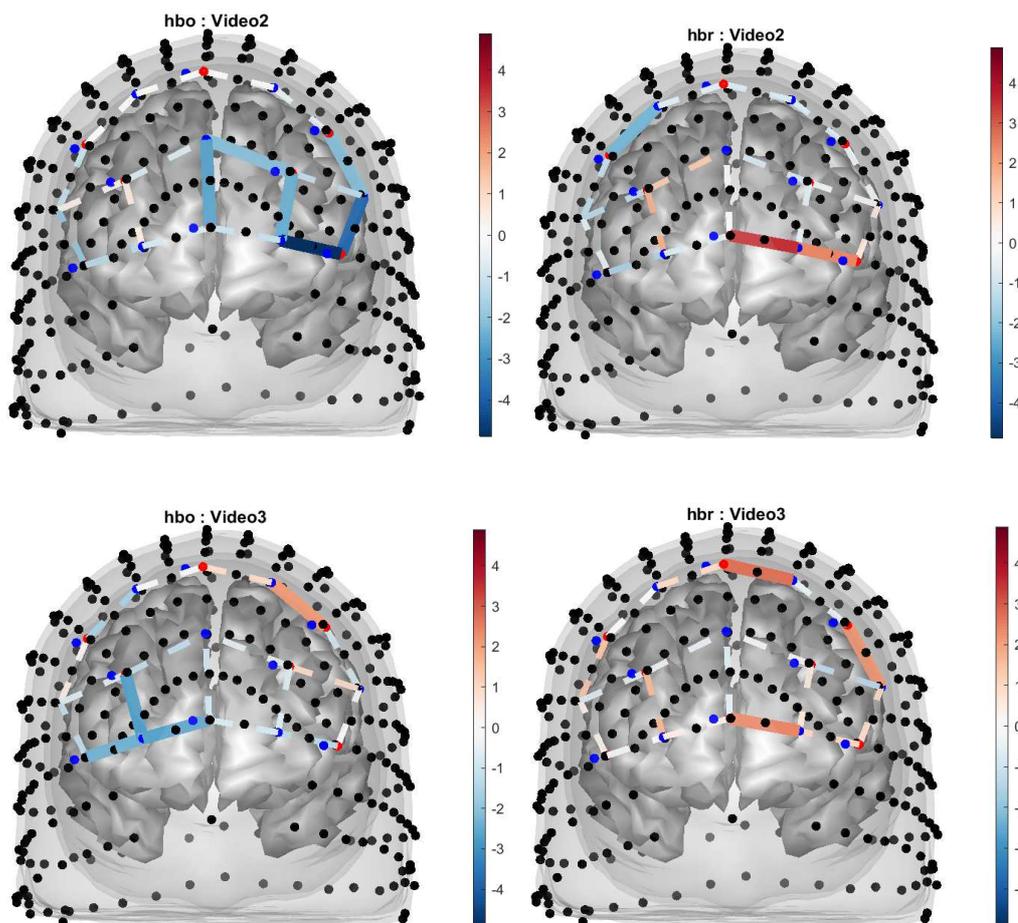
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


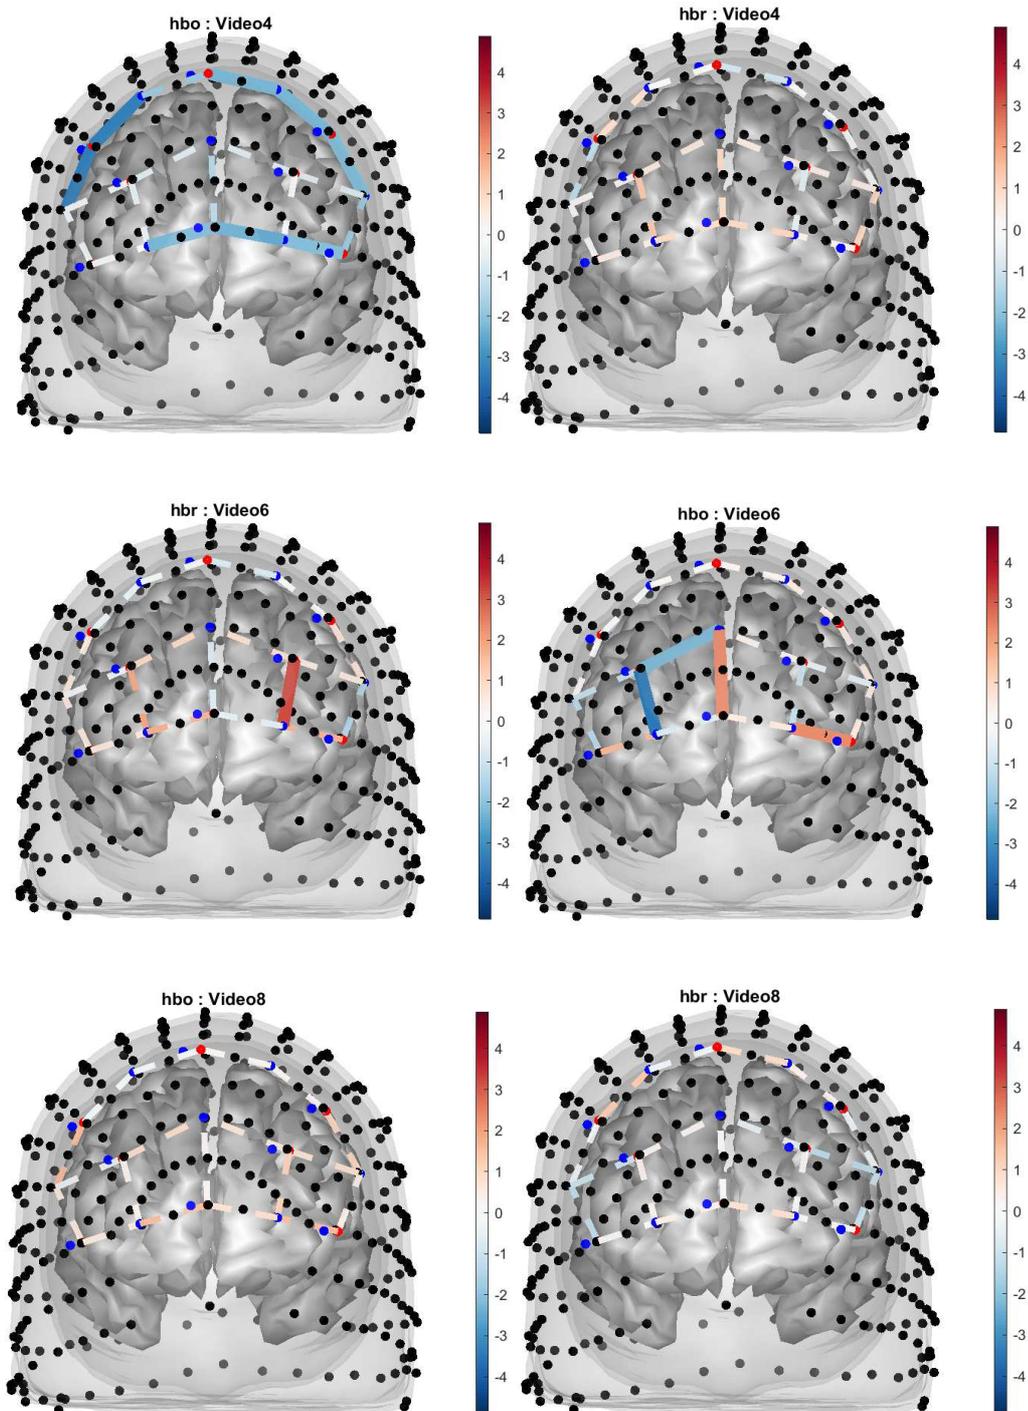


Figure 4: Main effects of watching videos 2, 3, 4, 6, 8HbO (left column) and HbR (right column) levels. The results are illustrated as t-statistic maps plotted onto the colin27 brain atlas, the colour bar represents the t-statistic scaled to [-5, 5], and solid lines indicate statistical significance (q<0.05).
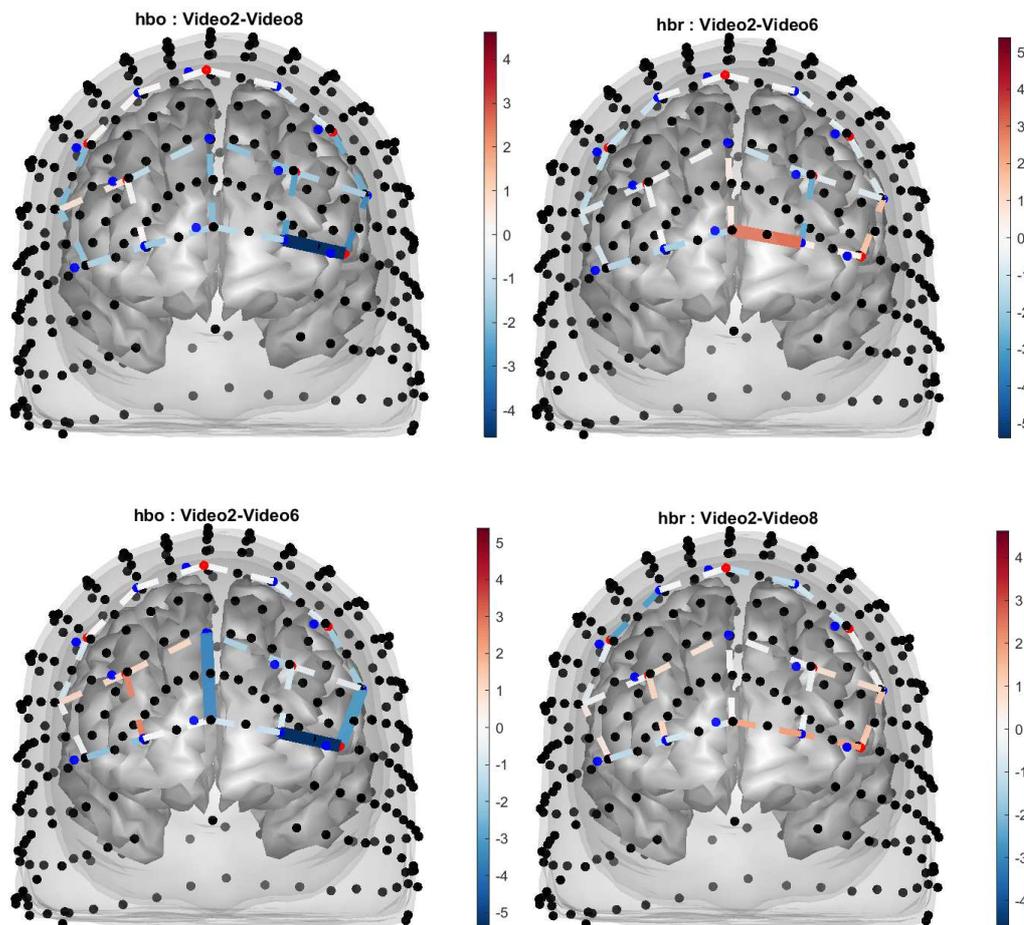

Figure 5: Examples of contrasts, comparing video 2 to videos 6 and 8. Video 2 shows a mixed-use old town street with colourful, diverse, open, and engaging facades and architectural details, small sidewalks but low levels of car traffic due to regulations. Video 6 shows a residential neighbourhood with monotonous architecture in industrialbrick style with no variation or integration of other uses, greening or spatial elements. Video 8 shows an inner city street with high levels of traffic and bicycle infrastructure besides the sidewalk, with monotonous and closed facades, no ground-level use on the street side, high noise levels, and little connection to surroundings due to the underpass situation. The contrastshowed a significant decrease in HbO when participants watched video 2, in comparison to video 6 and video 8.The results are illustrated as t-statistic maps plotted onto the colin27 brain atlas, the colour bar represents the t-statistic scaled to [-5, 5], and solid lines indicate statistical significance (q<0.05).

5 DISCUSSION

The purpose of this pilot study was to test the feasibility of implementing fNIRS for the study of the built environment and to propose fNIRS as a possible interdisciplinary research method for urban planning. Given the small sample size and exploratory nature of this study, we cannot make strong interpretations or conclusions. Despite this limitation, we were able to demonstrate that viewing pleasant walking environments (i.e. video 2, video 3, video 4) was correlated with a decrease in the hemodynamic response in the right and central areas of the PFC. In the context of walkability research, pleasant environments were generally characterised by varied facades, ground-level use, greenery (in video 4), low traffic volumes and the availability of spatial elements (e.g. benches). In contrast, observing less pleasant walking environments (i.e. videos 6 and 8) led to a slight increase in the hemodynamic response. This effect is also noticeable when comparing video 2 with videos 6 and 8. In a direct comparison, video 2 resulted in a significant decrease in HbO levels, i.e. a lower hemodynamic response. Videos 6 and 8 were characterised by monotonous and closed facades, no windows at ground level, no spatial elements or greenery and high traffic volume (video 8). As a result, we can observe differences between more pleasant and relaxing urban environments for walking and more stressful and unpleasant urban environments.

These primary findings are not supported by many other similar studies, but there may be some consistency with previous studies comparing natural and built environments (Song et al., 2020; Yu et al., 2017) or using positive and negative stimuli (Hoshi et al., 2011). Exposure to natural environments (such as forests, parks,

etc.) compared to urban environments has been found to decrease the hemodynamic response in the PFC(Song et al., 2020; Yu et al., 2017). Similarly, exposure to unpleasant emotions was associated with an increased hemodynamic response, whereas exposure to pleasant emotions led to a decreased hemodynamic response in the PFC (Hoshi et al., 2011). Studies of nature exposure often use the Attention-Restoration Theory to explain the relaxing effect of natural environments on hemodynamic response. According to this theory, natural environments lead to reduced attentional effort, mental fatigue and cognitive load (Weber & Trojan, 2018; Yu et al., 2017). Although evidence is still limited, the built environment has also been associated with restorative values, e.g. in terms of architectural features such as lower building height, variation in facades, architectural variation, aesthetic values or historic buildings (Weber & Trojan, 2018).

In the context of our study, research on restorative effects may support our findings on the effects of exposure to different types of built environments; that is, participants showed lower hemodynamic responses when they watched videos of a walk past historic buildings with interesting things to look at (video 2) than when they walked past a monotonous facade (video 6) and a busy street (video 8). More specifically, video 2 resulted in a significantly lower hemodynamic response. The video shows a pleasant walk through a historic part of the city centre, with colourful and open facades, shops, restaurants and cafes with outdoor seating, but no greenery. If the participant perceived the video as pleasant, it could have resulted in physiological relaxation and a consequent decrease in the hemodynamic response. Likewise, video 4 caused a reduction in HbO levels. The video shows a mixed residential area with historic buildings and ground-level use and is the video with the most greenery. The video passes several flower beds, trees and benches. There may be a correlation between the decrease in HbO and the relaxing environment, which is likely due to the presence of greenery. Unlike video 2, viewing both video 6 and video 8 resulted in an increased haemodynamic response. Video 6 shows a walk in a monotonous residential area without spatial elements, open facades or greenery. Video 8 shows a walk along a grey, closed facade, under a building and along a busy road with bicycle and car traffic. An increased hemodynamic response may be a consequence of the stressful and dynamic environment shown in the video. These initial interpretations require further examination in the full study.

This pilot study had some limitations. The participants were limited to a few researchers from the Faculty of Architecture with expertise in architecture and urban planning. The full experiment will include a larger sample size of non-architects, representing different age groups and an equal gender distribution. Moreover, the experimental design exclusively focused on the visual representation of the videos. Future experiments could take into account other senses, particularly the auditory sense. Finally, it is worth noting that although the videos showed the urban environment from a pedestrian's perspective, the participants themselves were seated to avoid motion artefacts on the one hand, and physical activity to influence cognitive outcomes on the other (Miyazawa et al., 2013). Future research may consider employing simulated walking setups in the laboratory (e.g. treadmills) or conducting in-situ experiments. Walking is generally associated with increased activation in the PFC (Herold et al., 2017). Additionally, perceptions of the built environment may be linked to physical and rhythmic experiences from an architectural perspective (Papale et al., 2016).

5.1 Future research

This pilot study opens up promising opportunities to explore the impact of urban environmental features on the pedestrian experience. A full-scale experiment is being conducted with 50-60 participants and an improved experimental design, including additional data on subjective perceptions of the urban environment, mobility behaviour and socio-demographics. The results will provide insights into the effects of four urban environments (Videos 2, 4, 6 and 8) on brain activation and further implications for walkable urban environments. Implementing fNIRS as a research method in walkability research could be a way to learn more about the factors of the built environment that contribute to the experience of walking environments, such as the effects of certain urban design features, façade design, greening, etc. The level of detail of our findings and discussions is unclear at this stage of the research, as we lack references and constructs to work with. Exploratory research is needed into the relevant brain regions and the constructs to be used.

With the prospect of increasing urbanisation, densification and other future challenges, we need a better understanding of how the urban environment affects health and well-being, and how people experience the environment, particularly in terms of emotions and stress responses. Combining fNIRS with health data and physiological sensors has the potential to advance research on urban health and well-being. Considering

social justice, accessibility and feminist planning perspectives, fNIRS appears to be a promising tool for investigating how the environment affects different user groups, including children, older people, people of different genders and identities, people with disabilities, and people from different socio-economic backgrounds. For example, research on diverse groups could explore gender-based differences in perceptions of urban safety, investigate the characteristics of pleasant environments, or gain insight into the perceptions and needs of children and elderly people in the city. To improve the research, scientists should explore the benefits of combining different methods and linking fNIRS data with socio-demographic, health, and qualitative data. The integration of EEG, eye-tracking devices and physiological sensors has great potential for in-situ implementation and the study of urban environments. More pilot studies are required to implement the combination of various methods and technologies, such as virtual and augmented reality.

6 CONCLUSIONS

Understanding the determinants and effects of the built environment on the experience of walking in cities is an important step in creating healthy and liveable urban environments for people. However, more research is needed on the microscaleand perceptions of comfort and attractiveness to understand the contributing factors to walkability. Advances and access to new technologies and methods from the human and cognitive sciences can help to understand pedestrians´ perceptions and effects on the environment.The main objective of this pilot study was to evaluate the implementation and feasibility of fNIRS for studying the built environment and to suggest employing fNIRS as an interdisciplinary research method in urban planning research.Although the study's primary nature and limitations should be considered, observing pleasant walking environments resulted in a significant decrease in HbO in the right and central areas of the PFC, compared to observing boring and stressful walking environments. The environments varied in the facades' character, level of greenery, traffic, and spatial components. These preliminary results could suggest that exposure to positively perceived walking environments results in lower HbO concentrations, which may be interpreted as physiological relaxation and an overall pleasant and less stressful experience for the pedestrian. While further research is needed, this study demonstrates the feasibility of using fNIRS to study the built urban environment and opens up promising opportunities to explore the relationship between people and the urban environment.

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Nature Based Solutions: More than Just Greening the City?

Judith Ryser, Teresa Franchini

(Judith Ryser, judith@urbanthinker.com)
(Teresa Franchini, terefran@temanova.com)

1 ABSTRACT

Today's relation between humans and nature is arguably still rooted in the enlightenment philosophy, or the "age of reason", asserting that nature exists to be tamed and submitted to the needs and wants of humans(Wallace et. al. 1996). This premise shows scant concern for social, cultural or economic consequences, let alone care for the survival of the planet. Accelerating adverse effects of climate change and rapid decline of biodiversity demonstrate that this exploitation principle of nature by humans has severe limitations (Folkard-Tapp H et.al. 2021). Facing this undeniable evidence, science and technology are envisaging alternative approaches, such as applying Nature-Based Solutions (NBS) to benefit people and nature conjointly(British Ecological Society 2021). This raises the issue whether NBS would be capable of moving away from the antagonism between nature - narrowly understood as the physical world of plants, animals and inorganic matter- and the human-made environment and its uses, and instead to conceive humans and their actions as an integral part of nature.

The paper attempts to explore this question from the perspective of physical planning of cities and territories by identifying the various and possibly contradictory characteristics of NBS and their interventions (Sowinska-Swierkosk et al. 2022) and to discuss whether and how NBS may differ from previous measures to protect the environment and to combat adverse effects of climate change (Stavroula Melanidis et al. 2022).To this end, the paper reflects on academic deliberations on the meaning (Osaka et.al. 2015) and purpose (Kiss et.al. 2019) of NBS and their site-specific, comprehensive, integrated and preferably co-beneficial effects at multiple spatial scales(Johnson et.al. 2022).It aims is to review how NBS currently contribute to the protection of nature and biodiversity by reversing ecosystem degradation, and how they are applied to achieve a more sustainable and liveable built environment. Finally it identifies changes needed for the current fragmented planning system to become more NBS-friendly, and to prevent further inequalities (Herrmann-Pillath C 2022).

The evidence-base of the paper relies on freely available references on the internet in solidarity with academics and professionals who are willing to share their knowledge and experiences widely.

Keywords: city planning, greening, nature-based solutions, urban planning, critical review

2 CLIMATE CRISIS AND UN SUSTAINABLE DEVELOPMENT GOALS

The World Meteorological Organisation forecasts a 98% probability that in the next five years the heat record reached in 2016 will be surpassed driven by the natural phenomenon of El Niño (WMO 2022). This situation will cause global temperatures to rise, alternating intense rains and droughts in some areas of Latin America, Africa and South Asia, with global effects and increasing the temperature of the oceans. The organisation also warns that the average annual temperature on the earth's surface could rise transiently by more than 1.5 degrees Celsius compared to the pre-industrial era, which is what the Paris Agreement COP15 seeks to avoid. At COP27 researchers explained and forecast that global warming is set to break the key 1.5 Celsius limit for the first time before 2027 (McGrath 2023). In 2022, the Intergovernmental Panel on Climate Change provided a summary for policy makers on Climate Change and its impacts, adaptability and vulnerability (IPCC 2022).

The impact of climate change on cities will be formidable in all aspects, making it imperative to reinforce the Sustainable Development Goals (SDGs) proposed by the 2030 United Nations Agenda and adopted in 2015(UN DESA 2015).Relevant specifically to planning and design are SDG 11, Sustainable Cities and Communities, SDG 13 Climate Action and SDG 15 Life on Land. Interrelated and strongly linked to the political dimension, these goals have been transposed into national, regional and local actions, albeit of an ad hoc nature with irregular compliance. At its 7th session in March 2023, The Regional Forum on Sustainable Development for the Economic Commission for Europe region focused on "Ensuring the implementation of the 2030 Agenda for sustainable development in the ECE Region in times of multiple crises" and organised peer learning round tables (UNECE 2023).

Scientific evidence on the acceleration of global warming(IPCC 2007) demands urgent action to counteract its effects on the environment, human welfare and human activity in general. Policies, measures and actions that address the challenges of climate change define a specific cross-cutting area of action, whose implementation should be promoted by all levels of government in the interests of sustainability of the planet as well as human life, fauna and flora. Local governments are responsible for the direct management of these measures in their respective jurisdictions.

From a technical point of view, reducing the adverse effects of climate change on the territory implies alternative measures that are easy to implement and maintain. SDGs and NBS are applied at different scales, globally, at regional, city and neighbourhood level, down to local everyday urban life, relevant to SDG 3 Good Health and Wellbeing, SDG 8 Decent Work and Economic Growth, and SDG 12 Responsible Consumption and Production. In this context, the concepts of sustainability and more specifically of NBS are used extensively by those involved in the built environment.

3 VISIONS OF NBS: TOWARDS A DEFINITION

NBS are one of the most recent approaches to combat global warming, focused on increasing urban resilience by harnessing the ecosystem services of natural capital. NBS differ from the traditional approaches to biodiversity conservation and management promoted since the 1970s in that their implementation must apply jointly to biodiversity and people(Folkard-Tapp et.al. 2021).NBS can be construed as one among many other methods of contributing to more sustainable cities. However, the concrete manifestations of sustainability and NBS are not easy to grasp, let alone to measure, not least because their effects and how to achieve them do not necessarily share commonly agreed criteria.

Scientific evidence has confirmed the role of natural habitats and its preservation and restoration for territorial sustainability in all its dimensions:

- environmental – improving ecosystem functioning, increasing biodiversity, reducing greenhouse gas concentrations, facilitating carbon storage, mitigating flooding, protecting coasts from rising sea levels and hillsides from landslides, reducing urban heat islands, providing clean air;
- economic – generating green jobs, producing business benefits, encouraging circular and regenerative economies;
- social – improving human well-being in all aspects, especially health and food security.

Although the benefits of NBS in either the short or long term have not been fully quantified, their effects are nevertheless undeniable (British Ecological Society 2021). Given the many stated positive effects of NBS on biodiversity and the quality of human life, their use was adopted by the United Nations in 2005 when it launched the Millennium Ecosystem Assessment project to analyse the state of the planet's ecosystems. In 2013, the International Union for Conservation of Nature (IUCN) coined a first definition of the NBS: "actions to protect, manage and address the remains of society in an effective and adaptive manner, while simultaneously providing benefits for human well-being and biodiversity"(IUCN 2022).

This vision was adopted and expanded by the European Commission in 2015, when considering NBS as a planning and urban design tool to re-naturalise European cities. In 2019 and during the UN Climate Action Summit, the European Commission promoted the use of NBS and adopted the European Green Deal, which favours their inclusion in a wide range of policies(European Commission 2021a). In the same vein, the EU Biodiversity Strategy 2030, adopted in 2020, promotes the integration of NBS in urban planning, public spaces, urban infrastructure and the design of buildings and their environment(European Commission 2021b). The launch of specific programmes and projects on the subject has been fruitful: Urban Green Up, Clearing House, Clever Cities, Connecting Nature, EdiCitNet, Grow Green, Nature 4Cities, Naturvation, Regreen, etc. These initiatives gave rise to responses of all kinds, understood as a complement - not a substitute - for other measures aimed at mitigating the effects of climate change. Given their potential, the NBS have been integrated into the agenda of policy makers at different executive levels(Rey Mellado et.al. 2021).NBS are also considered able to offer a transition path in realistic, incremental steps towards a sustainable economy (Maes et.al. 2015).

4 NBS IN PRACTICE: SCOPE AND EXPERIENCES

The numerous NBS experiences in the regions, cities, municipalities and neighbourhoods which have opted for their implementation demonstrate their potential to meet the objectives for which they were intended, while confirming the possibility of their incorporation into urban and territorial policies. Empirical evidence makes it possible to classify concrete NBS projects into two generic types according to their territorial coverage -regional and urban - regardless of the ecosystems on which they operate: soil, water and vegetation. In both cases, their declared aim is to result in socio-economic effects in favour of local or broader communities while fostering biodiversity.

In terms of technical measures NBS focus on improving the impact of the built environment on climate change or, conversely, on how the built environment can be adapted to climate change or mitigate it. Concrete-technical implementations of NBS are applied to the environment at regional level on the one hand (landscape, agriculture, resource extraction, biodiversity, ecosystem services, etc) and to the built environment on the other hand (cities, transportation networks, infrastructure, neighbourhoods, individual buildings and their uses, etc). NBS are also the subject of a more tactical discussion, exploring how NBS distinguish themselves from other interventions to preserve nature and whether they have a specific distinct purpose. For example, the UK House of Lords Science and Technology Committee explored the use of NBS to reduce carbon emissions and sequestering carbon towards zero greenhouse gas emissions and concluded that NBS could play an essential role in compensating residual emissions where total elimination would be impossible to achieve within the targeted timeframe (House of Lords, 2021-22).

4.1 Regional scale

Regional-scale NBS actions are strategic in nature and their implementation is linked to the conditions of the territory when seeking resilience to storms and intensive weather. They tend to be focused on specific issues, such as: erosion protection - combining afforestation (Throp et.al. 2023), reforestation (Webster, 2023) and conservation of natural forests in watersheds, or restoration of herbaceous and shrub vegetation on slopes; inland flood protection - through reforestation of headwater watersheds, regeneration of watersheds affected by forest clearing, regeneration of river banks to reduce flood damage or maintenance of wetlands (Thorslund et al. 2017); protection against coastal hazards and sea level rise- through the construction of natural (Doelle et al. 2021) or artificial (Morales et al. 2021)reefs to stabilise coastlines; or protection of natural resources in hot, dry regions - through agroforestry systems that combine trees, livestock, grasses and crops to reduce erosion, prevent fires and increase soil fertility (Seddon, 2020).

Overall, the impacts of NBS on ecosystems and the regional and/or general socio-economic context are numerous, including diversification of income sources, increased food security, community management of common resources and access to institutional services. Nevertheless, at the regional level biodiversity is a prominent objective of NBS while also focusing on landscape conservation and reinstating nature(WEF, 2022). From the economic perspective, NBS are often seen to contradict growth promoted by governance, although some politicians such as the Irish President Michael Higgins (Leahy, 2023)are contesting the growth paradigm. However, according to the concept of NBS economic security and competitiveness are directly dependent on the sustainable use of natural resources. Maes(2015) proposes specific criteria to focus, guide and evaluate the implementation of NBS towards producing both wider economic and social benefits, essentially provision of jobs and low-carbon technology innovations.

4.2 Urban scale

With regard to the urban scale, as the urban fabric is essentially an anthropic space, the general objectives of NBS are convergent: integrating nature into the city as a mechanism of conserving biodiversity, regulating the climate and promoting socio-economic activities. NBS adopt different approaches depending on space specificities and scale of intervention: cities, neighbourhoods, buildings. Generally, interventions are of a one-off nature, but they may be grouped into systematic proposals: eco-districts and green blue infrastructures. Pineda-Pinto et.al. (2020) carried out a literature review on the potential of NBS to deliver ecologically just cities, with lessons for urban planning. Arup (2014) have produced numerous projects, pamphlets and articles on their approach to NBS, including lessons for urban designers.

The objectives of these interventions focus on biodiversity and habitat conservation, climate change, urban resilience, public health and well-being, and the attractiveness of the built environment. The areas of action

are varied - forests, parks, gardens, urban woodland, orchards, lakes, ponds, drains, wetlands, permeable surfaces, rain gardens. The benefits are substantial: reduced heat island effects and flood risks, improved air quality(Mayor of London 2021), carbon dioxide sequestration, reduced energy use, benefits to public health and well-being, access to food, physical activity, mental health, improved community relations, and contributions to innovation, economic growth and job creation(Kiss et.al. 2019).The latter are also related to more general city greening initiatives (Froy et.al. 2023).Microclimates are capable of moderating climate change, due to their contextual characteristics such as local water management, drainage and permeable surfaces, seasonal shading, riverbank restoration, re-vegetation of brownfield sites, green corridors, which cities are increasingly including in their sustainable planning strategies (Ayuntamiento de Madrid 2016).

Applied to specific built environments, NBS tend to focus on technical-material measures. Akin to well established and practised methods of urban environmental improvements (e.g. ARUP undated), they are resorting to green infrastructure, green roofs, green walls, improved insulation and air tightness of buildings; tree planting in streets, even creating urban forests to reduce heat island effects, as well as managing stormwater to prevent flooding of insufficient drainage, creating sponge cities, building protections against rising sea levels, but also extending wetlands and woodlands to absorb excess water(Thames21, 2020). Other initiatives which could be construed as informal NBS are initiated by inhabitants, such as growing eatable plants on unclaimed spaces. Most urban experiences of NBS tend to be sectoral in nature, with diverse spatial coverage, leading to varied results. Their contribution could be greater if they would be included in comprehensive urban policies to facilitate planning, design and management processes.

Kabisch et.al.(2022) propose 5 principles for urban nature-based solutions capable of contributing to resilient urban futures. In their view NBS (i) require a systemic understanding and need,(ii) benefit both people and biodiversity, (iii)contribute to inclusive long term solutions, (iv) consider context and local conditions, and (v)foster communication and learning. However, NBS rarely include behaviour change, such as reducing energy consumption, motorised and air travel and meat consumption among many others which may have significant effects on urban resilience.

5   CONCEPTUAL RESEARCH: THE LIMITS OF NBS

Based on current, openly available literature on NBS and their implementation, the deliberations on NBS seem to divide functionally into two categories: concrete-technical and conceptual-theoretical. In terms of comparative reviews and case studies, research investigates the various empirical applications of NBS, their impacts on the environment and society, as well as their applicability to planning at regional and urban levels(e.g. Pineda-Pinto et.al. 2020). Scientific research on NBS explores conceptual-theoretical aspects of NBS including how to define them(e.g. Kiss et.al. 2019; Hanson et.al. 2020).

In their comprehensive review of research publications on NBS Hanson et.al. (2020) explored the use and interpretation of the nature based solution concept by science. They discuss various definitions and note that most empirical studies focus solely on environmental benefits delivered by NBS. They found few studies across scientific disciplines which assess social and economic benefits as well, despite both benefits being a central ambition of the NBS concept. They propose four core ideas relevant to planners: how to use NBS in the pursuit of sustainable development by handling societal challenges and how to seek co-benefits by including relevant stakeholders. In the Naturvation Project, another international comparison of NBS, Kiss et.al. (2019) map existing experiences and practices in the use of NBS. Based on 54 NBS interventions in 18 cities, their comparative analysis focused on governance arrangements, public participation, financing mechanisms, innovation patterns and social impacts. Their research concentrated on what is enabling NBS implementation. They noted that NBS, usually applied in complex institutional and governance structures, are multi-functional and resort to public-private collaborative arrangements when addressing sustainability challenges. Their findings show that municipalities are playing a key role in financing policy, but that the distribution of costs and benefits was encountering contradictions regarding transparency, accountability, justice and democracy. Discussing the definition of NBS, Seddon et.al. (2021) acknowledged the benefits of NBS, but affirmed that NBS are not a substitute for rapidly phasing out fossil fuels. Other academic deliberations are related to resilience (Ruiz-Mallen et.al. 2022), a concept intrinsically linked to climate change and the role of NBS. More specifically, Baro et al. (2022) explored the co-benefits NBS could create when making schools resilient to climate change impacts and saw potential in upscaling this approach to city level.

Other researchers are more skeptical about the merits of NBS. Stavroula Melanidis et al. (2022) discussed the competing languages of NBS. Based on contributions to the 2019 UN Climate Action summit and the 2019 UN Climate Change Conference (COP 25) they analysed the narratives connected with proposals for and against NBS and found two opposing standpoints: NBS as a powerful multifunctional instrument to leverage the power of nature; or as dangerous distraction perpetuating the unsustainable, unjust status quo. Others also adopt a critical, even politicised standpoint towards NBS. Marsh & Swyndgebouw (2002) see NBS as socially divisive and inequitable, thus in need of political redress with focus on the most deprived parts of society when implementing them. Hanson et.al. (2020) consider NBS possibly as a buzzword, solely delivering environmental benefits, without the expected economic and social benefits incorporated in the NBS concept, instead of being a pathway to broader and deeper development. Kotsila et.al. (2020) criticise NBS as resting on assumptions from positivist science providing space for neo-liberalisation processes of nature. They reckon that urban nature can serve economic elite players at the expense of widespread socio-ecological benefits. Conversely they see the possibility of NBS laying the ground for open participatory spaces beyond controlled stewardship of nature or market mediated interactions with it. Other researchers position themselves in between those stances when debating the value and limits of NBS (Seddon et.al 2020).

Based on the comprehensive surveys of NBS scientific research, the following key problematic aspects of NBS seem to emerge:

- Definition: There is a lack of a single definition of NBS that determines the conditions to single them out from other approaches. Despite institutional attempts to define NBS, there is no agreement on a single definition. The current diversity of definitions fails to define a specific profile that categorises a wide range of NBS actions and can respond to different objectives and this may be attributable to internal contradictions of the concept of NBS.

- Scope: The use of NBS is applied to a broad diversity of interventions. Most of the empirical studies point to the environmental benefits that NBS provide, while there are few studies that also evaluate their social and economic benefits, despite being a central ambition of the NBS concept (Hanson et al, 2020). Some studies highlight the role of NBS in resilience linked to climate change (Ruiz-Mallen et al. 2022), its application in specific buildings, as well as in the urban environment more generally (Baro et al., 2022). The most relevant contributions of NBS to the urban environment are the ones aimed at reducing the effects of climate change and at increasing the quality of life in public spaces.

- Evaluation: Evaluating the results of NBS in practice encounters many obstacles. A difficulty lies in the lack of appropriate indicators and metrics to assess biophysical, ecological, and socioeconomic effectiveness, which inhibits the creation of appropriate frameworks to estimate the scope of the benefits and long-term monetisation of NBS(Seddon et al, 2020).This may be due, inter alia, to the coexistence of numerous interacting and context-specific factors that vary over time, besides depending on the standpoints and needs of those involved.

- Financing: This is one of the main obstacles to the implementation and monitoring of NBS. Regardless of the origin of investments - public or private agencies, bilateral or multilateral funds, national or international the focus on the economic growth model and the need to obtain short-term benefits tend to reduce the option to implement NBS, exacerbated by the context of budgetary restrictions. The management of NBS projects, based on coordination between different levels of government and stakeholders is difficult to organise and can even contradict other projects. Overcoming these challenges requires strong institutions, well-established planning and stable available structures (Seddon et al. 2020).

- Collateral effects. Although there is consensus that NBS do not replace measures to restrict the use of fossil fuels, nor that they should distract from the need to protect a wide range of ecosystems (Seddon et al, 2020), some authors understand the use of NBS as a multifunctional instrument to harness the power of nature, or as a distraction to perpetuate the unsustainable and unfair status quo (Melanidis, et al. 2022). Others see NBS as socially divisive and inequitable, necessitating political redress with a focus on the most disadvantaged parts of society when implementing them (Marsh & Swyngebouw, 2002). Others view NBS as a buzzword that only offers environmental benefits,

without the expected economic and social benefits that lead to broader and deeper development (Hanson et.al. 2020). Others point out that excessive use of tree planting is an easy measure to implement for which there are no scientific criteria to link its benefits to specific ecosystems and human contexts, and which could eventually amount to "green gentrification". More radical views criticise NBS for relying on assumptions of positivist science that provide space for processes of neo-liberalisation of nature and serving elite economic actors at the expense of widespread socio-ecological benefits, rather than to see NBS as a possibility to lay the foundations for open participatory spaces beyond controlled stewardship of nature or market-mediated interactions (Kotsila et al. 2020). There is also concern about the occurrence of adverse social consequences of implementing NBS without the consent of the communities involved (Seddon et al. 2020).

6 Reducing Uncertainties

Even though the multifunctionality of NBS is recognised, scientific analysis indicates the presence of important conceptual and technical barriers that must be eliminated. The concepts and practices of NBS developed over the last decades have been numerous, including the multifunctionality of NBS. However, despite the benefits NBS bring, their adoption is far from widespread, possibly due to uncertainty about what is meant by NBS and their scope.

With respect to cost-effectiveness, there is some evidence that the benefits of NBS can outweigh the costs of their implementation and maintenance in a variety of contexts and that they may be more cost-effective than engineering alternatives(World Bank, 2019). Nevertheless, lack of funding for NBS which often require long term commitment, is a major obstacle to their implementation and follow-up, especially during severe budgetary constraints.

The issues that encourage uncertainty can be summarised in three generic themes:

- the challenges of measuring the effectiveness of NBS in relation to other alternatives;
- the difficulties in assessing costs and benefits in attracting public and private investment; and
- the institutional barriers that limit the incorporation of NBS into territorial policies.

IUCN adopted a Global Standard in 2020 to reduce these uncertainties. Aimed at national, municipal and local governments, planners, companies, donors, financial institutions and NGOs working on issues of global concern, The Global Standard consists of 8 criteria and 28 indicators valid for both small-scale interventions and large-scale actions, setting out the conditions NBS have to meet to perform their tasks(IUCN, 2022). These criteria give considerable weight to social and governance aspects when assuming the risks that could result from the outcomes of NBS implementation on ecosystem processes. The criteria propose the following principles:

- criterion 1: NBS are to respond effectively to one or more societal challenge(s), identified as a priority for directly affected societies, supported by transparent and inclusive consultation processes.
- criterion 2: The design of NBS will be adapted to the complexity and uncertainty of the context in which they are implemented, taking into account the biophysical or geographical perspective, economic systems, regulatory frameworks, cultural perspectives, synergies between sectors, and the identification and management of the risks involved.
- criterion 3: NBS should produce a net gain in terms of biodiversity and ecosystem integrity, ensuring their protection, functional integrity and connectivity in the long term.
- criterion 4: NBS must be economically viable, both in the design phase and during implementation, distributing costs and benefits equitably in the short and long term.
- criterion 5: NBS are based on inclusive, transparent and empowering governance processes, which delineate responsibilities and legitimise the sharing of burdens and benefits arising from the process in accordance with existing legal and regulatory provisions.
- criterion 6: NBS should strike an equitable balance between the achievement of their objectives, the benefits obtained and the necessary financial rewards based on credible assessments, transparency of information and stakeholder agreements.

530

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

- criterion 7: NBS are adaptively managed in response to uncertainty in ecosystem functioning, using data provided by continuous monitoring and periodic assessment.
- criterion 8: NBS are sustainable actions and are integrated into an appropriate jurisdictional context, taking into account existing sectoral and national policy frameworks, strategic communication and promotion of their use.

The application of these criteria is expected to guide both the actions of the institutional and governance bodies in charge of leading the implementation processes of NBS in their respective territorial jurisdictions, as well as the technical process involved in the design of these initiatives. Likewise, the criteria offer a reference framework for private initiatives that address NBS projects in rural territories and urban spaces. The role of urban and regional planning could play a determining role, but for this the NBS concept would have to undergo two structural changes: adopting them into comprehensive urban policies that facilitate their implementation and including them as a specification when drafting further planning instruments.

6 NBS, PLANNING AND GOVERNANCE

What use can planning and planners make of this discussion on research on the current state of NBS in terms of their practical implementation in regions and cities and at conceptual level to rebalance the ecosystem, combat climate change and make cities more sustainable?

The analysis of existing NBS experiences reveals that most of them are punctual and sectoral in nature, applied to very diverse spatial coverage, producing uneven results, but are scarcely included in traditional planning instruments. Instead, NBS tend to be implemented through ad hoc modalities, without anchoring them in the current regulatory structures, although this could also favour their development and acceptance over time and warrant their eventual inclusion in the monitoring and evaluation mechanisms of planning instruments.

The absence of a convergent definition of NBS may explain their slow take-up in plan making and regulations. Conversely, the diffuse meaning of NBS can provide planners with an opportunity to interpret them to their own advantage. The argument that NBS are just another term to describe measures already incorporated in development plans and planning regulations to protect the environment and mitigate climate change may provide incentives to refine and innovate existing planning instruments.

It has to be kept in mind that measures to safeguard and improve the environment have long been part of planning, thus NBS would essentially be an additional instrument, preferably in synergy with existing ones. The special characteristics of NBS demand the adoption of a comprehensive vision including their vertical and horizontal relationships between disciplines and sectors, their funding conditions and their inclusion of community participation, which require the involvement of specialists in the design of proposals, as well as in decision-making. Like any other aspect of spatial planning, the adoption and scope of an active NBS policy would depend on the priorities given to it by the political, economic and social context.

Assuming the potential of NBS in relation to climate change and quality of life, and given that plan making and project design are the key functions of planning, their adaptation into planning instruments requires a transposition of the concept into practice. For this, the role of academic research is essential, in identifying and assessing the environmental, social and economic benefits, as well as the adverse effects and possible contradictions associated with NBS. Such a research effort is directly dependent on adequate funding to advance this subject.

Planning instruments have their own mechanisms of monitoring and evaluating their long-term performance. Experiments with NBS at regional, city and neighbourhood levels could provide lessons for planners to incorporate findings into their approach to site-specific conditions and to adjust planning instruments accordingly.

Insights into the financing and funding of NBS implementation may lead to new ways of assessing environmental protection measures and their efficiency in relation to other planning objectives, in particular those aimed at improving living conditions and greater environmental and social equity. In the longer term, including the necessary public funding for NBS actions in the budgets of plans could foster the confidence of private investors.

A remarkable aspect of the NBS concept is the inclusion of public participation in the design process, a resource open to multiple competences but scarcely implemented. Incorporating NBS in planning would provide a valuable opportunity to reach out towards greater interdisciplinarity and more genuine public engagement from the conception of an intervention to its completion, thus NBS could become a trigger of much needed transformation of planning to become fit for coping with the challenges of the 21st century.

7 BY WAY OF CONCLUSION

As an outcome of this discussion, there are reasons to assume that, even with high costs and implementation difficulties, NBS can contribute positively to the fight against adverse climate change and enhance the sustainability of cities and regional ecosystems. NBS alone will not be able to overcome the lack of connection between a comprehensive application of NBS at regional level and fragmented NBS implementations at city and often only at building levels without being linked to a cohesive integrated policy for sustainable development and climate emergency. Incorporation of NBS into existing planning measures to protect and enhance the environment may provide an opportunity to improve the current fragmented planning system, subjected to multiple, uncoordinated, possibly contradictory policies and governance modes to become more effective in contributing to sustainable development while preventing further inequalities.

Nature-Based Solutions and a Just Transition: Understanding the Jobs, Skills and Training Requirements for NBS to Contribute to the Green Economy

Leslie Mabon

(Dr Leslie Mabon, School of Engineering and Innovation, The Open University, Milton Keynes, UK; leslie.mabon@open.ac.uk)

1 ABSTRACT

This paper evaluates potential for nature-based solutions (NbS) to contribute to a just urban transition, through fair and decent work for people in cities with industrial or high-emitting economies. The idea of a just transition –a move to a zero-emission and sustainable society that does not leave behind the people and places whose jobs and livelihoods rely on high-emitting industries – is gaining signficant attention in international scholarship and policy, including urban policy. However, although there is increasing awareness of the "green jobs" opportunity associated with energy, understanding of the potential for new jobs associated with NbS in the urban economy is more limited. At the same time, there is also a growing acknowledgement that successful urban NbS interventions will require long-term stewardship. Developing a workforce with the skills to maintain and enhance NbS is thus critical if multiple benefits are to be realised.

The role of nature-based solutions in a just transition, and skills requirements for NbS stewardship, are explored through the case of Glasgow in Scotland, United Kingdom. Glasgow is a valuable case as it is a post-industrial former manufacturing and shipbuilding city, which has in recent years suffered deprivation and public health. From an urban planning and policy perspective, city- and national-level climate adaptation and transition plans have given impetus towards a just recovery and transition towards resilience for the Clyde Corridor and for the Glasgow City Region more widely. Glasgow is thus valuable for understanding the jobs, skills and training requirements for NbS, in that it is (a) at a stage where there is a clear policy and planning vision of what NbS deployment in the city region might look like; and (b) home to a large workforce who are likely to need retraining or up-skilling in response to the climate change challenge.

A typology of jobs requried to realise a just urban transition through NbS is developed from review of international scholarly literature, and is used as the analytical framework for the paper. Key job areas that are identified include jobs in construction, land-based sectors, civil engineering and cross-cutting sectors to support societal transformation. Governmental statistics are then used to identify opportunities for particular neighbourhoods or sections of the workforce to benefit from training or upskilling, so that NbS jobs may contribute to just resilience for Glasgow. Existing skilled workers in sectors such as manufacturing and utility supply, which are projected to see declines, may be able to re-skill to support embedding NbS into new-builds and retrofitting in the construction industry. Expanding 'skills passports' to encompass NbS jobs may support this. Data also suggests, however, that in construction- and land-based sectors, there is an ageing workforce and a coming need for replacement labour. Particularly in employment-deprived areas, qualifications in construction, civil engineering and land-based sectors may provide younger people with vocational-level qualifications with an opportunity to develop a sustainable career pathway that will support stewardship for NbS. Moreover, the significance of cross-cutting skills at community level should not be underestimated as support for putting NbS implementation and stewardship into practice.

Reflecting on the urban just transitions and urban NbS policy literature more widely, based on insights from Glasgow City Region, I argue there is a need for particular attention to, and emphasis on, NbS jobs that may be available to sections of the workforce that may be more likely to struggle to find work as traditonal industries are wound down. In other words, there remains a need for more understanding of adaptation and resilience jobs for those with vocational qualifications, alongside the planning and management-type jobs that are perhaps better understood. There is also a need to ensure that understanding of the skills and capabilities for NbS stewardship are integrated into univeristy and college curricula for sectors such as construction and civil engineering, and to protect and update curriucla in areas such as land management and urban ecology Fuller spatial data on workforce skills and adaptation job requirements will help to better understand how the NbS urban green economy opportunity links to the existing and future workforce.

Keywords: climate adaptation; just transition; nature-based solutions; resilience; urban policy

2 INTRODUCTION AND RATIONALE

There is within Scotland and globally rising awareness of the need for consideration of the employment aspects of a resilient net-zero society. The importance of securing fair, decent and environmentally sustainable jobs for workers in sectors likely to be incompatible with climate change obligations in their present form (e.g. oil and gas, steel manufacturing, petrochemicals) has long been argued by trade unions (Rosemberg, 2015) and also by NGOs and political parties with stronger leanings towards environmental and social justice issues (Platform/Friends of the Earth Scotland/Greenpeace, 2020). In Scotland, this trend has been met with acknowledgement at national government level of the imperative to understand the jobs opportunities associated with Scotland's climate response. This interest is reflected in the establishment of a Just Transition Commission, tasked with (among other goals) advising on how Scotland can plan and implement a transition to environmentally and socially sustainable jobs, building on the strengths in Scotland's workforce (Just Transition Commission, 2021). Skills Development Scotland have also produced a climate emergency skills action plan (Skills Development Scotland, 2020) with the goal of identifying opportunities and challenges to developing new, quality green jobs associated with Scotland's response to the climate emergency. At a regional level too, the Glasgow City Region Adaptation Strategy raises the idea of 'just resilience', which includes ensuring workers whose jobs are impacted by climate change are able to requalify and move towards green growth sectors (Climate Ready Clyde, 2021).

The breadth of strategies and policy initiatives outlined above illustrate the growing awareness of the need for quality green jobs and of the opportunities for job creation in areas such as renewable energy and energy efficiency. Nonetheless, bearing in mind that adaptation to a changing climate forms another central component of Scotland's climate response, the potential for jobs associated with climate change adaptation and resilience more widely has perhaps received less explicit attention in Scotland to date.

The purpose of this report is therefore to review elements of recent and ongoing work on "green jobs" in Scotland and the wider UK that are relevant to climate change adaptation and resilience for the Clyde Corridor area of the Glasgow City Region; to characterise the extent to which current policy initiatives and practice may support adaptation- and resilience-linked jobs and training in the Clyde Corridor; and to inventorise programmes which may provide training opportunities for skills related to adaptation and resilience across Glasgow City Region.

Note that a longer and fuller verison of this paper, including underling data tables and fuller discussion (Mabon, 2023) is also hosted as a preprint on SocArXiv DOI: 10.31235/osf.io/fhgm and can be cited as Mabon L (2023) "Jobs and skills for adaptation and resilience in Scotland" SocArXiv DOI: 10.31235/osf.io/fhgm5 Available: https://osf.io/preprints/socarxiv/fhgm5/

3 CHARACTERISING ADAPTATION AND RESILIENCE JOBS

Although jobs related to emissions- and waste reduction tend to be more prominent in the scholarly and policy literature on green jobs, van der Ree (2019) argues that conceptions of 'green jobs' also ought to encompass the protection and restoration of ecosystems and adaptation to the effects of climate change. van der Ree continues that under a changing climate, some new jobs will be created (e.g. natural resource conservation, environmental advisors); some jobs will be eliminated; some jobs will be substituted for others; and that most jobs will be transformed, with workers, operators and managers in sectors including buildings, agriculture and transport learning to manage new technology and operating practices. Skills Development Scotland (2020) similarly categorise jobs under the climate emergency as fitting into: new and emerging jobs (e.g. technologies and actions that did not exist previously); jobs affected by transitions that will need enhanced skills e.g. architects, environmental consultants; and existing jobs that will be needed in greater numbers. Specific to adaptation and resilience, the Green Jobs Taskforce Report (2021) identifies adaptation-related jobs in each of these categories:

- New and emerging jobs: engineering for resilient infrastructure; construction and environmental monitoring; or adaptation finance (insurance and green bonds). Also adaptation jobs and skills for existing sectors such as housing and construction, water, infrastructure, local government, and nature conservation;

- Jobs affected by transitions that will need enhanced skills: heating and cooling (need to consider heat pump installation alongside wider measures for energy efficiency);

536

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

- Existing jobs that will be needed in greater numbers: building retrofit sector, to make buildings able to cope with conditions for which they were not designed.

In addition, the Green Alliance categorise adaptation- and resilience-related work as falling within at least two categories: (a) entry-level jobs with transferable skills (e.g. machinery operation, hazard assessment); and (b) high-level academic qualifications at e.g. degree or PhD level for ecological management (Green Alliance, 2021).Typologies and characterisations of 'green jobs' that are explicitly geared towards adaptation and resilience are limited in comparison to those that have been undertaken for climate mitigation and energy efficiency. However, Biagini et al (2014) produce a typology of ten categories of adaptation-related jobs:

- Human or Social Resources or Capital (jobs related to providing training and capacity building);

- Governance and Institutional Management and Planning (jobs related to management and planning for adapting to climate change);

- Changes in or Expansion of Practice or Behaviour (jobs in areas such as land management, rainwater harvesting, invasive species management etc);

- Governance and Institutional Policy Reform (jobs related to mainstreaming adaptation into other areas of policy);

- Information and Communications Technology (jobs linked to developing decision-support tools);

- Climate-Resilient Physical Infrastructure Adaptations (jobs linked to developing physical infrastructure for adaptation and resilience, e.g. retrofitting/constructing buildings, flood defences, sea walls etc);

- Early Warning Systems or Global Climate Observing Systems (jobs linked to developing weather and hydrometeorological systems);

- Climate-Resilient Biophysical or "Green" Infrastructure (jobs in areas such as landscape management and horticulture linked to nature-based solutions);

- Adaptation Related Financial Strategies (jobs related to financing adaptation initiatives and providing insurance);

- Expansion or Introduction of Climate Adaptation-Related Technology (jobs linked to developing technologies needed for adaptation, e.g. water purification).

Biagini et al acknowledge, however, that many of the adaptation actions they identify have in practice so far been focused on awareness raising, public engagement, and capacity-building. The evidence base is therefore more limited for adaptation- and resilience-focused jobs which involve putting adaptation rhetoric into practice through, for example, construction, implementation of nature-based approaches or construction.

4 ADAPTATION AND RESILIENCE JOBS SPECIFIC TO SCOTLAND

The Green Jobs Taskforce Report (2021) identifies adaptation-related green jobs as including flood defences, retrofitting of buildings to be resilient to extreme weather/climate events, nature-based solutions to reduce climate impacts and civil and mechanical engineering for infrastructure adaptation. In their Climate Emergency Skills Action Plan (2020), Skills Development Scotland similarly list a breadth of priority areas, of which three – construction, engineering, and agriculture and land use – are relevant to adaptation and resilience. The aim of this section is therefore to review the existing knowledge and evidence around each of these areas for Scotland and where possible the Clyde Corridor. Table 1 summarises how the 10 types of adaptation actions identified by Biagini et al (2014) map onto the existing skills requirements, supporting policies, and policy/knowledge gaps identified for adaptation- and resilience-focused jobs in Scotland.

Adaptation Category	Examples of Action	Potential relevant jobs for Glasgow City Region	Supporting Policies and Initiatives for Glasgow City Region	Potential Policy and Knowledge Gaps for Glasgow City Region
Capacity building	Training/workshops for knowledge/skills development, public outreach and education, dissemination of info to decision makers/stakeholders, Identification of best	-training and capacity-building; -facilitation; -community development and community-level interventions.	SCS CEAP (2020): need soft skills for e.g. behaviour change, stakeholder engagement, communication	

	practices, training materials			
Management and Planning	Developing an adaptation plan, livelihood diversification, drought planning, coastal planning, ecosystem-based planning, changing natural resource management	-environmental impact assessment; -adaptation planning; -urban ecological planning.	Skills Development Scotland Climate Change Strategy (2020) Business Processes workstream: support for skills in undertaking EIAs. SDS CEAP (2020): Leadership skills to support cultural change and change management as new technologies, behaviours and systems will need embedded.	Frantzeskaki et al (2020): lack of capacity in relation to innovation and entrepreneurship around NBS, so the focus on engineering solutions has led to missed opportunities for biodiversity, open space and health NatureScot (2020): loss of specialists due to austerity.
Practice and Behaviour	Soil/land management techniques; climate-resilient crops or livestock practices, post-harvest storage, rainwater collection, expanding integrated pest management	-woodland restoration and enhancement; -management of invasive species; -ecological engineering.	NatureScot Nature-Based Jobs Report (2020): peatland/woodland restoration; management of invasive species; planning, ecological engineering.	SDS CCAP (2020): need to refresh careers information and pathways into the sector which reflect both future technical requirements and the scope for the sector to contribute significantly towards addressing climate change. This is particularly important in the context of a sector (agriculture/land use) with fewer formal qualification pathways and upskilling opportunities.
Policy	Mainstreaming adaptation into development policies, land-use specific policies, improvement of water resource governance, revised design parameters, ensuring compliance with existing regulations	-adaptation, resilience and environmental management in local (and national) government; -resilience management for business and third sector organisations.	SDS CEAP (2020): Demand for higher-level skills in business and commercial management to respond to changing markets	Frantzeskaki et al (2020): need for skills to foster collaboration across silos and a need for contextual analytical skills relevant to urban planning
Information	Decision support tools, communication tools, data acquisition efforts, digital databases, remote communication technologies	-IT jobs linked to data management and communication; -community engagement on risk and adaptation.		
Physical infrastructure	Climate-resilient buildings, reservoirs for water storage, irrigation systems, canal infrastructure, sea walls	-retrofitting buildings to enhance resilience to extreme events (windproofing, rainwater protection, cooling); -skills for enhancing resilience of new-build construction (new techniques for roofing, integrating green infrastructure elements etc); -inspection and maintenance of built environment; -professional level jobs in planning, design, surveying and management; -flood prevention infrastructure;	Skills Development Scotland CEAP (2020): anticipated increased demand for professional level skills for jobs in planning, design, surveying and management and the deployment of nature-based solutions. SDS Climate Emergency Action Plan (2020): Co-design and development of a Construction Retrofit national training programme.	SDS CEAP (2020): need to demonstrate competence and recognise adaptability and transferability of skills across the sector, for instance through a 'skills passport' scheme. Ageing workforce with a third of construction workers aged 50+, and an estimated 50,000 construction workers retiring by 2029. NatureScot (2020): for flood risk management, major infrastructure players working at national level can find people with nature-based/ecological expertise, recruiting nationally and redeploying.
Warning or observing systems	Developing, testing and deploying monitoring systems, upgrade weather or hydrometeorological services	-scientific and research jobs for understanding risks and developing warning systems; -IT jobs for data management and communication.		
"Green" infrastructure	Revegetation, afforestation, woodland management, increased landscape cover	-restoration, enhancement and maintenance of urban greenspace, forestry, wetlands and community spaces; -urban ecological planning	Skills Development Scotland Climate Change Strategy (2020): 2024: 18,000 hectares of new woodlands created annually NatureScot Nature-Based Jobs Report (2020):	NatureScot Nature-Based Jobs Report (2020): "It is not possible to separately account for all elements in the NatureScot definition of nature-based activities. In particular, it is not possible to obtain specific data on nature-based solutions, environmental green

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

			peatland/woodland restoration; management of invasive species; planning, ecological engineering.	finance or urban green infrastructure activities." NatureScot (2020): how to stop losing skilled people to commercial forestry?
Financing	Insurance schemes, microfinance, contingency funds for disasters	-education and training in natural capital approaches; -financial management and monitoring; -fundraising and ensuring financial sustainability	Skills Development Scotland Climate Emergency Action Plan (2020): Ensure that natural capital and circular economy considerations are recognised as core skills across all disciplines. NatureScot Nature-Based Jobs Report (2020): existing finance sectors can adapt quickly?	NatureScot Nature-Based Jobs Report (2020): need for understanding of natural capital (and monitoring/ management skills) within finance industry.
Technology	Technologies to improve water use or water access, solar energy capacity, biogas, water purification, solar salt production		Skills Development Scotland CEAP (2020): Increased need for design, analytical and technical skills in new manufacturing processes (eco-design).	Skills Development Scotland CEAP (2020): Current skills shortages of engineers

Table 1: application of typology of adaptation jobs to Clyde Corridor and Glasgow City Region context

4.1 Nature-based solutions to reduce climate impacts

4.1.1 Jobs and skills

- peatland restoration: need field experience as well as academic qualifications; also skills in administrating/monitoring/reporting;
- woodland restoration: financing (especially as sector often charitable or public sector-funded); stakeholder engagement and cross-sectoral working;
- management of invasive non-native species;
- blue carbon;
- flood risk management;
- green finance; understanding of natural capital plus monitoring and management skills;
- planning;
- ecological engineering: natural capital approaches (all NatureScot, 2020);
- importance of skills in maintenance and stewardship of nature-based approaches, as well as initial implementation (Shimizu et al., 2016)
- higher-level skills in business and commercial management to respond to changing markets (Skills Development Scotland, 2020).

4.1.2 Opportunities and challenges

- sector predominantly made up of microbusinesses, with fewer formal qualification pathways and upskilling opportunities (Skills Development Scotland, 2020). Smaller enterprises may also struggle to recruit and retain staff against major infrastructure players (NatureScot, 2020);
- need for retraining and upskilling workforce, and to refresh careers information and pathways into sector to counter ageing workforce (Skills Development Scotland, 2020);
- challenge in creating paid jobs from conservation and restoration sectors that often rely on volunteer labour (NatureScot, 2020);
- risk of losing skilled workers to more lucrative sectors such as commercial forestry (NatureScot, 2020);
- in public sector, austerity and budget cuts mean local governments are likely to have lost people with skills in areas such as ecology (NatureScot, 2020);

- jobs in sectors such as natural capital accounting are likely to be highly skilled, i.e. Masters or PhD level, and in sectors such as financing existing staff may simply adapt or re-train Moreover, for areas such as flood risk management, major infrastructure players can recruit qualified and skilled labour nationally and re-deploy (NatureScot, 2020);

- importance of ensuring higher education remains up-to-date with ecological planning and natural capital approaches (NatureScot, 2020);

- 2023: Regional Land Use Frameworks developed (Skills Development Scotland Climate Change Strategy, 2020);

- 2024: 18,000 hectares of new woodlands created annually (Skills Development Scotland Climate Change Strategy, 2020);

- 2030: At least 250,000 hectares of peatland restored (Skills Development Scotland Climate Change Strategy, 2020).

5 EMPLOYMENT TRENDS IN THE CLYDE CORRIDOR

5.1 Labour market trends

The Green Alliance's report into Levelling Up Through Nature (Green Alliance, 2021) identifies the centre and west of Glasgow as experiencing very high labour market challenges post-pandemic; and the south of Glasgow and Clydebank as experiencing high labour market challenges post-pandemic. The rest of the Clyde Corridor is rated as facing 'average' labour market challenges, with the exception of Greenock, which faces "low" labour market challenges.

Skills Development Scotland's 2021 Regional Skills Assessments for the Glasgow College Region and the West provide a fuller and useful basis for understanding employment trends in the Clyde Corridor and their relation to adaptation and resilience-related jobs.

In the Glasgow College Region (Glasgow, City, East Dunbartonshire and East Renfrewshire), trends with relevance to adaptation and resilience include short- to mid-term declines projected in jobs in electricity, steam, gas and air conditioning supply (-300 by 2031); in financial and insurance (-900 by 2031); and in manufacturing (-3,300 by 2031), albeit with some replacement demand; plus short- to mid-term growth in professional and in construction jobs over the same time period, e.g. +500 in skilled construction, + 900 in science and technology professionals.

Glasgow College region also has Modern Apprenticeship redundancies above the Scottish average (291.4% from 2019-20 to 2020-21, compared to 135.2% over Scotland as a whole), mostly in construction but also in engineering and energy. Nearly half (48%) of the skills requirement for job openings up to 2031 is for people with higher education level qualifications at SCQF 7-10 (i.e. HNC/Modern Apprenticeship up to Degree level) (Skills Development Scotland, 2021a).

Key points to note for the upper Clyde Corridor (i.e. Glasgow City) hence include:

- Potential for current manufacturing jobs to transition to construction or nature-based jobs for adaptation and resilience;

- Potential for declines in utilities and ventilation sectors, plus growth in skilled construction, to support retrofit of buildings to enhance resilience to extreme events;

- Possibility for decline in financial and insurance jobs, coupled with growth in professional positions, to support deployment of adaptation and resilience via financing, natural capital approaches, and management?

- Importance of supporting younger/less qualified workforce in attaining qualifications which can support skills for adaptation and resilience, especially in sectors such as construction with Modern Apprenice workforce and growth projections.

In the West Region (Inverclyde, Renfrewshire, West Dunbartonshire, East Renfrewshire), trends with relevance to adaptation and resilience include short- to mid-term declines in manufacturing (-1,900 by 2031) and financial and insurance (-100 by 2031); plus short- to mid-term growth in professional, scientific and technical (+600 by 2031) and construction jobs (+300 by 2031); especially change in science and technology

540

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

professional positions (+200 by 2031). However, there is no growth in some other sectors relevant to adaptation and resilience e.g. skilled construction and building trades. The region is projected to have replacement demand (i.e. jobs to replace those leaving the sector) for agriculture, forestry and fishing (+300 jobs by 2031); also large replacement demand for construction (300 expansion jobs by 2031, plus 2,400 replacement jobs).

For the West Region, Modern Apprenticeship redundancies are well above Scottish average (363.2% from 2019-20 to 2020-21, compared to 135.2% over Scotland as a whole), mostly in construction but also some in engineering and energy. 46% of the skills requirement for job openings up to 2031 is for people with higher education level qualifications at SCQF 7-10 (i.e. HNC/Modern Apprenticeship up to Degree level) (Skills Development Scotland, 2021b).

Key points to note for the lower Clyde Corridor (e.g. downstream coastal areas) hence include:

- Potential for current manufacturing jobs to transition to construction or nature-based jobs for adaptation and resilience;

- Replacement demand for agriculture/forestry and construction may give an opportunity to upskill replacement workforce with capabilities in nature-based solutions and in construction/retrofitting for adaptation and resilience;

- Some limited possibility for decline in financial and insurance jobs, coupled with growth in professional positions, to support deployment of adaptation and resilience via financing, natural capital approaches, and management?

- Importance of supporting younger/less qualified workforce in attaining qualifications which can support skills for adaptation and resilience, especially in sectors such as agriculture/forestry and construction with significant replacement labour requirement projections.

5.2 Existing training and upskilling opportunities in the Clyde Corridor

The Green Jobs Taskforce's (2021) Recommendation 10 is to "map, review and enhance other training pathways […] to ensure they support a diverse, inclusive and net zero-aligned workforce across the UK". To undertake this exercise for the Clyde Corridor in the context of adaptation and resilience jobs, a reviewer was undertaken of the qualifications provided by further- and higher education institutions in the Clyde Corridor which may offer upskilling or retraining for adaptation and resilience-related jobs.

Construction and civil engineering qualifications appear to be well-represented across all levels. However, given the need to integrate future climate projections into present design (Shi and Moser, 2021) and for current buildings to need to be resilient to more extreme events in future (Stewart and Deng, 2015; Grynning et al, 2020), it is vital to ensure that adaptation and resilience content is embedded within curricula in the present – ideally with a specific focus on the conditions likely to be faced in the Clyde Corridor. It is notable that only a small number of institutions offer qualifications relating to landscape management or urban ecology. Given the prominence of nature-based solutions in both the Glasgow City Region Adaptation Strategy and the Glasgow City Open Space Strategy, the limited number of opportunities for building skills in implementation and stewardship (Shimizu et al, 2016) of natural and semi-natural spaces (especially at vocational and further education level) may require attention. It is also notable that at under- and postgraduate level, the Clyde Corridor's higher education institutions offer a breadth of cross-cutting qualifications relevant to the societal dimensions of adaptation and resilience. This could, however, be supplemented with more vocational qualifications in areas such as community development.

6 KEY ISSUES, LIMITATIONS AND FUTURE RESEARCH REQUIREMENTS

A critical challenge raised across several of the policy documents reviewed for this study (e.g. Skills Development Scotland Climate Emergency Skills Action Plan; Green Alliance Levelling Up Through Nature Policy Insight) concerns getting younger people into the workforce for the sectors that are likely to be critical to adaptation and resilience. The Skills Development Scotland regional audits for Glasgow and West note a particular need for workforce replacement in the construction, heating/ventilation and agriculture/land sectors. Recruiting replacements with the skills to implement adaptation actions may necessitate changing perceptions of sectors such as construction and nature-based jobs (Skills Development Scotland, 2020).

There is also a related issue around providing adaptation and resilience-related jobs which bring skilled employment for sections of the population who may struggle to find work (Brocklehurst et al., 2021). Existing research appears to have good awareness of the professional (i.e. degree) level jobs associated with planning and management for adaptation and resilience, whereas evidence on vocational skills and qualifications for sectors such as construction and nature-based adaptation is more limited. There may be particular need to build understanding of the potential for adaptation- and resilience-related jobs in urban areas that are suitable for those with vocational or applied qualifications, in addition to degree-level jobs in urban areas linked to adaptation, which are perhaps already better understood.

Another key challenge is ensuring there is a coordinated central source of data on the labour force, skills, and adaptation/resilience job requirements for the Clyde Corridor and wider Glasgow City Region. NatureScot (2020), in their comprehensive report on nature-based jobs and skills, note that it is not possible to obtain specific data on jobs and skills relating to nature-based solutions, urban green infrastructure and environmental green finance. Whilst Skills Development Scotland and Scottish Government Statistics provide a breadth of data on neighbourhood deprivation, labour force statistics and skills, less well represented are some of the jobs and skills requirements from private sector developers. Further research and enquiry may therefore wish to work with local authorities and private sector developers to quantitatively estimate the size of the jobs opportunity for adaptation-related actions in sectors such as construction, civil engineering and land management over the coming decades, and to break down the distribution of these jobs spatially. Data of this nature will help to provide a fuller picture of how closely the adaptation and resilience jobs opportunity in the Clyde Corridor maps onto locations which may stand to benefit.

7 CONCLUSIONS AND RECOMMENDATIONS

The following conclusions and recommendations are drawn for developing adaptation and resilience-related green jobs along the Clyde Corridor:

- The construction, civil engineering and land-based sectors are likely to be the main sources of adaptation and resilience-related jobs in the Clyde Corridor, along with cross-cutting positions linked to supporting societal interventions for adaptation and resilience-building;

- Communities in the east and west of Glasgow, as well as in West Dunbartonshire and Inverclyde, may benefit from targeted programmes aimed at upskilling or retraining workers to meet employment needs in the construction and nature-based adaptation sectors in particular. Data suggests these areas face high employment deprivation, as well as an above average proportion of either low-qualified adults or highly-qualified adults who are out of work. Particular job requirements may include retrofitting and enhanced maintenance/inspection of the built environment, as well as implementation and long-term stewardship of nature-based solutions;

- Projected labour declines in manufacturing and utility supply may provide a skilled workforce, or a workforce willing to undertake retraining, to meet skills and labour replacement requirements in construction and land sectors along the Clyde Corridor. However, 'skills passports' for more experienced workers and messaging/engagement to shift perceptions of construction/land sectors among younger workers may be required to maximise this potential;

- There already appears to be good awareness of the types of adaptation and resilience-related jobs in the Clyde Corridor that are open to those with degree-level qualifications. However, there may be need for greater empirical evidence, and also greater engagement with workers and trade unions, on the adaptation and resilience job opportunities that are open to workers with vocational qualifications in urban areas;

- Further- and higher education institutions along the Clyde Corridor offer qualification pathways to meet skills and training requirements for adaptation. However, it is imperative to ensure curricula embed adaptation requirements now in order to provide a skilled workforce for the near future. Further education/vocational training provision also ought to be enhanced for landscape and ecology and for community development sectors to support implementation in practice.

1 ABSTRACT

The impacts of the current urbanization and climate change challenges are well documented, as well as, the role of cities and the urgent action that needs to take place at the local level, especially in small and middle-sized cities. As extreme climatic events unfold, there is a need to identify the potential and the strategies that can help municipalities steer urban planning on a more sustainable and resilient track to reach the global climate goals within the next decade. Now more than ever, Nature-based solutions (NbS) such as Blue-green infrastructure(BGI) are proving to be a feasible alternative for cities to adapt their urban environment in response to climate change, while simultaneously obtaining economic, environmental, and social co-benefits.

Anticipating climate challenges in cities makes it vital to change today's traditional urban planning into initiatives that consider greener solutions like BGI. However, some implementation barriers such as the lack of stakeholders' involvement to navigate and co-create a more resilient and adaptive city environment, make difficult the transition.

As part of the Morgenstadt Global Smart Cities Initiative (MGI), financed by the German Government through the International Climate Initiative (IKI), the city of Saltillo located in the Northeast region of Mexico is paving the path towards sustainable urban planning through the City Lab project. In the first phase, the City Lab consisted of an integrated urban analysis, stakeholder engagement, and the co-creation of a roadmap of solutions by experts and local actors to tackle the city's urban challenges. The City Lab process allowed anchoring the identified measures in the planning documents of Saltillo, ensuring the implementation of the roadmap in the long term. Simultaneously, it opened up spaces for co-creation and community engagement valuable to understand the city´s local environment and identify its potential. In the second phase of the City Lab, the implementation of a pilot project based on BGI addressed the most pressing problems of the city such as pluvial floods, water scarcity, and depletion of aquifers. In this regard, the stakeholders were actively involved in analyzing, planning, formulating, developing, implementing, testing, evaluating, and maintaining the pilot project to cope with climate impacts and contribute to sustainable urban development in the short, medium and long term. In this paper, special attention will be given to the process of pilot project implementation, showing the efforts that the City Lab Saltillo is undertaking to implement BGI techniques such as rain gardens, infiltration basins, permeable pavement, and vegetation in a public and urban space as an adaptation measure in response to climate change. This effort is reshaping the city's discourse, shifting the role of urban planning, and highlighting climate action as a shared responsibility among the public, private, academic, and civil society.

Keywords: Urban planning and co-creation, Blue-green infrastructure, Nature-based solutions, Climate change adaptation, Governance of Nature-based solutions

2 INTRODUCTION

In the current race against climate change impacts, urban interventions for mitigation and adaptation gain relevance when dealing with middle-size cities, covering approximately 45% of urban areas in emerging economies like Mexico, and expected to bear the brunt of climate impacts in the coming decades (UN-HABITAT, 2022). On the other hand, the need to update the planning processes and urban interventions calls for immediate action and for pilot concepts that are easily implemented, tested and replicated in case of success. Implementing nature-based solutions (NbS) as actions that aim to protect, sustainably manage, and restore natural and modified ecosystems addressing current societal challenges (IUCN, 2020),is a feasible alternative to address current climate challenges in middle-size cities from emerging economies. NbS is also an umbrella term for a variety of nature-based approaches such as Low-Impact Development (LIDs), Best

Management Practices (BMPs), Green infrastructure or Ecosystem-based Adaptation (EbA) among others (IISD, et al., 2022). For the pilot project in Saltillo, the implementation of NbS has been done through Blue-green infrastructure (BGI). The latter offers the greatest benefits for the provision and control of water quantity and quality as well as biodiversity. Being flood control one of the key services of BGI, it allows substantial hydrological functions easing the interception and allowing the retention of rainwater and stormwater, and at the same time offers benefits along the recreational, cultural, and well-being dimensions (Bacchin, K., et al 2016; Kopp et al, 2021).The implementation of the pilot project in Saltillo is expected to increase and improve green permeable areas in the city, the reduction of floods and their impacts, and promote citizen engagement and participation in urban planning processes.

2.1 Saltillo climatic conditions

The Mexican city of Saltillo has a population of almost one million inhabitants (INEGI,2020). The city located in the desert of Coahuila is a highly vulnerable area exposed to variability in hot temperatures between spring and summer (Fig 1). Nevertheless, during the short rainy season, heavy rainfall and storms are frequent due to mainly intense atmospheric phenomena (Mok et al., 2021). Despite Saltillo´s average annual precipitation of 484 mm, the climatic conditions and extreme weather cause floods and droughts (IMPLAN, 2021). However, these extreme events are not the only ones; the city suffers heat waves during the spring and summer, and cold temperatures in winter.

Fig. 1: Localization city of Saltillo, Mexico.
