In addition to the above, the city of Saltillo has had rapid urbanization, growing extensively as a sprawling city. Its urbanization patterns characterized by the concentration of the population in the centre of the city with few green spaces and sealed permeable surfaces, exacerbate the increasing temperature, the urban heat islands (UHIs), and flooding in urban spaces due to the lack of pluvial drainage in most parts of the city and insufficient capacity in areas where it exists. It is expected that the effects and impacts of climate change in Saltillo and the region will be worse than today, and with the combination of rapid and unplanned urbanization, extreme events will be more frequent with many monetary and non-monetary consequences for the population (Mok et al., 2021).

2.2 Pilot project background: Saltillo's city profile and roadmap

Through the first phase of the City Lab, it was possible to identify opportunities to improve the performance of Saltillo in selected sectors and to develop custom-made, sustainable and integrated solutions to improve the urban infrastructure processes or services. This research phase was supported by interviews with local actors and resulted in a city profile as a diagnostic of the city with identified potentials and a roadmap with project ideas that were co-created between the City Lab team and the local actors. In the water sector, the urban assessment highlighted challenges such as flooding, lack of rainwater drainage, and water shortage as pressing in Saltillo. To address these challenges, a recommendation was made to integrate Blue-green infrastructure into the urban space, enhancing the city's green permeable areas and recharging already overexploited aquifers by creating a sponge city effect (Ordonez J.A., et al., 2021).Such a recommendation was taken forward in the pilot project implementation.

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3 METHODS AND TOOLS

The pilot project was developed by an international and interdisciplinary team composed of research institutions such as the University of Stuttgart IAT and the Fraunhofer Society and a local team formed by the Municipal Planning Institute (IMPLAN) and the Tecnológico de Monterrey. The international institutions performed the project coordination, and the local team provided the local know-how, conducted the stakeholder management and outreach, and coordinated the research and the pilot project implementation on-site. To achieve the implementation of the BGI techniques such as rain gardens, infiltration basins, permeable pavement and vegetation in a public and urban space as an adaptation measure to climate change five steps were developed (see Fig. 2).

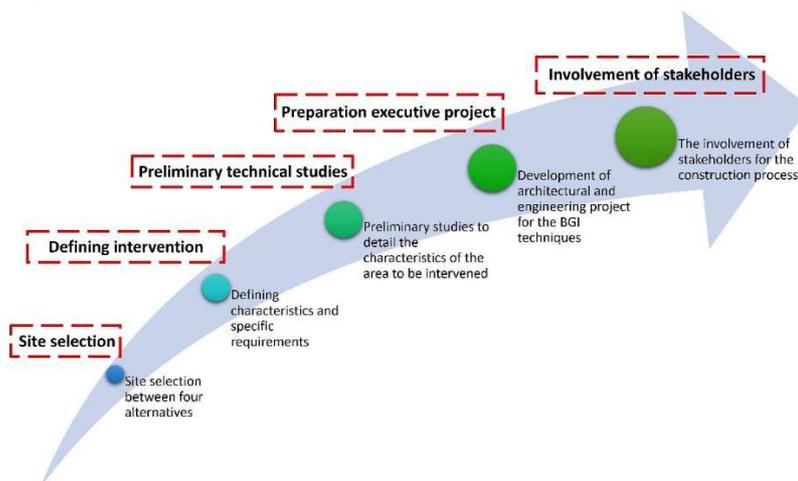

Fig. 2: Diagram process of the implementation pilot project.

For step one, site selection, the team performed a mapping exercise with a Geographical Information System (GIS)to identify public spaces that flooded after rain events and where citizens were affected by them. Then, the sites were evaluated using similar criteria and presented to the Mayor of the city, the Directorate of Public Works, and the Directorate of Urban Development to find the most suitable place to intervene. The following criteria were considered during the evaluation:

- Facilities and networks: No public networks were affected during the construction work.
- Flood risk and frequency: Frequency of flooding events per year.
- Social impact: Number of citizen complaints due to flooding.
- Land use: Public or private space.
- Population density: Benefited citizens.
- Aesthetic urban development: The potential of improvement of the green public space.
- Contribution to the achievement of the City Lab Project objectives: Demonstrative adaptation measure.

To define the intervention, a participatory process was carried out aiming to involve the neighbours in the co-creation of the pilot project. During this exercise, the neighbours were asked about the current use of the public space, their experiences during the flooding events, and their expectations from an urban intervention to improve the area. In the third step, preliminary technical studies were conducted to understand the characteristics of the area to be intervened. Technical studies such as a topographic survey, soil mechanics, hydrological study and vegetal inventory were executed. With this information, the next step consisted of the elaboration of an executive project, appointed through public bidding. The company selected for the implementation was responsible for making architectural and engineering designs for the public square. In this step, the City Lab local team and the selected company carried out a SWOT analysis of environmental and socio-cultural characteristics to be considered in the design process for the integration of BGI techniques. The design proposal, acknowledging the physical characteristics of the selected site, involved the topography, urban trees, landscape, and hydrographic and hydrology conditions of the site. Regarding socio-cultural aspects, the design proposal focused on multiple users and rights holders' involvement. To anchor

the project in the local environment, the fifth step consisted of the involvement of stakeholders that could support the project's implementation and maintenance after the end of the City Lab project in Saltillo.

4 RESULTS

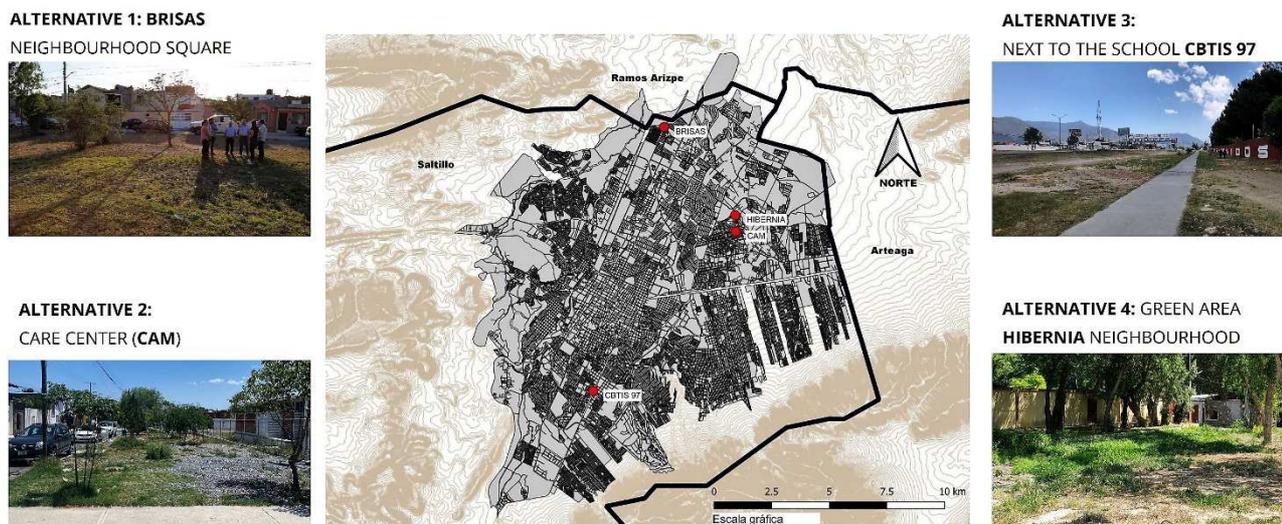
The implementation of the pilot project in Saltillo has been a joint effort that started with the MGI Initiative, and the City Lab project and was followed by city assessments, participatory workshops and the roadmap of project ideas. The integration of the Planning Institute of Saltillo (IMPLAN) in an international cooperation project like MGI drew the attention of local stakeholders and authorities, and the results of the research and the potential of the pilot project idea opened the door to in-kind cooperation from third parties. Regarding the best site for the implementation of the pilot project, mapping with GIS tools to identify the areas with pluvial flood risks showed four potential sites (Fig. 3).


Fig. 3: Pilot sites identified with GIS.

After mapping, the four sites were evaluated using similar criteria (see Table 1). Obtaining the best conditions to introduce BGI techniques was a square in the neighbourhood Brisas where there were no public networks affected, a high risk of flooding, and thus complaints from neighbours. Furthermore, the land use would allow an intervention and it could contribute to the overall MGI project objectives. The square has a total surface area of 0.35 hectares, with a total of 106 people living in 30 private homes. The population density of the area directly benefited by the pilot project is 30,388ha per km², and the housing density is 84 homes per hectare (IMPLAN, 2023). Being this square the site with the highest density of the shortlisted four, these figures highlight the overall low density in the city, one of the main characteristics of Saltillo´s urban fabric.

SELECTION CRITERIA	Alternative 1 BRISAS SQUARE	Alternative 2 CARE CENTER	Alternative 3 CBTIS SCHOOL	Alternative 4 LA HIBERNIA
Technical conditions (no public networks affected)	Good	Good	Good	Good
Flood Risk according to GIS and Saltillo´s Risk Atlas	High	Medium	Medium	High
Social Impact: Number of Citizen complaints due to flooding	High	High	High - Medium	Low
Land Use	Public Green Area	Public Green Area	Public Green Area	Private Residential
Population Density	High	Medium	High	Low
Urban Image Improvement	High	High	Medium	Low
Visibility	High	Medium	High	Low
Contribution to the achievement of the MGI Project objectives	High	Medium	Medium	Low

Table 1: Selection criteria pilot area

548

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

With the pilot site selected, a needs assessment with the neighbours of the pilot area was also undertaken. The local team contacted the Secretary for Social Development of Saltillo to gain an understanding of the procedures for citizens' involvement in planning processes. The first approach was done with the support of the Secretary and only to the local neighbours' council who manifested interest in the pilot intervention. After this encounter a workshop was organized for all neighbours to map the needs, the problematic areas after the rain events, and the current uses of the public space where the pilot is taking place. The latter was a crucial step to ensure the acceptance of the intervention and to recognise and incorporate the current dynamics and activities that take place in the pilot area (Fig. 4).

Fig. 4: Participatory processes to identify specific requirements for the neighbours.

To complete the site assessment, the City Lab team conducted technical studies with support from the Secretary of Infrastructure and Public Works of Saltillo. A topographic survey and a soil mechanics study were performed to identify the characteristics of the terrain and to assess the feasibility of the construction of a rain garden and an infiltration basin to tackle the pluvial floods in the selected area. Figure5 summarizes the topographic and hydrologic conditions of the area.

Fig. 5: Topographic and hydrologic conditions of the pilot area (Elaboration: PEW Studio)

The results of the topography survey indicate the runoff accumulates in this area without outlets or storm drains. Only one grate connected to the sanitary sewer with a reduced capacity was identified, which cannot be enlarged because it would cause an overflow through the sanitary pipes into the houses in the area. As a result, runoff accumulates in the area, causing flooding on the avenue, sidewalks and even, in heavy rains, flooding into the houses. This amount of water accumulation remains for days in the area until it is gradually drained through the sanitary sewer and evaporates or is absorbed in the green area.

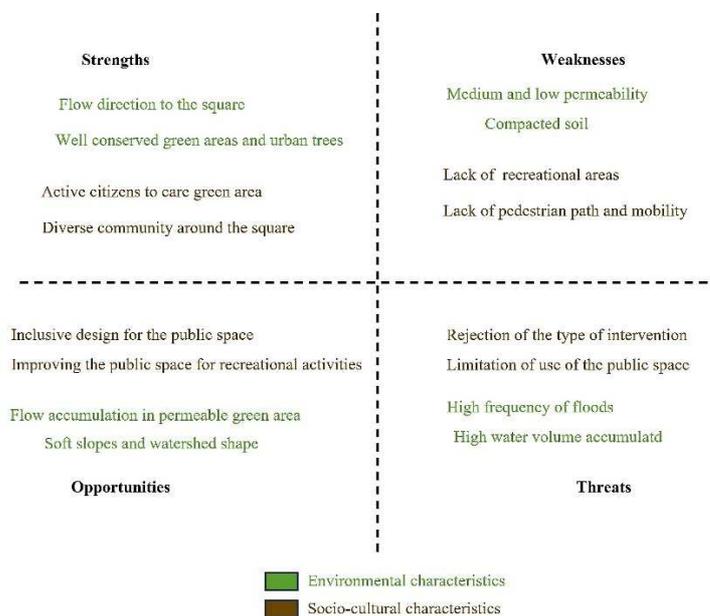
The estimation from the hydrological study shows that the maximum runoff volume that reaches the property in a two-year return period was 20,135 m3, in 5 years 42,000 m3, and in 10 years 61,740m3. In all cases, the runoff volume estimated is high. This is due to the urban basin with an area of 2.27 km2 being 95% impermeable. The simulation was carried out considering extreme storm situations with a duration of 24 hours, using the HEC-HMS software developed by the U.S. Army Corps of Engineers Hydrologic Engineering Center (HEC). Given these scenarios, it was decided to consider a large capacity for the design and size of the rain garden and infiltration basin techniques to reduce flooding events related to a year return period. Besides the technical studies forementioned, to develop the executive project, which included the landscape and engineering design for the public square, two characteristics were considered for the SWOT analysis (see Fig. 6).


Fig. 6: SWOT analysis for environmental and socio-cultural characteristics.

The analysis highlighted strengths, weaknesses, opportunities, and threats for each characteristic analyzed. The design proposal involved four BGI techniques to cope with the high water volume accumulated after rain events, the lack of pedestrian and path mobility, the limited quality public space, and the medium and low permeability, among other factors. Figure 7 shows the design of the public square integrating a rain garden, an infiltration basin, permeable pavement, and vegetation. The infiltration basin was located in the centre of the square where the run off accumulates after heavy rain. The calculation of its capacity considered the volumes identified in the technical studies. The rain garden was located along the street to mitigate the risk of flooded houses and reduce citizens' complaints. The existing vegetation was maintained and more was added to create comfortable spaces for the neighbours to stay, and permeable pavement was implemented in areas where the neighbours were already doing some activities. The considerations for the last two measures aimed to create inclusive public spaces with improved conditions for recreational activities for the local community.

550

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Fig. 7: Render of the pilot project.

During the implementation phase, a high level of involvement of local stakeholders was achieved. Not only the local community was involved and interested but also the Mayor of the city, various municipal directorates, as well as private sector representatives actively participated. The available budget of the MGI project for the pilot project in Saltillo was only allowing a percentage of the overall project design. Thanks to the outstanding project dissemination during the first phase of the CityLab, and the acknowledged relevance of the project by the local stakeholders, the municipality contributed with technical studies and the landscaping of the square. Private companies contributed to the excavations for the infiltration basin and the rain garden, and the local community contributed knowledge and valuable insights from the pilot area. Stakeholder outreach and management as well as the overall planning was performed by the City Lab team. The company appointed for the design, performed as well the construction and works management to deliver the BGI techniques.

5 DISCUSSION

In times of rapid urbanization, increasing population, resource depletion, degradation of ecosystems, growing pressures on urban land and water resources, and a climate crisis, Nature-based Solutions (NbS) such as Blue-green infrastructure (BGI) provide multiple opportunities for both society and nature to increase their climate resilience (Rizzi and Utkarsh, 2020). These solutions bring diverse natural and semi-natural features and processes into urban and rural landscapes, through locally adapted, resource-efficient, and systemic interventions to provide different ecosystem services that can be useful as adaptation and mitigation measures for climate change (EC, 2020).

Like many cities, Saltillo's future needs to be anticipated, changing from today's urban spaces into blue-green spaces, and implementing BGI as an adaptation measure for the climate crisis. However, the implementation of NbS is not yet well disseminated in certain areas and in some cities of emerging economies is still a mechanism to be explored. This was evident in Saltillo, where this type of infrastructure was not implemented before, and there is a shortage of contractors in the region with expertise on this particular topic.

While international cooperation projects such as the MGI Initiative and the City Lab in Saltillo opened the door for funds, stakeholder engagement, research and co-creation of solutions for sustainable urban development, they are only the first step in a socio-urban transformation that needs to be promoted by the city including all public, private, academia, and civil society sectors. This is a key finding that points to the role of the governance of NbS as the enabler of these types of interventions.

From the global perspective, although BGI plays a key role in sustainable urban development, their design and planning stress the need for multidisciplinary and integrated approaches that are aligned with frameworks of global relevance such as the SDGs(Kopp et al, 2021) and to the strategic planning documents in the city such as Climate Action Plans. On the other hand, despite the efforts of global agreements and instruments to make climate action more inclusive and transparent, in most countries, it continues to be considered primarily a government task. Being NbS a people-centric approach for climate adaptation that

involves decision-making over public goods, the involvement of different stakeholders with different interests is key to ensuring climate justice(GIZ, 2019).

In both phases of the City Lab project in Saltillo, the relevance of intersectoral participation to anchor the project results in the city's environment was evident and thus highlighted the role of the public, private, civil society and academic sectors in the urban transformation of the city. This is a key finding to understand and go beyond the limitations imposed by short-term projects, such as the City Lab, which come with time and financial limitations. The governance of NbS approaches such as BGI needs to be considered to overcome barriers to urban transformation. From the policy perspective, established visions, plans and strategies are necessary and need to be supported with laws that define institutions for the adaptation processes and that establish implementation mechanisms. Policies and laws need to be accompanied by processes that promote public participation and communication, monitoring and evaluation and conflict resolution (Iza A., 2019).

From the social perspective, BGI has the potential to empower communities when involved in the project phases, including their perspective and knowledge in the analysis, design, implementation and monitoring of the intervention (Kopp et al., 2021). The recognition of the current activities performed by the neighbours in the pilot area was crucial to engaging the local community and rights holders in the process. Thanks to the scope and size of the intervention of the pilot project in Saltillo it was easier to reach out to stakeholders with a clear message of what was intended and their replicability potential and benefits for the city.

With the selection of the four BGI measures in this pilot project their replication could be executed even in smaller areas that require less time, costs and effort in its interventions. From the experience of the implementation of the pilot project in Saltillo, the installation of permeable pavements and greening were the least time-consuming measures while the implementation of the infiltration basin and the rain garden required more work, machinery, and earth movements. The latter, of course, is because of the magnitude of the flooding in the area.

In terms of maintenance of BGI, it is important to highlight that each BGI technique is unique in terms of size, shape, components and service delivered, thus requiring specific maintenance actions (Langeveld et al., 2022).According to Vollaers et al. (2021), all BGI´s components could have specific failures that can occur within them, especially on the interfaces, and in some cases the responsibilities to solve them go from one actor to the next, impacting the cost. The experience in the case of Saltillo's pilot project showed that the decisions made by the implementing bodies played a role in how costly or easy would it be to maintain the techniques implemented. Low-cost maintenance should always be considered first since the long-term costs can be much higher than the costs associated with the planning, design, and construction phases. In this sense, it is relevant to involve the citizens and the staff taking care of the area and provide spaces for understanding the maintenance requirements. It is worth mentioning that some guidelines for maintenance activities exist, such as those proposed by Seattle Public Utilities (2019). This guideline recommends the maintenance actions needed before visual inspection. Finally, it is worth highlighting that if the maintenance of BGI is done correctly and promptly, it would dictate whether the long-term benefits intended are achieved.

Through the pilot project implementation, it was also evident that modular approaches with implementation phases make it easier to execute infrastructure projects, especially when time and financial resources are limited. In Saltillo, the modularity of the pilot project concept allowed the management of the financial resources available to give priority to the BGI techniques that would tackle the flooding in the pilot area.

With the implementation of the pilot project in Saltillo and the spaces for citizen participation that were opened, the municipality can work hand in hand with the local neighbours for the maintenance and monitoring of the pilot area. This was possible thanks to the timely involvement of the municipality and the local neighbours and the identification and protection of the current practices and activities of the neighbours in the pilot area. The monitoring of the project provides key input to the municipality to upscale or apply pilot projects like this in other districts of Saltillo.

6 CONCLUSION

The implementation of NbS such as BGI is proving to be a suitable approach to cope with the impacts of climate change in middle-size cities where the most urgent action is required. There are many derived benefits from the ecological, social, and economic perspectives that come along with this type of

552

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

intervention. However, the success of BGI depends to a large extent on the governance structures that are conceived for their design, implementation, and maintenance. Actors from all sectors need to be acknowledged and integrated according to their interest level and vulnerability towards climate change impacts. It is crucial to align the scope of the interventions with local and global agendas, but it is also relevant to intervene with a sufficient understanding of the areas of work, the community and the local environment. This opens the door for cooperation, and tailor-made solutions to adapt to the identified climatic risks and offers a solid base to introduce monitoring and evaluation processes that are key to building a solid base in the replication of such measures. While international cooperation and financing mechanisms are essential to kick-start rapid sustainable urban transformation at the local level, they are not sufficient to transform cities in their entirety. Thus, the need to anchor this type of scheme with strategic planning documents and to the local environment of stakeholders is the key to sustainable urban transformation, adaptation, resilience, and liveability in the face of climate change.

Neuroarchitecture Approach to Female Perception of Safety in Public Space

Nesreen Aiad, Khalid S. Al-Hagala, Hassan Abdel Salam

(Eng. Nesreen Aiad, University of Alexandria, Faculty of Engineering, Alexandria, Egypt, nesreenaiad@gmail.com)
(Prof. Dr. Khaled Al-Hagla, University of Alexandria, Faculty of Engineering, Alexandria, Egypt, khagla@alexu.edu.eg)
(Prof. Dr. Hassan Abdel Salam, University of Alexandria, Faculty of Engineering, Alexandria, Egypt, hasalam@alex.edu.eg)

1 ABSTRACT

In the creation of public spaces, there is a lack of articulation of specific desired emotion to be elicited or avoided, over and beyond just utilitarian functions. Moreover, there is a lack of metrics to measure such emotions stimulated by certain design features. The neuro-architecture approach - defined as the measure of potential feelings triggered by a designed environment in an organism tested by brain response - was adopted in this study. The feeling of safety is listed as a key element of the design of public space. Women have different experiences when it comes to public space, including their perceptions of safety. Perceptions of a lack of safety in public spaces can make women less likely to occupy these spaces and miss out on the positive effects of public space on their health and wellbeing.

This paper aims to identify the design indicators that address issues of women's fears when walking on foot. In order to validate such indicators, a mixed method approach was used; including mobile electroencephalography (EEG) to understand the impact of street design on women's brain activity, interviews and a questionnaire survey, to provide context for the neuroimaging data. Syria street - an urban mixed-use street - in the city of Alexandria in Egypt was chosen for the study, where a group of women users walk along and rate indicators of safety on a Likert scale. The questionnaire included 7 indicators of safety emergent from the literature: active frontages, lighting, visibility, perimeter protection, informal control, mix of people, locomotive pathways. Results yielded significant correlations between each of the indicators investigated and perceived safety. Moreover, it established the ability of neuroarchitecture, as a tool, to develop designs that elicit specific desired emotion in users of public space.

Keywords: EEG, Perception, Feminist, Neuroarchitecture, safety

2 INTRODUCTION

"The real importance of architecture is its ability to move people's hearts deeply" – Tadao Ando (2016)

The design of public space is perceived as physical entity –a structure or a built form only. However, these are not the only factors involved. The designed environment also has effects on humans at the cognitive and the emotional level (JL Higuera-Trujillo 2021). It is possible to predict this influence in the early stages of design and before the structure is built. An emerging discipline, one that bridges neuroscience and architecture, is beginning to provide more rigorous methodologies and a growing number of research reports that explores the interaction between brain, body, and the environment (EA Edelstein 2012). The discipline derived is termed "neuroarchitecture" which may be used to articulate a testable idea about how a specific feature of design may influence psychological or physiological processes that may in turn be associated with measurable changes that reveal the impact of the designed settings on human health. The modern possibility of recording the neural activity of subjects during exposure to environmental situations, using neuroscientific techniques, provides a promising framework for future design and studies of the built environment (JL Higuera-Trujillo 2021).

Safety as an emotion, overshadows the other basic human needs (such as 'love and belonging', 'self esteem', and 'self actualization') as argued by Maslow (1943) in his seminal paper, 'A Theory of Human Motivation'. Moreover, in the design of public spaces, safety is listed as a key element of sustainable communities and an important contributor to people's wellbeing (Allik & Kearns, 2017).

Women's experience of public space is shaped by their identity which includes their vulnerabilities, specifically to different forms of discrimination and violence and harassment. Addressing these factors is about establishing adequate measures to improve the safety of women (Bhattacharya, 2016). A fundamental step in this process is to identify the factors that affect the 'feeling of safety'(Blumenthal, 2014). Moreover, measuring this 'feeling of safety' to make public spaces inclusive and safe for women is key to the issue.

Recent global prevalence figures indicate that about 35% women worldwide have experienced violence in their lifetime (WHO, 2016). According to a poll conducted by the Thomson Reuters Foundation, Egypt was

the third most dangerous country for women in terms of violence. Moreover, the country topped the list of places that are dangerous for women to visit in a trip by Skyscanner survey released in August 2017. In large part this is due to the verbal and physical harassment that women routinely face there. According to a survey released in 2013 by UN-Women, 99.3% of Egyptian women reported being physically harassed in the street. Finally, a study launched in 2011, "Study on Ways and Methods to Eliminate Sexual Harassment in Egypt," was sponsored by UN Women in partnership with National Planning Institute and Demographics Centre in Cairo. The study showed that 86.5 percent of women in Egypt don't feel safe in public transportation and that it ranks high on the list of unsafe spaces, and is the second-highest place where sexual harassment takes place, with public streets being the highest.

Accordingly, the aim of this study is to identify the design indicators that address issues of women's fears when walking on foot in the Egyptian context. This is accredited by an empirical study for a mixed-use street in Alexandria city to validate the female indicators of safety deducted in the theoretical part. In order to validate such indicators, a mixed method approach was used, including a site analysis as a preliminary stage were the female indicators of safety have been sited on maps of the street; mobile electroencephalography (EEG) to understand the impact of street design on women's brain activity; and questionnaire and self-reported measures to underpin interpretations of the EEG data.

3 LITERATURE REVIEW

"Every significant experience of architecture is multi-sensory; qualities of matter, space and scale are measured equally by the eye, ear, nose, skin, tongue skeleton and muscle." – Juhani Pallasma (1994).

Rapoport (1977) highlighted that perception is the key process to connect people within the surrounding environment (Emel Birer, Pınar Çalışır Adem, 2022). Actual safety is highly important, but it is the perceived safety that impact people's lives (Van der Giessen et al. 2017). Perception of safety (POS) is a concept that refers to an emotion generated by the perception of the potential risks to safety (Ruiter R, Abraham C, Kok G, 2001). As related to the perception of individuals, perceived safety is not directly related to objective measures of crime or of threats to safety (Bedimo-Rung AL, 2005). Low perceived safety is a negative emotional state of anxiety that is often considered as a larger problem than crime itself.

POS is considered as a multifaceted concept; thus, different measures to study the phenomenon may tap various aspects of it (Abbott et al., 2020). Jackson (2005) describes POS as a group of related concepts reflecting emotion, perceived risk, and vulnerability. The British Crime Survey (BCS) resorts to three indicators in the evaluation of POS as a construct, namely: no worry of victimization, perceived order and organization, and perceived risk or personal safety, which focus on both cognitive and emotional dimensions.

Low perceived safety has been shown to affect women's decisions and behaviours, leading to the avoidance of certain places (Miethe T., 1995). A growing research literature has investigated the factors that can affect perceived safety in open space (Maruthaveeran S, van den bosch CC, 2014) (Jansson M, Fors H, Lindgren T, Wiström B., 2013). The international research literature emphasises three groups of factors associated with perceived safety in open space: (1) personal attributes, (2) physical attributes (3) and, social attributes.

A theoretical review has been done in order to identify the factors that affect the 'feeling of safety' that are key elements to make public spaces inclusive and safe for marginalised groups. Since safety is critical to the wellbeing of all citizens, regardless of gender, the position was taken that despite group difference there are some universal principles underlying evaluation which most people share. In order to identify these principles, a literature review was conducted to identify the most effective approaches of several cities around the globe to urban safety. Approaches offers practical tools for how to begin building a safer, more inclusive city and address the causes of different forms of violence and physical harassment.

Each approach suggested various aspects that affected the feeling of safety in public spaces. These aspects were skimmed through and sorted to attain a coherent set of indicators that can be defined as general indicators of safety in public space. Each indicator was mentioned by several theories, using various terms that reflect the same value. Figure1 shows the different approaches to safety and the pinciples of each approach that has been consolidated into nine general indicators of safety.

In order to identify indicators of safety that specifically relate to female subjectivity, further review has been conducted. The literature review explored a number of reports, articles and empirical studies about street design and women's safety perception. Moreover a number of women's safety audits, conducted in different

countries, was reviewed to extract strategies and policies which aim to reduce violence against women. Principles of such literature have been matched wth general indicators of safety to be short listed to six indicators of safety related specifically to women as seen in Figure 2.

4 THE RESEARCH FRAMEWORK AND CONCEPTUAL MODEL

The research perspective on physical and social indicators was predicated upon a combination of the environmental/physical POS theories (i.e., Broken Windows Theory, CPTED, and Defensible Space), which underpin the theoretical knowledge of the study and combination of principles of the most effective approaches of several cities around the globe to urban safety (i.e. The Healthy City-Jane Jacobs, "Safe City" UN-Habitat, Gender Equity in Design Guidelines-City of Whittlesea, The safety audit methodology-METRAC, The City of Montreal for safe cities, The Safer Sweden, BoTryggt2030). In the mentioned literature, some indicators for each factor are emphasised; however, the simultaneity of their effects has not

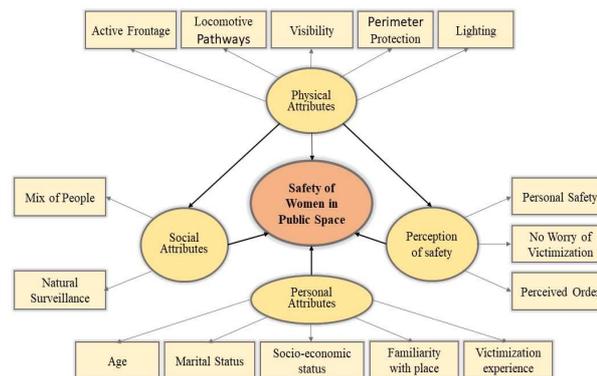
been investigated yet. The current study hence aimed to bridge the gap by modelling the possible relationships between these factors and their indicators. The research approach to women's POS was not based on unequal gender structure assumptions. However, in order to concentrate on women's POS, the search was for the indicators which affect POS among women with different individual characteristics in public spaces by reviewing a number of reports, articles, women safety audits and empirical studies about street design and women's safety perception (Study by Harkot, et. Al., 2017), Transportation Research Procedia 3 (2018), Women's Health East, Melbourne study (2020), Building safe and inclusive cities for women-2011 (a practical guide), Street Design and Women's Safety Perception Research (Rashid, Suhaila & Wahab, Mohammad Hussaini & Wan Mohd Rani, Wan., 2017) and a number of safety audits (Towards a Gender Inclusive City-Delhi, ActionAid International, 2013; UNHABITAT et al., 2010; Jagori, 2007, 2010; SAKHI, 2011; Women in Cities International, 2010a, 2010b) conducted in both the developed and the developing world. Figure 3 illustrates the conceptual model, including the primary factors of safety and their indicators, and in order to test this model, some demographic characteristics are taken into account.


Fig 3: Conceptual Model of Feminist Safety Perception in Public Space (The Researcher, 2023)

5 METHODOLOGY

The aim of this study is to identify the most important indicators of public space that evoke appropriate emotional response (feeling safe) contributing to engagement of women in public space. This will be achieved by adopting a neuroarchitecture approach to validate how the identified indicators affect the neurophysiological correlates of emotion in women.

In order to achieve such aim, this paper uses a mixed method approach for the study, conducted in three phases: The preliminary phase (Site Analysis) where activities were mapped along the entire 630 m stretch on both sides of the street between the months of April–May (2023). Through this mapping all zones of the street, were identified for detailed study. Thereafter, the indicators affecting the perception of safety, as identified in the literature review, were listed and mapped along with the activity mapping in the different zones of the street. This was followed by an in-depth study of the gendered usage of space day and night. The outcome of the site analysis was the availability of most indicators of safety along the street except for a deserted area near the end of it.

Second phase was a questionnaire based survey, where 104 female users were surveyed using a structured questionnaire where they rated the female indicators of safety extracted from literature on a Likert scale, as well as unstructured questionnaire wherein questions were asked about their social background, their experiences of harassment on the street, and there familarity with place.

Third phase was the EEG Measurments, where female participants were asked to wear the non invasive Emotiv mobile electroencephalography (EEG) to understand the impact of the street design on women's brain activity. During navigation experiment participants were asked to move from an origin to a destination, simulating naturally occurring condition in the street while the eeg device recorded their brainwaves.

6 CASE STUDY

6.1 Study Area and Sampling

The study is conducted in Syria street in Alexandria city of Egypt. The street is one of the most famous streets in the city and considered one of the best places to go out. It includes a wide variety of facilities such

as banks, school, shops, and luxury apartments. Best street sights are a Jewelry trade building, Industrial School for Girls, shopping mall and an abandoned Palace. The street was selected as it represents some of the different kinds of urban mixed-use streets common in Alexandria city and include areas differing in visibility, vegetation density, extent of facilities and level of development.

The survey sample consisted of a number of 104 random female subjects who participated in the experiment with different demographic characteristics. An online advertisement was launched on social media apps seeking female volunteers. They were asked to walk through Syria street and observe the indicators of safety before rating them in the questionnaire form on the Likert scale.

The route was the same for all participants, it was selected to include all Syria street classified into two zones. Zone A,C (mixed use,busy commercial containing banks and a girls school, shops, residential buildings and many pedestrians); Zone B (residential use, path through 160 meter blank facade of a palace wall, residential villas, graffati and rubbish, poor lighting, few pedestrians). Photographs of the two zones are shown in Figure 4. The walk was conducted during day and night time to assess how lighting changes at different times of the day affected visibility.

Fig.4 : Photos and Map of Syria street showing two different zones A,B,C

6.2 Questionnaire Survey Method

The questionnaire administrated to the sample of female participants was designed in two main sections. The first section included questions about the respondent's demographic characteristics including age, gender and occupation. In the second section, the respondents were asked to walk through the street and observe the naturally occuring enivironment to rate 28 indicator of safety investigated on a 5-point Likert scale. The street was selected upon the availability of safety indicators presenting sufficient variability in the physical and social attributes investigated. The research hypothesis to be tested is that the female safety perception has a positive relationship with the extracted safety indicators. The two versions of the questionnaire survey were pilot tested prior to data collection to insure clarity of the questions. This led to some improvements in the formatting of the questionnaire. The questionnaire form is illustrated in Table 1 with the coded street features to be rated.

Safety Factors	Code	Indicators	Architectural Features	
Physical attributes	PH1	Active Frontage	PH1.1- Density of buildings /no. of premises	
			PH1.2- Number of entrances	
			PH1.3- Number of windows	
			PH1.4- Transparency of facades	
			PH1.5- Variety of activities	
	PH2	Locomotive Pathways	PH2.1- Adequate width of pathways to walk freely without brushing	
			PH2.2- Good quality of the pavement	
			PH2.3- Absence of obstacles to locomotion	
	PH3	Visibility / Prospect & Refuge	PH3.1- Absence of obstacles that block view	
			PH3.2- Density of trees	
			PH3.3- Clearings between trees	
			PH3.4- Form of tree not blocking visibility	
			PH3.5- Possibility of being seen and seeing around	
			PH3.6- Absence of places for offenders to hide	
	PH4	Perimeter Protection	PH4.1- Availability of possible escape routes	
			PH4.2- Visibility of entrances	
			PH4.3- Permeability of fencing system towards the street	
	PH5	lighting	PH5.1- Amount of lighting	
			PH5.2- No obstacles covering light posts	
			PH5.3- Amount of glare	
Social attributes	S1	Mix of people	S1.1- Presence of people on the street	
			S1.2- Absence of threatening people (homeless, drug takers....)	
			S1.3- day	Presence of women compared to men
			S1.4- night	
	S2	Natural Surveillance	S2.1- day	Degree of observation from inside buildings, (shops or restaurants with large windows, housing with balconies)
			S2.2- night	

Table 1: Coded Items To Be Rated In The Questionnaire Survey Form (The Researcher, 2023)

6.3 Neuroarchitecture Approach Method

Neuroarchitecture is the built environment designed with principles of neuroscience, which establishes spaces that enhances wellbeing, improve cognitive abilities, stimulate brain and eases nerves. Its goal is gaining a better understanding of the relationship between emotions and architectural design by observing people's responses and measuring the relevant regions of the brain. It provides an empirical basis for the design choices made by architects, rather than settling for purely theoretical debates in design.

Feminist Safety Perception	SP1	Personal safety	SP1.1- Feeling of safety while walking alone at night
			SP1.2- The level of presence in the street at night
			SP1.3- Lack of zones you avoid walking through
	SP2	No Worries of Victimization	SP2.1- Absence of sexual harassment (verbal, touching, chasing
			SP2.2- Absence of Violent Physical attack
			SP2.3- Absence of Robbery, murder, …
	SP3	Perceived order and organization	SP3.1- Absence of young hooligans
			SP3.2- Absence of ruined places
			SP3.3- Absence of rubbish or graffiti

Neuroarchtecture relies on philosophical constructs or analysis of behaviour patterns in order to relate human responses to design. Psychological studies using subjective methods, such as surveys or interviews, have also been used to test such relationships; however, these methods rely on the subject's understanding or ability to articulate why they respond to a design element in a particular way. In contrast, neuroscientific investigations offer a higher degree of objectivity, providing a number of additional tools that can measure both conscious and sub-conscious responses without the need to interrupt the subject. Nor do researchers interfere with the results themselves by asking subjects to think about how or why they respond as they do.

This paper builds on research using Emotiv mobile electroencephalography (EEG) to investigate particular indicators of safety extracted from literature, and explore it within the theoretical paradigm of neuroarchitecture to generate specific hypotheses for the design of public spaces that are safe for women.

To achieve such an objective, the literature review incorporated studies investigating design characteristics of the urban environment that included measuring objective neurophysiological response. The neuroimaging based studies have shown that different environments may be associated with distinctive patterns of brain activity (Chang, C.Y.; Hammitt, W.E.; Chen, P.; Machnik, L.; Su, W., 2008) (Ulrich, R.S., 1981). Further research has shown differences in neural activity derived and interpreted via Emotiv electroencephalography (EEG) proprietary software when walking in various urban environments, indicating changing neural activity in response to changing urban environments (Aspinall, P.; Mavros, P.; Coyne, R.; Roe, J., 2013).

Based on psychological and neuroscience research, it has been suggested that the responses along the dimensions of stress assosiated with feeling of fear and relaxation assosiated with feeling of safety are correlated with activity in particular regions of the brain.

6.3.1 The Expirement

For the naturalistic experiment, a pilot sample of female participants, who conducted the questionnaire survey, wearing EMOTIV EPOC headset were asked to walk along the same route in Syria street that took them through the busy commercial area into the deserted area. A custom-software platform to geoannotate emotional states from Emotiv's Affectiv suite was developed in the conduct of the outdoor studies.

6.3.2 EEG Data Acquisition

Brain electrical activity was recorded non-invasively from the scalp using the Emotiv EPOC+ EEG headset with 14 channels corresponding to the international 10–20 position system (AF3, AF4, F3, F4, F7, F8, FC5, FC6, T7, T8, P7, P8, O1, and O2). P3 and P4 acted as reference electrodes. Data was recorded using Emotiv Pro software. Where different recordings of each subject have been exported as CVS files to Emotiv cloud for analysing. The output from Emotive Performance Metrics is deduced emotional reactions from brain activity. The Performance Metrics creates a different profile for each subject then interprets the EEG activity from the available channels into six emotional parameters;"Engagement" En, "Excitement" Ex, "Focus "Fo, "Interest" In, "Relaxation" Re and "Stress" St (Emotiv, 2011).

Moreover, the Emotiv testbench provides Fast Fourier Transform (FFT) Method. This method employs mathematical means or tools to EEG data analysis and transforms a signal from the time domain into the frequency domain. Where the power of the different bands could be extracted in different lobes of the brain.

560

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

In this experiment the relaxation and stress parameters were selected for analysis. These parameters were normalised for each individual and scaled as values between 0 and 1, which allowed between subject comparisons, at each sampling point. Due to the intellectual property rights of Emotiv, it is unclear what particular EEG signature underlies each of the Performance Metrics outputs. Based on findings from previous research (Aspinall, P.; Mavros, P.; Coyne, R.; Roe, J, 2013). "Relaxation" is associated with a calm relaxed state and "Stress" has negative valence. The EEG data set was generated by creating three sequential means per walking segment at the individual level and then averaging these means across the whole cohort for each walking route. These means were generated using the time taken for a given participant to complete a particular section of the walk and then dividing this into three time locked sections. It is these means that are used for the analysis of the Performance Metrics data extracted from the Emotiv pro software.

The experiment also builds on the scientific fact that Alpha and Beta frequency power are linked to negative mood, stress and depression. whereby Alpha band has higher activation in the frontal lobe in non-stressful environments (active zones of the street) and Beta band higher activation in the stressful deserted area of the street. This is associated with an increase in the P7 and P8 electrodes which are closest to the amygdala in the brain, which is a fear-related area (Pizzo et al., 2019). Therefore, using the Emotive pro tesbench, the power of Alfa and Beta bands were extracted in the frontal lobe channels F3 and F4, and in the parietal lobe channels P7, P8. The research hypothesis that there will be an increase in Alfa power band in zone A, C and an increase in Beta band in zone B, is associated with the Performance Metrics results hypothesis that there will be an increase in stress along zone B and an increase in relaxation along zone A, C.

7 RESULTS

7.1 Questionnaire Survey Analysis

The analysis of the questionnaire survey method was done using the statistical package for social sciences (SPSS V. 28) for basic descriptive statistics, and (SmartPLS 3.2.9) for SEM-PLS modeling. The first section deals with demographic characteristics. The measurement model was evaluated for the reliability and validity of the instruments with several descriptive statistics and bivariate correlations in the second section. Finaly, the examining structural model for testing hypotheses underlying this paper includes path coefficients, collinearity diagnostics, coefficient of determination (R2), effect size (f²), predictive relevance (Q2), and global goodness of fit criteria.

7.1.1 Measurement Model

Factor loadings, average variance extracted (AVE), composite reliability (CR), and discriminant validity were used to assess construct validity (Hair & Lukas, 2014). (Hair et al., 2017). The values of composite reliability should be greater than 0.6 and AVE above 0.4 (Fornell and Larcker, 1981). These indicate that the study satisfied these requirements for convergent validity and internal consistency of the scales. The values for Skewness between -2 to +2 and kurtosis between -7 and +7 are considered acceptable in order to prove normal distribution (Hair et al. 2014; Byrne 2016). The results of the normality test show that the values of Skewness and kurtosis for the constructs of the model were within the specified range.

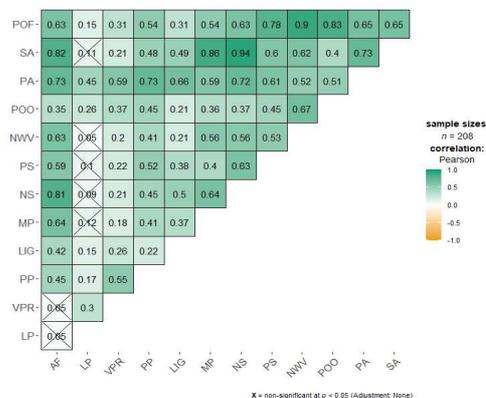

Fig. 5: Visualization of the correlation matrix

The Pearson product-moment correlation coefficient was calculated to determine the strength and the direction of the relationship between the selected constructs. Figure 5 shows the matrix of Pearson

correlation coefficients between all constructs and the dimensions. It was indicated that there is a positive relationship between the independent variables (and its dimensions) with the dependent variable (and its dimensions). It is also observed that there is a significant positive relationship between Physical attributes and Perception of Safety since $(r(208) = .649, P < 0.001)$ and between Social attributes and Perception of Safety since $(r(208) = .651, P < 0.001)$.

7.1.2 Assessing the Structural Model

Examining the structural model includes path coefficients, collinearity diagnostics, coefficient of determination (R³), effect size (f²), predictive relevance (Q²), and global goodness of fit criteria. Prior to analysing the structural model, the collinearity between constructs was examined (table 2) using variance inflation factors (VIF), and found that all values were less than the threshold of 5 (Hair et al., 2017).

Path	B	t-value	P-value	95% Bias-Corrected CI		Remark
				LB	UB	
H1: Physical attributes -> Perception of Safety	0.544	6.269	0	0.377	0.712	Supported
Active Frontage -> Perception of Safety	0.348	3.297	0.001	0.151	0.554	Supported
Locomotive Pathways -> Perception of Safety	0.028	0.539	0.59	-0.081	0.12	Not Supported
Perimeter Protection -> Perception of Safety	0.186	2.413	0.016	0.023	0.33	Supported
Visibility/Prospect & Refuge -> Perception of Safety	0.128	2.196	0.028	0.002	0.231	Supported
lighting -> Perception of Safety	0.033	0.473	0.636	-0.11	0.168	Not Supported
H2: Social attributes -> Perception of Safety	0.223	2.421	0.016	0.028	0.385	Supported
Mix of people -> Perception of Safety	0.122	2.03	0.043	-0.008	0.234	Supported
Natural Surveillance -> Perception of Safety	0.174	1.873	0.061	-0.016	0.349	Not Supported

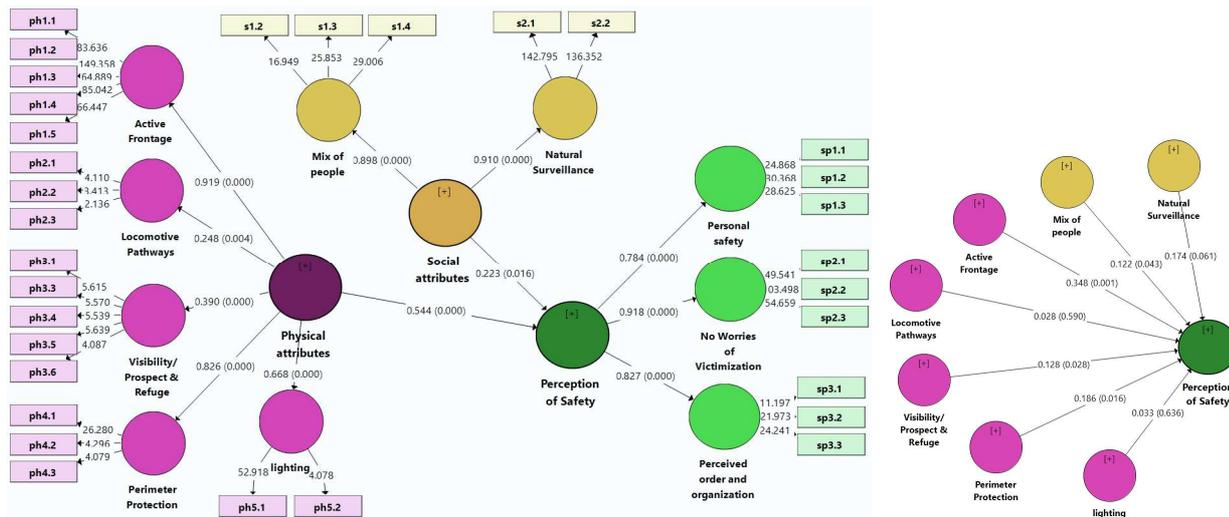
Table 2: Results of Hypothesis Testing


Fig. 6: Structural model assessment. Fig. 7: Sub-hypotheses testing

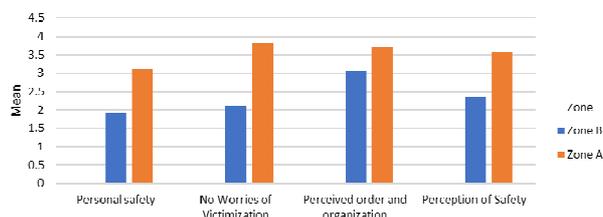
The results of hypothesis testing in Table 2 and Figure 6 showed that Physical attributes yielded a significant positive effect on Perception of Safety since $(\beta = 0.544, t = 6.269, P < 0.001, 95\% \; CI \; for \; \beta = [0.377, 0.712])$, consequently, the first hypothesis is confirmed. Moreover, Social attributes yielded a significant positive effect on POS since $(\beta = 0.223, t = 2.421, P < 0.001, 95\% \; CI \; for \; \beta = [0.028, 0.385])$, consequently, the second hypothesis is confirmed. The sub-hypotheses were also tested and given in Table 2 and Figure 7.


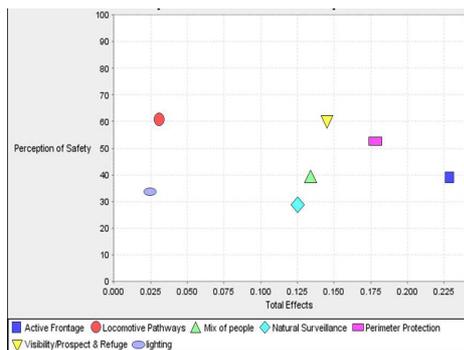


Fig. 8: Importance Performance Map. Source: Researcher, 2023. Fig. 9: Difference in perception of safety across zones.

7.1.3   Importance Performance Map Analysis

Importance performance map analysis (IPMA) was utilised to provide additional insights by combining the importance (I) and performance (P) dimensions analysis (Ringle & Sarstedt, 2016). IPMA enables the identification of places where action is necessary. Figure 8 depict the dimensions of the constructs that influence the dependent variable Perception of Safety. Figure 8 show that Active Frontage was the most important construct, followed by Perimeter Protection, Visibility, Mix of people, Natural Surveillance, Locomotive Pathways, and lighting. Moreover, Locomotive Pathways performed the best, followed by the Visibility, Perimeter Protection, Mix of people, Active Frontage, lighting, and Natural Surveillanc.

7.1.4   Personal Attributes Testing

In this section the analysis of the personal attributes will be investigated upon the respondent's satisfaction. The appropriate tests are the parametric tests, since the data were normally distributed (Table 3). The demographic variables are categorical variables with more than two independent categories, so the suitable parametric test is the analysis of variance (ANOVA) test. Concerning the age; the results show that there is a significant difference in Perception of Safety and its dimensions. Furthermore, the results for marital status show that there is a significant difference in only Perceived order and organization across the levels of marital status. Moreover, the results of Familiarity with Space show that there is a significant difference in only Personal safety.

Variable	Age		Marital Status		Familiarity with Space		Zone	
Test	F	*P-value*	F	*P-value*	F	*P-value*	t	*P-value*
Personal safety	4.438	0.013	0.378	0.686	3.506	0.032	9.968	<.001
No Worries of Victimization	1.092	0.337	0.361	0.697	0.870	0.421	12.378	<.001
Perceived order and organization	3.192	0.043	3.453	0.033	2.159	0.118	5.017	<.001
Perception of Safety	3.594	0.029	1.037	0.356	1.978	0.141	11.755	<.001

Table 3: Personal attributes results

7.1.5   Difference in Female Safety Perception Across the street zones

Since the zones of the streets are categorical variables with two independent categories, so the suitable parametric test is the independent-samples t-test. The results show that there is a significant difference in Perception of Safety and it's all dimensions between zone A and zone B since P-value is less than 0.05 as for Personal safety $(t = 9.968, P < 0.001)$, No Worries of Victimization $(t = 12.378, P < 0.001)$, Perceived order and organization $(t = 5.017, P < 0.001)$, and OS $(t = 11.755, P < 0.001)$. These differences were visually represented in Figure 9.

7.2 Neuroarchitechture Approach: Results

Although based on a small sample, the results of this pilot study was in line with the paper's hypothesis that the extracted female indicators of safety trigger a positive emotion in subjects concerning their safety perception. The results also demonstrated the potential of mobile EEG to tap into the emotional and cognitive states of women who are engaged in naturalistic tasks, like walking in urban environments. The analysis of the extracted EEG data are analysed using two methods elaborated in the following sections.

7.2.1   Performance Metrics Analysis

This anylsis is to test the first hypothesis of the neuroarchitecture approach method. At a descriptive level, a map of the route and a typical EEG record from one participant are shown in Figure 10 . The chart at the top shows the emotional levels from relaxation (1) and stress (2) that have been smoothed by Emotiv's software.

A record of the fluctuations in relaxation and stress is plotted as a map according to their geographical location in figure 11 below. For example, this participant remains relaxed through zones A and C, which are full of active frontages, whereas relaxation falls in zone B which is a deserted blank frontage. Conversely, stress seems to be lowest at the start of the walk and highest towards the end.

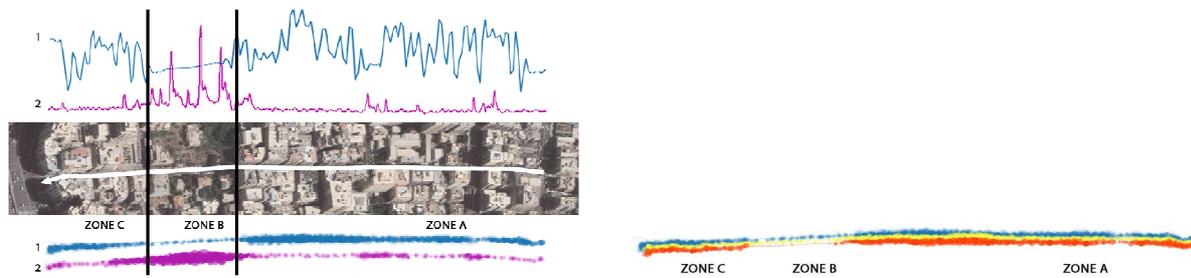
An aggregate visualisation of the relaxation levels of three participants (peaks are in red, yellow and blue, respectively) Figure 11, reveals shared patterns of emotional activity, even though the experiment was performed on different days.


Fig. 10: Map of the route in Syria street. Emotional activity of one participant during the route, in charts (top of the map) and plot in space (bottom of map). Cyan shows relaxation; Magenta shows stress. Source: Researcher, 2023. Fig. 11: Shows aggregate of relaxaion levels from the three participants. Peaks are in red, yellow and blue, respectively, for each participant. Source: Researcher, 2023.

7.2.2 Fast Fourier Transform (FFT) Method

Testing the second hypothesis of the neuroarchitecture approach method, the outcomes were in line with the FFT extracted results. As seen in Figure 12, the readings of one participant shows an increase in Alpha bands associated with relaxation in Zone A,C of the street in the F3 and F4, P6, P7 channels after 5 minutes walk and conversely an increase in the power of Beta band associated with stress in the F3 and F4, P6, P7 channels when the participant walked through zone B after 7 minutes walk shown in Figure 13.

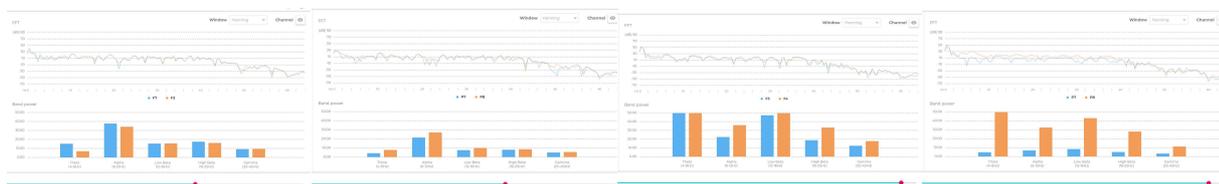

Fig. 12: Increase in Alfa band in F7, F3, P7, P8 in Zones A & C (FFT of Emotiv Pro Software). Fig. 13 : Increase in Beta band in F3, F4, P7, P8 in Zone B (FFT of Emotiv Pro Software)

8 DISCUSSION AND CONCLUSION

This paper piloted and presented a novel mixed methods study focusing on the changing mood of female subjects while walking in an active mixed-use urban street with one deserted area, using interpretations of EEG along with subjective scales. This approach allows for a deeper understanding of mood variation amongst women by identifying the indicators of safety of the physical and social environment, which influences how they feel during a walk in the street at day and night time. A Female Safety Conceptual Model was conducted to identify the different attributes that affect the safety of women in public space, which was a base for validating the indicators of safety through the questionnaire survey method. The analysis of the indicators of safety using the questionnaire survey method was done using the statistical package for social sciences (SPSS V. 28) for basic descriptive statistics, and (SmartPLS 3.2.9) for SEM-PLS modeling. The results showed that physical and social attributes yielded a significant positive effect on women's perception of safety in public space. Consequently the first hypothesis of the paper is confirmed. Only three of the indicators were found to have no effect on perception of safety which are locomotive pathways, lighting, and natural surveillance which contradicted with literature and previous studies.

Importance performance map analysis (IPMA) was used to identify the most important indicator for the perception of safety. Active Frontage was the most important indicator, while lighting was the least important. Moreover, Locomotive Pathways performed the best and Natural Surveillance performed the least. Concerning the personal attributes and the perception of safety, the paper used the analysis of variance (ANOVA) test. The results showed that there is a significant difference in Perception of Safety across the levels of age, marital status and familiarity with space. The levels of POS tend to increase with age, which is contradicting with the reviewed literature. The familiarity with space was found to help increase the POS while the divorced category was found to be the highest in their POS.

The independent-samples t-test was conducted to show that there is a significant difference in Perception of Safety between zone A (active) and zone B (deserted) of the street. Where, the perception of safety was high in the presence of such indicators in the active area of the street and the POS dropped down in the deserted area of the street, which was the base to examine the validation of such hypothesis in the context of neuroarchitecture.

The EEG recordings extracted from the Emotiv pro software has been analysed using two methods; the Performance Metrics Analysis and the FFT analysis method. The Performance Metrics Analysis presented the findings from the female participants that started their walk in the active Zone A of the street and then walked into the the deserted zone B. This pilot found evidence of high relaxation when walking through zone A, and higher stress when moving into zone B—and higher relaxation when moving out of it. The FFT analysis found an increase in the power of the Alpha band associated with relaxation while walking along the street and conversely an increase in the power of Beta band associated with stress in the deserted fearful area of the street. Consequently the second and third hypothesis of the paper are confirmed.

Results of the Neuroarchitecture approach method were found to be consistent with the results of the qustionnaire survey method. Analysis of the Performance metrics and FFT data appeared to show interpretable differences between walking through the two zones of the street, further supported by the questionnaire survey analysis, which suggested that participants experienced a beneficial effect all over Syria street except for the deserted area towards the end of it. Such evidence shows that the availability of the proposed safety indicators along the street has a main role to play in contributing to women's safety perception through mediating the stress induced by the fearful zone of the street.

This paper seeks for improvement of women engagement in public space. It is a search for the scientific evidence which could support the design. The innovative part is that instead of asking subjects about their feelings towards different design features, their brains were "asked" directly by observing which brainwave patterns were active while moving along different areas of a street setting. This new approach highlighted the most important features of public space contributing to safety perception.

This study is one of the first to use a mobile EEG system outdoors and EEG-based emotion recognition software to record emotional changes as female subjects walk through an urban environment, supported by a questionnaire survey method that provided insight into interpretations of the Emotiv testbench. However, there is still difficulty in establishing reliable interpretations of the Affectiv terms for use in this context, suggesting that further research is required using a larger sample.

Nonetheless, the paper findings are consistent with the theories and principles of perception of safety in public space and encourage the use of the technology to extend current research by developing novel and objective cortical correlates of emotion. This would be particularly beneficial in exploring the health improving potential of environments while women are on the move.

1 ABSTRACT

Rapid urbanization in cities has increased the demand for sustainable mobility options. At the Centre of sustainable urban mobility is Non-Motorized Transport (NMT). Nevertheless, NMT is confronted with lack of sufficient infrastructure despite being at the forefront of sustainable urban mobility initiatives in Lilongwe city. Therefore, this paper explores the barriers faced by implementation of infrastructure supporting NMT and the experiences of pedestrians and cyclists. The study employs a case study research design using mixed methods approach along M1 road in Lilongwe city. An open-ended questionnaire was administered to cyclists and pedestrians along the M1 road. Additionally, interviews with the officials from Malawi police road traffic and physical planning departments were conducted. The findings reveal that inadequate NMT infrastructure is due to lack of institutional capacity failing to enforce bylaws, using outdated urban structure plans and the city's prioritization of Motorized Transport. As a result, both pedestrians and cyclists are excluded from having access to economic activities which sustain their livelihoods. Pursuant to that, the study recommends institutional capacity development by prioritizing investment and development NMT for promotion of sustainable and resilient Lilongwe city.

Keywords: Infrastructure, Non-Motorised Transport, Sustainable urban mobility, Institutional Capacity, Mobility planning

2 INTRODUCTION

Globally rapid population growth has a significant impact on the urban landscape in cities leading to increased motorized transportation while neglecting non-motorized alternatives (Diao et al. 2021). As a result, African cities have made efforts to integrate Sustainable Development Goals (SDGs) in local initiatives which seeks to promote sustainable transportation that is inclusive, safe, and resilient (Bamwesigye and Hlavackova, 2019). Non-motorized transport (NMT) is at the Centre of development goals creating sustainable urban cities with improved social equity, resilience, safety and respect for the environment thereby achieving the SDGs (Risimati and Gumbo 2022). NMT leads to reduction in air pollution, alleviate traffic congestion, create safe conditions for NMT users and improve environmental conditions (Mansoor et al. 2022). However, NMT is faced with numerous challenges that emanate from the lack of integration with Motorized transport (MT) mainly because of ineffective policies deteriorating urban environment and lack of infrastructure for NMT (Lukomona and Nchito, 2022). In Lilongwe city of Malawi, NMT is at the forefront of sustainable urban mobility projects because of the city's initiative to promote sustainable transport modes, particularly NMT. Nonetheless, the existing initiatives have not been successful in addressing existing NMT challenges that are manifested through the lack of adequate infrastructure such as a number of lanes, street width, Zebra crossing, overpass, road markings and separation of pedestrian sidewalks and cycling lanes along M1 road.

The lack of NMT infrastructure has negatively affected economic growth, congestion, longer trips and increased road fatalities in Lilongwe. A sustainable urban transport system is characterized by efficiency, equitability and environmentally sensitive to social, political, environmental, and economic constraints. To ensure that there is an achievement in sustainable transport, Abu-Eisheh (2019) emphasized the need for investigating the complexes of transport infrastructure designs. The holistically approach will bring solutions to transport challenges, thus this paper aims to explores the barriers faced by implementation of infrastructure supporting NMT.

The paper is structured as follows; Section 1 is the abstract while section 2 is the introduction. Section 3 presents the literature review on NMT and its benefits. Section 4 and 5 present the study area and the

methodology respectively. Section 6 presents results and discussions. Lastly, Section 7 discusses policies and legislation guiding NMT while section 8 discusses the policy implications, recommendations, and conclusion.

3 LITERATURE REVIEW

3.1 Sustainable Transport

There are debates around what constitutes sustainable transport. Sustainable transport system is a system that is affordable, accessible, efficient and that meets the needs of society and is environmentally friendly, Ogryzek et al (2020). Conversely, Ndwandwe and Gumbo (2018) defines the sustainable transportation system as the system that allows the basic access of individuals and societies to be met safely and in a manner consistent with human and ecosystem health, with equity within and between generations. It must also be affordable, operates efficiently, offers choice of transport mode, and supports a vibrant economy and reduces production of noise. Many urban poor cannot afford motorized transport such as public buses and private cars, so they must cycle or walk to their work and business places (Bruzzone et al, 2021). The transport sector needs to create separate NMT facilities and ensure that motorized and non-motorized transport users do not use the same facilities as well as to ensure safety.

3.2 Non-Motorized Transport (NMT)

Non-motorized transport refers to any mode of transportation that does not include motorized devices or is unduly reliant on engines for motion (Astrid, 2019). Walking and cycling are the dominant NMT modes. There are various benefits of NMT that promote socio-economic development in cities.

3.3 Benefits of NMT

3.3.1 Increased livability

Non-motorized transportation promotes liveable urban environments and neighbourhood communities (Patil, 2021). For example, NMT allows the implementation of public spaces, the presence of pedestrians in the streets, and the creation of structures that incorporate a feeling of place and significance. People can interact with one another as they stroll together across urban surroundings to various destinations such as school, employment, and other opportunities when NMT mobility is effective.

3.3.2 Economic benefits

Non-motorized transportation is a common mode of transportation that is affordable, dependable, and convenient (Mbatha and Gumbo, 2022). NMT is less expensive than motorized transportation in a way that when one is walking or cycling, there are no transport fare, no parking fees, no fuel is needed, as well as lower operation and maintenance costs. It may also lead to shorter travel times in heavily populated cities and towns. Additionally, NMT offers advantages such as serving as a stand-alone mode of public transportation and incorporating affordable, efficient travel for marginalized people, particularly in emerging and transitional nations (Venter et al, 2019).

3.3.3 Environmental benefits

Increased usage of NMT in cities leads to reduced traffic congestion which ultimately results in increased mobility (Amaniyo, 2022). The environmental effects of NMT are favourable. It does not produce local air pollution or greenhouse gases, which are bad for the environment and people's health. As a result, whenever a motorized trip is replaced by a non-powered one, emissions are directly reduced.

4 STUDY AREA

Lilongwe is Malawi's capital city, located in the country's central region as shown in figure 1. The Lilongwe Central Business District is under the administration of Lilongwe City Council. The most recent census in 2018 reported that 989, 318 people live in Lilongwe (Madinga, 2021). The study covers a popular M1 road in the high-density Lilongwe town. M1 road is the backbone, as it interconnects all three cities in Malawi. This indicates that it is the most used and crowded road. M1 forms a significant part of the daily activities of people as they commute to and from public transport stations and places of work, education, and worship. It is about 347 km, but the research focused only 1.59 km which is a distance from Lilongwe town hall to

568

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

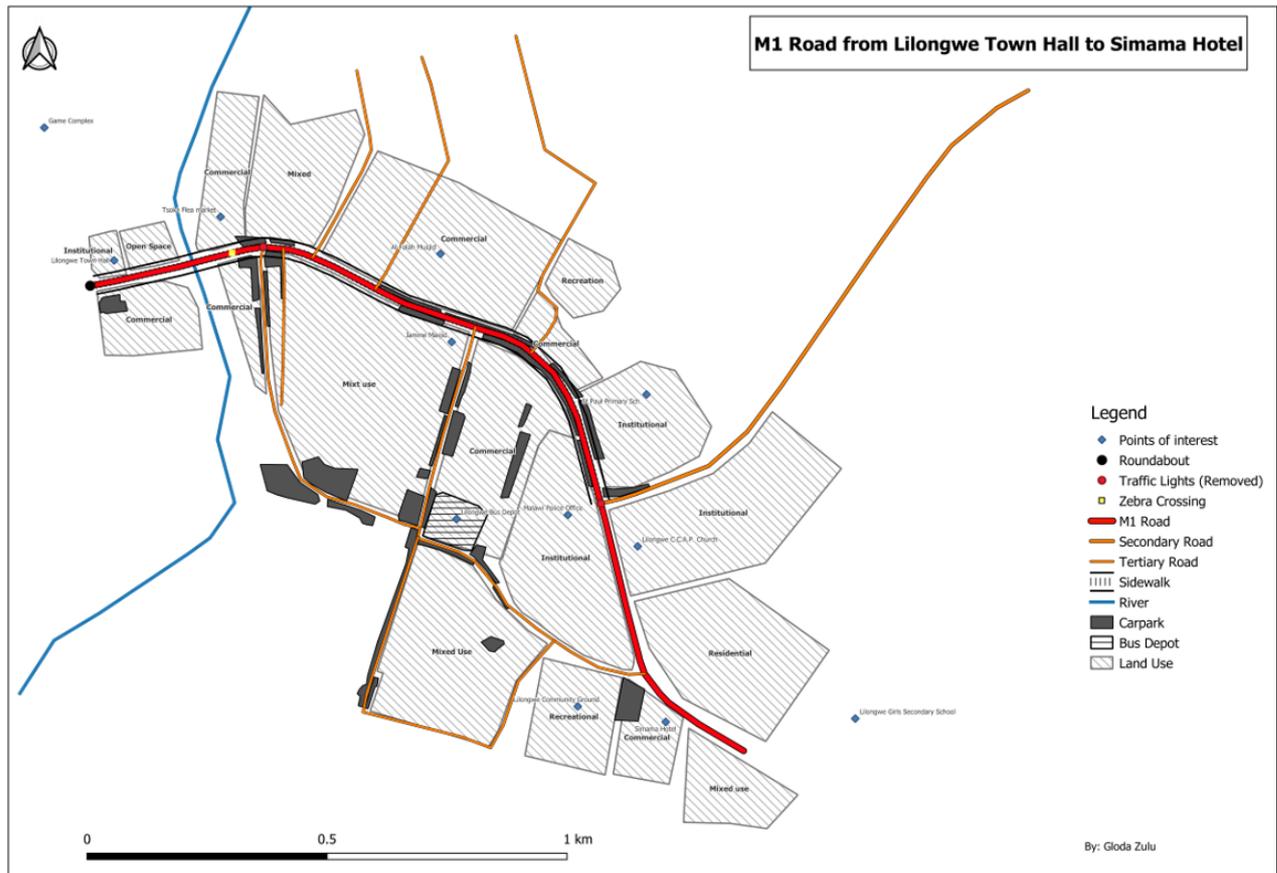
Simama hotel. 1.59km was selected because of its compactness, constant congestion from both MT and NMT. In addition, there are shops along the selected route and it is the inlet of the popular Tsoka flea Market in town. The disconnect between urban motorized and non-motorized has been exacerbated leading to multiple challenges in the city thus making M1 road (1.59km from Lilongwe town hall to Simama hotel) a suitable research area.


Fig. 1: Study Area M1 Road

5 METHODOLOGY

The study adopted case study research design which aided a comprehensive understanding of the state of NMT in Lilongwe. Using a mixed method approach, interviews and questionnaires were conducted to further analyze the barriers faced by NMT. During data collection process, questionnaires containing open ended questions were administered to NMT users which were cyclists and pedestrians. 64 NMT users were randomly selected along M1 road and given questionnaires to fill in.

Additionally, semi-structured interviews were conducted with 15 different stakeholders responsible for NMT planning. The stakeholders compromised of planning officials, officials from Roads Authority, Civil engineers, traffic police officers and association representatives. Purposive sampling was used to select key informants because they play an important role in the transport system. The data collected from the research was analyzed by two methods of data analysis which are thematic and descriptive. In thematic, the researcher read all the transcripts to identify, analyze, and report repeated patterns. These patterns and trends from data collected were coded in, and general themes were constructed for summarization. On the other hand, Quantitative data including demographic information was analyzed using descriptive data analysis where distribution of the study population, central tendency and dispersion of other quantitative variables was generated. This information is presented in the form of frequencies and percentages using Microsoft Excel.

6 RESULTS

The results presented in this section are conveyed through modal share, population distribution, experiences of pedestrians and cyclist, institutional capacity in investing in NMT infrastructure and the main barriers for NMT.

6.1 Modal Share

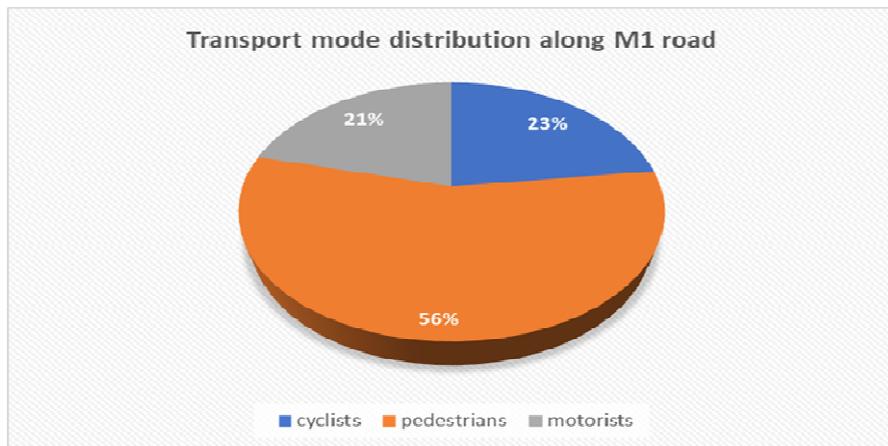
The modal split in figure 2 shows the percentage of travelers who use non-motorized and motorized transport along the M1 road in Lilongwe town. A total of 96 respondents filled in questionnaires of which the majority were pedestrians 56% while cyclist recorded 23% and vehicles consisting of minibus and private vehicles recorded 21%. The results indicate a high usage of NMT. This means that people are heavily reliant on this mode of transportation, this can be so because it is cheap and faster when there are traffic jams.


Fig. 2: Modal Share of Transport

6.2 Population distribution

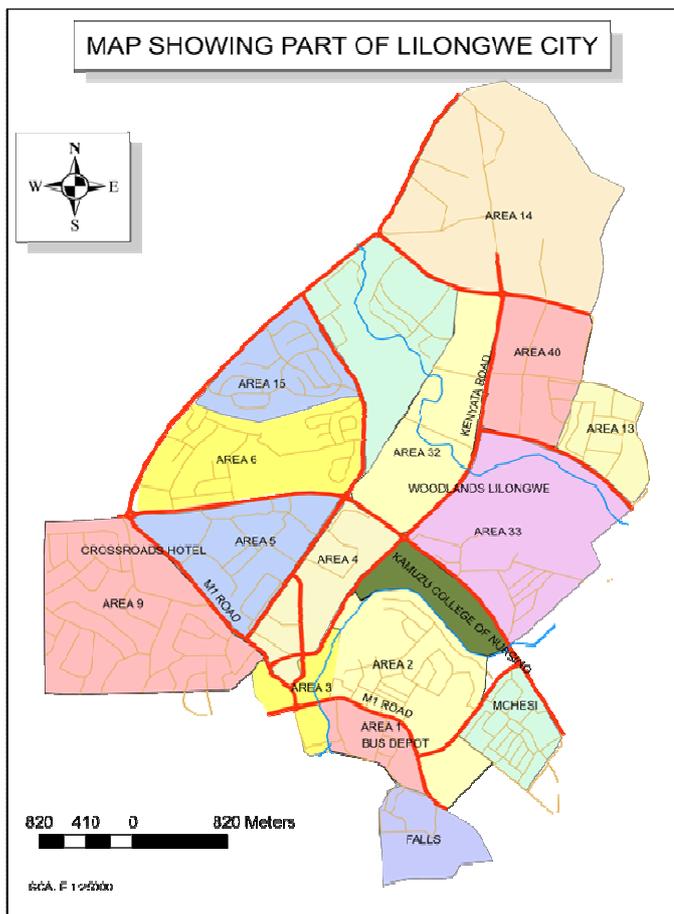
Respondents were probed on their place of residence and from the responses, there was variation in terms of where they reside. The respondents were from Area 14, Area 10, Area 15, Mchesi and many other residential areas as shown in figure 3. This ensured diversity of M1 road users from all over Lilongwe. It also indicates that M1 is a connecting route in all areas in Lilongwe which confirms its frequency of use.


Fig. 3: Lilongwe residential Areas of M1 users

6.3 Experiences of Pedestrians and Cyclist

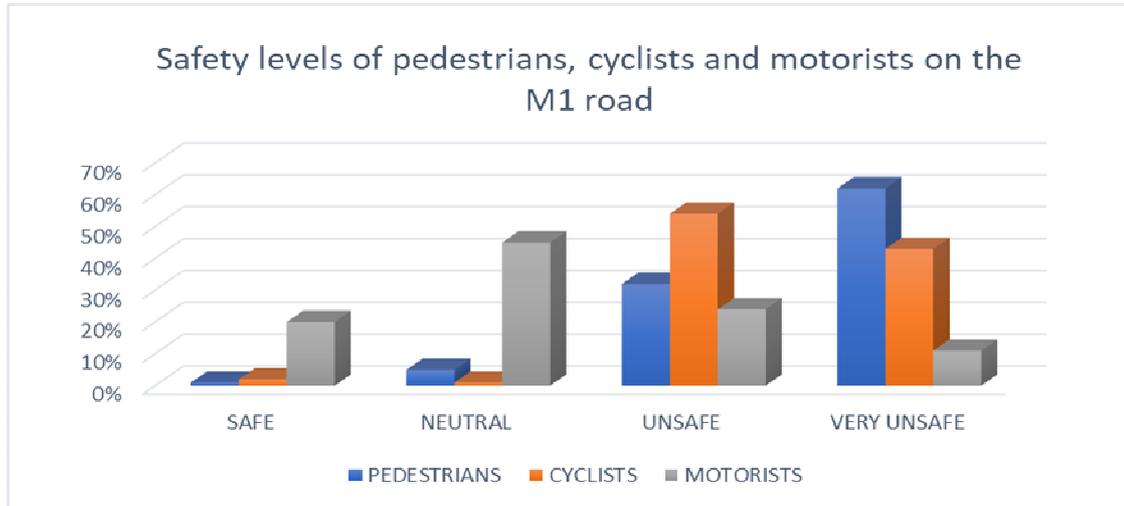
Findings from the study indicated that the majority of pedestrians and cyclists felt unsafe while using the M1 road and this attributed to the poor state and lack of NMT infrastructure. Figure 4 shows safety levels of pedestrians, cyclist and motorist.


Fig. 4: Safety levels of M1 road users

6.3.1   Pedestrians

The responses from pedestrians mostly focused on the lack of NMT infrastructure, unsafe conditions caused by over speeding of motorists and overtaking unnecessarily in a road that has limited to no pedestrian sidewalks. The absence of pedestrian crossing was also pointed out as one of the challenging experiences that pedestrians face along the M1 road. Lack of zebra crossing, and sidewalks creates unsafe travelling conditions for them. There are no designated crossing zones for pedestrians, and this leads to a lot of jaywalking along the road, which subsequently causes road accidents and inconveniences to motorists.

6.3.2   Cyclists

Cyclists expressed their discomfort when using the M1 road due to lack cycling lanes. The M1 road has no cycling lanes and any visible road marking as shown in Figure 6. This has negatively affected cyclists as they always struggle and compete with other motorists on the M1 road. One cyclist said:

"We are at always at a disadvantage because other road users do not respect us, sometimes we end up cycling in between vehicles which is dangerous for us"- cyclist

Fig. 6: Part of M1 road without road marks and cycling lanes.

6.4 Institutional Capacity in investing in NMT infrastructure.

Malawi Roads Authority initiated the Malawi M1 Road Rehabilitation 1 project under the supervision of Ministry of Transport in October 2019 to integrate NMT to the existing transportation system. The government was given K131 billion financial assistance from European Investment Bank for the M1 road project (Times news, 2022). The primary goal of the rehabilitation project was to increase the reliability and durability of the M1 road's roadway. Despite the existence of strategic plans and approaches responsible for efficiently investing in NMT in the Lilongwe city, the rehabilitation project is a failure. The NMT infrastructure looks to have outlived its economic life and has deteriorated overtime. The lack of infrastructure of NMT poses a plethora of challenges jeopardizing the NMT users and overall sustainable urban mobility of Lilongwe city.

6.5 Main barriers for NMT in Lilongwe

There are many hindrances affecting the NMT from effectively saving its purpose. There are physical and organization barriers that reduce and remove the opportunity of the performance of NMT in Lilongwe city.

6.5.1 Physical barriers

The M1 road is a congested route in terms of traffic and pedestrian flows, yet it lacks readily apparent infrastructure that might enhance walkability and cycling, such as pedestrian walkways and cycle lanes for NMT. There are no facilities on the street to handle Lilongwe's large number of pedestrians. Unmaintained pedestrian pathways are congested by parked cars, forcing some walkers onto the road and raising the possibility of MT-NMT conflict. Road signs and zebra crossings are absent on M1, which heightens the possibility of conflict with MT. To aid NMT users' mobility, there are no pedestrian crossings or lights. There are no facilities for cycling. The biker must take a chance when using the road with MT who disobeys NMT. Overall, M1 Road was created without giving proper thought to NMT as a mode, much like many other streets such as Malangalanga and Gyln Jones in the Lilongwe Municipal area, which explains the absence of pedestrian pathways and cycle tracks among other NMT facilities. Lilongwe generally lacks a sufficient NMT infrastructure.

6.5.2 Organizational barriers

The NMT project is failing to be properly implemented because of lack of institutional capacity, the projects stand halfway through construction due to a lack of oversight, planning and budgeting by the Malawi Roads Authority. On the other hand, The Lilongwe city council lack a framework to make plans and prepare projects, the city is still using outdated urban structure plans. Even when money and financing are available, each of these situations shows how a lack of institutional competence can prevent the implementation of NMT infrastructure growth.

7 POLICIES AND LEGISLATIONS GUIDING NMT

7.1 Road Traffic Act 2014

The Road Traffic Act aims at safe regulation of traffic for both NMT and MT users in Malawi. Subsection (1) of the Road Traffic Act provides instructions for carrying out national-level road traffic law enforcement. To ensure the safety of all road users the Act stipulates that pedestrians are not permitted to walk on a public road except when moving from one side to the other or for other legitimate reasons and are only allowed to use the sidewalk or footpath. Contrary to the regulations of the Act, pedestrians are forced to walk on the road because of lack of infrastructure and street vending. The Act, however, is failing to regulate NMT to ensure safety on the M1 road.

7.2 Malawi National Transport Policy 2017

The policy aims to promote equity among all road users, increase understanding of the social and cultural aspects associated with non-motorized modes of transportation, increase the visibility of NMT modes of transportation in transportation planning and programming, and encourage the integration of amenities for non-motorized road users like women, children, seniors, and people with disabilities (Malawi National Transport Policy, 2015). It also encourages the maintenance of the infrastructure as needed. The government pays a blind eye when it comes to maintenance. One key informant lamented the corruption in the building

572

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

sector, which he thinks is one of the causes of the nation's subpar infrastructure. There are many factors at play when it comes to the state of Malawi's roads; many contractors take corners, which lowers the standard of the projects' work.

7.3 Malawi Road Transporters Authority Act, 2014

The Authority's goals and functions are to advance, promote, and protect the welfare of approved transporters and the land transportation industry in Malawi, as well as to establish locations where approved carriers can meet for business like bus terminus, designate pedestrian and cyclists' zones and facilities. The Authority also works with the government and municipal authorities to advocate for the improvement and preservation of roads, overpasses, footpaths, and walkways in a satisfactory condition. The Malawi Road authorities is accountable for protecting limited public financing in the road infrastructure itself to ensure fair allocation of both mechanized and non-mechanized infrastructure facilities finance. To build or maintain roads, the government has hired a variety of contractors through the Roads Authority. However, excessive prices, corruption, and subpar roads are costing the nation billions of Kwachas. Many of these roads have questionable pricing. Instead of just accepting the lowest bid price, the Roads Authority and councils may do Malawians a great favour by awarding contracts to contractors that charge fairly for high-quality services.

8 POLICY IMPLICATIONS, RECOMMENDATIONS AND CONCLUSION

The Malawi Road Authority Act of 2014 advocates on improving overpasses and footpaths conditions, the municipality has never maintained them along M1 road. The flyover was removed in 2020 and the footpaths are damaged, broken and with lots of potholes. It has been over 20 years since its construction, but no maintenance work has been done. It has been learnt that poor to no maintenance of NMT creates accessibility problems for its users.

According to the Malawi National Transport Policy (2017), a road reserve includes a utility strip, footways, on-street parking and lines of trees and space for future widening of the road. However, the reality is that the above-mentioned NMT facilities such as walkways for pedestrians and cyclists, zebra crossings and road signs are still absent and insufficient. People see no use for the NMT infrastructure, and they have turned it to be used as a site for business opportunities whereby street vending is booming along the sidewalks. This has created unsafe conditions for NMT users as they use the same facilities as motorized transport mode.

This study has presented evidence that Lilongwe city of Malawi, lacks infrastructures that support walking and cycling. NMT infrastructure is partially provided specifically along the M1 road used frequently for pedestrians and cyclists, however, those few places do not even have road signs for the other road users to acknowledge and give access to the NMT users. These problems result in congestion, longer commuting hours and accidents are inevitable. The study recommends that, Policy makers, transport planners and engineers will require to make changes in infrastructure maintenance in a way that avoid liability costs and to keep road users safe, they must assure quick reaction to newly discovered road problems, prioritize preventative maintenance, and integrate modern technology into road infrastructure management systems. Another recommendation can be on providing efficient intermodal transportation connectivity points within and between modes, in order for each to function properly and users to connect easily, and where the capacity to switch between modes should be in a timely, cost-effective manner where performance is measured on the capacity to interconnect in order to optimize the end-to-end movement with the most effective system.

1 ABSTRACT

In general, the trend prevailed in recent years that the effects of civilization's interventions in environmental conditions have not been as prominent in publications as they were before the outbreak of the Corona pandemic. The Corona pandemic has focused attention on the most pressing problems in recent years, such as, in metrological terms, the dispersion of liquid aerosols. Although incidences due to Corona are still extremely high, and the number of days of illness has a massive impact on industrial and societal processes, Corona is no longer considered the No. 1 issue. This is due in particular to the lower mortality that has resulted from the immunization of the population and the attenuation of the dangerousness of the new generations of the pathogen. By pushing the topic of Corona off the front pages of journals, previously discussed priorities are increasingly resurfacing.

Against this backdrop, the long 'dead' discussion about the occurrence and effects of particulate matter is gaining momentum again. This paper revisits a previous Real Corp conference paper (Westphal et al., 2022), in which the authors suggest and explain the contributions of an innovative measurement device (ProxiCube) developed by the City of Mannheim's ecosystem addressing the key success factors for awarded Smart Cities and the various factors of an urban management model. This paper exemplifies the cube's contribution by a specifically designed and conducted research experiment.

In the research setting of the City of Mannheim, a city in the forefront of the Smart City movement in Germany, the empirical part of the paper comprises the parameters of liquid aerosol, dry particulate matter, CO_2, humidity, temperature, pressure and light conditions which were measured by innovative and internationally awarded air quality measurement devices (ProxiCube) (see Westphal et al., 2022) simultaneously at five parallel measurement points of the city at a high data rate. With the measurement constellation, influences can be visualized such as the daily course of all these measured variables at a busy street juxtaposed to the backyard of adjacent buildings or to the building itself implying a crucial impact for the citizens' life quality.

Keywords: carbon dioxide, environment, green spaces, ventilation, air quality

2 INTRODUCTION

The term particulate matter covers airborne particles up to 2.5 µm in diameter and is an important factor in the air quality index. Both, directly emitted particles and particles generated by secondary particles are included in this category. Tucker lists as PM 2.5 particles sources combustion processes and high temperature metallurgy, secondary particles from atmospheric reactions, and fine particles deposited and resuspended by wind or human activities, and adds that it is difficult to identify the main sources of the particles because of the interaction of numerous emission sources (Tucker, 2000). The Federal Environment Agency lists combustion processes in the home, from road traffic and from agriculture as sources of particulate matter 2.5 (Umweltbundesamt, 2023).

The results of the study shed light on the following research questions: does living in a high-rise building at a great height offer environmental advantages or how densely planted and how large must green areas be in order to filter fine dust? This leads to further implications of deep penetration of particulate matter into green strips within urban facilities. The building implications of the findings derived via the data, furthermore, allow conclusions to be drawn about optimal ventilation behavior, hereby assessing how CO_2 and particulate matter accumulate kinetically during the time of the ventilation process of shock ventilation. Summarizing,

the environmental loads of humans exposed to the given measured variables are measured and presented graphically.

3   MATERIAL AND METHODS

The measuring device used as basic hardware, called ProxiCube NX3, is a cube-shaped multi-sensor system with an edge length of approx. 8 cm (Figure 1). It simultaneously measures various environmental data such as CO_2, TVOC, temperature, pressure, humidity, but also fine dust and liquid particles (Westphal et al., 2021). The device categorises the fine dust into different size classes and enables the exact identification of the respirable load. The instrument is capable of producing the same readings as highly complex reference instruments and can enable the correlation between different environmental influences on indoor and outdoor conditions, as confirmed by recent publications (Westphal et al., 2022). Depending on the test set-up, several Proxicube NX3s, with or without additional GPS trackers, are used at specific points or distributed over longer distances. The basic ProxiCube is modified for the shown measurements to increase the measurement frequency rate. All data are transmitted via the mobile network to the cloud storage, where they are retrieved from the database, displayed, compared and further processed.

Figure 1: ProxiCube NX3 multi-sensor system

The measurement data for the fine dust class PM2.5 are presented and compared with the official air measurement values of the two measuring stations (identifier DEBW098 and DEBW005) of the Federal Environment Agency in Mannheim.

4   RESULTS AND DISCUSSION

Six series of measurements were planned and carried out to determine the local particle concentrations in green, rural, industrial and built-up areas in the city of Mannheim and the concentrations to which cyclists, for example, are exposed.

Indoor/outdoor air measurement Institute kitchen

Figure 2 shows the PM2.5 fine dust pollution on 12 May 2023 from 9:00 to 14:00. The PM2.5 measurement values of the measuring stations DEBW098 and DEBW005 in Mannheim as well as the measurement values of three Proxicube measuring devices are plotted. The values of the measuring stations of the Federal Environment Agency are plotted as hourly moving averages. One Proxicube is located outside on the windowsill facing NW, another Proxicube is located in the middle of the kitchen on a table. The third sensor is located in the hallway leading to the kitchen. The outdoor air readings largely correspond to the air measurement of DEBW098 with a slight tendency towards slightly higher particle densities. At the beginning of the experiment, the sensors inside the building show significantly lower particulate matter levels of about 3-4 µg*m-3. In the period from 10:20 a.m. to 10:30 a.m., the window of the room is completely open (shaded grey area in the figure). During this period, a clear increase in the fine dust particle

576

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

density in the room can be observed. After closing the window, the concentration drops back to the initial value. In the period from 11:20 to 11:30 a.m. the window is fully opened again, with identical results. From 12 to 14 o'clock the window is tilted (shaded area in grey in the figure). The fine dust concentration rises to the level of the outside air - and remains at this high level. The measurement in the corridor to the kitchen shows an increase in the fine dust concentration at 11:30 and 13:00. This can be attributed to the fact that the door to the kitchen was repeatedly opened and closed from 11:30 to 12:00 and is permanently open from 13:00.

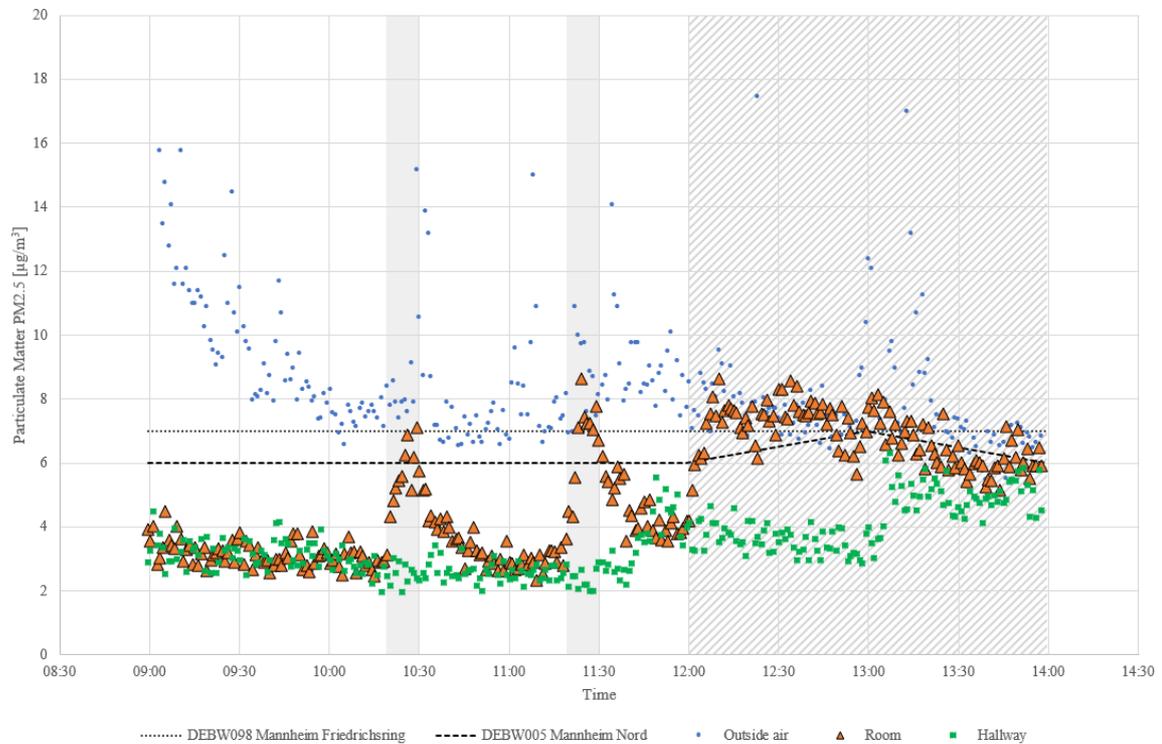

Figure 2: Indoor outdoor comparison in office kitchen, PM 2.5

Figure 3: Indoor outdoor comparison in office kitchen; carbon dioxide concentrations

In Figure 3, the carbon dioxide concentrations are plotted for the same period as in Figure 2. With the windows open and tilted (10:20 - 10:30, 11:20 - 11:30 and from 12:00), the carbon dioxide concentration drops significantly, followed by an increase with the windows closed (from 10:30 and 11:30). From 12:00 - 13:00 there are about 5 people in the room. The tilted window is not sufficient to remove the carbon dioxide, so the concentration rises again. At the same time, however, fine dust enters the room, as already shown in Figure 3. The carbon dioxide concentration in the hallway increases continuously throughout the day. The concentration only decreases after the door is permanently opened.

Based on these results, short-time shock ventilation is preferable to permanent tilt ventilation in order to achieve a more efficient air exchange and a temporally lower exposure to fine dust.

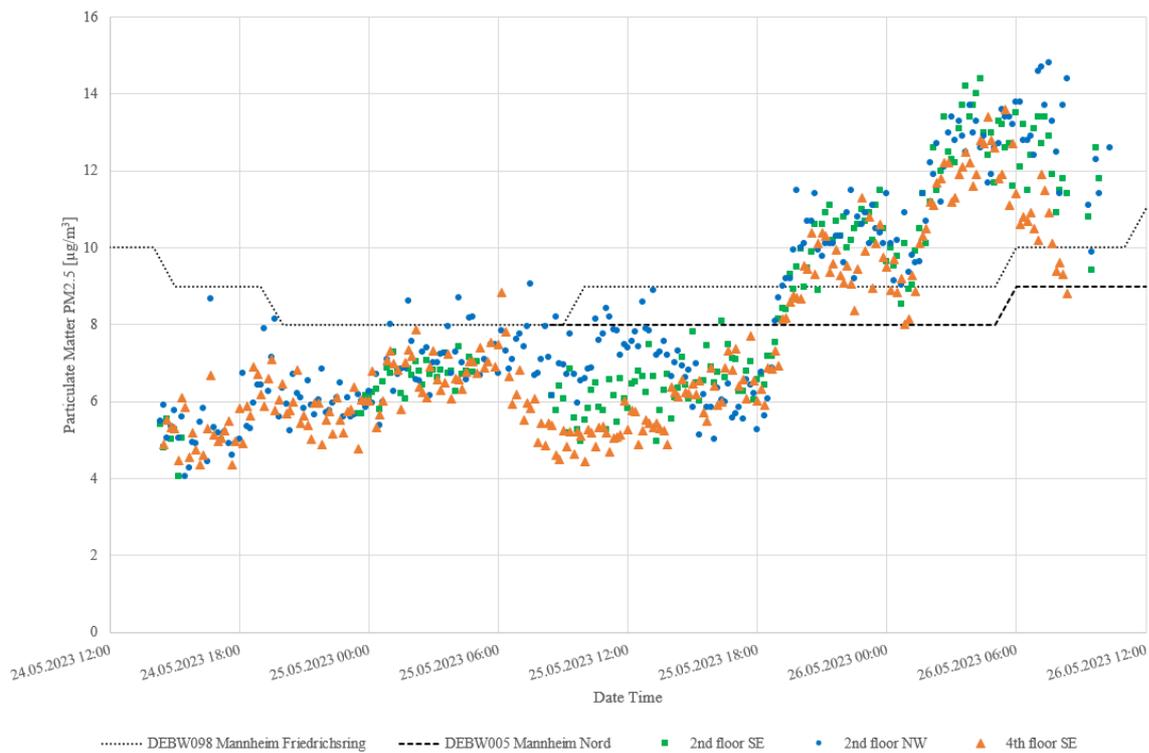
Measurement of the outside air at different heights


Figure 4: concentration in the outdoor air in different heights

Figure 4 shows the fine dust concentration in the outdoor air from 24.05.2023 to 26.05.2023. In addition to the official air measurement values for PM2.5, the measurement results of three Proxicube air sensors are entered. One sensor unit is located on the second floor facing southeast. Another Proxicube is located on the other side of the building, also on the second floor, facing northwest. The third Proxicube is located on the 4th floor facing south-east. All three sensor units are outside the building on window sills. The readings from the proxicubes are below the official air readings in the first half of the experiment from 24.05.23 14:00 to 25.05.23 18:00, in the second half above them. The official readings show an increasing trend, which is reflected in the readings of the proxicubes. Comparing the measured values of the proxicubes with each other by median formation shows that there is only a slight difference in concentration for PM2.5 between the sensors on the 2ndfloor. If one compares the measured values from the 2nd floor with those from the 4th floor, greater differences become apparent. Thus, the proxicube on the 4th floor has a median fine dust concentration that is 9 - 10 % lower than the proxicubes on the 2nd floor. This indicates that, for example, residents of attic flats are exposed to lower levels of particulate matter than their neighbours on the lower floor.

Air measurements around the coal-fired power plant Mannheim Grosskraftwerk

Figure 5 shows the results of the air measurements from 05.05.2023, 11:00 a.m. - 4:30 p.m., around the coal fired power plant Mannheim (GKM) in comparison with the measured values of the measuring stations DEBW098 and DEBW005. One Proxicube is located east of the GKM at the Stengelhofweiher, opposite the GKM on the banks of the Altrhein and west of the GKM, downstream on the flood embankment. The

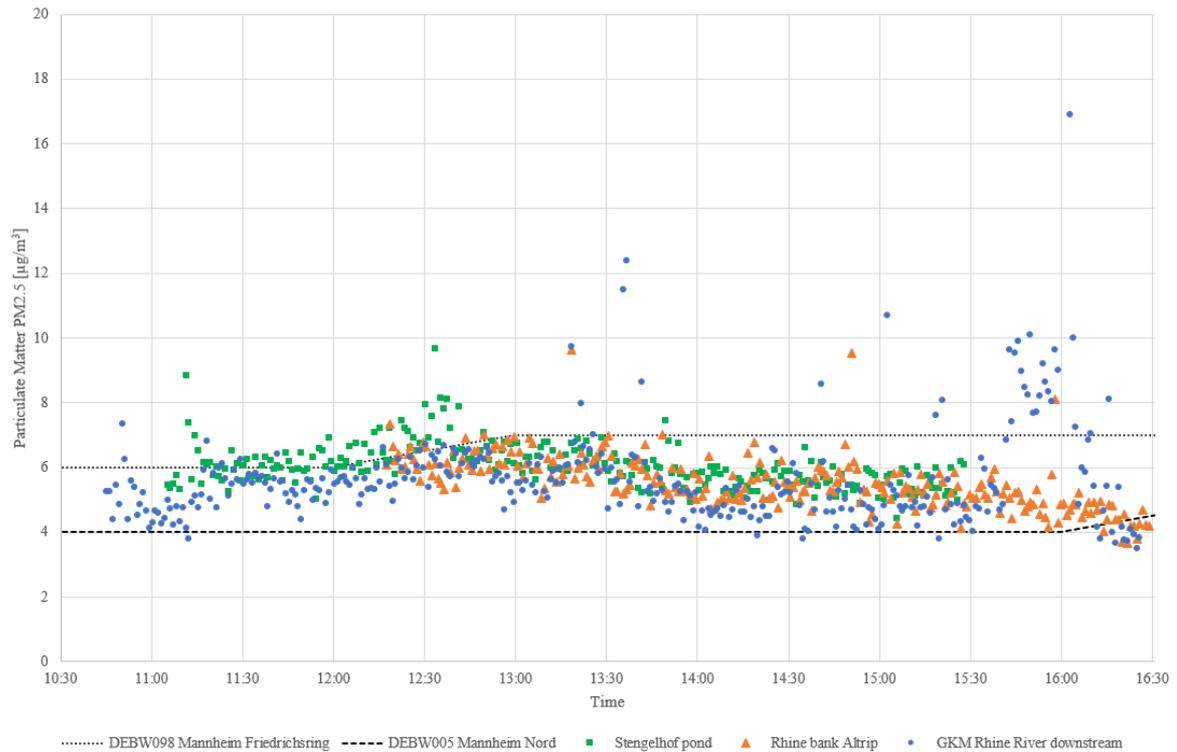
measured values of all three sensor units lie between the measured values of the Federal Environment Agency. Conspicuous or increased fine dust concentrations due to e.g. blown coal dust, fly ash or FGD gypsum are not detectable.


Figure 5: Air measurements around the coal-fired power plant Mannheim Grosskraftwerk

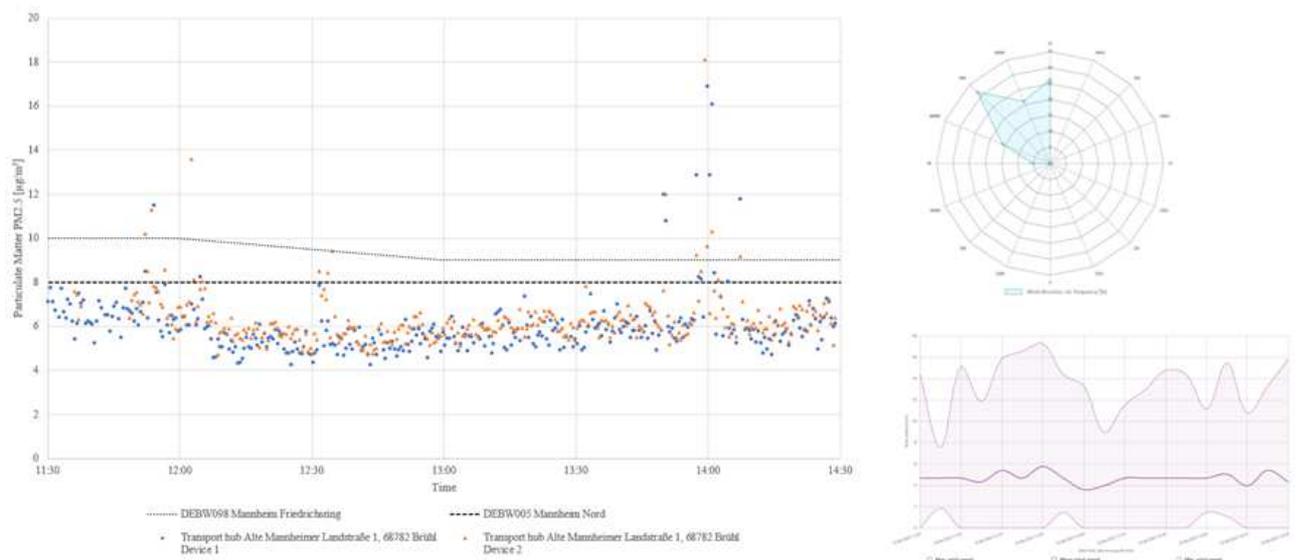
Traffic node


Figure 6: Traffic node and wind data

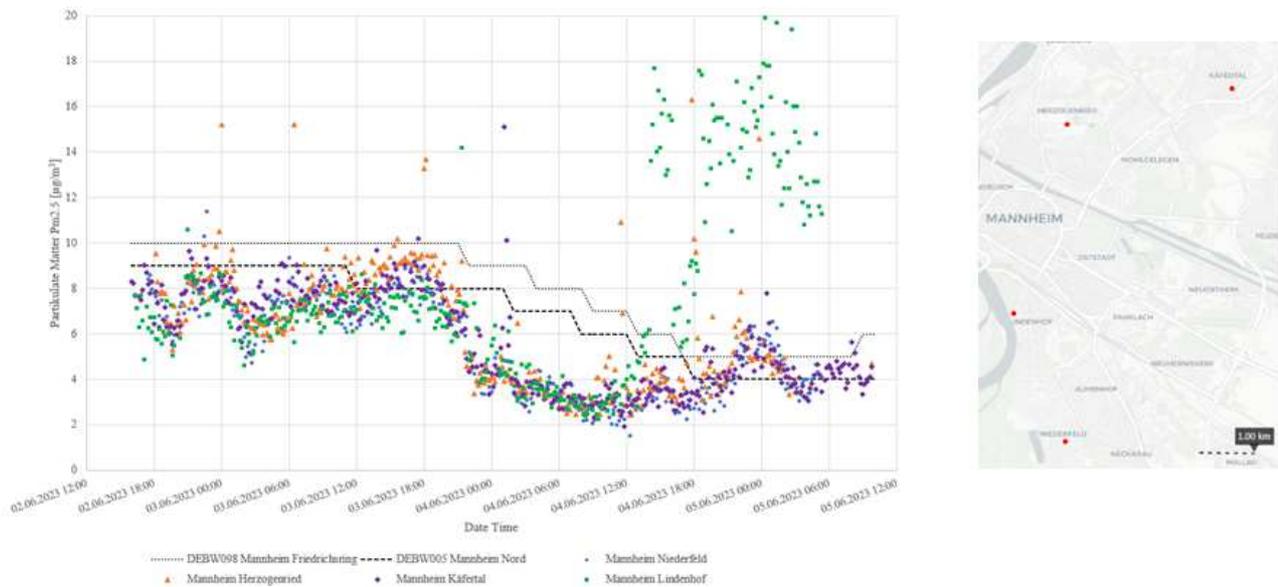
The two measurements in ABB ran in parallel at a traffic junction point in Mannheim. The measured PM2.5 values are somewhat lower than at the measuring points of the city of Mannheim. The fine dust pollution does not have the same effect at this well-traveled location as in a street surrounded by buildings. The wind speeds indicated by the city of Mannheim for this time period are 5 km/h on average. Here, the assumption can be made that the particle pollution caused by traffic is diluted continuously by the light wind. Locally recorded increased measured values can be attributed to the drive-in station in the vicinity.


Figure 7: Measurements on four different parts of the city

The measurement cubes were positioned in four districts in Mannheim for three days and the measurement results were presented in Figure 7. At all four locations the basic course is the same and the changes of the particle concentrations are similar to the measured curves. Locally measured higher particle concentrations cannot be justified with certainty, but there are numerous sources in residential areas, such as cigarette smoke, barbecues, a running motor under the balcony, etc., which can lead to these measured values.

Bicycle tours

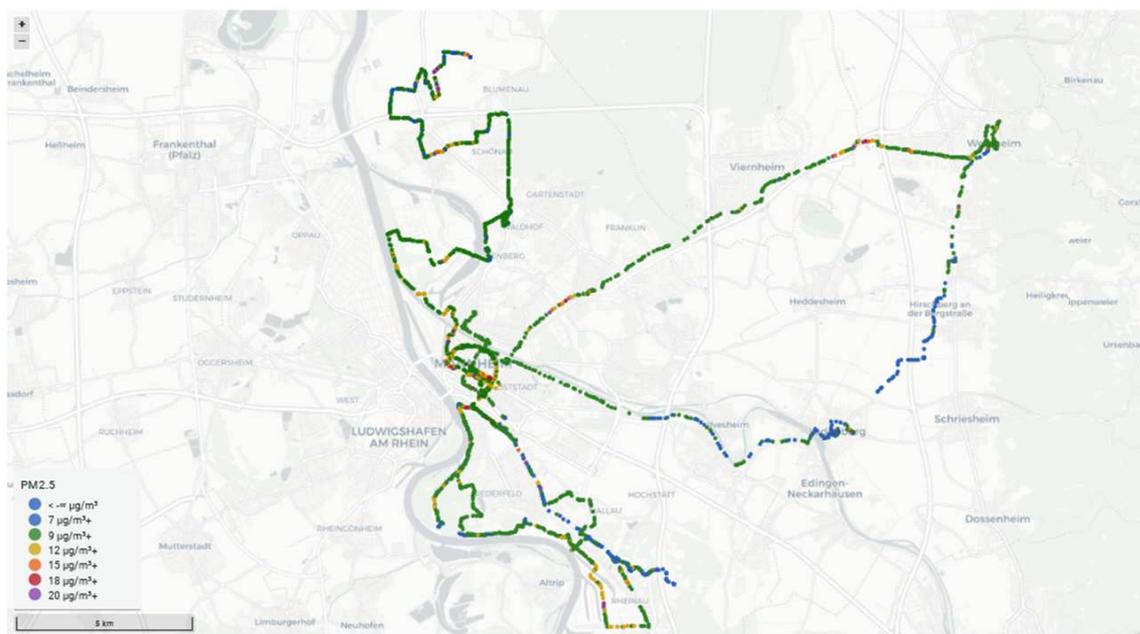
The measuring boxes are attached to the bicycle basket at a height of approx. 50 cm. Three people set off in the direction of the north-west, north-east and south-east of the city. The aim of the study is to identify zones with comparatively higher particulate matter pollution within the city and in the peripheral areas. Figure 1 shows the entire distance travelled with the measured PM 2.5 values.


Figure 8: Bike route between 8:30 and 15:30

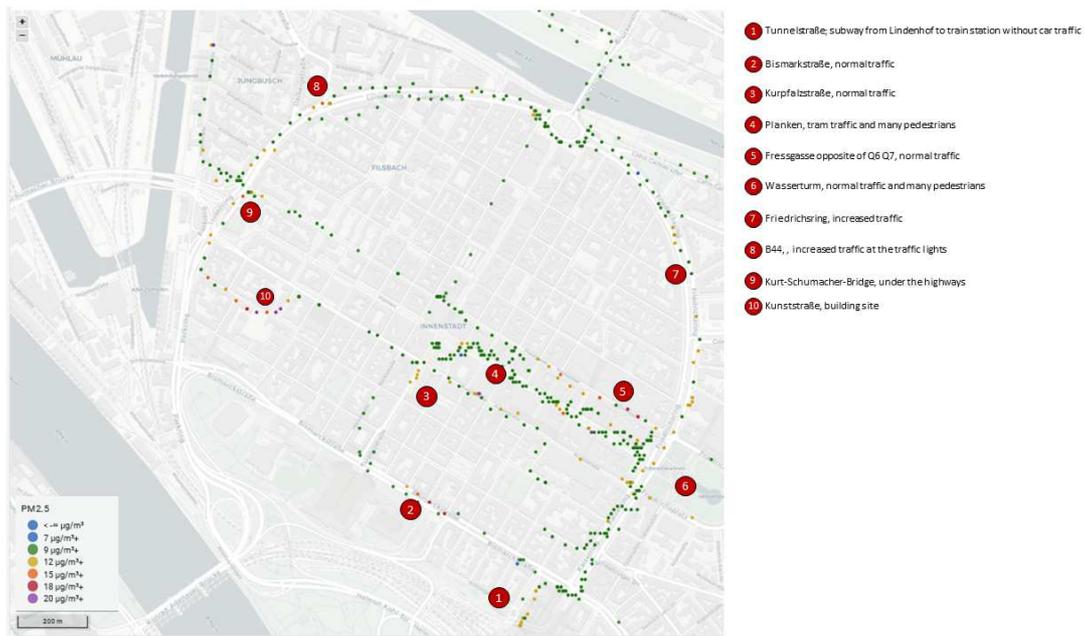
In the following, sections of the map are enlarged for a better overview and the hotspots are marked individually. The areas with special observations are noted in the legend.


Figure 9: Cycle route between 9:40-10:30 in city centre

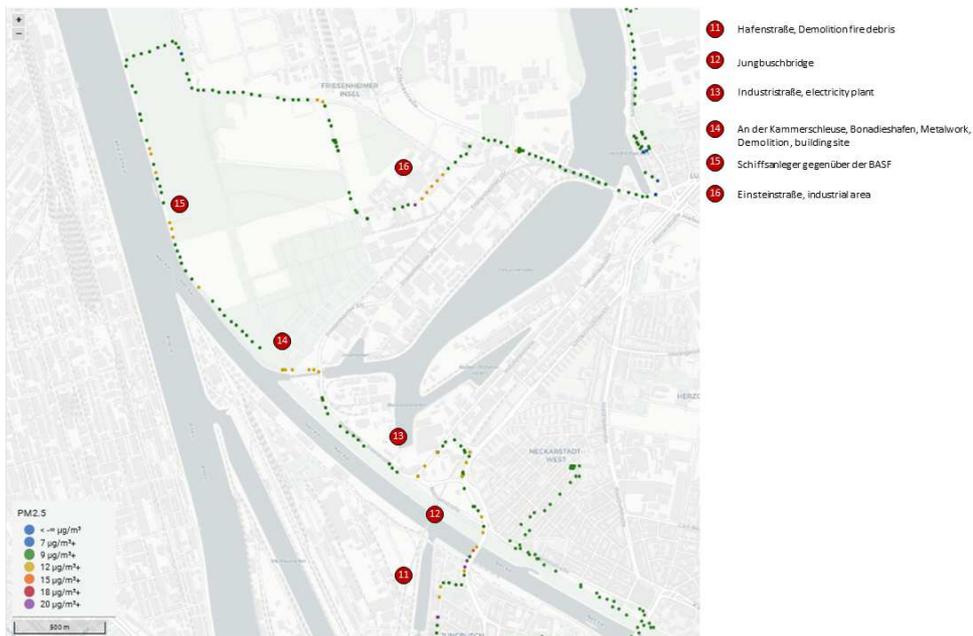
In Figure 9, ten zones stand out. Most of the areas with comparatively higher readings have in common that they run along a busy major road or that many pedestrians are on their way. In the case of point 10, the higher readings could be attributed to the adjacent construction site. Here, the air circulation is lower than on an open road, which is probably why the swirled-up particles reach a higher concentration. The section at point 8 is located at a junction with traffic lights with higher traffic volume.


Figure 10: Cycle route between 11:00-12:30, north west route part 1

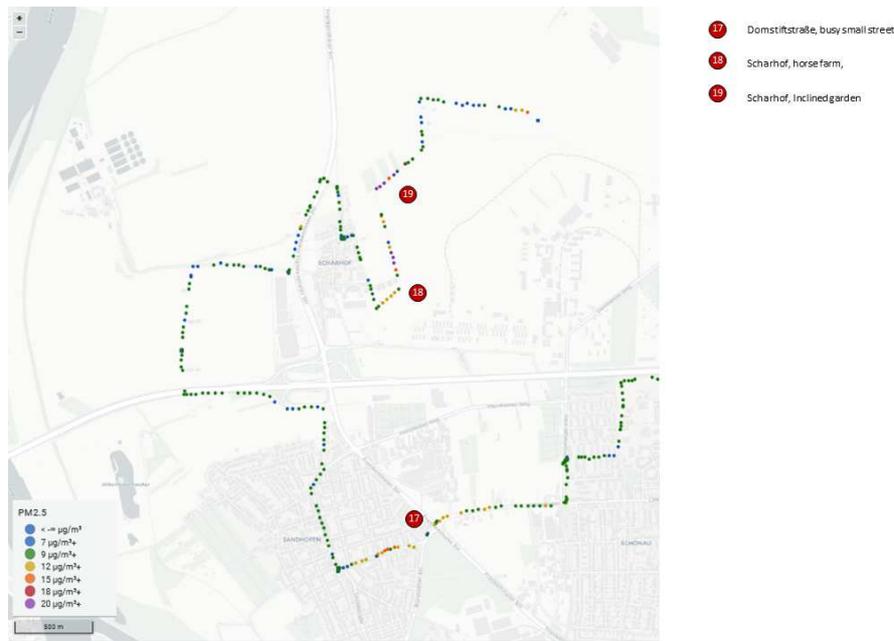
In Hafenstraße at hotspot 11, there is a burnt building in the route that is currently being dismantled. There is also a work site at 14. The other hotspots marked in Figure 10 are located near industrial facilities.


Figure 11: Cycle route between 12:30-13:30, north west route part 2

The track at point 17 is a small but busy road surrounded by buildings. The assumption here is that the particles are not blown away well enough and the concentration is higher than with open roads. The more rural stretches at 18 and 19 also show increased concentrations of particles, which could possibly be caused by the blowing of unpaved road sections, animal feed or similar bulk material.

Figure 12: Cycle route between 10:15-15:30, north east route

Figure 12 also shows that higher values are measured in places close to industrial facilities and with heavy traffic or where cars have to stop and go and drive more slowly.

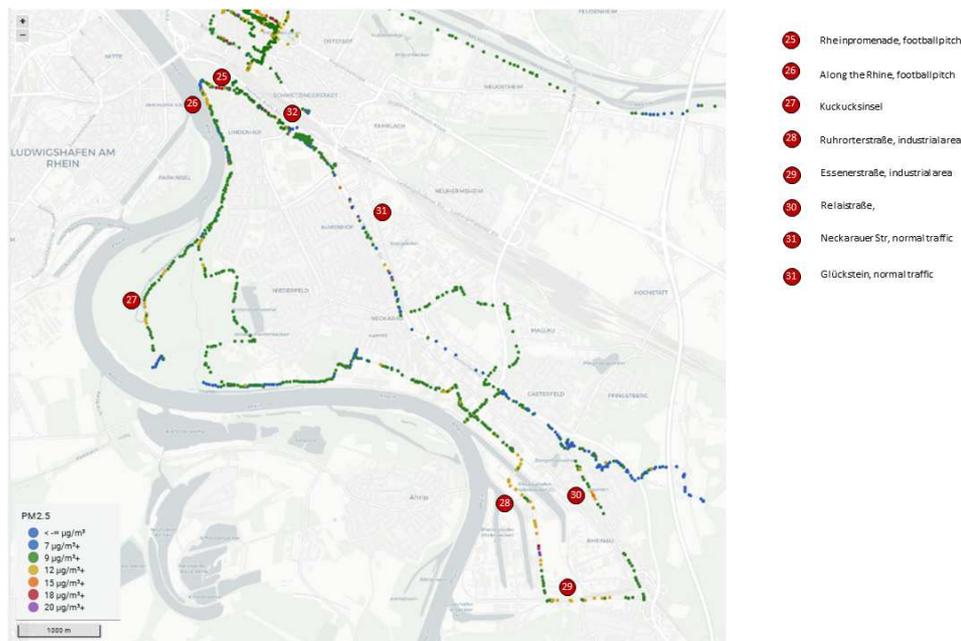
Increased values measured at points 25 and 26 in Figure 13 could be attributed to the football pitch. Dust stirred up by the wind and people is measurably distributed in the surroundings. The other hotspots are again routes with city traffic and industrial sites.


Figure 13: Cycle route between 9:40-16:10, south east route

5 CONCLUSION

The empirical experiment reflects the contribution of a measurement device (ProxiCube) to the key success factors of awarded smart cities highlighting the central importance of its citizens' health. It is an important ingredient of a smart city's technological infrastructure, informs the strategy for digital transformation i.e. in terms of planning the nexus between streets, factories, construction sites and residential areas evtl. via digital twins, providing the necessary skills, i.e. in terms of transversal (research), general or specific IT competences, informs the awareness and health education of citizens, and contributing to the authentic implementation of a Smart City's identity, i.e. in terms of a health orientated or life quality related identity. Furthermore, the experiment illuminates the interplay of the factors of an urban management model relating to competences, implicit SC domain priorities and the necessary collaboration of the SC ecosystem actors to achieve the SC objectives and outcomes (Westphal et al., 2022).

In more detail, the experiment determines the distribution of CO_2 and particulate matter as a function of the height of the measuring point and the cross-influences of the other environmental parameters (temperature, humidity, dew point…). As to specific health orientated citizens' behavior, short-time shock ventilation is preferable to permanent tilt ventilation in order to achieve a more efficient air exchange and a temporally lower exposure to fine dust. Interestingly, residents of attic flats are exposed to lower levels of particulate matter than their neighbours on the lower floor. Numerous sources in residential areas, such as cigarette smoke, barbecues, a running motor under the balcony, etc., need to be taken into account to avoid excessive exposure.

In busy, major roads, the air circulation is lower than on an open road, which is probably why the swirled-up particles reach a higher concentration.

In general, it can be summarised that elevated PM 2.5 levels were measured on routes that run close to urban traffic or industrial facilities. In addition, construction sites with demolition work and unpaved roads or playgrounds could be sources of particulate matter.

1 ABSTRACT

Transportation is one of the major sources of economy for any country. But the main problem with the vehicles is the amount of pollution conducted by them. One needs a particular source that creates Net Zero Carbon Emissions. Electric vehicles are becoming a popular source of transportation as they do not produce any carbon emissions. But due to a lack of proper infrastructure and customer awareness, consumers hesitate to decide on an Electric Vehicle to date. The paper also covers the expansion of VANET Technology that can improve the traffic management system and reduce the number of accidents. For this reason, this paper aims to identify the area of improvement in building the infrastructure of electric vehicles with economic policies.

Keywords: management systems, VANET, mobility, sustainability, transportation

2 INTRODUCTION

As the climate is changing rapidly, a growing concern can be seen for the environment. The fuel market is unreliable, and electrification of the transport system entails a major systemic overhaul in a country. Strategies are being discussed by every major country to reduce the overall CO2 emissions and go all-electric by 2030. The paper introduces an overview of the present electric vehicle (EV) market scenario. This market follows certain standards like charging standards, safety standards, and grid integration (Das, 2019). The EV infrastructure covers certain things like power, control, and communication. As different companies are producing these vehicles, each vehicle will impact the power system, which is why grid system optimization is summarized. Lastly, the paper will cover challenges and suggestions for the development and challenges for future vehicles. It refers to major aspects from the perspective of the world being ready to go for EVs and will introduce the idea of bringing smart grid technology to charging stations. Moreover, to build a sustainable infrastructure what policies should be taken for the charging stations, use of renewable energy and connecting it with smart grids, and VANET Technology (Das, 2019).

3 RESEARCH GAP

According to Das and Rahman (2022, p. 24), "future research could be done on implementing in expansion in VANET technology along with a well-developed business model which can be beneficial for EV owners, users as well as utility companies". A further gap is provided by Ahmad and Iqbal (2022, p. 16) stating that "future research and challenges faced are related to include optimal places and sizing of charging stations with renewable energy sources and integrating the load for power management problems". Consequently, this study aims to investigate the factors that lead to a solution for optimizing the infrastructure for electric vehicles and closing these gaps.

Four research questions are derived from the literature to achieve the research objective:

(1) How can renewable energy play a major role in providing clean energy to EV charging stations?

(2) What role does a charging station play in creating a sustainable business model?

(3) How can we provide VANET Technology to improve traffic Management systems?

(4) How can we establish a radio communication channel by reviewing security challenges and testing VANET in a critical case scenario?

4 LITERATURE REVIEW

The chapter deals with previous studies on the elements leading to increasing sales of Electric Vehicles in the past decade. It provides a clear picture of previous research initiatives having identified some major problems related to the infrastructure and availability of charging stations. To find relevant literature for this paper, the research was done in different phases. At first, several articles and journals were looked at by

using keywords like Renewable Energy, Charging Infrastructure and Policies, VANET Technology, and Electric vehicles on open platforms. For the research, data were filtered via journals and articles from Google Scholar, Research Gate, and IEEE Explorer.

4.1 Renewable Energy

Today, global warming has become a major issue that needs to be urgently resolved. With a vision of having a clean environment-friendly energy source, it has become a prime topic of interest to many environmentalists. With a rise in population, it is becoming difficult for governments to fulfill the need for electricity as our society is progressing towards high standards of living. According to Elavarasan et al. (2020, p.1), "the power systems energy production sector contributes nearly 75% of total CO2 emissions in the world which contributed to Greenhouse Gas (GHG) emissions as well as in Global warming".

4.1.1   Role of Renewable Energy

With a dramatic rise in the purchase of EVs, the demand for the use of EVs globally has increased dramatically. The global electric car market has shown a significant jump in sales as people are more concerned about zero carbon emissions. But this upsurge has created a problem with the provision of proper charging infrastructure as people are using the current charging system. The latter is pressuring the load on transformers, especially during the night, as people charge their vehicles overnight. One of the drawbacks of renewable energy is its inconsistency to offer energy all the time. To tackle the problem, it is required to get optimal planning for allocating EV charging stations. The proposed solution could be to use solar energy panels by creating a "Green Roof" that will create a balance in the temperature due to its ecological benefits. At the same time, solar panels can provide a clean source of energy to charge EVs.

4.1.2   Renewable Energy Transition in EU by 2050

The European Union is a key influencer in reducing carbon emissions by 2050 to meet the target of climate change to have a competitive, efficient, and sustainable source of energy supply network. The Paris Agreement is a step towards the transition in energy supply to achieve the goal of a carbon-neutral EU. As we know, dealing with climate change is one of the major challenges in modern society. Therefore, the European Commission proposed a target of net GHG emissions to neutralize climate change by 2050. The Paris Agreement aims to reduce global warming below 2 degrees Celsius, but the preferred number is 1.5 degree Celsius (Sanja, 2021).

Supply of Renewable Energy Networks and Large-scale Biofuel Production

There are some extensive studies in past years relating to the development of renewable technology and optimizing technology on a large scale with a supply chain of networks. This is confirmed in the study conducted by Sanja (2021, p. 14), "This study shows that a significant amount of additional land (about 6%) is needed to achieve a climate-neutral EU. Therefore, further development of technologies should aim at minimizing land use. Offshore wind turbines and PV panels do not require additional land, full electrification of the transport sector and mastering fusion-based nuclear reactors could be examples of such technology". This study was based on criteria including geographical locations, biofuels, and renewable energy, driven by the research objective to achieve biofuel production by 2050.

Critical Analysis of Biofuel and Technology

The author Sanja et al. (2021), p. 14 "To implement the technology, there are several things that need to be considered. At the first stage, some existing technologies are available like dry goring which is a commercialized system that can be installed all over the world. Several other technologies like sugar fermentation could also be considered. The second stage, which is the most challenging stage, is the availability of biomass in abundance. To make biofuel, biomass must be available in large amounts to meet the demand and supply for clean energy. However, the production cost of the energy will be lower". To implement a sustainable energy network there must be the availability of cultivation areas along with machinery through which we can extract the oil and can store it in large facilities to ensure an uninterrupted supply chain of oil so that it can reach the end users.

4.2 Charging infrastructure and policies

In recent years, the world has faced serious climate change problems, leading to the burning of forests, drought, and floods in most of the world. These climate changes occur due to the overuse of fossil energy as most countries are today using this source of energy to power their nation. With the emergence of greenhouse gasses, most of the countries like China, India, USA, and Germany are reducing their dependencies on the use of fossil fuels. The countries have signed a cause to reduce the use of fossil energy and adopt better ways or green sources of energy to power their countries (Jang, 2020).

4.2.1 Characteristics of EV Batteries

Today, EVs are mostly equipped with Lithium-ion batteries which are the leader of the market due to their high energy lifecycle and efficiency. These batteries consist of a large number of single battery cells which are arranged in serial or parallel ways. To monitor the charging, a battery management system must be installed to manage and protect the Li-ion battery while charging. It is considered that the ideal charging with the operating range is 90% within such management.

4.2.2 EV Charging Habits

EV charging habits are one of the major concerns when it comes to sustainability. The use of energy depends on the consumers' habits of charging their vehicles. The frequency of charging a vehicle matters: the more often it is charged, the more electricity will be consumed. As the number of EV users is rising over the period, the use of energy and power is also increasing (Andresen, 2021).

4.3 VANET technology

Vanet (vehicular ad-hoc network) is a modern technology that allows vehicle-to-vehicle communication through the Internet in which various networking and communication channels are transmitted among cars. The technology was first introduced in 2001 and operates on a similar concept of mobile networking which is known as MANET (mobile ad-hoc networks). Vanet is an integral part of the intelligent transportation system as it works with the help of the Internet of Things (Shrestha, 2018).

4.4 Expansion on VANET

VANET being a modern technology could help to better traffic management in cities, especially cosmopolitan ones like New York, Frankfurt, and Mumbai. To do so, it requires further improvement and expansion as its main criteria are road safety and vehicle entertainment. As VANET is working on ad hoc networks, the system will pass the information via the wireless medium of a network (IoT) to the devices which can help to predict the possible circumstances of moving vehicles. This will form a chain of networks (Saleem, 2019) like a node that will transfer the information to other nodes. Once the information is received, it will be transferred to other nodes and this process will go on. These nodes will be an open source of networks that will be free to join or leave due to high vehicle mobility conditions.

4.4.1 Testing VANET in Critical Scenarios

It is important to test this technology to ensure its reliability in different case scenarios. While testing this technology, there must be certain variables such as the number of vehicles in a particular area, weather conditions, road temperature, and wind speed should be considered (Saleem, 2019). As stated by Duarte et al. (2021), "automobile environments are spending new set of requirements on today's wireless communication system".

The scenario explains to us that two emergency vehicles are approaching from different directions towards the intersection. They will reach the intersection almost at the same time and at least one EV may be at the intersection. Now the system should cope with this situation to avoid conflict if more than one EV shows up. To do this, it is considered that the transmitter will communicate with the traffic light controller that can control the state of traffic lights based on intersections. The transmitter will send the controller the relevant information related to EV status like speed, position, and direction. The controller will decide to handle and proceed to coordinate traffic lights to ensure a safe journey (EDUARDO, 2021). Finally, as the EV clears the intersection, Roadside Unit (RSU) will alert with a specific message from the EV or via Basic Safety Message (BSM), and this process will be broadcast continuously.

5   INITIAL CONCEPTUALIZATION MODEL

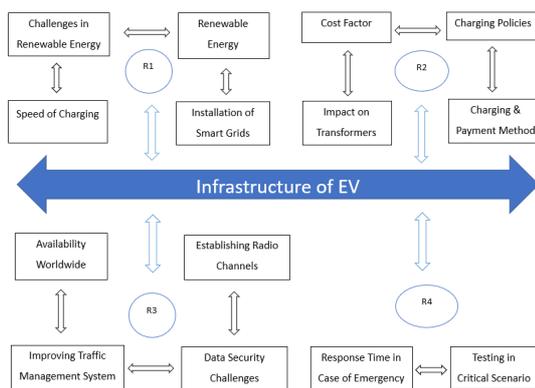
Derived from the literature review an initial conceptualization has been developed to be validated by the empirical research stage (figure 1).


Figure 1: Initial Conceptualization Model, Image Source: Morton2021, Lee 2020, VINEL 2021.

6   RESEARCH METHODOLOGY

6.1 Research design

The objective of this research is to explore factors that reduce carbon emissions and build a sustainable infrastructure that would provide a feasible solution by eliminating different challenges as described in the literature. The research also aims to optimize the infrastructure and improve the existing technology to make it more reliable by providing examples for different scenarios. As this study is exploratory in nature, the qualitative approach is the best fit to narrow the gaps for this study.

6.2 Data collection

For data collection, 7 semi-structured interviews were conducted with open-ended questions to understand and interpret each interviewee's thinking. Purposive and Snowball Sampling were chosen as the sampling method for obtaining data information. The selection was done based on the people who are industry experts in the field of sustainability and the automotive industry. The age group from 25 to 40 years covered mostly EV Charging Experts, Senior Managers, Low Carbon Vehicles & Fuels advisors, and ambassadors for Clean Mobility.

6.3 Data analysis

Interviews that were conducted were manually transcribed and analyzed by MAXQDA. All the information like the respondent's body language, tone of voice, expressions, and gestures was considered during the process which resulted in the richness of data collection. The exchange of information and ideas from both sides was highly appreciated and showed a belief in the research. A qualitative technique was followed for analyzing the content standards, Qualitative techniques are simple, transparent, and highly reliable to master content analysis. The data were evaluated by the content analysis method suggested by Kuckartz (2019). The following categories emerged as a result of the analysis.

Categories	Procedure	Presentation	Anchor Example
Renewable Energy	Deductive	All passages mentioning about renewable energy sources, types, and challenges.	Renewable energies like solar and wind are the most crucial and dynamic solutions to fill the gap and support the charging infrastructure.
Battery Characteristics	Deductive	The passage mentioning about battery type and lifecycle in the market.	EVs are mostly equipped with Lithium-ion batteries which are the leader of the market due to their high energy lifecycle and efficiency.
Location	Inductive	The statement given by the respondent emphasizes the country's location.	"Location plays an important role and of course the climate. For example, if it's a bright sunny day, you can charge your vehicle easily".
Data Centres and Cyber Attacks	Inductive	The statement given by the respondent emphasizes data security.	"Not all the countries have capabilities to build data centers".

Table 1: Categorization Table

6.4 Renewable energy

To recap, the purpose of the study was to connect the infrastructure with renewable sources of energy that can help the environment to reduce carbon emissions and meet sustainability goals. After interviewing seven experts in the domain, it was noticed that many respondents were in favor of using renewable energy like Solar and Wind as they believed it is the cleanest form of energy. Unanimously, R1, R4, R5, and R6 highlighted the importance of renewable energy.

6.4.1 Transition

To begin with, the transition phase is a phase from which we need to switch from 1st Generation fuel to 2nd Generation fuel. Second-generation fuels are much cleaner and produce low carbon emissions. R2 emphasizes this aspect: "More energy transitions and natural development employing current enterprise resources". The respondent also highlighted that the "European Union has advanced on developing lots of policies and with the current situation in EU, they have passed some budgets to go fully on their natural resources". On the other hand, R3 mentioned: "The grids are coping in the world with all these transitions from lower to high consumption".

6.4.2 Policies

Policies are critical to creating since they drive the project in the appropriate path. In this regard, R2 has stated that "environmental regulations from the United States and China are the biggest polluters in the work like didn't like Stein?? The situation is unclear. The European Union is establishing environmental regulations to rely entirely on natural resources such as wind energy."

6.5 Supply chain

6.5.1 Labour

The aspect focuses on the manpower to build the infrastructure. This could include anyone who relates to the project like managers and workers. R1 highlights this factor: "The installation is huge, and the biggest element is the labor aspect of implementing this".

6.5.2 Raw Material

The raw material involves the supply of things that are required in the infrastructure. R1 emphasizes the availability of raw materials: "You've got to install a lot of wires, lot of cables to make it work. You know, we got to think also of the supply of the materials as the material comes from China".

6.5.3 Covid and War

One of the major concerns is to affect the supply chain of raw materials and to build the infrastructure. One of the future concerns that needs to be addressed is to develop a solution. R1 highlights "The supply chains have been affected since COVID and obviously with China being in lockdown for a couple of months as well that says affected". R2 says "Right now like with all like let's say the crisis with Russia and the Ukraine War, all the energy transitions are becoming slower, and the Issue for the EU is to move from Russian Dependency and have multiple suppliers of energy for Temporized from Africa". R3 was not sure if the raw materials were available it stated, "Since the war in Ukraine, I think it must be available". So, we can see a major impact on the supply chain due to these situations and must ensure that in the coming future, we must have different suppliers or supply chains available as a backup and not just be dependent on one variable only.

6.6 Cost

6.6.1 Household Income

An area addressed by another respondent was household income. R2 stated in this context: "Companies are taking new strands and they will be like it is necessary to reduce the consumption of the personal car. But I think it is a long process. Like me, at least in Europe, for middle- and lower-income households, just like it happens. Maybe like once in 10 or 20 years, of course, every household will change and adapt. There is time for implementing electric vehicles and creating an infrastructure around them in Europe".

6.6.2   Budget and Investment

Funds are the most essential part of any infrastructure. R1 stated: "Investments need to happen to build the infrastructure. Any specific region may have specific investment requirements which need to be considered, and there are a lot of opportunities as well". R2 confirmed the view of R1: "There is a cost of infrastructure and there will be a need for funds to make it". Furthermore, R4 supported this view as well: "You need a huge investment capital to build the infrastructure".

6.7 Location

6.7.1   Inner-city

R1 state concerning inner-city travel: "There are a lot of opportunities available and to adapt this technology by looking at the current infrastructure and charging capabilities and existing charging stations, one needs to discover the aspect on how inner-city mobility can relate to the charging. Energy renewable aspects can influence our people who may don't even have an opportunity to charge their vehicle overnight". R2 also highlights the city situation: "I am from Rome, and let's say there is traffic in the city, I believe that there should be traffic management systems linked in a trampoline creating more less energy consumption and strategically since it should be possible to introduce traffic management system so that every time a person is encouraged to reduce the demand for power and energy consumption".

6.7.2   Country and Climate

This section highlights the importance of climate estimates in various countries. R1 mentioned: "I think this matters a lot as some of them are utilizing, depending on where geographically, they are utilizing solar power to generate some power back to the units". R3 states: "In Singapore, there are 100s of 3-wheelers driving with a 5kW hour battery pack and an onboard charge is only 3.2kW. The customer doesn't require any big and fast change. The charging also depends on vehicle type and battery size".

6.8 Charging frequency

6.8.1   Charger Types

As we know, for charging EVs, there are multiple types of chargers available. R3 emphasized: "To make charging simple, there must be a solution with a single segment charger for each EV segment. For me, the perfect charging speed is always 50 kW below as the speed doesn't degrade". R4 expresses it in simple terms: "Slow charging is healthy charging as it generates less heat due to steadiness and has a very steady way of pumping energy inside".

6.8.2   Habits and Patterns

Charging of vehicles is directly connected with people's and cultural habits and it is important to track the patterns of charging the vehicle. R1 highlighted - supported by R5: "Some people like to leave the battery running flat before you charge it and then some suggest you better keep topping it up". R2 states: "People mostly charge their vehicles overnight which is the peak hour, but it also depends on the class like working class, they still charge their vehicle at night".

6.9 VANET

6.9.1   Artificial Intelligence

This category describes the role of Artificial Intelligence. R1 responds: "Reacting to an incident, AI has a big impact". R2 - supported by R3 - responds: "The system based on Artificial Intelligence could help in prioritizing the emergency levels for a vehicle, and I think GM is implementing this technology". R5 - supported by R6 - says: "Artificial Intelligence can help in finding alternative routes during peak hours and measure the response time in case of critical emergency".

6.9.2   Testing VANET

To implement this technology, it is important to test it in a real scenario. R1 specifies: "It will require high-performing computers as the camera will capture billions of photos in a real-time scenario". Similarly, R3 confirms the usefulness of the technology: "This is a very useful technology as GM is already using it as it

beeps and alerts driver before the collision". In the same vein, R5 -supported by R6- said: "It's hard to tell what the situation is. As vehicles are getting smarter, the technology will be programmed in such a way that it could alert the driver or programmed with all the possible situations that could tell the vehicle how to react before the collision".

6.10 Technology

6.10.1 Radio Communication

Radio communication will help VANET in guiding the technology to send signals over radio communication channels. R1 points to the important role of telecommunication companies: "Telecommunication companies can play a major role and they will require huge investment. It will give more chances for new talents to hire network communication experts. We can also use 5G, and 6G technology in the future". R5 relates to an infrastructural component: "We can put a communication tower near each data center to actively communicate with the vehicles".

6.10.2 Data Centers

Data centers are the structures in which all the information will be stored, and they will manage all the operations of the technology that will be available. R1 mentions in this context: "Not all the countries have capabilities to build data centers". R4 stated: "There must be a traffic management system that could logically balance the traffic".

7 DISCUSSION

Renewable energy like solar and wind can fill the gap to support the infrastructure but some areas need to be explored like the use of nuclear-based energy, and sustainable energy from Bio- Fuel. The amount of energy consumption must be calculated as the charging of an Electric Vehicle majorly depends on the Speed of charging and the impact on transformers that are transmitting the energy into the EV. During the interviews, it was found that the speed of charging can be still controlled as there are different types of chargers with specified kW's that can reduce the impact on transformers which I found to be consistent. During the research, it was important to address synergistic as well as adverse mutual effects and the overall micro-climate of the build-up area. This area was left undiscovered as it was not discussed in the interviews and it would be interesting to see how this factor will be considered during future research. Location and Data Centers were both new categories that were discovered during this research. These categories were innovative as they covered very detailed levels of information related to the inner city, country, and a center point where all the collected data will be stored that can further be used to make our EVs smarter by constantly feeding them with different data. This will make our EVs smarter as they would be programmed through blockchain on how they can react in the possible situation which can reduce the number of accidents.

8 CONCLUSION

As climate conditions are changing, it has become important to focus on Sustainability. One of the concerns was the lack of awareness amongst people about renewable energy. As pollution is increasing at an alarming rate, its effects can be seen in different parts of the world. With the Paris Agreement, the European Union along with other countries are taking some serious measures towards the environment. India is one of the major concerned nations and has strengthened its knots with Germany to achieve the goal of Carbon Neutral by 2050.

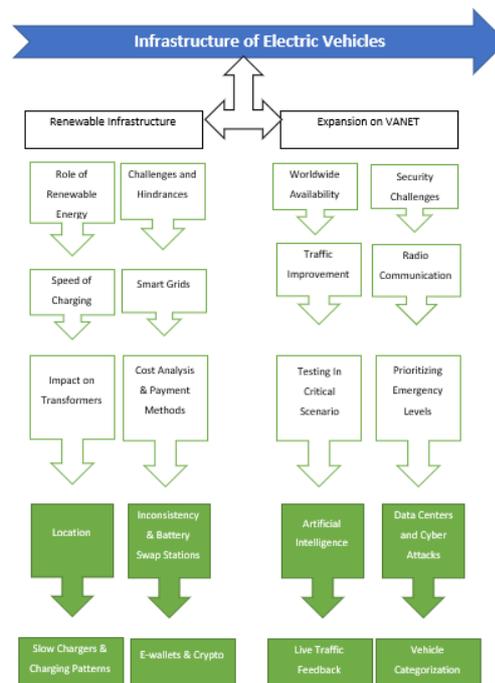
With the rise in demand for Electric Vehicles, it is important to develop and focus on new technology that is environment friendly and fulfills the need for energy production. So far undiscovered new technologies like VANET can prove very helpful in many ways. With the proper traffic management system, there will be a reduction in air pollution. Solar and Wind energy are the main source of renewable energy. As the population will rise, the energy demand will get higher which could create problems like load-shedding or blackouts in many countries.


Figure 2: Final Conceptualization Model.

9   LIMITATIONS AND FUTURE RESEARCH

The research was exploratory in nature and the sample size was small based on a global sample lacking national or cultural differentiation. As a result, all interviews had to be performed online rather than in person. Future research could be done on an expansion in VANET technology along with more detailed well-developed business models as it was difficult to cover both aspects due to time limitations. There were some discussions on heat island effects in literature reviews but it also seems necessary to address synergistic as well as adverse mutual effects and the overall micro-climate of the build-up area. Future research is also suggested on how developed countries can help developing nations adapt to technology. Moreover, studies on the use of hydrogen and biomass as 2nd Generation fuel are suggested.

1 ABSTRACT

The study compares the overall layout of socialist (old) and post-socialist (new) large housing estates (LHEs) in Croatian large cities that depends on daily basis equipment and public infrastructure. The existence and quality of primary facilities and infrastructure is different in new settlements, where it is more often reduced in comparison to old settlements. The main differences occured during the last three decades of transition and market-led economy adopted by Croatia, when the construction of multi-family buildings became commercial and private, and when the construction of urbanistically planned housing estates as housing units became mostly abandoned. For the analysis, the qualitative method of semi-structured interviews with experts (N=26) was used, which was conducted in Croatia during 2022 as part of a joint and bilateral project between Croatia and Slovenia. The current study analyses attitudes of experts on how socialist and post-socialist LHEs in four major Croatian cities (Osijek, Rijeka, Split, and Zagreb) fulfill residents' daily, primary level needs. Experts show that it is the level of neighborhood in which elementary differences in these estates can be seen, and that basic facilities used daily by the residents (school, kindergarten, health center, public transport, green spaces, public spaces etc.) often lack in new residential construction. Therefore, at the level of estates, socialist estates show that they are often better equipped than post-socialist estates, with more public and green spaces and facilities. Due to a large density of building during the transition period new housing estates experience a reduction in public services, green areas and equipment, and therefore a neglect of residents' needs. New residential construction is shown to be reduced in terms of the multifunctionality of space and estate, which should be urbanistically, sustainably and ecologically desirable, but it is often not the case. Thus, the architectural appearance of the post-socialist estate is inadequately adaptive for the residents, because it is too densely built and inhumane in its overall layout, with inadequate infrastructure and facilities, unlike the socialist estates that are, although older and more derelict, more desirable to the residents for everyday living. It is therefore necessary to regulate the future process of planning and housing construction through the national legal framework.

Keywords: primary neighbourhood equipment, residential satisfaction, old (socialist) and new (post-socialist) large housing estates, quality of housing, comparative analysis

2 INTRODUCTION

The study is related to a research conducted bilaterally between Slovenia and Croatia[1] that aimed to analyse the quality of housing and estate equipment at the level of both states, and to explore the residents' perception on housing in large housing estates of the socialist and post-socialist period. Large housing estates built after the Second World War in the socialist system period (1945-1990) were comparatively selected, along with new or post-socialist estates built in the period of transition, or the post-socialist period, respectively (after 1990). Two types of estates in these neighboring countries have a similar history of development of large housing estates, both in the former system in Yugoslavia, and after the 1990s, since their independence until today. This common tradition is in the context of housing policy interesting for comparison in the research and scientific sense, but also for bringing certain recommendations for possible improvements and renewal of housing estates and multi-family buildings at the level of each particular country. Nevertheless, the aim of the present analysis was only Croatia and its sample of largest cities, because the common methodology did not employ all identical mehods.

The joint project included the use of mix methodology, i.e. the quantitative method of questionnaire survey and the qualitative method of focus groups, conducted at the level of both countries. Nevertheless, for the purpose of this paper there was not enough space to present all the employed methods and obtained results.

Additionally, in Croatia the qualitative method of semi-structured interviews with experts was also carried out, which was not conducted in Slovenia, so that we decided to present only the basic findings of this qualitative method. Therefore, the current study will explore how experts in Croatia see socialist and post-socialist LHEs comparatively between these two types of estates, socialist and post-socialist. The content analysis of experts' attitudes, whose domain of work is related to spatial and urbanistic topics, explored to what extent the differences between these estates are present at the level of neighborhood and everyday life, and of their overall layout. It was especially analysed how much LHEs fulfill residents' daily needs for public and green spaces and facilities, and what suggestions and improvements they offer. These improvements are important in the context of potential renewal and revitalization of old, and improvement of life quality in new estates. As Croatian national housing policy is still in the process of development, and political and legal formulation, it needs to be pointed out that it is still trying to adapt to existing European trends, declared primarily in The New Leipziger Charter, 2020 and the New Urban Agenda 2023. In these documents, basic principles of development of contemporary cities are highligthed, such as sustainable, safe, inclusive, green and resilient cities. Nevertheless, everyday life in Croatian LHEs, especially in the largest cities, demonstrates how much these principles are still deviated from and hard to implement. In that sense, there is a national housing strategy envisioned for 2024 in Croatia, which could additionally strengthen a more sustainable and nature-based developmental direction, which has to this point been minimal.

3 SOCIALIST AND POST-SOCIALIST LHES

For Croatia it could be said that it belongs to Central and Eastern European pathway (Dekker et al., 2005) characterized by a significant percentage of former housing estates in the existing housing stock, and a more positive image of living in estates of this type than is present in the estates of Western cities. The estates of Western and North European cities far more often feature numerous social problems linked with economic poverty and issues of segregation and stigmatization (Dekker et al., 2005; Hess et al., 2018), which are for now rarely present in Croatian estates, and residents mostly feel safe and do not wish to move out from them.

Fig. 1: Socialist estate in Zagreb with more public and green space. Source: authors

Similar to other European countries, especially the ones of the former Eastern bloc, LHEs in Croatia were built primarily to resolve the housing issues within the broader processes of post-war regeneration, state-level industrialization and mass urbanization. Socialist LHEs (Figure 1) were supposed to provide housing mostly for the members of working and middle-class in the cities of the newly industrialized society (Rogić, 1990; Sendi and Kerbler, 2021). Because of that mass and urgent need for housing production in socialist LHEs, often cheap and prefabricated elements and suboptimal architectural and constructional solutions were implemented (Hess et. al., 2018; Pojani and Barr, 2016; Nedučin et al., 2019), but they were also built with solid reinforced concrete construction, which even today gives them a safe and good quality of housing in high-rise buildings. LHEs were often located on the periphery of the cities resulting in more dispersed

housing, spatial isolation, higher costs of commuting, higher infrastructure costs, and higher energy costs (Hegedüs et al., 1996, 106; Hegedüs and Tosics, 1998). High building density, monolithic design and focus on residence were the customary characteristics of socialist LHEs (Seferagić, 1988; Rogić, 1990; Dekker and Van Kempen, 2004; Musterd et al., 2017) and after more than 50 years most of them became neglected and deteriorated. Therefore, with the passage of time, in combination with poor maintenance and management, housing in these estates often led to further decay of external and internal layout of buildings (problem with elevators, dilapidated facades, old windows, bad roofs, poor isolation etc.), and with neglected built environment and public infrastructure in the estates (Seferagić, 1988; Černič-Mali et al., 2003; Svirčić Gotovac et al., 2021).

The new, post-socialist housing estates (Figure 2) are those built after 1990, and they could be independent housing units, but also building complexes interpolated into already existing estates. Most of the new residential construction situated either on city outskirts or in the city zones, is being built "in spots" (Svirčić Gotovac, 2015). These new housing locations were built by private investors and real-estate entrepreneurs looking for extra profit in the housing sector. Almost three decades since, these locations in large cities are overbuilt and lacking basic infrastructure requirements and public facilities for daily urban life. All this puts extra pressure on the old estates, formerly better urbanistically planned as autonomous housing units with basic and additional infrastructure (services, public institutions, public and green spaces, etc.) (Svirčić Gotovac, 2015). In Croatian cities, commercialization and gentrification that has occurred in the newer housing estates, has thus created large contrasts between old buildings and new ones. Destructed and overbuilt public spaces often "become a battleground in the competition between different users" (Madanipur, 2004, 271; Petaccia and Angrilli, 2020; Vasilevska et al., 2014). There is also not only a physical lack of space, but also a lack of the social content necessary for different activities that would meet the sociability needs of all their residents, no matter of their age, socio-economic status and cultural background (Petaccia and Angrilli, 2020), especially of children and the elderly population. Lack of public and green spaces especially in the summer months, threatens, for example, the residents' stay in outdoor spaces and often leads to high temperatures in these city zones that are not pleasant for housing. Thereby, in the context of public health, specific groups of residents are at additional risk, particularly children and the elderly.

Fig. 2: Densely built post-socialist estate in Zagreb. Source: authors

Therefore, it is not surprising that socialist LHEs, because of their better equipment, spatial and urbanistic layout, still maintain their reputation as desirable places to live (Kovacs and Herfert, 2012; Grossmann et al., 2017). It is the urban design of these estates, with an adequate ratio of green spaces (parks, walks, tree alleys) and public services (kindergartens, schools, health center) that brings an additional positive image of residing in them, 50 and more years after their construction. This difference occuring between socialist and post-socialist estates affects the perception both of residents and experts, the latter particularly pointing to it.

4 QUALITY OF HOUSING ENVIRONMENT

The existence and quality of public facilities should improve the quality of housing environment and quality of living in the neighborhood, and could add to its use value (Seferagić, 1988; Svirčić Gotovac, 2015). When a housing estate has well-developed equipment, its use value is high. An ill-equipped housing development does not satisfy the needs of its residents and its use value is low. Furthermore, the perception of these attributes of the estate is important for the residents' overall feeling of satisfaction, and influences the decision on a possible relocation (Sirgy and Cornwell, 2002). Sirgy and Cornwell (2002) also state that the dissatisfaction with the physical attributes of the estate, such as the disrepair of buildings, yards and environments, is important for the residents' overall feeling of satisfaction with housing environment. Outdoor services or elements may contribute to the quality of the housing stock, urban design, physical appearances, cleanliness, quality of public space, safety, etc. (Van Gent, 2009; Diaz-Serrano, 2006). In general, it can be said that the perception of the neighborhood is a result of the interplay between various factors (Pan Ké Shon, 2007). They often depend on specifically and spatially driven urbanistic standards by which everyday resident's needs could be better fulfilled.

Thus, in the post-socialist context of housing in Croatia the notion of the so called spatial standards, which has for decades defined the basic urbanistic parameters of the housing estates' development, is gradually lost. Therefore, analyzing the standards of housing and their equipment by comparing the spatial standards for building and the urbanistic-technical conditions of building set in the Zagreb Master Plans of 1971, 1986, 2000, 2003 and 2007, it can be concluded that for decades they have been gradually reduced, and some disappeared completely (Jukić et al., 2011, 103). The problem is in inconsistent implementation of existing urbanistic regulations, for example by the loss of the role of the General Master Plan. This has led to the problem of commercialization of the urban space and the loss of the housing estate standard, and the so called scattered building that even in the new housing locations often leads to the downfall of the quality and equipment of housing estates, and eventually lowers the residents' satisfaction (Svirčić Gotovac et al., 2021). Therefore, the main differences can be seen in the level of neighborhood basic equipment with utilities/facilities used daily by the residents (school, kindergarten, health center, public transport, green spaces, public spaces etc.), which is in new housing estates reduced and inadequate (Svirčić Gotovac and Đokić, 2023), and also by the experts who emphasize these disadvantages and unbalanced housing development, often not in line with the European sustainable and Nature-based solutions (Bush & Doyon, 2019; Zlatar Gamberožić et al., 2021; Snep, et al., 2023).

5 METHODOLOGY

5.1 Semi-structured interviews with experts

The method of semi-structured interviews with experts was within the project conducted only in Croatia. This paper presents results obtained from semi-structured interviews with experts from Croatia, and the thematic and content analysis of the interviews was related to LHEs and the quality of life in them with regard to the two explored periods. In the analysis of results, the emphasis was put on experts' opinions on the situation in Croatian cities, and the attitude of urban policy towards the built and housing space in the context of everyday life and residents' needs.

The total number of experts interviewed by the researchers was N=26, and the majority were according to their specific scope of work from the architectural and urbanistic profession (18), then the urban-sociological (6), civil engineering (1), and the art historical (1). The interviews were carried out during 2022, from April till September in 4 Croatian cities (Zagreb, Split, Rijeka and Osijek), according to an a priori developed writing protocol. Most interviews with experts were conducted in Zagreb (13), Rijeka (6), Osijek (5) and Split (2). The questions from the protocol were then additionally adjusted to the specific professional working domain of a particular expert. The duration of talk per an interview was 40 minutes. Interviews were recorded by a dictaphone and transcribed, and data was analysed in NVivo-12. Ethical consideration included informing the respondents about the purpose of the research, and guaranteeing them confidentiality.

6 RESULTS

The coding of obtained data was conducted at thematic level, which was building on the specific research questions (Elliot, 2018), and the analysis resulted in the following two thematic codes: a) advantages and disadvanatages in LHEs and b) partial urbanism and planning process today.

In the first thematic unit called advantages and disadvantages in LHEs, statements of experts of various profiles were extracted, in which they mostly pointed out the shortcomings of new estates visible in excessive building and reduced green and public areas, such as squares and streets, while advantages of old estates were underlined.

As of green areas, I think that a big problem is that 'toothless' building. We increase the density, which is not followed by public areas. Nothing of new parks, children's playgrounds, and here is a kind of an imbalance. We increase the number of people, and that's why old estates appear better in that sense. (architect, Osijek).

Further, it is pointed out that "generally, it can be assessed that housing estates lack green areas and public space, primarily the one that is designed and functions as a public area of pedestrian character (square, street) with the central amenities of the estate" (architect, Rijeka), and that it is a fact for most housing estates in Croatia.

Such a situation is present primarily in new estates, which are also called 'parasite', due to their frequent reliance on old infrastructure from the socialist period. This happens because new infrastructure is not built, so most of accompanying public institutions and services are missing.

We have these buildings that I call parasite buildings. So, investor, if he/she has a 5-meter access to a road, nobody checks whether he/she has further access, then whether the capacity of kindergartens is adequate, the capacity of schools, etc. (architect, Zagreb).

Nevertheless, besides disadvantages, they also pointed out certain advantages of new estates, such as better building quality, better solutions for traffic and parking spaces, and their better demographic structure (more families with children) 'preventing' them from further degradation and neglect, present in older estates.

The advantage of "new" estates lies in the better quality of building, solving of stationary traffic (in the greatest number of cases), better demographic structure and a relatively balanced social structure (architect, Rijeka).

In the second thematic unit called partial urbanism and planning process today statements on an inadequate process of planning were pointed out, the one that no longer cares for the quality of housing, but instead for the occupation and consumption of space by new and permanent building. Additionally, certain neglect of public spaces is pointed to in new estates, which are on the other side reduced only to a street, but not to a structure of estate as a whole.

In new estates public spaces are almost non-existent, because what the market, finances, investments do is leads to a situation in which they are willing to sell everything that can be sold. In former times during the social ownership, it was not that important to sell everything, but the quality of housing was what mattered. And this is our problem (architect, Osijek).

The relation towards public space and estate is abandoned or criticized, as something that is not structured, and the concept of street is affirmed. When you look at certain solutions, it is visible that there is a vagueness of public space, which is between semi-neglect and neglect (sociologist, Zagreb).

They also point out the importance of regulations in spatial documentation for instance for green areas, which are omitted, and due to which the neglect of public space happens. Today they are viewed in the urbanistic process as a 'loss', because they do not yield profit and cannot be commercialized. Experts see in it the guilt of both their own profession and the legal framework at the level of state, which has adjusted to the post-socialist transformation of space.

Unlike for some other areas, not the smallest regulations are prescribed for the dimensioning of green areas. In the nowaday situation, when green infrastructure is so much emphasized, there should be at least some binding basics of dimensioning established, because the practice of spatial/urbanistic planning shows the following: public green areas are treated as a "loss" of space (no commercialization oportunity), expense for the state budget (buying of the land and further actions), and the support is lacking even within the architectural profession, which is primarily oriented towards designing (architect, Rijeka).

The expert then emphasizes the difference between urbanisms of these two periods, pointing out their different values and concluding "it could be ascertained that with time the civil engineering quality of building has risen, while the urban and esthetic has declined".

On the other side, it is stated that there is awareness on the importance of adopting the sustainability paradigm and, within it, of strengthening of the participation process of citizens and local community, i.e. neighborhood, who themselves need to work more actively on the raising of life quality in a sustainable and contemporary way.

LHEs in the future – if wishing to ensure the quality of life to their residents, will have to include sustainability paradigms. It means green, but also social sustainability, relying on participation, local community, and eventually, on the readiness to connect together in one sustainable social community (sociologist, Zagreb).

According to the statements of experts, it can be concluded that there is a clear difference between the two examined types of estates in terms of urbanistic standards for providing the neighborhood with infrastructure and equipment. The standards related to public infrastructure were more adequate in the socialist period than during the processes of shifting to market capitalism and privatization, introduced from the 1990s onwards. Nowaday context of urbanism has brought a gradual reduction of standards visible in urbanistic plans, and in the housing construction that was not equipped with complementary infrastructure. An overview of the largest differences in the built primary and public infrastructure is presented in Table 1.

BASIC INDICATORS	Socialist estate	Post-socialist estate
school	often built	rarely built
kindergarten	often built	rarely built
green spaces/parks	often built	reduced on smaller place
children's playground	often built	reduced on smaller place
health center	predominantly exists	does not exist
market place	predominantly exists	does not exist
parking places	inadeguate (for today's car number)	inadequate (the advantage is the occasionally construction of underground garages)

Table 1: Built primary and public infrastructure in socialist and post-socialist estates. Source: authors.

7 CONCLUSION

In the current study, it was explored how experts for spatial themes in Croatia see socialist and post-socialist LHEs in the comparative sense of these two types of estates. The content analysis of experts' attitudes revealed that there are significant differences between these estates at the level of neighborhood and everyday life quality, but also the overall layout of these estates. The thematic analysis of interviews with experts points out that in the previous, socialist, system it was easier to protect and build public spaces because there was no market, which nowadays evaluates space differently, i.e. only to the extent at which it brings profit. Urban design of housing spaces used to be planned as a housing unit, which had certain spatial standards and regulations, which were in the post-socialist period brought into question or even partly lost. Thus, a space for significant commercialization of housing space was left open, and for private investments and thickening of the remaining city space, primarily for housing purposes. Professional remarks especially of the architectural profession emphasize that nowaday practice of spatial and urbanistic planning in Croatia shows that public green areas are treated as a "loss" of space that does not bring additional profit, and that they are often viewed only as an expense for the state budget. This way investing in them is either postponed or minimized, and urbanism is replaced with the process of designing, but not planning, at least not on the long term. In that context, in the last three decades public interests have been continuously threatened and destructed in Croatian cities, especially the largest ones. In addition, it can be emphasized that the basic foundations of development of contemporary cities such as sustainable, safe, inclusive, green and resilient principles are better incorporated in the old, or socialist, than in the new, or post-socialist, estates. At the national level it is therefore important to bring a housing strategy by which further housing construction would be controlled and planned more clearly, and which would be based on the mentioned nature-based principles.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Current lack of urbanism and urbanistic standards is particularly visible in new housing estates, which are mostly overbuilt with housing construction and suffer from reduction of public and green areas and basic services. Thus, the architectural appearance of the post-socialist estate is inadequately adaptive for the residents, because it is too densely built and inhumane in its overall layout, with inadequate primary and public infrastructure and facilities. Therefore, despite the old age and neglect of old estates, their advantages in equipment with accompanying infrastructure are pointed out, which was urbanistically planned in the former system and is more adoptive in the architectural sense. With regard to the differences occuring between these estates, experts conclude that it is necessary to follow and incorporate European sustainable trends on liveable, resilient and green cities so that the quality of life and housing at the level of neighborhood would be raised, especially in new estates. This is possible with nature-based solutions by turning the remaining unused spaces into public and green spaces (urban parks, urban gardens, more bicycle paths and recreational zones, etc.) at a small-scale level. In this process it is necessary to activate also the local community and the residents themselves, so that they could reach concrete improvements more successfully. Finally, although the recommendation for the first phase of changes is aimed at short-term solutions, because long-term are harder to achieve and oblige the city and state authorities to be involved, for the second phase it is recommended that exactly the city and state institutions become more intensively involved in urban development, so that post-socialist cities would come closer to desirable European trends.

Paratransit, Built Environment, and Urban Mobility – a Responsive Relationship

Ahmed A. Elsawy, Hany M. Ayad

(Assistant Lecturer Ahmed Elsawy, Alexandria University, Department of Architectural Engineering, Alexandria, Egypt, a.atef@alexu.edu.eg)

(Prof. Hany Ayad, Alexandria University, Department of Architectural Engineering, Alexandria, Egypt, hany.m.ayad@alexu.edu.eg)

1 ABSTRACT

Transit and mobility in developing countries are crucial issues, achieving appropriate mobility in residential neighbourhoods can be a huge challenge; due to the complex urban structure of the built environment and the prevalence of paratransit service that evolved to fill the formal public transportation system gap. This paper tries to answer the dilemma of the chaos and informality in local urban mobility inside residential neighbourhoods in Egypt through a systematic review that analyzes paratransit service in Egypt, discusses its role in supporting local urban mobility, and analyzes its relationship to the built environment in the local urban context regarding land use, accessibility, and socio-economic conditions.

To conduct this study, a comparison is made between paratransit services in Egypt and in some Asian countries that depend on paratransit as an official system that has its laws and guidelines and operates in an integrated manner with public transit. Also, a residential neighbourhood that depends mainly on paratransit in local mobility was selected in Alexandria, Egypt, and several components were assessed through the neighbourhood including service characteristics, pattern of movement, stops, congestion zones, regulations, safety … etc.

The results of the study highlight the deficiencies in Egyptian laws and regulations concerning the planning and design of residential streets and neighbourhoods to accommodate paratransit service. and recommend some regulations to be covered to achieve better local mobility inside residential neighbourhoods.

Keywords: Urban mobility, Built environment, Paratransit, Accessibility, Mobility planning

2 INTRODUCTION

Unlike most developed countries worldwide, which work to develop smart and sustainable mobility plans for people, including all means of transportation (train, metro, light rail, BRT, bus, and bicycle), most developing countries barely have any vision for a better and integrated transportation system. According to the United Nations' Sustainable Development Goals 2030 (SDGs), Goal 11: sustainable cities and communities "make cities and human settlements inclusive, safe, resilient, and sustainable"(United Nations 2015), where mobility is a main target to provide sustainable public transportation system that ensures safety, affordability, and accessibility for all people. However, in developing countries, transportation lacks the primary qualities for adequate urban mobility that are centered on: affordability, availability, accessibility, acceptability, safety, and sustainability (El-Khateeb 2017). Moreover, the prevalence of paratransit service that covers more than 60% of the transportation network is considered a main challenge for these countries (Williams, White et al. 2015, Behrens, McCormick et al. 2016).

Paratransit is an informal and semi-formal network that evolved to fill the gap in the formal public transportation system which does not respond quickly to the population growth and mobility demands in developing cities, and mitigate poor accessibility in low-income communities (Lubis, Buchori et al. 2020, Acheampong, Lucas et al. 2022), it has no specific routes, stops, schedule, or fare, and always develop in response to customers' demand (Cervero 2000, Cervero and Golub 2007, Finn 2012).While some see paratransit as a threat that weakens the transportation system of the city and causes congestion, others find it an opportunity for sustainable mobility. Paratransit network is complex, it is not a sign of informality or rural areas, It appears in most urban regions of cities, reaches the zones where the public transit failed to cover, and provides excellent accessibility. Consequently, it should be recognized as a constituent component of the public transportation system, and there is a need for an integration between the formal and paratransit systems, where the two systems serve each other in a reconciliation (Gota 2018, Talamini and Ferreira 2019).

Service between urban, rural, and peripheral zones is provided by paratransit, which begins at the neighbourhood level and adapts to reach main transit stations, markets, and core parts of the city, and serves as intermodal connections to the formal public transportation system (Gamble and Puga 2017, Talamini and Ferreira 2019). It operates mainly in the zones surrounding the main transit stations and stops, carries

commuters from their place to destination, and ensures accessibility to the zones outside the catchment areas of the mass transit, so its role is important however its spontaneity is an obstacle.

This paper focuses on the informal transit in Egypt as a constituent of paratransit. It reviews and examines the laws and regulations of informal transit in different developing countries, especially in Asia, compares it to the current situation in Egypt, and highlights the main shortcomings and recommendations that should be taken into consideration to achieve an adequate integration between formal and paratransit systems. The paper's structure will continue as follows: section 3reviews the literature on paratransit and previous studies in developing countries and compares it to Egypt, section 4discusses the parameters of the built environment that affect urban mobility, section 5 presents the selected case study, findings and discussion, section 6 the main conclusion is given, and section 7 is concerned about recommendations and intervention scenarios.

3 PARATRANSIT IN DEVELOPING COUNTRIES

Paratransit is mainly concentrated in developing countries, and low and middle-income communities, its modal share represents nearly 50% in Asia, 80% in Africa, and 70% in South America(Salazar Ferro 2015, Behrens, McCormick et al. 2016). However, some countries have succeeded in dealing with, organizing, regulating, legalizing, and converting it into a complete local mobility network that operates in harmony with the official transportation system. While others are struggling to accommodate.

Paratransit mobility depends on affordability, availability, reliability, door-to-door accessibility, comfort, flexibility in schedule, routes, and stops, and speed of the service(Lubis, Buchori et al. 2020). However, many problems are associated with it, including traffic congestion, road accidents, noise and air pollution, and fuel consumption. Many scenarios were set up to overcome these problems including age-based retrofit programs, emission-based regulations, use of electric vehicles, fuel economy standards, and restrictions at sometimes.(Hook and Fabian 2009). WHO (2017)put strategies for paratransit accident reduction to ensure safer vehicles, roads, mobility, and road users' safety, and improve the built environment parameters and road infrastructure to accommodate different mobility options. This includes some interventions including exclusive paratransit lanes, traffic calming, improving road conditions, widening sidewalks, providing cycling facilities, providing vehicles with antilock brake systems and headlights, enforcing drivers to compulsory training, mandatory licensing of vehicles, enforcing speed limits, and enforcing alcohol and medical legislations.

3.1 Paratransit in Asia

The most successful paratransit models can be found in Asian countries like India, Thailand, Bangladesh, the Philippines, and Indonesia. The annual expansion average rate in paratransit system in these countries is 7% and their fleets are expected to double every five years especially the two and three-wheeler vehicles which currently constitute close to 30% of total motorized vehicles worldwide and is expected to reach 1.5 billion vehicles by 2050 (Kumar, Singh et al. 2016, Gota 2018).

3.1.1 Current situation

Paratransit appears in several modes in Asian countries including Auto Rickshaw, Bajaj, Minibus, Tata Magic, Vikram, Mahindra, Angkot, and Becak. It operates either motorized or manually and its capacity varies from 1-2 passengers to 20 passengers. These means vary from one context to another for example in the rural zones it has no license, fare, or route regulations, however, in urban cities, the paratransit is subjected to restricted regulations by the government and transport authorities considering licensing, fare, route, safety standards, and organizational structure(Kumar, Singh et al. 2016, Phun, Kato et al. 2019).

3.1.2 Laws and Regulations

The research reviewed the laws and regulations of paratransit applied in developing countries in India, Thailand, Bangladesh, Malaysia, Singapore, Vietnam, Indonesia, and Cambodia, these laws provide an effective model for regulating paratransit where the government, department of Transport, and regulatory bodies are always present to contribute to safe mobility, create convenient environment for paratransit operation, and work to integrate between paratransit and the formal transportation system. These regulations can be divided into two sections as follows:

(a) Legalizing Framework

- Licensing and permitting: To establish new paratransit services, operators must request a permit from the government's Department of Transport. The government's approval is based on the current service situation and passengers' demand; as the number of permits is limited to control the number of service vehicles.

- Route planning: To ensure traffic flow, avoid conflicts with the main transportation system, and cover the demand pattern, the service routes are designed and indicated through the regulatory bodies, and a fine is applied for not adhering.

- Fare regulation: The regulatory bodies are responsible for setting mechanisms to calculate the appropriate fare and periodical fare revision. In some places, metered fares are applied to calculate fares based on distance.

- Safety standards: Paratransit vehicles are required to meet certain safety standards, such as first aid kit, fire extinguisher, drivers' training, and periodic inspection to ensure compliance with these standards.

- GPS tracking: for real-time monitoring of vehicles; to make sure of their adherence to the designated routes and their adherence to regulations. In some cities, paratransit is organized through dedicated Apps-based systems that are used for booking and payment.

- Electric vehicles: encouraging sustainable mobility through the usage of electric vehicles and providing charging facilities to lessen environmental impacts on transportation

(b) Organizational Structure

- Public and private ownership: Ensure the ownership and operation of paratransit vehicles whether by individuals or components of a bigger organized private fleet

- Operators associations: The role of the associations is to represent paratransit drivers and their interactions with transport authorities.

- Coordination with transport authorities: verify the interaction between paratransit operators and transport authorities in charge of monitoring their activities. This includes data sharing, reporting procedures, and compliance monitoring.

- Road Infrastructure: To accommodate paratransit, the government makes investments in strengthening road infrastructure including widening streets and providing dedicated lanes for paratransit vehicles in which street design includes defined lanes inside residential neighbourhoods; to avoid conflicts with other modes of transportation and pedestrians and ease mobility and traffic flow, particularly in congested areas. These lanes are integrated into the built environment with consideration to lane width and turning radii. These street design considerations are planned to fit the movement and space needed for paratransit vehicles.

- Parking and stations: Create centralized pick-up and drop-off points for paratransit close to transit terminals, markets, and residential areas. This will give passengers a convenient and organized space to wait without being stacked in traffic congestion on main streets or around mass transit stations. and make it easier for people to switch between public transport and paratransit.

- Traffic management: using traffic signals and signages for paratransit vehicles to organize their movement in the built environment without contradiction with pedestrians, cyclists, and traffic.

- Road safety campaigns: The government aims to decrease accidents and increase transportation effectiveness by enhancing road safety. It runs initiatives for paratransit passengers and drivers to promote road safety, these campaigns raise public awareness of the value of safe driving and compliance with traffic regulations.

3.2 Paratransit in Egypt

Paratransit in Egypt is mainly focused on small vans, microbuses, minibuses, and three-wheelers tuk-tuk. On one hand, it is accompanied by many problems like traffic congestion, and lack of the primitive qualities for adequate urban mobility, and sometimes leads to social segregation based on the local urban context, built environment, and socio-economic status of the people. However, on the other hand, the paratransit's

complementary role as an essential mode of mobility that people depend on is non-negotiable; it acts as a feeder for the main public transport, solves the challenges of accessibility and the first and last-mile connection problems in the peripheral urban zones of the city, and provide thousands of employment opportunities for unskilled workers (Cervero 2000, Valenzuela Jr, Schweitzer et al. 2005, Neumann 2014, C. Liu 2018, Acheampong, Lucas et al. 2022).

3.2.1 Current situation

Paratransit modal share in Egypt is nearly 55% of the whole transportation system (Salazar Ferro 2015, Behrens, McCormick et al. 2016), and it represents almost 83% of all motorized trips (Abd Alla, S. 2017). People depend on paratransit in their daily life routine; as it is the most available, flexible, and extended schedule means of transportation that respond to the shortage in the formal transit system.

Paratransit service in Egypt is divided into semi-formal and informal transit. The semi-formal transit is organized and licensed by the city's public transport authorities, it has specific routes and fares but no fixed stops, frequencies, schedules, or times. While, informal transit -which is the focus of this research- is mainly represented in the following classes (small vans, old microbuses, and 3-wheelers tuk-tuk) as shown in (Figure 1), It is not licensed or organized, has no exact information, has no specific routes, stops, frequency, fare, or time, operates on an extended schedule based on customers' demand, and concentrated on the local scale of the neighbourhoods.

A big share of the informal transitis represented in the tuk-tuk; a small size 3-wheeler vehicle that operates almost 24-7, especially in the inner local zones. It started to appear in 2005, according to CAPMAS (2021), Egypt contains 5,600,000 tuk-tuk, of which only 306,917 are licensed which is nearly about 5% of the total number of vehicles and the rest are informal ones. Egypt imports 50,000 tuk-tuk each year, which provide 150,000 job vacancy (Hosny 2013), It is an effective mean of transport; due to its small size and fast service that makes it easy to operate in the small zones, narrow streets, and complicated urban fabrics that public transport cannot reach.

However, the informal transitsector in Egypt is accompanied by several problems which can be grouped under three main categories: traffic congestion, accidents, and personal safety. This is due to the absence of regulations, surveillance, and law force.

3.2.2 Laws and Regulations

Several governmental documents, mobility reports, official plans, and transportation laws and regulations were reviewed, it was found that Egypt has no clear laws to regulate informal transit, there is no specific data or counts regarding their numbers or operators, and no definite legislation to regulate their routes, fare, schedule, operation zones, or safety standards. There is no force to legalize and license them except for some practices from the local authorities of each district, otherwise, they operate either without a license like in the case of tuk-tuks, or they are licensed as private cars like in the case of small vans, however, they operate commercially and pay no taxes.

Many governmental plans noted the importance of stopping importing the tuk-tuk, pan its mobility in the streets, and replacing it with small vans that operate on natural gas; due to its implications as it exceeds the capacity of cities and towns (Arafa 2021). However, all these plans failed to be achieved; due to the rapid and vast spread since 2010 especially in the local urban contexts, which led to the necessity to license and authorize the informal transit and find ways to regulate and integrate it into the whole transportation network of the city as an effective way for sustainable mobility.

Some successful attempts were made to organize tuk-tuk which resulted in organized fleets operated by private companies like Uber and Careem, these fleets have specific fees, facilities, and schedules, ensure personal security and safety standards considering drivers and vehicles, and sometimes they use Apps for booking and GPS tracking. However, these fleets operate on a small scale for local mobility inside private gated communities and residential compounds like El-Gouna City in Hurghada governorate on the Red Sea, and Marassi City on the North Coast of the Mediterranean Sea(Figure 2).

Table 1 represents a comparison of the paratransit service in Asian countries and Egypt; to summarize and highlight the main shortcomings and the promising interventions that were applied in these developing countries and achieved convenient practices and regulations for urban mobility.

4 BUILT ENVIRONMENT FACTORS THAT AFFECT URBAN MOBILITY

In studying the relationship between urban mobility and the built environment inside the neighbourhoods, most studies highlighted that the characteristics of the built environment are the potential that encourages informal transit to evolve, urban structure elements including land use, public transport planning, street pattern, urban fabric, demographic characteristics, social aspects, and economic status all influence travel behavior and mode choice, in addition to different measures of the built environment including the 5Ds variables defined by Cervero (density, diversity, design, distance, and destination accessibility) (Ewing and Cervero 2010, Guerra, Cervero et al. 2012, Gamble and Puga 2017, Tong, Wang et al. 2018, Kumar, Sekhar et al. 2020, Falchetta, Noussan et al. 2021, Acheampong, Lucas et al. 2022, Gupta, Bivina et al. 2022).

4.1 Land use diversity

Many scholars have cited that land-use patterns affect travel behavior and mode choice; this then impacts how paratransit is planned and spread. Studies defined land-use diversity as a combination of eight land-use categories that exist within the neighbourhood context: residential, commercial, industrial, recreational, transportation, government buildings, utility, and vacant land. When all amenities: schools, grocery, hospitals, facilities, and open spaces are in proximity and within walking distance, people depend less on informal transit for mobility.

4.2 Transportation accessibility

Representing the distance and time needed to access public transit and stations from the center of the neighbourhood, this gap determines where informal transit works as an intermodal system to achieve first and last-mile connectivity between homes and destinations.

4.3 Road infrastructure

Streets in terms of (design, width, pavement, and geometry) affect the ability to accommodate public transportation systems to serve the district, which in turn affects the use of informal modes that can reach these zones. sidewalks in terms of(presence, width, and quality), facilities for the physically disabled, presence of pedestrian crossing, traffic signs and signals, traffic speed, and volume. All these factors affect travel behavior and mode choice.

4.4 Walkable and friendly environment

Providing spaces that encourage active modes of travel in which sidewalks are well-designed to attract pedestrians and positively influence them to walk; as they find comfort, safety, cleanliness, continuity, surface quality with no obstacles, a buffer from traffic, greenery, shading, shops to screen, open spaces, and adequate lighting. Also, providing safe cycling lanes that are separated from traffic encourages people to use bicycles safely and reduces depending on the informal travel modes.

4.5 Population density

In densely populated neighbourhoods the demand for transportation service is high, and informal transit often meets this demand and provides flexible transportation options that adjust routes, patterns, and schedules based on the local needs and amenities.

5 CASE STUDYALEXANDRIA, EGYPT

To better understand informal transit in Egypt and how it operates inside neighbourhoods, an analysis of a residential neighbourhood in Alexandria, Egypt was undertaken. The selected study area (Moharam-bek district) is considered a condensed middle-class residential neighbourhood within the urban context of Alexandria. The neighbourhood is served by public transit on the periphery however the inner zones inside the neighbourhood are barely accessible by public transport, a matter that leads to the revealing of informal transit the achieve local mobility inside the neighbourhood.

5.1 Methods

The survey is based on two steps; first, an observational analysis is carried on by taking rides on the existing modes of the informal system operating in the neighbourhood; to analyze the current situation, and second, conducting discussions with users and drivers about the service. The following key components were studied in the survey:

- Types of existing informal transit
- Vehicles' characteristics (safety, design, manufacture, etc.)
- zones of operation, and pattern of movement
- service stops, hotspots, and congestion zones
- Routes and scheduling
- Fare structure
- Operational characteristics
- Role and contributions of the service
- Existing regulations
- Licensing
- Social concerns and personal safety

Figure 3: paratransit vehicles in Moharam-bek, Alexandria – represented in tuk-tuks that operate illegally (researcher, 2023)

5.2 Findings

The study area is featured by the spread of tuk-tuks as shown in figures 3 and 4 in which they operate illegally, move in opposite directions without any regulations, and cause congestion and conflicts with trams

608

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

and vehicles. The key components of paratransit that were analyzed in the study area are summarized in table 2.

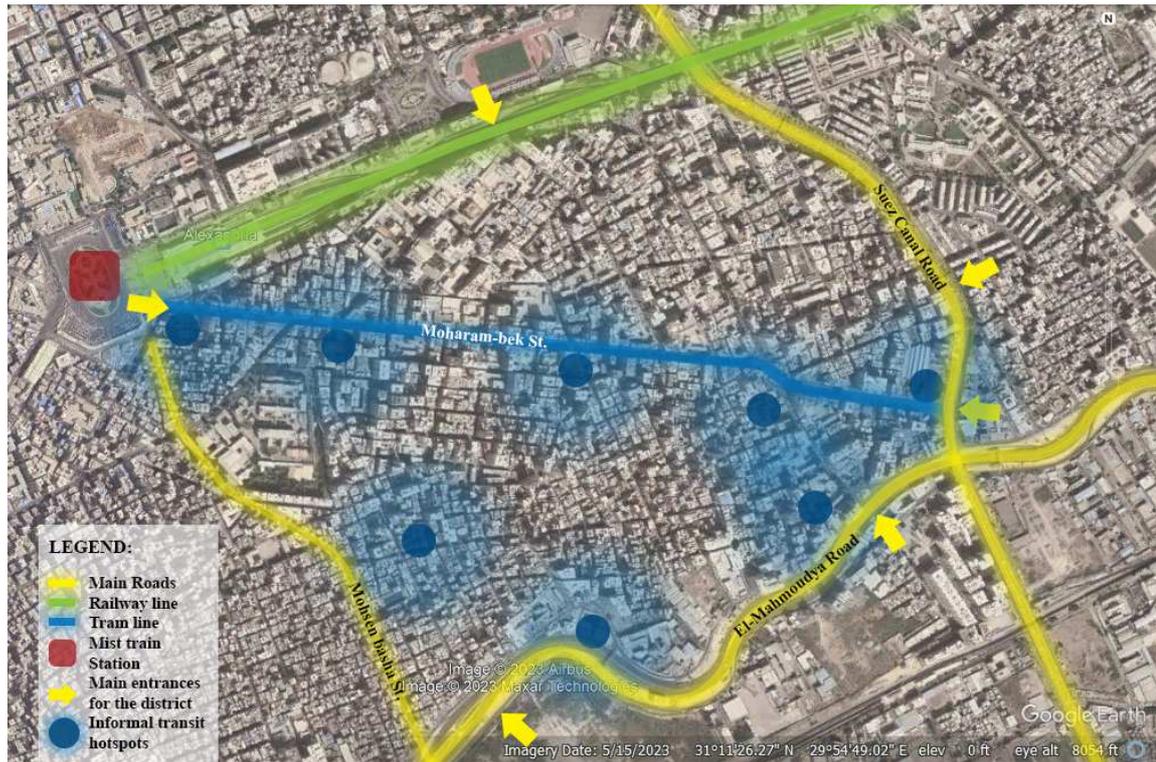

Figure 4: illustrative satellite image indicating context & mobility options in study area (source: Google earth, 2023)

Component	Description
Existing informal transit	Motorized tuk-tuk: a three-wheeled vehicle with a capacity of 2 passengers
Vehicle characteristics and safety standards	Vehicles are of poor quality, sometimes there is an overcapacity of 3-4 passengers, all vehicles run on diesel, and lack any safety standards considering driving techniques, maneuvering, their rush driving cause accidents with vehicles and pedestrians.
zones of operation, and pattern of movement	Tuk-tuks mainly operate in the inner zones and streets. And the main collector street in the neighbourhood (tram street) is their reference, where they start from or end at. The pickup points can be anywhere if the vehicle is empty.
service hotspots and congestion problems	Vehicle pick-up/drop-off stops are near the main railway station and bus stop at (Misr Station)and near the main markets; to carry people to their homes. And the main congestion appears when they move in opposite directions with the tram.
Routes and scheduling	Routes are highly flexible and dynamic based on customer demand, they operate in opposite directions to reach their destination. Scheduling is extended 24-7, and at the main hotspots the vehicles work on a queue system
Fare structure	There are no definite measures to calculate fares based on distance, drivers charge passengers at their discretion or based on negotiation; which leads to over-charging causing problems between drivers and passengers.
Operational characteristics	Tuk-tuks provide door-to-door and ride-hailing services. As soon as the passenger gets down, the drives tend to move back to the main hotspot zones.
Role and contribution	Tuk-tuks play a critical role in addressing local mobility needs inside a neighbourhood, providing connectivity between highly generating and attracting points, and achieving first and last-mile connectivity to public transit.
Existing regulations	There are no regulations applied to tuk-tuks, they operate chaotically.
Licensing	The majority of tuk-tuks are not licensed, a few tuk-tuks were noticed to carry license plates but that doesn't exceed 5% of the total number.
Social concerns and personal security	There are many concerns noticed regarding inappropriate drivers' behavior with users when negotiating fares and with other vehicles' drivers when complaining about their movement out of their lanes and in the opposite direction. Also, there are some accidents regarding kidnapping and harassment using tuk-tuks.

Table 2: Characteristics of the informal transit in the case study area (Moharam-bek district, Alexandria, Egypt)

5.3 Discussion

In the absence of adequate official data, the methods used for the case study formed a significant input, it provided information concerning informal transit operations and characteristics in urban neighbourhoods. The case study area showed that however tuk-tuks are accompanied by a huge amount of problems and have a lot of concerns: safety, personal security, congestion, traffic, fare, routes, and regulations, these modes of informal transit provide the needed local mobility inside the neighbourhood which is not served by public transport; this service is the only way to connect people to their destination whether to the main transportation terminals, markets, and other amenities.

The study revealed that the characteristics of the built environment played a vital role in the spread of paratransit; high population density, condensed urban fabric, poor road infrastructure, irregular geometry of streets, and poor road planning hierarchy, all these factors obstruct public transit accessibility which in turn open the space for paratransit, also the deteriorated conditions of sidewalks and the unfriendly walkable environment prevent people from active transportation.

6 CONCLUSION

This paper has contributed to a better understanding of the role of paratransit service in meeting the needs of local urban mobility in Alexandria, Egypt. It helped to answer several questions considering: What type of local mobility inside neighbourhoods? What contribution does it add? What type of users does it serve? and What problems are accompanied with? On one hand, the paper showed that paratransit service is a problem that causes chaos and congestion inside neighbourhoods. However on the other hand, it highlighted its role in local urban mobility, it showed that this service is indispensable in the areas poorly served by public transit, this service is highly flexible to fit users' needs, although it may not be comfortable and safe, sometimes they represent the only choice for people to move to/from their destinations.

When comparing the situation in Egypt to the successful examples in Asian countries, it was found that Egypt almost has done nothing to solve the chaos and informality of paratransit service, the only consideration is some calls to license these vehicles and this is not the regulatory decision that ensures a better organization to the network. With more than 6millionvehicles that operate informally in the streets of Egypt, more decisions and laws have to be made to regulate and accommodate this service.

Learning from the Asian lessons, Egypt has to focus on the legalizing framework considering: obligatory licensing, route planning for the service, fare regulations based on the distance, GPS tracking for each vehicle, and safety standards including vehicle compliance, driver training, and regular inspections. Also, the organizational structure has to organize this service through specific laws and regulations for this type of transit and paratransit has to be represented by operators associations that are responsible for organizing public and private ownerships of vehicles, coordinating with transport authorities, ensuring continuous inspection and laws implementation, and solving the drivers' problems.

Moreover, one of the main problems of paratransit service is the accompanying congestion and accidents. Specific rules have to be formulated concerning traffic management that regulate the movement inside the built environment, indicate separate lanes especially on the main streets to prevent conflicts with cars, and determine specific parking and stations which have to be well designed and placed based on the analysis of the hotspots and transit terminals for each neighbourhood; to prevent overcrowding and street blocking

7 RECOMMENDATIONS

This paper sets the basic guidelines for the role paratransit plays in the urban environment and its effect on local mobility in Alexandria, Egypt. However, it highlighted the deficiencies and shortcomings in the Egyptian transportation laws that failed to accommodate paratransit service. These laws need to be considered by the government and decision-makers; to ensure adequate and safe mobility for all people.

First: mobility in Egypt has to be planned on two levels (two services) that work in integration with each other. The primary service is dedicated to long-distance mobility including railways, metro, tram, and BRT (known as trunk network), and the complementary service for local mobility, acts as an intermodal network that connects commuters to the primary service including local microbuses, vans, and tuk-tuks (know as the trunk-feeder network).

Second: Governments, transport authorities, and policymakers should acknowledge the presence of paratransit modes in cities and the role they play in urban mobility, analyze their challenges, and develop laws and policies that enhance the quality of services, organize their operation, and achieve safety based on the successful practices applied in Asian countries as discussed before.

Third: urban planners have to pay attention to the planning standards of the built environment and residential neighbourhood that achieve strategically placed hotspots like markets, hospitals, schools, amenities, and transportation hubs, smart planning enables residents to access services without the need to distant move and has enormous promise for reducing the demand for local urban mobility.

Fourth: attention should be paid to the improvements in roads and sidewalks infrastructure, urban design, and landscape, which in turn shall provide a friendly environment that encourages people to active means like walking and cycling, and reduce the need for local mobility.

Future research should consider how to apply these regulatory and organizational frameworks in the field, measure their effectiveness, and ensure law adherence.

1 ABSTRACT

Urban parks are a crucial component of the city fabric but their intended use is overlooked by informalities and activities that distort the user's positive experience. South Africa has been investing massively in urban parks to improve the fabric of cities. However, the approaches to enhancing the functionality of urban parks have not yet been studied and documented convincingly, particularly in most urban areas. Consequently, this paper highlights the pathways to enhance the effective use of urban parks, specifically focusing on Gugu Dlamini Park, eThekwini Municipality. The study adopted a case study research design and applied a qualitative approach to gather relevant data on the current use of urban parks. Specifically, data was collected using geo-spatial mapping, in-depth interviews, and observation schedules. The paper reveals that the elements such as safety and placement affect park users, mainly due to poor management and enforcement. The paper recommends the incorporation of urban parks within government and municipal strategic goals. There is also a need to integrate informal trading into formal spaces in urban parks. In conclusion, the paper recommends that to achieve effective utilization of urban parks they must be inclusive and vibrant. The enhancement of urban park functionality fits well into the broader phenomena of the current use of parks in urban areas.

Keywords: Urban Parks, Urban Green Spaces, Placement, Public Spaces, Informality

2 INTRODUCTION

Historically, urban parks were intended to offer open spaces inside cities to diminish the harmful impacts of industrialization. Lately, many countries have acknowledged the importance of the multi-functional use of urban parks (2017 Kothencz, G.; Blaschke). Nevertheless, many of these urban open spaces suffer from underutilization due to several reasons that among others include a lack of social activities and sports, inadequate facilities, and poor maintenance and safety (Akpınar, 2020; Babey et al., 2015). This study aims to evaluate the factors desirable to enhance the park's functionality and also analyse the subjects influencing the use of urban parks in South Africa.

Urban parks have always been an element of the city structure; though it is not been an occurrence since the nineteenth century (Abdelhamid, 2019). For example, up to the nineteenth century, Britain's towns were characterized by low-density growth (Gunn, (2013). According to Walker and Duffield (2007), citing Chadwick (1966); Perrin and Cochrane (1970), states urban areas were not developed at densities that were high enough to totally remove open space until the nineteenth century. Walker and Duffield (2007), add that the nineteenth century stood out due to rapid urbanization, and the exceptional speed at which cities were growing, this resulted in the first active promotion of urban open space. They further explain that urban open spaces must be viewed essentially as the consequence of the emerging industrial cities as well as of the social and geographical organization of fast-growing expanding populations.

According to the United Nations (2018), the total urban population of the world is set to intensively grow, it is highly expected that by 2050, three billion more people are projected to reside in cities, bringing the proportion of urban dwellers to two-thirds of the global population. In spite of this, the rapid growth of cities and urban areas and how urban parks are used have led to the clear decline of urban open spaces around the world, resulting in significant social and ecological problems (Faragallah, 2018). Urban park functionality enhancement has become a prime essence of restoring the intended use of green spaces in urban areas.

3 PUBLIC SPACE AND THE ROLE OF URBAN PARKS

Alwah et al. (2020) argue that urban parks are crucial for the social growth of city dwellers, pointing out that social interactions are developed in these settings. Soltanian & Mohammadi (2015) agree to state that more than serving a purely functional purpose, urban public open spaces are essential for fostering social connections or ties among residents. They further state that public spaces in a city are impacted by the social

and economic developments of the era, which result in altered cityscapes. Thus, continuing in their explanations, they state that social problems in cities might result from a lack of an appropriate urban space. It points out that the rapidly changing social conditions have increasingly affected how people use and influence their surroundings. In addition, Abbasian (2016); Balogh & Takacs (2011) state that overall, the urban population has been dramatically growing, and this results in the physical makeup of metropolitan regions constantly changing, typically in negative ways. In another instance Memluk (2013) adds that infrastructure and equipment are more in demand as the population grows, which results in "increased mobility, communication technology, and globalization causing metropolitan areas to grow and change in size, resulting in a shift in lifestyle and use of public places." On the contrary, Abbasian (2016) and Mehmet NCEOLU (2009) place emphasis on the impact of technological advancements on causing worry, which worsens daily to the point that the effects have further isolated and privatized people's lives. As a result, the significance and importance of public spaces in social life decrease resulting in urban open spaces being used inappropriately as designed or intended.

Furthermore, according to Abdelhamid, & Elfakharany (2020), Berg et al (2022), research on the use and significance of urban environments have been carried out in Europe, America, Australia, China, and several East Asian nations. These studies have confirmed the various aspects of using and visiting open spaces. This study fills in a knowledge gap. For instance, a study on urban open spaces in Yemen, an East Asian country, reveals that the majority of the population uses open spaces for walking, playing with their children, relaxing, and amusement. Users also like locations that offer suitable and ample seating places, a variety of contemporary entertainment options, a high standard of hygiene and maintenance, and secure locations free from intruders (Alwah et al., 2020). Such information, they say, helps Yemeni urban planners and developers create new public spaces and help restore deteriorated open spaces (ibid). According to Fan et al. (2017) Faragallah 2018, Niemelä (2014), Wolch et al (2014), public open space is one of the most important components of sustainable urban design and development. They explain that in addition to providing ecosystem services to the populace. These ecological services include changing the climate, managing stormwater, and enhancing air quality as well as regulating leisure, sports, and recreation (Elsheshtawy, 2011).

Conversely, urban parks are essential for fostering individuality and cultural variety, which exemplifies democracy through open-access public places (Thompson, 2002). Instead of seclusion in situations with only one type of culture, intercultural interaction in public places helps to foster tolerance and understanding among people (Salama & Gharib 2012). Additionally, parks are good for people's health and fitness when they engage in exercise activities or simply walk outside to appreciate or enjoy nature. This is crucial given the rise of age-related disorders like heart disease and obesity brought on by new lifestyles (Salama & Azzali, 2015). However, in order to create lively and dynamic urban park environments that improve well-being and quality of life, it is important that the design, planning, and administration of these open spaces consider the needs and expectations of users by being cognizant of their experiences and preferences (Alwah et al., 2020).

4 MATERIALS AND METHODS

The study adopted a phenomenological case study research design as it seeks to investigate pathways to urban park enhancement in Durban, South Africa. The case study assists in conducting a systematic, critical inquiry into a phenomenon of choice and generating understanding to contribute to cumulative public knowledge of the problem (Simons, 2009). A qualitative research approach was used which qualified the collection of qualitative data (Mohajan, 2018). The study was carried out through in-depth interviews with personnel from users of the park, officials from the eThekwini municipality Department of Parks, Recreation and Culture, and an academia from the Department of Town and Regional Planning, University of KwaZulu-Natal.

To reveal the condition of the park and complimentary amenities (street furniture), geo-spatial mapping was applied as a visualization tool for the spatial arrangement of the study setting. The research area was visited for direct observations and photographic assessment purposes. The convenience and purposive sampling methods were employed to recognize all the study respondents, and further adopted a descriptive-analytic strategy but relied more on developing case descriptions. The intention of making a case description was to

614

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

postulate the activities observed at Gugu Dlamini Park and put these observations into context (Yin, 2002). The techniques of pattern-matching, explanation-building, and time-series were developed for data analysis

5 RESULTS

This section presents the findings of the study. It highlights the pathways to Urban Parks functionality enhancement. UN-Habitat (2015) has been in the lead in enhancing the improvement and provision of urban open spaces. ''Cities that have a strong impression of the public, demonstrate an obligation to an improved quality of life of their residents by providing suitable green area, street space and recreational facilities'' (UN-Habitat 2015:4). The results from the empirical investigation are based on three thematic areas namely; planning for a variety of activities, enhancing physical attributes of the park and ensuring safety and maintenance.

5.1 Planning for a Variety of Activities

According to observations conducted over three weeks during morning hours, afternoon hours, and evening hours at Gugu Dlamini Park, it was discovered that the space is dominated by myriad activities including vagrancy, illegal trading, cultural dances as well as young adults consuming alcohol on the edges of the park. According to the eThekwini Municipality Parks and Recreational Bylaws (2015), alcohol is prohibited in the urban open space unless it is consumed in designated areas, which unfortunately are not present at Gugu Dlamini Park, and the bylaws further prohibit any form of trading without obtaining a permit from the municipality. Figure 1 shows the different activities that occur in the park and includes users of the space frequently taking pictures next to the HIV/AIDS sculpture.

Figure 1. Various activities. Source: Author; field observations (2019

Patterns in urban park activity and use appear to be associated with characteristics of the surrounding areas as well as the social environmental and physical characteristics of the park (McCormack et al., 2014). The types of visitors and times of use vary. The park is situated next to the Workshop Mall, during the lunch hour, workers from the mall tend to use it often and in the late afternoon is dominated by school children. Table 1 summarizes the prominent activities according to their time of occurrence.

Activity types	Time		
	Morning 06:00-09:00 09:00-11:00	**Afternoon** 01:00-01:00 01:00-03:30	**Evening** 03:30-07:00
1. Seating and relaxing	***		
2. Vagrancy	***		
3. Informal trading	**		
4. Football play		*****************	
5. Performances	**************************		

Table 1 Activities vs. time observed at Gugu Dlamini Park

5.2 Enhancing physical attributes of Parks

Gugu Dlamini Park is positioned in a strategic position, which makes it easily accessible by the surrounding land uses. The nature of the area is associated with human interaction because of the adjacent mall to the park. The trails of the park are well-designed and connect both to the streets and other services (see Figure 2). Timmermans and Cilliers (2016), support the view that the physical attributes of a successful urban park can be quantifiable and tangible with attributes such as accessibility, location, shape, size, and natural features. Caryn et al (2018), further confirm that hardscape, landscape and services designs affect physical activity and influence the degree of urban open space usability.

Regarding supporting amenities, the urban park is furnished, however, it was observed that some of the street furniture has deteriorated. The elementary function of street furniture in urban open spaces is to assist the lives of citizens and provide them with a comfortable space (Tereci and Atmaca, 2020). The work anticipated from the space design is that its street furniture prevents redundancy and complexity. Therefore, the user will receive the best service in an original, harmonious, and comfortable place. About 56 % of the respondents at Gugu Dlamini Park complained about the lack of shelter during rainy and hot days as enormous portions of the park are deprived of shelter. The park further lacked essential facilities such as bathrooms and water fountains. Caryn et al (2018), A National Study of Neighborhood Parks in America approved that number of park users may decrease if the park does not have comfortable public toilets and clean water, even if it has great amenities and is easily accessible.

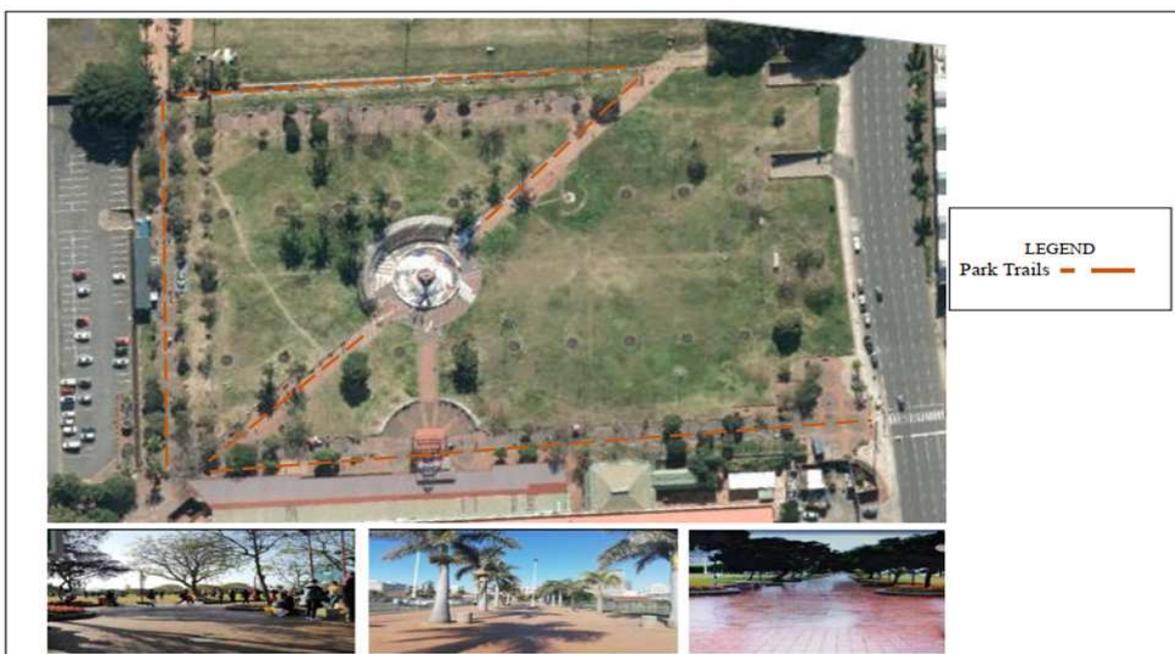
Although other facilities are not found, the remnant amenities are still crucial for the attraction of people to the space. The park has trees along the perimeters and the trees proffer a sense of boulevard scenery in the space. Users of the park enjoy taking photographs of the natural landscape and flowers.


Figure 2: Aerial view and existing park trails

5.3 Ensuring safety and regular maintenance

Urban parks are central to the functioning of cities and strongly impact the quality of life of city dwellers (Camargo et al., 2017; Koramaz & Türkoğlu, 2018). However, if urban parks feel unsafe, users are less likely to visit them. 76% of the respondents perceive Gugu Dlamini Park as an unsafe space because of the high presence of homeless people who pester and ask for money. Table 1 further substantiates and gives a clear insight into the vagrant people who occupy the park during the day. Dogrusoy and Zengel (2017) mentioned that the perceived safety of parks is a vital aspect that may discourage many potential visitors from enjoying and using available urban open spaces.

Observations from the researcher exhibited that users of the park use the green grass as an alternative to the designated pathways and trails. As a result, the presence of bare land in the green zones of the park is causing environmental degradation. Damaged waste receptacles and signage within the park were observed as a hindrance to the user's experience of the urban open space.

6   DISCUSSIONS

Understanding urban park purpose use and evaluating visitor perspectives on physical attributes, accessibility, safety, and maintenance can assist to advance planning, management, and design across a range of city parks. The research study was unique in that it applied a qualitative methods approach with on-site observations to evaluate urban park users' activities, as well as in-depth interviews to differentiate various viewpoints on access, use, improvement, and enhancement preferences.

616

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

The results obtained from empirical investigation reveal that enhancing urban park functionality is not a generalized topic. Urban park functionality comprises optimal landscape features such as plants and trees and physical attributes such as linkages that proffer excellent connection with adjacent land uses (PPS, 2015b). It is also argued that urban park functionality is dependent on social interaction environments and it has to be emphasized and addressed from an architectural perspective (Liu T and Liu W, 2016).

From the study observations, there were imperative highlighted park uses and discoveries that relaxation, adult interactions, and solitude were some of the most common park activities. These results are consistent with other studies that demonstrate urban parks as crucial places for encouraging psychological health (Bratman et al., 2019; Frumkin et al., 2017; Schnell et al., 2019). It is also evident that the use patterns of the park are influenced by a variety of socio-spatial factors. These findings were constantly disturbed by the presence of vagrant people who brought a sense of insecurity as submitted by users of the park.

As indicated in Table 1, informal traders and different performances as a form of entertainment are common activities in the park. Such activities received positive feedback from interviewed users of the space even though they are highly prohibited by the eThekwini Municipality Parks and Recreational Bylaws (2015) if they occur without the municipal's approval. Wood (2003), green spaces offer not only active and passive recreation but also include numerous socio-economic activities. In African cities, informal trading rests as a daily reality because it is the source of livelihood in today's extreme poverty and unemployment and it remains a call for urban planners to incorporate such activities in urban parks but also not compromise their functionality.

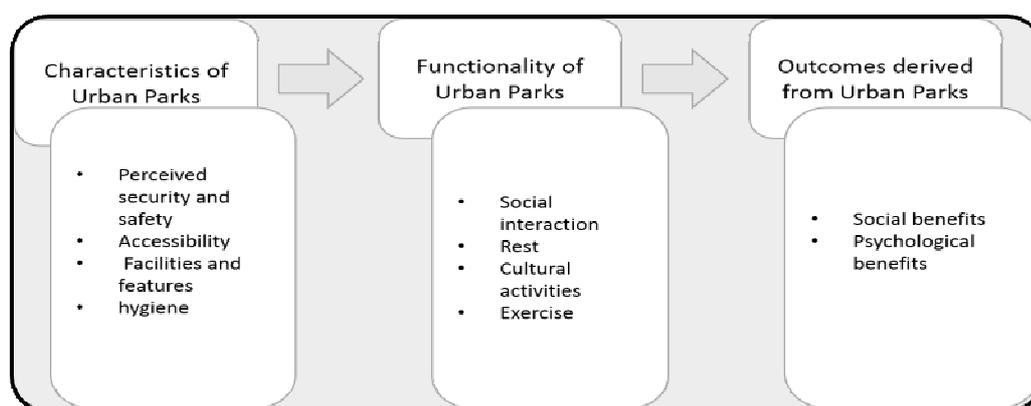
7   TOWARDS FUNCTIONAL URBAN PARKS


Figure 3: Relationship between urban park characteristics, functionality, and outcomes. Source: M. Mndzebele (2023)

As assumed by the empirical and literature reviewing outcomes, the characteristics of urban parks entail features and facilities, accessibility, hygiene, attractiveness, security, and perceived safety. The potential outcome is having functional urban parks that constantly encourage social integration and tranquillity aswel as cultural activities as seen in Figure 1. The relationship between urban park characteristics, functionality, and outcome is demonstrated in Figure 3.

As part of facilities, to address informal trading in urban parks, it is of high importance for municipalities to provide unique and designated selling points within the spaces. It can be linked to the government policy of permitting informal traders to do business there so that the traders will not have to fear being evicted (Widjajanti et al., 2022). It is also advocated that a place makes sense when it is rich in urban park features such as sculptures, food concessions, benches, and water features. However as observed at Gugu Dlamini Park, these features are not enough to provide an exceptional user experience. Understanding the controls for change is an essential prerequisite for urban planners to be able to address joint concerns of planning as exemplified in urban park challenges.

The concern of vagrancy in urban parks is a sensitive social issue and cannot be dependent on urban planners only to proffer solutions. Institutions such as homeless shelters, rehab facilities, the private sector, and NGOs that deal with social development complications could be brought in as an intermediary to assist vagrants lodging in urban parks to be integrated well within the communities. Our analysis further reveals that cultural and social interactions were not appreciated with low tree cover. Plenty of the respondents found the park inefficient in terms of providing adequate shelter, especially during harsh weather conditions. Shade is

an important feature in urban parks concerning the improvement of social benefits as it allows users to stay longer, protected from over-exposure to unfriendly weather. Improving the attribute of shade can be a positive measure to further better physical activity levels and enhance the comfort of people's use of these types of spaces (Liu et al., (2023).

The approach to curb most urban park challenges and enhance functionality is by fully incorporating parks within the government and municipality's strategic goals. For example, as municipalities plan for security and safety, they must prioritize providing security for adjacent land uses for urban parks. If surrounding land uses for city parks have good surveillance, urban parks are most likely to benefit. This approach is not limited to safety but also accessibility. Gugu Dlamini is easily accessible according to respondents as the park was designed on the notion that supports the principle of ease of movement which presents the park in well-connected streets and adjacent land uses. Spaces that are easily seen from the street by passers-by are most likely to be used than those that are visually obscured, explaining the high patronage of space (Corbett, 2004:82). Access to transport and urban open spaces in particular, is important for human well-being as acknowledged by the UN sustainable development goals (UN, 2015, see 11.2 and 11.7).

7 CONCLUSION

It is clear that urban parks are important for the city of Durban and its users, therefore, not only the eThekwini Municipality and city planners should be responsible for making sure they are usable. Urban parks are an element that brings a refreshed atmosphere to cities, making it essential that they are well-maintained, regulated, and monitored for users. If the responsibility of making them usable is neglected by city residents, we will most likely experience and have similar issues with urban parks.

The findings associated with informal trading, vagrancy, and cultural activities signify that urban parks in the context of Durban are beyond the traditional intended meanings. The discoveries of this paper further confirmed that urban parks are shared by strangers who are generally not associates but peacefully coexist. However, these noble models are threatened by several issues, such as ablution facilities, lack of maintenance, and problems related to security and safety. These are imperative indicators that influence the current use, making it essential to critically find a holistic approach that will assist to encourage safe, friendly, healthy, and welcoming urban parks in Durban and South Africa.

Programmmanagement als Grundlage zur Umsetzung von Stadtentwicklungskonzepten

Max Gebhard Haug

(Dipl.-Ing. Architekt, M.Eng, MBA Max Gebhard Haug, Karlsruher Institut für Technologie, KIT/ IESL/ StQP , max.haug@kit.edu)

1 ABSTRACT

Die aktuellen Herausforderungen der Stadtentwicklung in Deutschland sind komplex und vielseitig: Digitalisierung und Energiewende, Strukturwandel und Zuwanderung, Wohnraumknappheit und demografischer Wandel, um nur einige zu nennen. Mit ihren Verwaltungen haben Kommunen eine Schlüsselfunktion zur Bewältigung dieser Herausforderungen inne. Zu viele Behörden dienen jedoch als reine Abwicklungsapparate und können selten eigenständig Innovationen anstoßen oder größere Wagnisse zur Bewältigung der Herausforderungen eingehen. Aktuell werden unter anderem Ansätze zu nachhaltigen resilienten Smart Cities, ob blau oder grün, diskutiert und erprobt. Die Förderlandschaft fokussiert somit auf vorherrschenden Zeitgeist und verleitet Kommunen dazu, auf gewisse Trends aufzuspringen. Aus dieser Grundkonstellation heraus stellt sich die Frage, wie für Städte langfristig und nachhaltig Handlungsoptionen entwickelt werden können, um die resiliente Stadtentwicklungsplanung agil und innovativ zu bewältigen.

Untersucht wurde der Zusammenhang zwischen erfolgreicher nachhaltiger Stadtentwicklung und der organisatorischen, strukturellen und prozessualen Leistungsfähigkeit von Mittelstädten in Deutschland. Hierzu wurden gemischte Methoden angewendet, die sowohl deduktive als auch induktive Ansätze verfolgen. Wie für gemischte Ansätze üblich, ist die Forschungsarbeit problemorientiert aufgestellt und zieht Rückschlüsse aus verschiedenen Blickwinkeln.

Verknüpfung zu Wissenschaft und Forschung, Kooperationen zwischen Städten, Netzwerke mit der Wirtschaft, Austausch mit der Bevölkerung, sowie interne Kommunikation und Wissenstransfer sind die entscheidenden Faktoren, die untersucht wurden. Festgefahrene und veraltete Strukturen sind daher aufzubrechen und Städte auf diesen Wandel vorzubereiten, um mit innovativen und agilen Impulsen aufzuschlagen und die Stadtentwicklung kontinuierlich voranzutreiben.

Zu einzelnen Herausforderungen der Stadtentwicklung liegt eine Vielzahl an Forschungsarbeiten vor, jedoch fehlen Anknüpfungspunkte zu den Alltagsrealitäten der Verwaltungen. Es gilt also, die interdisziplinäre Lücke zu schließen und eine Methodik zu entwickeln, welche die Anpassungsfähigkeit hinsichtlich Stadtentwicklung nachhaltig und kontinuierlich verbessern kann. Demzufolge darf der Fokus nicht auf die planerische Lösung der Probleme selbst gerichtet werden, sondern muss auf die Erneuerung der Rahmenbedingungen von Stadtentwicklungsmanagement gelenkt werden: strukturell, organisatorisch und prozessual.

Die Studie startet mit dem klassischen Top-Down-Ansatz, also einer deduktiven These. Diese These gründet auf dem Meinungsbild aus nichtwissenschaftlichen Quellen, welche Aufschluss über das Lager der Kritiker geben und die Daseinsberechtigung der Arbeitbegründen.Nach intensiver Literaturrecherche erfasste eine erste Impulsphase die vorherrschenden Bedingungen in teilnehmenden Kommunen der „Zukunftsstadt". Anschließend erfolgte eine Feldforschung in vier Untersuchungsräumen (kommunale Planungsämter), um eine stichhaltige Grundlage zur Beweisführung zu erhalten und die Relevanz von nachhaltigem Stadtentwicklungsmanagment zu unterstreichen.

Der folgende induktive Ansatz erschien zunächst weniger strukturiert als der deduktive, weshalb hier der Standard für Programmmanagement[1] des Project Management Institute (PMI) zur Strukturierung unterstützend verwendet wurde. Durch die angewendete Szenariotechnik wurde den untersuchten Kommunen ein großer Freiraum überlassen, denn die persönlichen Erfahrungsschätze der Gesprächspartnerflossen in die Analyse ein und ergaben eine dichte qualitative Datenerhebung. Hierwaren deshalb widersprüchliche und paradoxe Ergebnisse möglich. Methodisch wurden neben semi-strukturierten Interviews, Dokumentenanalysen, Fallbeispiele und Observationen pandemiebedingt virtuelle Workshops durchgeführt. Mit Beobachtungen zu strukturellen, organisatorischen und prozessualen Rahmenbedingungen in der Stadtentwicklung wurde das Wechselspiel zwischen Ursache und Wirkung weiter herausgearbeitet und mündete in einen resilienten und nachhaltigen Leitfaden für Stadtentwicklungsmanagement.

2 EINLEITUNG

2.1 Ausgangspunkt

Die Städte in Deutschland gehen mit den einzelnen Herausforderungen sehr unterschiedlich um. Es ist davon auszugehen, dass einzelne Städte konkrete Treiber haben und in den örtlichen Schwerpunkten auf hohem Niveau performen. Flächendenkend kann jedoch nicht von einer gleichmäßig hohen Qualität ausgegangen werden. Aktuelle Forschungsprojekte, beispielsweise die vom Bundesinstitut für Bau-, Stadt- und Raumforschung (BBSR) durchgeführte „Stadt von Übermorgen" (Petrin, Köhler, Ackermann, Da Costa, & Sibum, 2022)geben konkrete Arbeitshilfen zur Umsetzung von Zukunftsdiskursen, die den Städten helfen können, ihre Stadtentwicklungskonzepte aufzusetzen oder zu überarbeiten.

Bereits nach der ersten Recherchephase ließ sich feststellen, dass die Stadtentwicklung gegenüber den Schwester-Disziplinen Architektur/ Hochbau/ Tiefbau deutlich besser vernetzt ist. Der höhere Vernetzungsgradlässt sich durch das größere politische Interesse und vermeintlich weniger Expertentum erklären. Dennoch war festzustellen, dass trotz guter Strukturen und Vernetzungen, die Ämter der Kommunen dem Rhythmus, der auf Bundesebene angeschlagen wird, nur schwer folgen können. Die Umsetzung der großen Agenden (Charta von Aalborg 1994, Neue Charta von Athen 1998, Leipzig Charta 2007, Marseille Statement 2008, Toledo-Deklaration 2010, Zukunftsstadt 2015, Pakt von Amsterdam 2016 (New Urban Agenda), Smart City Agenda 2017) werden lediglich in Pilotprojekten ausreichend unterstützt. Jedoch werden nicht ausreichend nachhaltige Ansätze zur Verstetigung der Prozesse innovativer Stadtentwicklungsprojekte verankert.

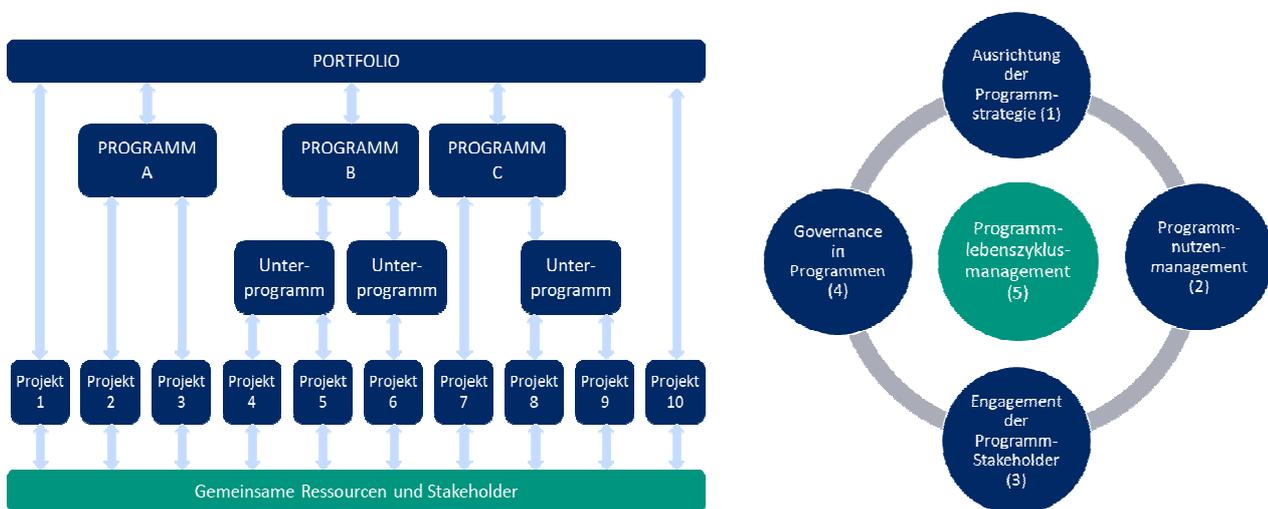
Ohne Einbindung in ein kontinuierliches einfassendes Stadtentwicklungsmanagement bleibt zu befürchten, dass auch nach Durchführung der Zukunftsdiskurse eine Verstetigung der Herangehensweise in den Stadtplanungsämtern ausbleibt. Ein übergeordnetes Umdenken zur Einordnung und Verknüpfung von Stadtentwicklung im Gesamtkontext zwischen Portfolio einer Stadt und den einzelnen stadtplanerischen Projekten ist dringend erforderlich.


Fig. 1, li.: Zusammenhänge von Portfolio, Programmen und Projekten, gemäß dem Standard für Programmmanagement, PMI. Fig. 2, re.: Leistungsbereiche im Programmmanagements, gemäß dem Standard für Programmmanagement, PMI.

Ohne auf die städtebaulichen Inhalte konkret einzugehen, stellt sich die Frage, ob die allgemeinen Rahmenbedingungen in den Verwaltungen die gleichen sind. Ist es erstrebenswert, eine Vergleichbarkeit herzustellen? Ist es überhaupt möglich, eine Vergleichbarkeit herzustellen? Strukturell, finanzstrategisch, organisatorisch und prozessual lassen sich durchaus Maßstäbe ansetzen und vergleichen, da in anderen Branchen bereits mehrere Reifgradmodelle entwickelt worden sind. Zu vergleichen wären für den Fall der Stadtentwicklung neben Kompetenzen und Kapazitäten auch der Grad der Vernetzung zu Wissenschaft und Forschung, Kooperationen mit anderen Städten, Verknüpfungen zur Wirtschaft, der Austausch mit der Bevölkerung, die interne Kommunikation, sowie der Umgang mit Risiken undWissensaustausch.

Somit ist klar, dass die Herausforderungen in den Stadtplanungsämtern sich stark gewandelt haben und auch weiter stark verändern werden. Meistens haben Mitarbeiter und Führungskräfte in Stadtplanungsämtern einen planerischen Hochschulabschluss und selten weitere Zusatzqualifikationen, die eigentlich erforderlich wären, um den gewandelten Anforderungen gerecht zu werden. Auch herkömmliche Ansätze für Projektmanagementsind dabei nicht mehr ausreichend, da es um weit mehr geht als Termine-Kosten-Qualitäten.

2.2 Aktuelle Beobachtungen und Tendenzen (akademisch)

Bisherige Ansätze, wie die städtischen Gesellschaften die Aufgaben der Zukunft lösen sollen, werden durch Agenden undExperten teilweise zwar aufgezeigt, aber in der Umsetzung nur bedingt weiterverfolgt (Schubert, 2015). Die Erfahrung und das generierte Mehrwissen aus Untersuchungsräumen wird nicht nachhaltig dokumentiert und transferiert. Folgende Probleme sind festzustellen

- Verschärfung der aktuellen Probleme: Zu den bekannten Herausforderungen ist mittelfristig eine weitere Verschärfung zu prognostizieren. Dies lässt sich an den Beispielen Zuwanderung, Digitalisierung, Klimawandel oder Verkehr und Mobilität deutlich vor Augen führen: Es ist zu erwarten, dass wir in allen drei Bespielen momentan nur mit der Spitze des Eisbergs konfrontiert sind. Es ist kaum vorstellbar, wie unsere Städte eine wirkliche Mobilitätsrevolution oder eine größere Flüchtlingswelle als 2015 oder aktuell aus der Ukraine stemmen sollen. (BBSR, Aktuelle städtische Herausforderungen, 2017).

- Faktor Unbekanntes - neue Herausforderungen: Die Plattform „Zukunftsstadt" formuliert, dass „die grundlegenden Bedingungen für die Entwicklung der Städte (…) sich in den kommenden Jahrzehnten deutlich verändern" werden. (BMBF, 2015) Hierzu werden integrierte und kontinuierlich geführte Vulnerabilitäts- und Risikoanalysen erforderlich werden, die eine vernetzte Strukturder Städte voraussetzt.

- Verschärfung der Geschwindigkeit: Zu beobachten ist ein immer schneller werdender Wandel und verstärkte Gleichzeitigkeit von Trends und neuen Herausforderungen. Dies führt bei gleicher Personalstärke zu Verwässerung von Themen oder Nichtabschließen von Maßnahmen und Aktivitäten.

- Kluft zwischen Theorie und Praxis: Der Kluft zwischen politischer Willensbekundung und der Umsetzung der theoretischen Agenden in den einzelnen Städten ist enorm groß. Es könnte auch heißen: Kluft zwischen Politik und Verwaltung oder zwischen Strategie und Operative oder zwischen Vision und Mission.

- Vernachlässigte Konsultative: Gemäß Leggewie und Nanz in „Die Konsultative" (2016), könnten sogenannte Zukunftsräte aus Bürgerinnen und Bürgern beratend, konfliktbearbeitend undzukunftsorientiert wirken. Sie könnten Werte, Prinzipien und Visionen vieler Menschgruppen repräsentieren und damit klassische demokratische Strukturen um eine Vierte Gewalt ergänzen.

- Dokumentenschwemme: Die Förderlandschaft bei Stadtplanung und Stadtentwicklung generiert bei Kommunen eine unkoordinierte Produktion an Dokumenten, welche nicht zusammengeführt und rückverankert werden.

- Forschungsdilemma: Die wissenschaftliche Forschung zu Stadtentwicklung erfolgt selten über die Kommunen selbst. In den meisten Fällen werden sie in laufenden Förderprogrammen von außen evaluiert. Hierbei wollen sich die Städte aus nachvollziehbaren Gründen im guten Licht präsentieren. Der Erkenntnisgewinn und die Selbstreflektion werden vernachlässigt.

2.3 Ansatzpunkt

2.3.1 Absicht und Ziele

Die Absicht der Arbeit ist es, Wege für Städte und Gemeinden herauszuarbeiten, um die neuen Herausforderungen der Stadtentwicklung agil und innovativ zu bewältigen. Das Promotionsvorhaben soll die Notwendigkeit wissenschaftlicher Arbeit mit, durch und über öffentliche Vertreter unterstreichen. Wenn Städte und Gemeinden an der Verbesserung ihrer Leistungsfähigkeit in der Stadtentwicklung wirklich

aufrichtig interessiert sind, dann sind neue Impulse durch die politischen Entscheider zu setzen, um für die anstehenden Aufgabengewappnet zu sein.

„Darüber hinaus benötigen einige Forschungsziele, wie beispielsweise die Einführung von Wissensmanagement oder die Förderung der Innovationsfähigkeit, ein kontinuierliches Prozessmanagement als Basis. Da für den nachhaltigen Erfolg von Projekten im Bereich der prozessorientierten Verwaltung das Prozessmanagement langfristig aufgestellt sein muss, besteht hier ein dringender Bedarf, die Strategieentwicklung im Bereich des Prozessmanagements sowie das vor allem sehr wichtige Verstetigen des Prozessmanagements zu vertiefen." (Becker, et al., 2012)

Veränderungsbereitschaft und das Vertrauen in Forschung und Innovation sind der Schlüssel für eine erfolgreiche Zukunft. Die nationalen PlattformZukunftsstadt unterstreicht diesen Missstand:

„Rechtliche, finanzielle, organisatorische und prozessuale Rahmenbedingungen müssten entsprechend gestaltet und Erfahrungsaustausche organisiert werden." (BMBF, 2015) und weiter:

„Für die langfristige Planung und Begleitung der Umsetzungsprozesse müssen neue Grundlagen geschaffen werden. Mit der Einbeziehung des Wissens aller relevanten Akteure wird eine neue Basis geschaffen." (BMBF, 2015).

Ziel ist es, Grundlagen zu schaffen, um die vorliegenden Stadtentwicklungskonzepte (Dokumente) in ein Stadtentwicklungsmanagement (Instrument) zu überführen. Hierbei werden die Grundsätze des Programmmanagements herangezogen.

2.3.2 Forschungslücke

Die Forschungsarbeit platziert sich im Spannungsfeld zwischen Planungs-, Verwaltungs-, Politik- und Wirtschaftswissenschaft. Die aktuellen Themen der Stadtentwicklung sind allseits erkannt und Herausforderungen identifiziert. Zu den Planungsthemen liegen eine Vielzahl an Forschungsarbeiten und Untersuchungen vor, jedoch fehlen nachhaltige Ansätze zur Verstetigung der Prozesse innovativer Stadtentwicklungsprojekte für die Verwaltungen. Die Forschungsaufgabe besteht darin, die interdisziplinäre Lücke zwischen Management, Verwaltung und Planung zu schließen und nach Möglichkeit eine Methodik zu entwickeln, welche die Leistungsfähigkeit aller deutschen Mittelstädte nachhaltig verbessern kann.

Zentrale Fragen

Wie können Kommunen dem immer schneller werdenden Wandel und dem immer schnelllebigeren Erscheinen neuer Trends und Herausforderungen gerecht werden? Wie können Städte und Gemeinden ihren Wirkungsgrad und ihre Schlagkräftigkeit in der Stadtentwicklung verbessern? Wie kann dabei Innovation und Agilität flächendeckend sichergestellt werden? Wie können Städte ermutigt, ermächtigt und befähigt werden, um vom Reagieren zum Agieren, vom Passiv zum Aktiv und vom Verwalten zum nachhaltigen Erschaffen zu kommen?

2.3.3 Fokus

Die Forschungsarbeit fokussiert sich demzufolge nicht auf die inhaltliche Lösung der Probleme selbst, sondern auf die Analyse und Erneuerung der Rahmenbedingungen: strukturell, organisatorisch und prozessual. Neben planerischem Verständnis sind Projekt- und Programmmanagementfähigkeiten in den Ämtern grundlegende Voraussetzung zur Umsetzung von neuen Ansätzen. Die Literatur zeigt, dass seit 2000 Projektmanagementexperten die Standards des PMI oder APM hinterfragen und neu überdenken. Vor allem Wissensmanagement, „Organisational Learning" und Programm- und Portfoliomanagement sind neue Herausforderungen für eine sogenannte Rethinking Generation (Andersen, 2008). Limitiert ist die Arbeit auf Städte und Gemeinden mittlerer Größe in Deutschland.

3 ABLAUF UND ERGEBNISSE DER DATENERHEBUNGSPHASE

3.1 Auswahl der Untersuchungsräume

Die Forschungsarbeit beschränkt sich bewusst auf die Mittelstädte Deutschlands, da in Großstädten bereits von den Stadtplanungsämtern losgelöste Einheiten zur Stadtentwicklung gebildet wurden und dadurch die Verwaltungen in puncto Governance abweichend aufgestellt sind. Eine Vergleichbarkeit ist bei Mittelstädten wesentlich höher und dadurch der Verallgemeinerungsgrad der Arbeit deutlich besser.

Der Radius auf Baden-Württemberg beschränkt. Es wurden acht Städte angeschrieben, die bezüglich Stadtentwicklung unterschiedliche Ausprägungen erwarten lassen. Vier Laborräume konnten zur Untersuchung ausgewählt und zur Kooperation überzeugt werden. Die Laborräume werden in der Arbeit anonym behandelt und werden im Folgenden als Stadt B, E, G, und T benannt. Je Laborraum wurde die Datenerhebung mit verschiedenen Akteuren innerhalb der Verwaltung über einen längeren Zeitraum hinweg angesetzt.

3.2 Ablauf der Datenerhebung

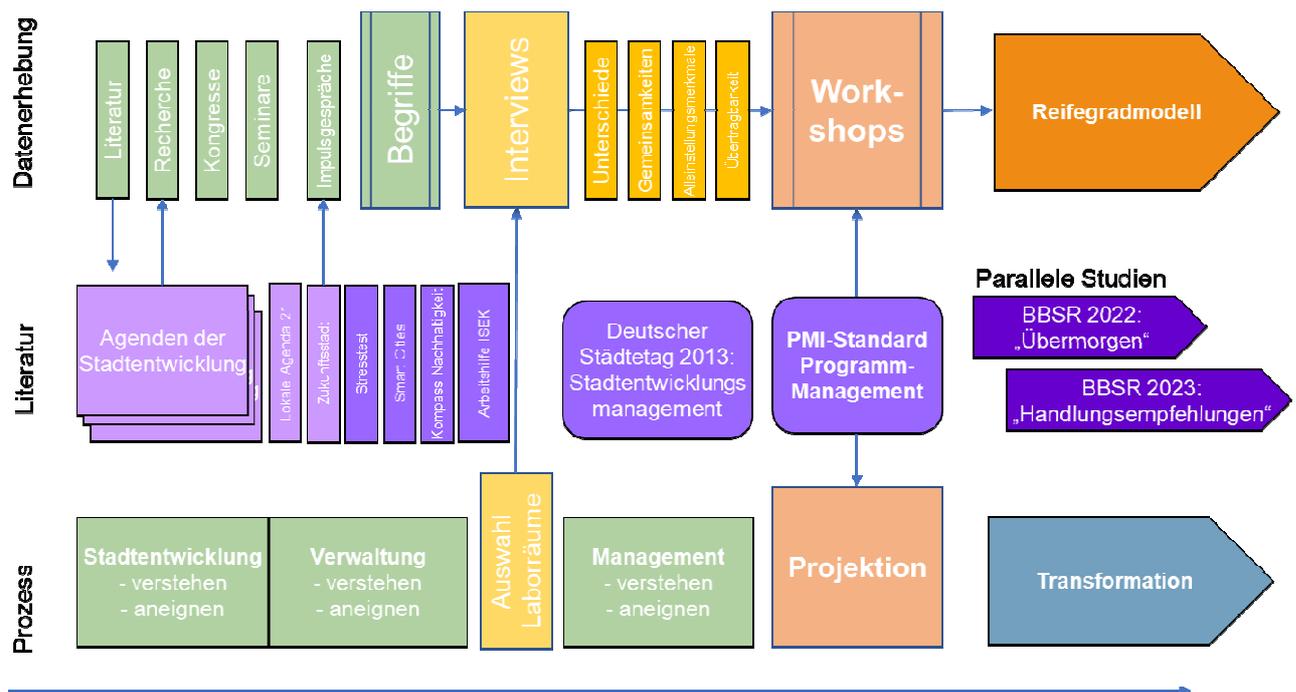
Die Datenerhebung erfolgte in drei Phasen von September 2019 bis Juli 2021. Die Vertiefung erfolgte schrittweise über semi-strukturierte Interviews, problemzentrierte Expertengespräche und abschließenden konfrontationsorientierten Workshops, die pandemiebedingt virtuell erfolgten.


Fig. 3: Schema zu Methodik und Prozess der Datenerhebung, eigene Darstellung.

Bereits in den ersten beiden Phasen konnten einige Missstände detektiert werden: Dokumentenschwemme, Kapazitätsengpässe/ Überlastung, Kampf um gute Köpfe, Arbeitsmarktsituation, Frustration durch Haushaltskürzungen, Austragung von Konflikten auf Projektebene, Frustration, sich als Einzelkämpfer zu fühlen, Hinterherlaufen bei Zukunftsthemen, resultierender Aktionismus, Mehraufwand aus mangelnder Transparenz gegenüber Dritten, fehlende Verlinkung der Projekte, fehlende Wissensgenerierung, Gefühl des Ausgeliefertseins aufgrund von Willkür und Zufall, Partizipation als Stressfaktor, Feigenblatt oder Alibiveranstaltung, fehlende Werkzeugkiste Partizipation.

Die folgenden Workshops erfolgten nach dem Prinzip der Szenariotechnik, d.h. die Experten wurden aufgefordert, sich in die Lage einer vergleichbaren fiktiven Mittelstadt in Deutschland zu versetzen, in der noch kein(e) Stadtentwicklungskonzept(e) aufgestellt wurde(n) und noch keine kanalisierten Strukturen zur Stadtentwicklung in der Verwaltung hinterlegt wären. Die Aufgabenstellungen der Workshops bezogen sich somit auf den fiktiven Idealfall, wie Stadtentwicklung platziert und aufgezogen werden sollte. Dadurch sollten auf neutralem Terrain die Erfahrungswerte der Experten einfließen und eine kritische Auseinandersetzung mit dem eigenen Umfeld erfolgen. Im Diskurs wurde die vorausgegangene akademische Analyse zum eigentlichen Untersuchungsraum herangezogen und in Vergleich gesetzt. Zusätzlich konnten auch die Erkenntnisse des Forschers aus den anderen Untersuchungsräumen in den Diskurs mit einfließen.

Zur Anleitung des Diskurses dienten dem Forscher die Erkenntnisse aus der Arbeitshilfe des BBSR, die Positionspapiere des Deutschen Städtetags, sowie die Workshopberichte der städtebaulichen Begleitforschung der Städtebauförderung.

Die Untersuchungsräume sollten im Szenario das gewohnte Umfeld verlassen und sich außerhalb der Komfortzone auf die gezielten Konfrontationen des Forschers Lösungen für einen Idealfall entwickeln. Sie wurden somit zu einer Reflektion und zum Schulterblick geleitet. Durch die Durchführung der Szenario-Technik in allen vier Untersuchungsräumen wurden aus den unterschiedlichen lokalen Situationen heraus die Erfahrungswerte abgeschöpft, ohne einen Untersuchungsraum für Misserfolge oder Fehlentwicklungen bloß zu stellen. Das Übereinanderlegen und Vergleichen der unterschiedlichen Erkenntnisse aus den vier Workshopsituationen erzeugte eine Bündelung der relevantesten Sichtweisen und Perspektiven undgenerierte ein verdichtetes Bild zur idealen Entwicklung von Stadtentwicklungsmanagement.

Zur Überprüfung der theoretischen Ansätze des Programmmanagements des PMI wurden weitere Dokumente aus dem Bereich der Stadtentwicklung analysiert und in Kontext gesetzt:

- Arbeitshilfe zur Erstellung von Stadtentwicklungskonzepten
- Positionspapiere des Deutschen Städtetags
- Evaluations- und Monitoringberichte der Städtebauförderung

3.3 Ergebnisse aus der Interviewphase

3.3.1 Diversität der sogenannten Stadtentwicklungskonzepte

Die Stadtentwicklungskonzepte der untersuchten Städte sind sehr unterschiedlich einzustufen. Stadt G überzeugt durch ein Stadtentwicklungskonzept, dass sowohl im Prozess als auch im formalen Ergebnis und den hinterlegten Handlungsperspektiven den Anforderungen gerecht wird. Es ist ein publiziertes Heft, welches auch der Öffentlichkeit zugänglich ist. Untersuchungsraum E hingegen hat das sogenannte Stadtentwicklungskonzept selbst verwaltungsintern erarbeitet, genügt aber nicht den Ansprüchen gemäß Leitfaden des BBSR (BBSR, 2016). Es ist der Öffentlichkeit nicht zugänglich und dient eher dem verwaltungsinternen Überblick zwischen der Vielzahl an Portfolio-Dokumenten, Unterprogrammen und Einzelprojekten. In den Kommunen B und T liegen keine Stadtentwicklungskonzepte vor. Im Stadtraum T überzeugt die vorbildliche integrierte Umsetzung auf der Ebene der Unterprogramme, die Leitfäden auf Portfolioebene sind hingegen veraltet und überholungsbedürftig. Der Laborraum B wird versuchen über den aufgesetzten IBA-Prozess eine Verstetigung zu entwickeln und perspektivisch Grundlagen für ein Stadtentwicklungskonzept zu erzeugen.

3.3.2 Dominanz von spezifischen Unterprogrammen

In allen Untersuchungsräumen ist zu konstatieren, dass Unterprogramme die Gesamtkonzepte überstrahlen, sei es durch dominante Stadtteilkonzepte, durch starke Einzelunterprogramme (Mobilität, Klima, Hochwasser, Einzelhandel etc.) oder durch einzelne Stadtplanungsprojekte (Leuchtturmprojekte).

3.3.3 Unverknüpfte Dokumente aus Unterprogrammen und Projekten

Die Vielzahl der vorliegenden Dokumente ist in allen Kommunen gleichermaßen erschlagend und in Gänze kaum erfassbar. Ein Großteil der erarbeiteten Dokumente ist älter als 10 Jahre und überarbeitungswürdig. In den seltensten Fällen sind die angestoßenen Prozesse rückverankert in das Gesamtkonzept. Selbst wenn die Dokumente in Prozesse oder Projekte überführt wurden, sind die Erfahrungen unzureichend dokumentiert und können deshalb nicht in die Fortschrittsmessung oder in ein Wissensmanagement für Stadtentwicklung übertragen werden. Die Mehrwertgenerierung und Rückverankerung ist also stark vernachlässigt.

3.3.4 Risikomanagement und Änderungsmanagement

In keinem der vier Untersuchungsräume ist ein Risikomanagement oder Änderungsmanagement für Stadtentwicklung systemisch aufgesetzt.

3.3.5 Wissensmanagement

In keiner der vier untersuchten Kommunen ist eine Wissensgenerierung systemisch aufgesetzt. Die Verwaltungen verlassen sich auf den internen Flurfunk. In einzelnen Fällen wurde zwar in Projekten Lessons-Learnt-Protokolle erstellt, jedoch beziehen sich diese auf planerische Schwerpunkte und weniger auf Struktur, Organisation oder Prozess.

3.3.6 Stakeholdermanagement

Ein pro-aktives Akteursmanagement für sämtliche Beteiligte ist systemisch/ konzeptionell in keinem Untersuchungsraum aufgesetzt. In einzelnen Untersuchungsräumen (Städte E/T) erfolgen partizipative Prozesse ausschließlich über eigens geschaffene Stabfunktionen.

Beteiligungsprozesse mit der Bürgerschaftsind in allen vier Untersuchungsräumen angekommen. Die Ausprägung und Umsetzung von Beteiligungen erstreckt sich von Information über Mitwirken bis hin zur Mitentscheidung. Beteiligung von weiteren Akteuren erfolgt in deutlich geringerem Umfang.

Auch wenn die Vielzahl an möglichen Formen der Beteiligung hinlänglich bekannt sind, werden in den untersuchten Kommunen bei Weitem nicht alle Werkzeuge verwendet. Weder konzeptionell flächendeckend, noch mit einem Wissenspool rückverankerte Mehrwertgenerierung ist hinsichtlich Stadtentwicklung zu erkennen.

Peer-Kooperationen mit vergleichbaren Städten und Vernetzung mit Wissenschafts- und Forschungseinrichtungen konnten nicht identifiziert werden.

3.4 Projektion von Programmmanagement auf Stadtentwicklung

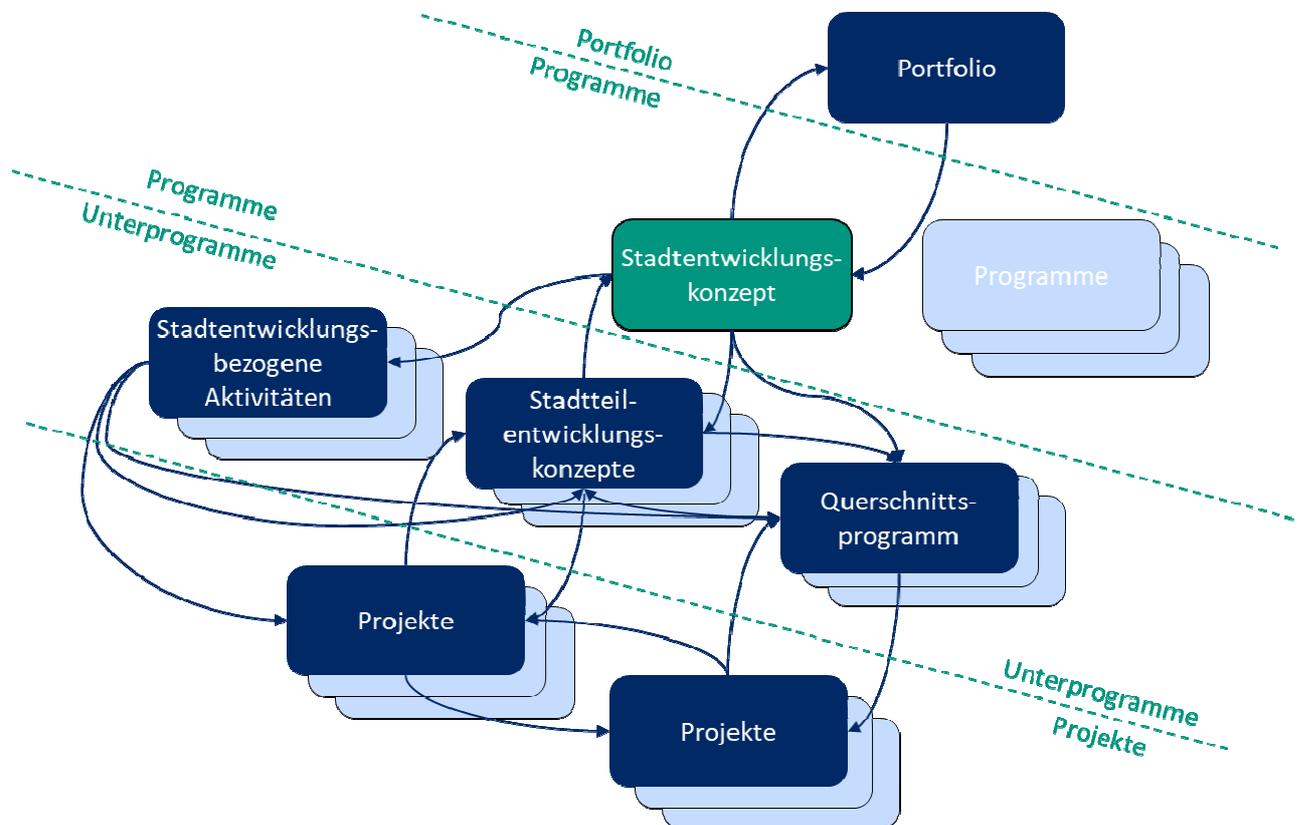
Zur Klärung von Tätigkeiten und Aktivitäten von Stadtentwicklungsmanagement wurde als grundlegender Ansatz das Prinzip des Programmmanagements gemäß PMI zugrunde gelegt.


Fig. 4: Projektion von Portfolio, Programm, Projekte auf Stadtentwicklung, analog dem Standard für Programmmanagement, PMI.

Die Verknüpfung des Stadtentwicklungsprogramms mit den Leitlinien und Leitbildern der Stadt ist ein grundlegendes Merkmal um übergeordnete Ziele stadtplanerisch einzufangen. Entscheidend ist eine klare Definition, was über die Stadtentwicklung im Bereich der Stadtplanung umgesetzt werden kann.

3.5 Ergebnisse aus der Workshopphase

3.5.1 Definitions- und Schnittstellenklärung

Das Verständnis für Projekt, Programm und Portfolio ist dringend in allen Untersuchungsräumen zu schärfen, denn in allen Untersuchungsräumen lässt sich feststellen, dass das Verständnis für diese Aufteilung sehr unklar ist. Das hat zur Folge, dass auch die Schnittstellen zwischen Portfolio, Programm und Projekt nicht geklärt sein können. Logischerweise folgt ein Zuständigkeitsproblem zwischen Politik und Verwaltung

und auch zwischen den einzelnen Ämtern. Dementsprechend ist die Aufgabenteilung und die Aufgabenverteilung sehr schwammig. Tendenzen zu Konkurrenzkampf und Aktionismus in den einzelnen Ämtern sind die Folge.

Aus Sicht des Beobachters lässt sich feststellen, dass ein gewisser Handlungsdruck auf den Amtsleitern wirkt, in regelmäßigen Abständen mit neuen Überschriften und Dokumenten aufzuschlagen, um zu zeigen: wir haben da was Neues aufgesetzt, wir arbeiten da dran. Wenn allerdings die einzelnen Dokumente (meist Querschnittsprogramme) nicht rückverankert und integriert werden durch ein Stadtentwicklungsmanagement, werden sie nicht in ein Instrument überführt. Die festgestellte Dokumentenschwemme in allen Untersuchungsräumen ist also eine Ursache dafür, dass die meisten Produkte nicht über den Status eines Dokuments hinauskommen. Gestärkt wird dieses Beobachtung durch die vielschichtige Förderlandschaft, welche viele Einzeldokumente provoziert.

Am meisten überrascht die Unklarheit der Schnittstellen ausgerechnet in dem Untersuchungsraum, wo rein formal die Stadtentwicklung am stärksten im Organigramm abgebildet ist. Dieser Untersuchungsraum E hat das Dilemma, dass das eigene sogenannte Stadtentwicklungskonzept, trotz angeschlossener Überarbeitungsphase nach drei Jahren, keinen Beschluss und damit keinen ordentlichen Auftrag erhalten hat.

Der Prozess ist mit Erstellung des Stadtentwicklungskonzepts nicht abgeschlossen. Das Programmmanagement kann erst ab Auftragserteilung durch den Gemeinderat starten. Die Erstellung des Dokuments namens Stadtentwicklungskonzept ist ohne ein hinterlegtes Stadtentwicklungsmanagement von geringem Wert. Meist ungeklärt bleibt die Frage, was ein Stadtentwicklungskonzept leisten kann und was nicht. Die resultierende Anschlussfragen daher:

Was leistet Stadtentwicklungsmanagement? Und was leistet Stadtentwicklungsmanagement nicht?

Zu Umfang und Schnittstellen von Stadtentwicklungskonzept und Stadtentwicklungsmanagement ist grundlegend mit allen Beteiligten das gleiche Verständnis zu erzeugen.

Die Analyse der Laborräume zeigt auf, dass aufgrund der fehlenden Rückverankerung in ein zentrales Instrument oft nicht möglich ist, da entweder a) ein aktueller Treiber alle Nebenschauplätze in den Schatten stellt oder b) es schlicht zu viele Dokumente aus Unterprogrammen vorliegen, welche eine Verknüpfung nahezu unmöglich erscheinen lassen.

3.5.2 Fortschrittsmessung

Im Untersuchungsraum T wird die Programmebene vollständig vermisst. Der Sprung erfolgt direkt von Portfolioebene (Leitbild) auf Unterprogramme (Quartiere). Im Verständnis des Untersuchungsraums T könnte die Programmebene/ Stadtentwicklungsmanagement die fehlende Fortschrittsmessung ausfüllen. Über das Portfolio wurden keine Indikatoren festgelegt und somit sei keine Erfolgsgeschichte kommunizierbar. „... das ist übrigens, was dem Leitbildprozess von 2003 gefehlt hat: Es waren keine Indikatoren erkennbar, es war alles schön, aber man konnte es nie messen." (Untersuchungsraum T, 26.05.2021) Man würde sich selber gerne an den gesteckten Leitplanken orientieren: „Haben wir es nun erreicht oder nicht? Oder befinden wir uns auf dem richtigen Weg oder driften wir ab?".

Das eigentliche Ziel von Stadtentwicklungsmanagement sei nach Aussage der Teilnehmer aus Untersuchungsraum G die Entwicklung der Ziele unter Einbindung der verschiedenen Akteure. Kommune G machte sich stark für ein Stadtmonitoring, das gekoppelt sein müsste mit gewissen Indikatoren, die statistisch erfassbar sein sollten. Man könne sich vorstellen, dass ein Teil des Stadtentwicklungsmanagements das Nachhalten dieser Kennzahlen beinhaltet. „Das heißt, wenn man das Wort Ziele in den Mund nehmen möchte, (…) dann braucht es sogar auch die Entwicklung eines Zielsystems."(Untersuchungsraum G, 08.06.2021) Gleichzeitig gibt man auch zu bedenken, dass eine zu starke Ausrichtung an Statistik in anderen Städten einen Graben zwischen Stadtentwicklung und Stadtplanung aufgeworfen hat.

3.5.3 Finanzierung/ Fördergelder

Seitens zweier Untersuchungsräume (G und B), wurde die Verknüpfung des Stadtentwicklungsmanagements mit Finanz- und Kostenmanagement als zentrales Argument für die Daseinsberechtigung von Programmmanagement, denn die Förderlandschaft sei sehr divers.

Untersuchungsraum B zielt speziell auf die Verknüpfung der Förderlandschaft und die enge Zusammenarbeit mit der Kämmerei ab. Die klare Forderung alles der Städtebauförderung unterzustellen und alle restlichen

Förderoptionen nur dann zu beantragen, wenn diese zeitlich und kapazitiv mit dem Prozess der Städtebauförderung in Einklang gebracht werden können.

Im Kontext der Fördergelder noch strategischer zu denken und quasi ein koordiniertes Fördergeldmanagement zu optimieren könnte ein wesentlicher Mehrwert des Stadtentwicklungsmanagements darstellen. Es ist vielleicht die einzige Möglichkeit, den chronischen Ressourcenmangel in den Stadtplanungsämtern zu entgegnen.

Untersuchungsraum G hingegen setzt darauf, dass ein Stadtentwicklungsmanagement die Einsparpotenziale monetär aufzeigen müsste. Zum einen könnte die Daseinsberechtigung sich darüber bestätigen, dass man alle unnötigen Tätigkeiten entferne (1). Dies bedeutet, der Mehrwert von Stadtentwicklungsmanagement müsste sich abbilden, indem man aufzeigt, welche Tätigkeiten im Alltag der Mitarbeiter im Stadtplanungsamt dadurch effizienter gestaltet werden könnten. Die Prinzipien des Lean Managements könnten hier ihre Anwendung finden. Zum anderen sollte man sich die Einsparungen durch Priorisierung und agiles Umschichten von Haushaltsgeldern herausarbeiten und den Mehrwert und damit die Daseinsberechtigung von Stadtentwicklungsmanagement ersichtlich machen (2).

3.5.4 Begleitforschung

Die in allen Untersuchungsräumen geäußerte Ressourcenknappheit lässt kaum Spielraum, sich mit der eigenen Performance auseinanderzusetzen. Es stehen weder ausreichend finanzielle Mittel noch personelle Kapazitäten zur Verfügung, um analytisch an der eigenen Organisation, an den Strukturen und Prozessen zu arbeiten.

Ein Gedankengang des Forschers ist es, diesem Dilemma durch Einbindung von externen Forschungseinrichtungen entgegenzuwirken. Das Thema Begleitforschung ist jedoch in allen Untersuchungsräumen die große Unbekannte. Die bisherigen Kooperationen mit externen Fachleuten erfolgte in Untersuchungsraum G bei der Erstellung des Stadtentwicklungskonzepts. In den Untersuchungsräumen T und E wurden die Portfolioprozesse durch externe Berater, Moderatoren und Mediatoren unterstützt. In Untersuchungsraum B erfolgt aktuell eine intensive Betreuung im IBA-Prozess. Alle Untersuchungsräume lassen sich also bei Beteiligungsprozessen beraten, entweder durch installierte Stabstellen innerhalb der Verwaltung oder durch externe Konsulenten. Die Begleitung erfolgt mit dem Ziel, Neutralität zu wahren und Vorbehalte gegen die Verwaltung abzubauen. Das Produkt, welches die Beratenden meistens vertraglich schulden, ist die Dokumentation und Kommunikation des Prozesses gegenüber allen Beteiligten. Der Adressat ist dementsprechend die Öffentlichkeit.

Die Einbindung von Hochschulen und Universitäten bezog sich bislang auf a) entwerferische Arbeiten, welche b) durch Studierende erarbeitet wurden und c) sich über eine maximale Laufzeit von einem Semester erstreckten. Der Mehrwert für das Stadtplanungsamt ist dabei sehr überschaubar. Erforderlich jedoch sind

a) analytische Untersuchungen durch b) wissenschaftliche Mitarbeiter über c) einen längeren Untersuchungszeitraum von einem bis zu fünf Jahren. Die Adressierung der Erkenntnisse richtet sich ausschließlich intern an das Stadtplanungsamt. Sollten Erkenntnisse aus mehreren Städten in die Forschung einfließen, könnte anonymisiert gearbeitet werden.

In den Werkstätten wurden die Teilnehmer mit dieser Option konfrontiert und es konnte ein gemeinsames Verständnis dafür entwickelt werden, dass eine langfristige Beobachtung und Betreuung durchaus sinnvoll wäre, um eine Verstetigung in der Stadtentwicklung herbeizuführen.

Die funktionierende Verwaltung könnte durch folgende Ziele der Begleitforschung erreicht werden: Best-Practice und Lessons-Learnt institutionalisieren, am Puls der Zeit sein, Werkzeugkiste ertüchtigen, Kommunikation verbessern, Bandbreite der Kanäle erweitern, Transparenz schaffen, Netzwerk ausbauen und pflegen, Arbeitsatmosphäre verbessern, Effektivität und Effizienz steigern, Sicherheit im eigenen Tun steigern, dabei mehr zu steuern weniger zu planen.

4 FAZIT UND AUSBLICK

Die Daseinsberechtigung von Stadtentwicklungsmanagement wird über die dystopische Inversion verdeutlicht: Was wären die Folgen eines Weiterarbeitens ohne Stadtentwicklungsmanagement?

- Weiter Überlastung

- Weiter Dokumentenschwemme

- Weiter Austragung von Konflikten auf Projektebene

- Weiter den Zukunftsthemen hinterher laufen/ weiter Aktionismus

- Weiter Konsequenzen aus mangelnder Transparenz gegenüber Dritten nachlaufen

- Weiter Frustration durch Haushaltskürzungen

- Weiter Frustration, sich als Einzelkämpfer zu fühlen

- Weiter unkoordiniert Projekt für Projekt bearbeiten ohne Wissensgenerierung

- Weiter Willkür und Zufall ausgeliefert zu sein

- Weiter Partizipation als Feigenblatt/ Alibiveranstaltung

Die Leistung von Programmen ist die Verknüpfung von Portfolio-Ebene und Projekt-Ebene mit der Funktion als Bindeglied zur Überwachung, Steuerung und Evaluierung (Reflektion) zu wirken. Es geht darum Arbeitspakete zu schaffen, die zeitlichen und räumlichen Bezug haben, um Inhalte aus der Portfolio-Ebene in die Projekt-Ebene einzusteuern. Programmmanagement überwacht und evaluiert fortlaufend strukturelle, organisatorische und prozessuale Vorgehensweisen.

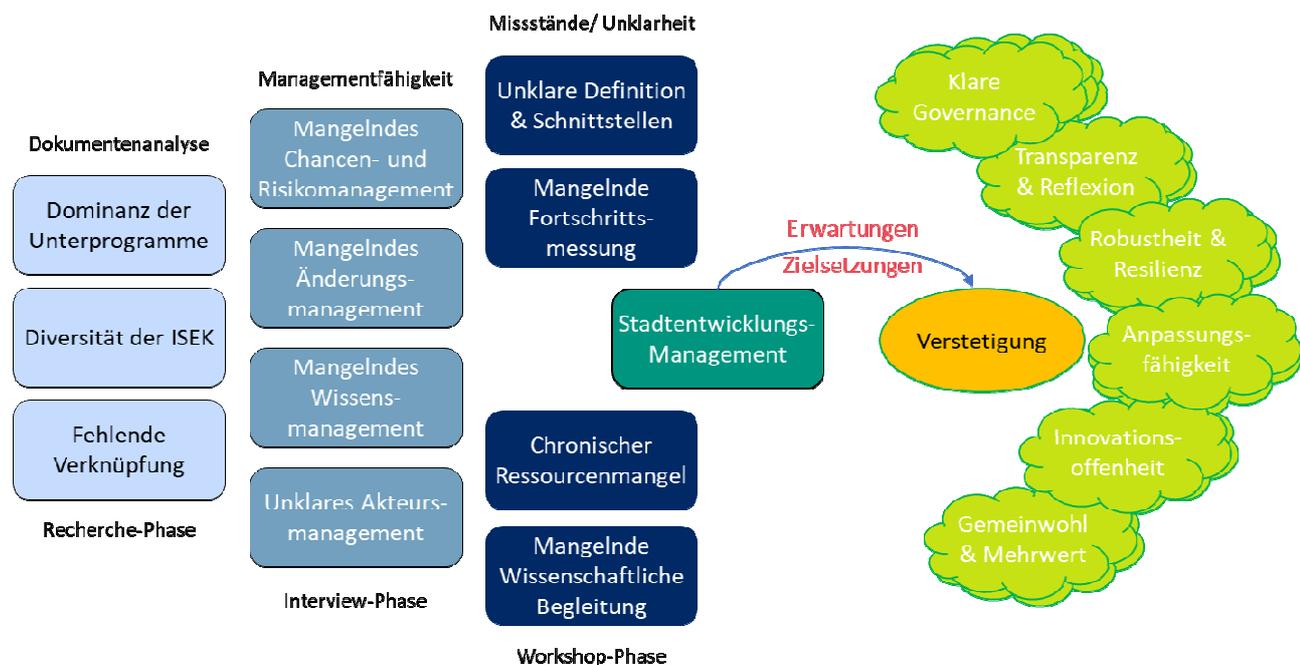
Als Grundlage zur Ermittlung der Robustheit des Stadtentwicklungskonzepts und der Managementfähigkeit der Stadtplanungsämter sollte eine Bestandsaufnahme über ein Reifegradmodell entwickelt werden, welches die Prinzipien des Programmmanagements (Wissens- und Leistungsbereiche)zugrunde legt.


Fig. 5: Erwartungen und Zielsetzungen für die Implementierung von Stadtentwicklungsmanagement, eigene Darstellung.

(Prof. Trynos Gumbo, University of Johannesburg, Department of Urban and Regional Planning, Leader of the Smart and Sustainable Cities and Regions Research Group, Johannesburg, South Africa, tgumbo@uj.ac.za)

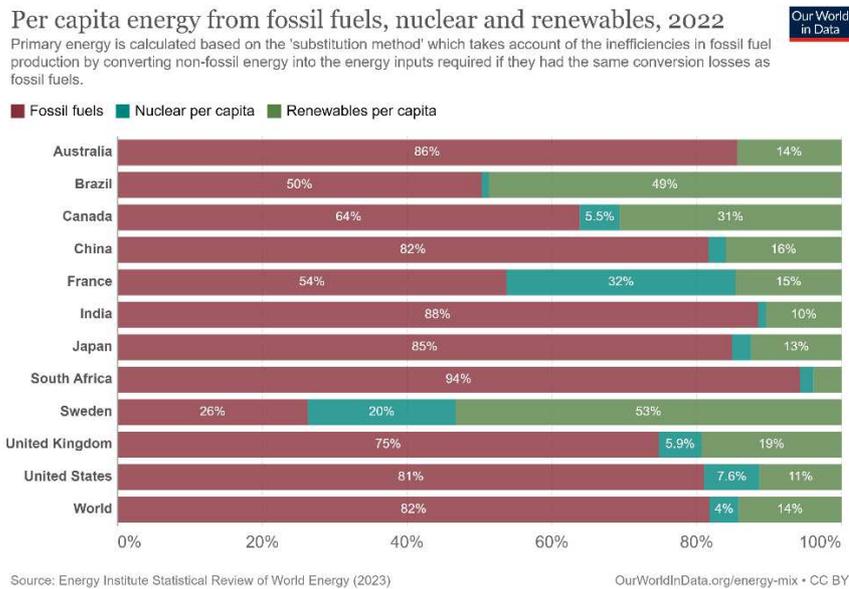
1 ABSTRACT

The study explores the potential of converting existing buildings into green buildings in South African cities for environmental sustainability and economic efficiency. It compares the costs, carbon footprint, and use of recycled materials between refurbishment and new construction. Refurbishment offers advantages in these aspects but presents technological challenges. The study uses Zero Emission Neighbourhood (ZEN) and Zero Energy Building (ZEB) frameworks to evaluate sustainability in refurbishment projects. It concludes that while refurbishment is a promising strategy, standardized evaluation methods, comprehensive databases of projects, and enhanced regulations are needed to support the green building industry in South Africa.

Keywords: Zero emissions, Refurbished Green Buildings, Spatial Planning, Construction, Net carbon

2 INTRODUCTION

2.1 Introduction

As energy demands increase and environmental concerns arise, innovative solutions for sustainable infrastructure are needed. Conventional energy sources, such as coal, pose risks due to high carbon emissions and contribute to global warming, affecting over 90% of South African energy production(Stefanakis, 2019:6981, Lützkendorf and Balouktsi, 2022:964-973).The energy-mix graph below indicates that over 90% of South African energy is produced from fossil fuels (coal) to date.


South Africa's economy has grown annually due to international crises, including global warming. The Paris Agreement, initiated by the United Nations in 2015, aims to combat climate change by reducing greenhouse gas emissions from human activities. Countries like South Africa have embraced the agreement and international businesses are supporting it. The South African government has developed a national coordination mechanism to strengthen development policies and improve sustainability.Architects are transforming primitive structures into smart living spaces to combat climate issues and carbon emissions. Modern refurbishment aims to increase sustainable value by integrating technological advancements and renewable energy sources. Green buildings, incorporating advanced technology, reduce dependence on

electricity and increase safety. South Africa's green building industry has moderate development, but financing is limited. The Green Building Council South Africa (GBCSA) has certified over 7.7 million square meters of green buildings since 2007, demonstrating the importance of sustainability in the South African building sector.

The National Department of Public Works has established a green building policy to construct sustainable buildings, leading to substantial savings in finance, time, and space. Cape Town is recognized as the greenest city in South Africa, providing clean energy solutions across various sectors. Recognizing opportunities for refurbished green buildings is crucial for a safer future.

2.2 Role of Refurbishment in Meeting Climate Goals

Refurbishment is a key strategy for achieving climate goals by reducing greenhouse gas emissions and promoting sustainability in the built environment. It involves upgrading systems, improving insulation, and implementing energy-efficient technology to reduce reliance on fossil fuels. Refurbishment projects often incorporate renewable energy sources, such as solar panels, wind turbines, or geothermal systems, to reduce carbon emissions. Water conservation is also a key aspect, with water-efficient fixtures, rainwater harvesting systems, and greywater recycling mechanisms reducing water consumption. Using environmentally friendly materials and practices minimizes the embodied carbon footprint, while enhancing indoor environmental quality through improved ventilation systems and natural daylight. Refurbishment projects offer immense potential for transforming existing buildings into greener, more sustainable structures(van Noorloos and Kloosterboer, 2018:1223-1241).

2.3 Lack of Comprehensive Evaluations for Building Refurbishment

Building refurbishment faces challenges due to the lack of comprehensive evaluations. Robust assessment frameworks are needed to address the complexities of refurbishment projects. Comprehensive evaluations provide a holistic perspective on environmental performance, including energy efficiency, resource utilization, and sustainability. They also identify potential risks and challenges, quantify environmental and economic benefits, and support knowledge sharing and best practices. Life cycle assessment in energy refurbishment is crucial for a holistic understanding of a building's environmental performance. These evaluations help stakeholders make informed decisions and promote sustainable practices in building refurbishment.

Time Period	Evolution in Building Refurbishment	Evolution in Climate Change Understanding
Pre-Industrial (up to mid-18 Century)	Focus on maintaining structural safety and functionality using available materials and techniques.	Natural factors primarily drive climate fluctuations.
Industrial Revolution (mid 18th Century to late 19th Century)	The advent of modern architecture and engineering led to more systematic approaches to building refurbishment.	Increased burning of fossil fuels due to the Industrial Revolution contributed to CO_2 emissions.
Early 20th Century (1900-1950)	Preservation of historic and cultural buildings became a key consideration. Energy efficiency started to be considered.	Spread of industrialisation led to increased emissions. Svante Arrhenius proposed that fossil fuel combustion could lead to global warming.
Mid 20th Century (1950-1970)	Sustainability and energy efficiency became more central to building refurbishment.	Massive increase in industrial activity and greenhouse gas emissions. Introduction of the Keeling Curve.
Late 20th Century (1970-2000)	Emergence of certifications like LEED to guide sustainability in building refurbishments.	Establishment of the IPCC, signing of the UNFCCC at the Earth Summit in Rio.
Early 21st Century (2000-2010)	Revolution of the evaluation process for building refurbishment using Building Information Modeling (BIM). Shift towards holistic evaluations began.	Kyoto Protocol came into effect in 2005.
Early 21st Century (2010-2023)	Evaluations started considering factors like potential for renewable energy use, carbon footprint, and resilience to climate change impacts.	Signing of the Paris Agreement in 2015.

Table 1: Evolution of comprehensive evaluation for building assessments and climate change

In conclusion, the current absence of comprehensive evaluations of building refurbishment poses a challenge to effectively addressing the complexities and maximising the potential benefits of such projects.Robust assessment frameworks are necessary for assessing environmental performance, identifying risks, quantifying benefits, and promoting knowledge sharing in building refurbishment.The development and implementation of comprehensive evaluations will contribute to advancing sustainable building practices and achieving climate change goals.

REAL CORP LET IT GROW

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Outstanding Aspects	Description
Life Cycle Assessment	Comprehensive life cycle assessment, which considers the full environmental impact from extraction of raw materials to end-of-life disposal or recycling, is not universally applied in building refurbishment evaluations.
Embodied Carbon	Embodied carbon, i.e., carbon emissions associated with construction and material production processes, are often overlooked in evaluations. Consideration of embodied carbon could reduce the overall carbon footprint of buildings.
Resilience	Building refurbishment evaluations do not yet standardly include assessments of a building's resilience to predicted climate changes, such as rising temperatures and extreme weather events.
Socio-economic Factors	Evaluations tend to focus on technical and environmental factors, often neglecting socio-economic impacts. Future evaluations should consider effects on local communities, affordability, and improvements in users' quality of life.
Regulatory Compliance	There is a need for better integration of evaluation results into regulatory compliance checks. Compliance checks may not be stringent enough or fully consider comprehensive evaluation results.
Data Accuracy	Evaluation data, especially for older buildings, can be inaccurate or incomplete. Improved data collection methods are necessary for more accurate evaluations.
Technological Developments	Given the rapid pace of technological advancements, evaluation standards must be constantly updated to incorporate new possibilities, especially in areas like renewable energy, energy storage, and digital technology.

Table 2: Outstanding aspects of comprehensive evaluation for building assessments

2.4 Building Refurbishment Evaluation through the ZEN and ZEB Concepts

Building refurbishment is crucial for achieving sustainability goals and reducing environmental impact. Zero-emission neighbourhood (ZEN) and zero-energy building (ZEB) concepts offer a holistic approach to evaluating refurbishment projects. ZEN evaluates energy efficiency, renewable energy use, waste management, transportation systems, green infrastructure, and environmental performance. ZEB focuses on achieving net-zero energy consumption in refurbished buildings, quantifying energy savings, carbon emissions reduction, and economic viability. Standardized data collection methods and a comprehensive database of refurbishment projects are essential for effective evaluation. Integrating these concepts allows for a more informed understanding of environmental, economic, and social effects, enabling stakeholders to make evidence-based decisions and accelerate the transition towards more sustainable built environments(Dong, et al. , 2021:111313).

2.5 The dilapidation and tipping point in structural integrity

The rapid growth of the population and urbanization in South Africa has led to increased construction and maintenance of buildings, which may deteriorate over time due to aging and environmental factors. The Government Immovable Asset Management Act (GIAMA) was introduced in 2007 to guide the management of government-owned assets, including building maintenance. Regular condition assessments must be conducted every five years, but the implementation adds complexity and legal obligations.

Preserving the safety and durability of buildings or infrastructure relies on monitoring deterioration and reaching stability thresholds. Dilapidation refers to the decline or degradation of structures over time, compromising structural integrity. Regular assessment and monitoring are essential to identify signs of deterioration or imminent failure. Engineers and experts can evaluate a building's reliability and take measures to maintain its structural soundness. Managing building maintenance involves establishing thresholds for dilapidation detection and identifying tipping points. Integrated sensors embedded within structures and infrastructures play a crucial role in gathering data on building integrity and environmental conditions. Structural health monitoring (SHM) can help detect and evaluate performance degradation and damage in civil infrastructure as stated below.

Stage 1: Initial Wear (Minor Dilapidation)

Characteristics: Cosmetic damage, minor cracks, paint peeling, early signs of wear in non-structural components.

Recovery Strategy: Regular inspection and monitoring, cosmetic repairs and preventive maintenance, application of weatherproofing where necessary.

Stage 2: Moderate Degradation

Characteristics: Noticeable deterioration in structural components, leaks, rusting, functional impairment of non-essential systems.

Recovery Strategy: Detailed structural assessment to identify affected areas, targeted repairs and replacement of compromised components, Implementation of routine maintenance schedules as per SANS standards.

Stage 3: Advanced Decay (Major Dilapidation)

Characteristics: Serious structural issues, extensive corrosion, compromised safety, and functionality of essential systems.

Recovery Strategy: Comprehensive structural evaluation by certified engineers, major renovations and overhauls, following local regulations such as OHSA, collaboration with local authorities to ensure compliance and safety.

Stage 4: Critical State (Tipping Point)

Characteristics: Imminent failure or collapse, extensive damage that affects the building's overall integrity, immediate threat to safety.

Recovery Strategy: Immediate evacuation and securing of the site, engaging specialized emergency response teams.

Building maintenance in South Africa is crucial due to climate conditions, usage demands, and socio-economic issues. To ensure long-term durability and efficient resource utilization, it's essential to establish phases of deterioration and effective restoration methods. Recommendations include using technology like Building Information Modelling, collaboration among engineers, local authorities, and stakeholders, and implementing training initiatives. Sustainability should be integrated into maintenance practices, and emergency protocols should be in place. This framework addresses South Africa's circumstances while incorporating global best practices.

3 PROBLEM STATEMENT

South Africa's urbanization leads to increased demand for built environments, resulting in increased carbon emissions. Older structures, often inefficient, hinder green practices. Renovating these into green buildings could reduce emissions, but their impact on net carbon emissions in cities is not well understood. This research is crucial for understanding the transition and developing strategies for a sustainable urban future.

4 AIMS AND OBJECTIVES

This study aims to understand whether refurbished buildings help reduce net carbon emissions. This study examines the current state of green building refurbishment in South Africa, comparing it with global standards. It evaluates its contribution to reducing carbon emissions and aligns it with climate change mitigation strategies. It also identifies barriers and enablers to green refurbishment, assesses its social, economic, and environmental impacts, and explores public-private partnerships in fostering it. The study also proposes policy recommendations to enhance green building refurbishment practices and align with South Africa's sustainability goals.

5 RESEARCH METHODOLOGY

This study explores the intersection of refurbished green buildings and net carbon emissions in South African cities, thereby delineating the implications of eco-friendly renovations for sustainable urban development and carbon neutrality.The study employed a robust and integrative mixed-methods approach, coupled with quantitative data analysis and qualitative insights, to comprehensively understand the challenges, opportunities, and impacts of green building refurbishments(ISO 14040, 2006:).

5.1 Materials and Methods

5.1.1 Methodology of building refurbishment to achieve net-zero carbon

Achieving net zero carbon emissions from building refurbishment involves a comprehensive approach that considers the entire life cycle of a building. This includes conducting life-cycle analysis (LCA) to assess the carbon footprint of a building, including embodied carbon emissions from construction materials, transportation, and manufacturing processes. Energy efficiency measures, renewable energy generation, and electrification are implemented to minimize operational carbon emissions. During the refurbishment process, low-carbon and sustainable materials are selected to reduce embodied carbon. Monitoring and control are implemented to optimize energy performance, identifying areas for improvement. Education and occupant engagement are also crucial for promoting sustainable behavior and reducing energy consumption. Integrating ISO 14040 and NZED principles can lead to a more sustainable built environment, optimizing energy performance and achieving net-zero carbon emissions.

5.2 Data Collection

The study used SPSS to collect and analyze data from a 200-participant sample. The process involved selecting variables, designing instruments, sampling participants, collecting data, entering and cleaning the data, conducting descriptive analysis, formulating hypotheses, testing hypotheses with one-way ANOVA, interpreting results, and reporting findings. The online survey included participants from various age groups, financial backgrounds, and working experience levels. The analysis included a one-way ANOVA test to test the hypothesis and ensure accuracy in results(Evon Abu-Taieh, Abdelkrim El Mouatasim, Issam H. Al Hadid, 2020:).

6 RESULTS

The results section of a research report or study provides a detailed presentation and interpretation of the findings obtained from the data analysis. This is a critical component of the research report, allowing readers to understand the study's outcomes and evaluate the validity of the research objectives and hypotheses.

6.1 Profile of respondents

The total number of participants selected for this survey was 200, belonging to different South African construction industry departments. Participants selected for this survey ranged in age from 20 to 60 years, with work experience ranging from 1 year to more than ten years.

	Categories	Frequency	Percentage
Sex (Gender)	Male	45	45
	Female	55	55
Age	20 – 30 yrs	54	27.0
	30 – 40 yrs	45	22.5
	40 – 50 yrs	55	27.5
	50 yrs& above	46	23.0
Income	0 - 1,00,000 ZAR	46	23.0
	1,00,000 - 2,00,000 ZAR	48	24.0
	2,00,000 - 5,00,000 ZAR	54	27.0
	Above 5 000 000 ZAR	52	26.0
Work Experience	None	51	25.5
	1 – 5 yrs	44	22.0
	5 – 10 yrs	57	28.5
	Above 10 yrs	48	24.0
Role in the construction industry	Newly joined	73	36.5
	Junior level	73	36.5
	Senior level	54	27.0

Table 3: Profile of the Respondents

The above table shows that the total number of males in the survey was 45%, whereas the total percentage of female respondents was 55%. The table also shows that the study included participants from multiple age groups. Participants aged 20-30 and 40-50 share the same percentage (27%). In contrast, the percentage of people aged > 50 years in the study was 23%. Evaluating the results obtained from the descriptive analysis, 27% of the participants had an income range of 2,00,000 -5,00,000 ZAR.

In comparison, only 26% of the participants had an income range above five million. Similarly,, around 24% of the participants had an income range of 0-1,00,000 ZAR. It also mentioned that more than 28% of participants have work experience of 5-10 years. Similarly,, the graph confirms that more than 25% of the participants had no work experience. It also mentions that the survey comprises 24% of respondents with more than ten years of working experience. The above table confirms that 36.5% of respondents were newly joined, level, and junior-level employees. Conversely, 27% of participants were senior employees.

6.2 Overall assessment of the refurbished buildings helps reduce net carbon emissions

The study compares refurbished buildings with newly constructed ones to assess the suitability of recycled content. Results show that recycled content is more suitable for refurbished buildings, and prefabricated materials can reduce carbon footprints. Refurbished buildings are less expensive than new construction, and refurbishment is a more effective strategy based on life cycle assessments. However, factors like structural feasibility should be considered before implementing refurbishment strategies. The study concludes that refurbishment outperforms new construction in terms of life cycle assessments, but requires careful consideration of all relevant factors(Corrado and Ballarini, 2016:91-106, Aghasizadeh, et al. , 2022:106897, Palacios-Munoz, et al. , 2019:106203, Sundayi, et al. , 2015:77-82, Loli and Bertolin, 2018:22).

6.3 Assessing the Impact of Refurbishment on the Environment of Energy

Refurbished office buildings, often aligned with the zero-energy building (ZEB) model, can significantly reduce carbon emissions. By modifying structures with recycled and modular components, these buildings can optimize energy efficiency and meet residual energy needs through renewable technologies. The ZEB model exemplifies building refurbishment. A 20% increase in green buildings in South Africa could lead to a 16% reduction in carbon emissions. Prefabricated buildings could also contribute to carbon emission reductions, but their impact on environmental impact is not well understood.

6.4 Alternatives for managing resource policies and building-specific characteristics.

The study compares refurbished buildings with newly constructed ones to assess the suitability of recycled content. Results show that recycled content is more suitable for refurbished buildings, and prefabricated materials can reduce carbon footprints. Refurbished buildings are less expensive than new construction, and refurbishment is a more effective strategy based on life cycle assessments. However, factors like structural feasibility should be considered before implementing refurbishment strategies. The study concludes that refurbishment outperforms new construction in terms of life cycle assessments, but requires careful consideration of all relevant factors(Pons-Valladares and Nikolic, 2020:9741).

6.5 Assessing the Impact of Refurbishment on the Environment of Energy

Understanding the defining attributes of such structures is crucial for understanding the environmental influence of refurbished office buildings. (Rahman, et al. , 2017:112-126) defined a refurbished office building as a structure modified according to specific needs, utilising recycled and modular components. This refurbishment process often aligns with the principles of the zero-energy building (ZEB) model.

A residential or commercial ZEB optimises energy efficiency so that any residual energy need can be met via renewable technologies. This model can function within both off-grid and on-grid frameworks. However, the precise definition of ZEB can vary across enterprises, organisations, and nations. Fundamentally, the ZEB model exemplifies the essence of building refurbishments.

During the implementation of refurbishment processes, it is vital to consider all factors influencing the modification of the structure. A noteworthy observation made by(Lützkendorf and Balouktsi, 2022:964-973)was that a 20% increase in the number of green buildings in South Africa could lead to a 16% reduction in carbon emissions. These data suggest that refurbishment, in line with green building principles, can have a positive environmental impact.

An ancillary hypothesis was examined, which proposed that prefabricated buildings could contribute to carbon emission reductions. However, the one-way ANOVA quantitative analysis technique yielded a p-value of 0.67, exceeding the statistical significance threshold. This result parallels a study by(Ma, et al. , 2021:39-44) in China, which explored factors impacting environmental carbon emissions at prefabricated building construction sites.

6.6 Alternatives for managing resource policies and building-specific characteristics

South African cities often have small buildings with concrete walls and clay brick, leading to increased carbon emissions from new construction projects. Renovating buildings with low-carbon materials can mitigate environmental degradation. A study using a one-way ANOVA test found that recycled content, due to its lower carbon content, is more suitable for refurbished buildings and has general applicability.

Variables	Sum of square	df	Mean square	Sig.
Life cycle assessment of buildings for refurbishment is difficult as there are no regular protocols	2.49	4	0.623	0.019
The use of prefabricated building elements could help in reducing the carbon emission in refurbishment	0.43	2	0.218	0.69
Low-carbon materials are better for refurbishment	2.62	2	1.310	0.13
The use of prefabricated building elements could help in reducing the carbon emission in refurbishment	34.15	4	8.53	0.00
Cost is an essential factor to be considered for refurbishment	2.88	2	1.43	0.39

Table 4: Summary of measures

7 DISCUSSION

The concept of refurbished buildings supports energy and environmental conservation, with South African citizens and the government supporting refurbishment over construction. Recycled content is the most suitable refurbished building material, as approved by the Green Building Council of South Africa. Prefabrication during refurbishment is easy, and the presence of a modular element during prefabrication provides a more satisfactory result.

The primary results show that refurbishment costs are lower and environmentally friendly compared to the construction of new buildings. The current scenario of the South African construction industry supports the primary result, with the refurbishment rate of green buildings being 3500 Rand per m². However, proper

planning and design are required to increase success rates. Refurbishment of a structure is diverse and requires more attention and monitoring.

Using low-carbon materials in refurbished buildings is better because it reduces the cost of construction and supports environmental construction. The life cycle assessment of a building with low-carbon materials is better than that of conventional construction materials. The possible adverse ecological effects of refurbished buildings following each of the three possible government initiatives can be significantly less compared to refurbished buildings operating in the baseline scenario.

Generalised Additive Models (GAM) and Life-Cycle Assessment (LCA) are two distinct approaches used in separate situations. LCA is used to assess the environmental effects of a good or service over the course of its life cycle, while GAM is used to model interactions between variables. Both have various non-exclusive financial benefits, such as flexibility, interpretability, management of missing data, and predictive power.

In the Business-As-Usual (BAU) scenario, external building material, thermal impedance of the ceiling, window-to-wall proportion, number of heating systems placed, annual power consumption, and affect capacity all significantly impact the effect of huge refurbished building structures. Concrete structures require the most energy to produce, accompanied by bricks and concrete structures.

In conclusion, refurbishing green buildings is an effective way to achieve a safer environment in South African cities, with the benefits of refurbishment being lower and more environmentally friendly compared to the construction of new buildings..

8 CONCLUSION

Refurbished green buildings in South African cities like Cape Town and Johannesburg are beneficial economically and environmentally. Recycling content and modular prefabrication reduce carbon content in the construction industry. Enforcing regulations, implementing low-carbon innovation, and limiting energy usage are methods for reducing CO2 emissions. The construction industry must be given due consideration to reduce CO2 emissions and develop a holistic structure to combat climate change. A thorough evaluation is needed to achieve sustainable development goals.

1 ABSTRACT

To ensure a liveable, resilient and sustainable city in the future, climate change adaptation and mitigation measures must be integrated into urban development projects. This is necessary to counteract the negative effects of climate change, as Austria is already experiencing a noticeable increase in the number of hot days and an increase in extreme weather events (ÖKS 15). Adaptation to climate change requires that the impact of an urban development project on the local microclimate be assessed as early as possible in order to minimise the effects and optimise the project. Microclimate analyses can be used to assess the impact of a development project or to compare different variants of a project and show the effects on local temperature, perceived temperature, wind field or humidity (Oswald et al. 2020). At the same time, urban planning processes are increasingly influenced by digitalisation in the form of Building Information Modelling (BIM).

Linking microclimate simulation and BIM is therefore an important step for the future of sustainable cities. So far, however, no tool exists that combines the various requirements and enables microclimatic assessment or optimisation of urban development projects. Some planning or assessment tools, such as microclimate models or green area indicators, allow for sectoral assessments. What is missing is a comprehensive tool that makes it easy to present the various impacts of a project to spatial planning and development decision-makers, investors and planners and, last but not least, to the general public, such as (future) residents.

This contribution analyses and describes the requirements for such a tool in the form of a web-based dashboard that uses BIM models, links them to microclimatic simulations, and additionally presents key performance indicators (KPI), such as green area indicators, in a structured way. The design of the dashboard is data and task dependent (Conrow et al. 2023); in light of the challenges and opportunities associated with optimising urban development projects from a microclimatic point of view, we set out to address issues related to (i) the requirements for the user interface, i.e. the dashboard, (ii) the requirements for the models (BIM model and microclimatic numerical simulation model), (iii) the possible applications in different planning phases, and (iv) the necessary requirements for data and data preparation.

The aim of the contribution is to analyse and describe the requirements, implementation perspectives and application possibilities of a web-based dashboard, which enables climate impact assessments, macro-ecological data for properties and neighbourhoods in an early planning phase ("climate check") on the basis of three-dimensional building models.

Keywords: Simulation of microclimatic effects, Building Information Modelling, Dashboard, Climate change adaption, Blue and green infrastructure

2 INTRODUCTION

Climate change puts pressure on the sustainable development of cities. To ensure a liveable, resilient and sustainable city in the future, climate change adaptation and mitigation measures must be integrated in urban development projects. This is necessary to counteract the negative developments of climate change, as a noticeable increase in hot days and in extreme weather events is already present in Austria (ÖKS 15). Cities suffer from heat islands also known as the Urban Heat Island effect (Oke 1967). This is the warming of cities compared to the surrounding countryside. The main reason for the stronger heating in fine weather periods is above all the overbuilding and sealing of natural, water-permeable surfaces and thus the related loss of green

and blue infrastructures. This leads to the fact that hardly any precipitation can be absorbed within urban spaces, and thus the subsequent local cooling of the ambient air by evaporation and transpiration cannot take place. Urban heating is intensified by heat-absorbing building materials such as asphalt, concrete or glass. This effect is exacerbated by inappropriate building (block) layouts that prevent ventilation (MA22 2015).

2.1 Climate change adaption in urban development projects

The consideration of these microclimatic effects in planning processes of urban development projects is crucial for the successful adaptation of cities to climate change. Assessing these effects as early as possible in the planning process is necessary to minimise the negative climatic impacts of urban development projects by optimising the project. Optimisation of urban development projects in terms of microclimate and outdoor comfort can address the modification of the urban form, the building orientation and position, the architectural design, façade configurations, the building materials, but also urban green and blue infrastructure etc. There are four areas of action for adapting to climate change and anchoring in urban planning: i) precautionary reservation of land or forward-looking consideration of its use regarding climate change adaption measures, ii) unsealing or avoiding further sealing and increasing the infiltration capacity of the soil, iii) increased use of green and blue infrastructure and nature-based measures and iv) technical measures and protection of property (Jiricka-Pürrer et al. 2021). Adaptation measures of urban development projects can range from minimising sealed surfaces, to appropriate shading and ventilation considerations, and, of course, integration of blue and green infrastructure on both, plot and buildings. The effects of these adaptation measures are well known and have been proven by numerous research projects (e.g. Choi et al. 2021, Dennis et al. 2020, Elmqvist et al. 2015, Demuzere et al. 2014, Peng and Jim 2013). Nevertheless, a concrete assessment of the (inter-)effects of such measures is a complex task. Many variables need to be considered and aligned in order to successfully implement climate change adaptation for urban development projects.

2.2 Building Information Modelling

Meanwhile, planning processes are increasingly influenced by digitalisation in the form of Building Information Modelling (BIM). BIM is a digital and integrated approach to managing projects in the construction industry. In this process a three-dimensional model stores all architectural, technical, (structural-) physical and functional building data in a structured way to create a digital twin of the planned object(s). The "Open BIM" approach (exchange of data via an open, universally readable format) was established for the mutual exchange of this data. Central to this approach is the IFC format (anchored in ISO 16739 and readable for at least 60 years), which provides a standard for structuring the data and is constantly evolving. Compatibility of data formats is a major challenge. Object-related planning is currently largely decoupled from the prevailing microclimatic conditions of the site. Although (landscape) architecture has always responded to its built environment, building design usually follows only spatial-infrastructural parameters or influences such as the course of the sun. However, planning for adaptation to climate change requires the consideration of a number of other conditions. Current planning software (e.g. ArchiCAD, Revit, ...) is only able to consider parameters such as precipitation, temperature gradients, wind situation or shading performance of greenery on building optimisation to a very limited extent. The simulation of ecological and microclimatic effects – if carried out at all – is only done in a decoupled manner and thus causes additional costs (double modelling).

2.3 Microclimate analyses

In parallel, specialists deal with the simulation of the microclimatic effects of buildings and neighbourhoods. These microclimate analyses allow for an impact analysis of a project or the comparison of different variants and show the effects on local temperature, perceived temperature, wind field or humidity (Oswald et al. 2020). Meteorological large-scale and meso-scale models used for weather forecasts do not resolve surface features in the built environment to the extent that allows small-scale microclimate assessment. There are only a small number of different simulation software packages available that are capable of this and consider the conjugate heat transfer, radiation and evaporation effects, which is needed to accurately simulate urban microclimate conditions. Almost all models use regular computational grids with a fixed, spatial resolution, so that there are computational limits for resolving small/thin structures like shading structures.

All of these mathematical models for simulating microclimate in the urban/built environment at neighbourhood level require technical experts to run them and most of them also require high-performance computing. The technical complexity and large amount of data, that these simulations generate means, that the results are not readily available to the layperson or even to urban planning experts.

2.4 Urban planning indicators and certification schemes for assessment

The use of various urban planning indicators is another approach to analyse the qualities of a project in relation to climate change adaptation. In the field of climate change adaptation, there is a wide set of possible indicators. These range from "classical" urban indicators of density and land use (e.g. floor area, built-up area, building mass) to climate indicators (e.g. perceived temperature, wind comfort) to so-called green space indicators. These green and blue area indicators make the extent of blue and green infrastructure measurable and comparable (Ring et al. 2021). In addition, indicators such as the percentage of imperviousness or the degree of sealing are used, which document soil consumption and are an indicator of local water cycle disturbances as well as water drainage.

Another approach used, which usually includes or evaluates several indicators, is certification schemes at building or neighbourhood level, such as klimaaktiv, ÖGNI (Austrian Sustainable Building Council), TQB and LEED (Leadership in Energy and Environmental Design). They play a crucial role as urban planning indicators for evaluation. They consider factors such as energy efficiency, water management, indoor air quality, materials used and the overall environmental impact of the building (klimaaktiv 2023, ÖGNI 2023). By incorporating these certifications into urban planning processes, city authorities can ensure that new developments meet sustainable standards that can be documented and contribute to the creation of more sustainable and resilient cities.

2.5 Tools and instruments for a "climate check"

The link between microclimatic simulations, BIM and climate change adaptation indicators is an important step for the future: A "climate check" for urban development or redevelopment projects is included in or required by numerous national and international climate adaptation strategies or spatial development concepts (e.g. Stadt Wien 2022, Greater London Activity 2023). Within the framework of these development procedures, fundamental decisions are made at a very early stage on urban design and building typologies, which have a major influence on later (climate) resilience, energy requirements or greening options. The assessment of the impact of a project is usually carried out on a sectoral basis and through expert assessments.

So far to the best of our knowledge no instrument or tool is available that unites the multiple requirements and enables an assessment or optimisation. Some planning or assessment tools, such as microclimatic models or green area indicators enable sectoral assessments. What is missing is a comprehensive tool that makes it easy to present the different impacts of a project for decision-makers in spatial planning and development, to investors and planners and, last but not least, to the general public such as (future) residents.

This contribution analyses and describes the requirements for a tool in the form of a web-based dashboard that uses BIM models, links them to microclimate simulations and additionally presents KPIs such as green area indicators in a structured way. Starting with (i) the requirements for the user interface, i.e. the dashboard, (ii) the requirements for the models (BIM model and microclimatic numerical simulation model), (iii) the possible applications in different planning phases as well as (iv) the necessary requirements for data and data preparation are presented.

The aim of the contribution is to analyse and describe the requirements, implementation perspectives and application possibilities of a web-based dashboard that enables climate-impact assessments, macro-ecological data for properties and neighbourhoods in an early planning phase ("climate check") on the basis of three-dimensional building models.

3   MATERIAL AND METHOD

This contribution presents a simulation and visualisation framework representing an interdisciplinary approach to urban microclimatic assessment. This contribution is based on the collaboration of the following fields of expertise: architecture, microclimatic simulation, building information modelling, planning sciences, compliance with quality assurance aspects, e.g. the standard L1136 and L1131 (Austrian Standards,

2010, 2021) and planning practice. In order to provide a microclimatic simulation and visualisation framework, desktop research was carried out on (geospatial) dashboards as well as on the requirements of dashboard design in order to analyse existing methods and steps to conceptualise the dashboard architecture. The development of a dashboard for visualisation of microclimatic data of urban development projects relies on a cyclical process that involves various data, model and user interfaces (Oates 2005).

3.1 Digital Models and Simulators operation

In order to find a convenient workflow for the integration of microclimatic analysis into the planning process of urban development projects, the interdisciplinary project team works at the interface of digital models and tools from different disciplines (architecture, landscape architecture, microclimatic analysis/modelling) to qualify a transdisciplinary workflow for the exchange of data and digital geometry as well as the display of the microclimatic model and information. In particular, a 3D visualisation of an exemplary development project embedded in the existing urban environment is created and the analysis of its microclimatic impact on the urban development project are interactively presented to the user. The simulation model has two main interfaces with the BIM model:

(1) Geometric and spatial information, like terrain, building envelopes, vegetation are inputs for the simulation model. Also, physical properties that influence the microclimate simulation, like heat capacity, heat conductivity, albedo, opacity (for glass surfaces) etc. which are defined in the building information model, are inputs for the simulation.

(2) Simulation results (temperatures, fluid velocities,…) are imported into the BIM Model and displayed in the dashboard alongside the 3D model as supplementary information.

The microclimatic simulation model "UHISolver" was developed by Rheologic on basis of the widely used OpenFOAM library (Jasak 1996, Weller et.al. 1998, Jasak et.al. 2007). The simulation are run transiently (time dependent) over typical time periods of 24h and even longer with coupling of the various heat transfer effects. The spatial resolution is flexible: surface areas are usually resolved around several tens of centimetres, so that the BIM geometry can be represented with high accuracy in the simulation.

4 RESULTS – REQUIREMENTS FOR A CLIMATE CHECK DASHBOARD

The basic idea of implementing a climate check instrument is that of a "dashboard". A dashboard is generally referred to as a graphical user interface that is used to visualise data. The name comes from the English term for a dashboard in a car that displays information from various sources at a glance. Originally, the term referred to the board or leather apron at the front of a vehicle that prevented horse hooves and wheels from spraying mud into the passenger compartment (Mattern 2015).

So-called geospatial dashboards have been used in research and practice since the 1990s (Jing et al. 2019). In the beginning, there was the development of dashboards that were located at the level of the entire city. Only later were object and building-related dashboards developed.

A dashboard usually comprises a user interface that is coupled with models or analysis methods, which in turn process and evaluate certain data bases in order to display (key performance) indicators (Jing et al. 2019, Stehle and Kitchin 2020).

In order to develop a dashboard for the assessment of climatic impacts, an interplay of these elements is necessary. In the following, the requirements for the individual elements are described to enable both experts and laypersons to evaluate and compare projects.

4.1 Requirements for the user interface

To provide planners and other users with valuable insights, the output of simulations and models needs to be effectively presented in the dashboard interface. Planners typically develop different design variants through integrative processes or through competition procedures in the early development stages of urban development processes. A key requirement for the use of a dashboard in these early development stages is therefore to evaluate different variants in order to assess their potentially divergent qualities and compare their microclimatic impacts. This evaluation requires the selection and display of KPIs representing microclimatic information, urban design features and information about green and blue indicators in the

interface of the Dashboard. The interface should be designed with clarity and simplicity, presenting the data in a concise and visually appealing manner.

4.1.1 Requirements for the display of data and indicators in the Dashboard

A successful dashboard must be adapted to the characteristics of its users, so one of the initial steps is to define the target users of the climate check dashboard (see chapter 4.4.). Following Fernandes (2017) the following rules will furthermore help design and implement a successful dashboard:

- "Enable drill-down or drill-through to underlying data sources or reports and filters for flexibility and customisation;
- Provide explanation and context prior to information;
- Require minimal training and easy to use by anyone;
- Stay within single screen boundaries without displaying excessive detail;
- Use modularity to compact information and visual cues to direct attention" (Fernandes 2017, 18f).

4.1.2 Three-dimensional and interactive representation of the urban/architectural model

To present the three-dimensional BIM model in the dashboard interface, a web application with a 3D/BIM viewer can be used. This web application serves as a user-friendly platform for interactive exploration and visualisation of the urban development project and its various information layers. The 3D/BIM viewer provides a realistic and immersive representation of the urban environment, including the architectural elements and spatial layout of the buildings. This viewer acts as a visual medium to convey information and facilitate understanding of the project design. As the design process progresses, urban development projects are further optimised based on an initial assessment. It is therefore necessary to present and evaluate development variants – which may differ in terms of building structure, urban layout, height or density – and design variants – which may differ in terms of different surface textures and colours, or the proportions and locations of green and blue infrastructure. As mentioned above, a central requirement for the use of the Dashboard in the early stages of development (see also chapter 4.3) is the ability of the 3D/BIM viewer to evaluate and compare these different project variants in order to assess their different (microclimatic) impacts and qualities. In Summary, the BIM model must be represented as an interactive 3D model in the projected 3D space with users being able to freely move, zoom, rotate and interact with the model.

4.1.3 Representation of climate indicators

The user interface will present climate indicators such as the typical summer- or hot-day that is used for the simulation – for example according to the DEED-Standard.[1] The external "forcing" conditions for the project domain are for example the air temperature or velocity of incoming wind. Climate KPIs such as the apparent temperature (e.g. UTCI[2]), or wind comfort are derived from these basic indicators (see chapter 4.1.5.) to analyse the projects microclimatic performance and evaluate different development and design variants of the project.

The 3D model of the Dashboard will show spatially resolved KPIs for the local microclimate in the form of color-coded 3D surfaces that can be overlaid optionally. To further enrich the information, it will be possible to select points within the geometry to display time-series of variables at that point, for example the 24h air temperature or surface temperature over time. This gives users deeper insights into the dynamics of the microclimate.

4.1.4 Representation of urban design and planning indicators

The use of different urban planning indicators is a further approach to analysing the qualities of a project in relation to climate change adaptation. Typical urban indicators can either address the building or the plot and usually describe the density and land use intensity (e.g. floor area, built-up area, building mass).

These indicators (see Table 1), such as gross floor area, number/size of flats, and the area of (semi-)private open spaces, offer a quantitative representation of the built environment. Gross floor area serves as a

---

[1] https://rheologic.net/articles/definition-DEEDS/
[2] Universal Thermal Climate Index

measure of the overall size and scale of a building or development project, indicating its spatial footprint. It helps assessing the intensity of land use and the potential population density in a given area.

By representing these urban design indicators, planners can assess the spatial layout, functionality, and amenity provision within neighbourhoods and developments. They can use this information to inform decision-making processes, such as zoning regulations, building codes, and urban design guidelines.

Additionally, the area of balconies, loggias, and gardens provides insights into the availability of open spaces within the urban fabric. These private open spaces contribute to enhancing the quality of life, promoting well-being, and improving the overall liveability of urban areas (Giannico 2022).

4.1.5 Representation of green and blue area indicators

Green and blue infrastructure and nature-based solutions make a significant contribution to the adaptation of urban areas to climate change. Only by identifying the benefits that nature provides, and by understanding the value of these benefits can planners, managers and decision-makers move towards creating a sustainable city. The four most important functions of green infrastructures are: (i) shading of surfaces and spaces, (ii) low reflection of incoming solar radiation, (iii) cooling of themselves and the surrounding environment due to evapotranspiration, and (iv) storage of CO_2 in biomass and substrate. These so-called ecosystem services include the Provisioning services, Regulating services, Habitat or Supporting services, and Cultural services (Millennium Ecosystem assessment 2005; TEEB Foundations 2010). The Provisioning services describe the material and energy outputs from ecosystems (like food, water, medicinal resources, etc.); the Regulating services are the services ecosystems provide by regulating the quality of air and soil as well as providing flood and disease control; the Habitat or Support services means that ecosystems provide and maintain living spaces for a diversity of plants or animals; and the Cultural services include the non-material benefits like aesthetic, spiritual and psychological benefits that people obtain from contact with ecosystems (TEEB 2011).

In order to integrate nature-based solutions into urban development projects, the share of green and blue areas is required as a basic indicator (see Table 1). Other factors, such as the green area factor or rainwater management indicators, are based on the area share of green and blue infrastructure. Thus, to convey the importance and microclimatic impact of nature-based solutions, the area share of green and blue infrastructure must be displayed as key information.

Climatic indicators/parameters		Urban indicators/parameters		Green and blue infrastructure indicators/parameters	
Urban heat	Wind	Quarter/Parcel	Building	Green infrastructure	Blue infrastructure
Air temperature	Wind velocity	Sealed surfaces	Building height	Extensive green roof area	Area of waterbodies
Air humidity	Wind direction	Partly sealed surfaces	Façade area	Intensive green roof area	Stream lines
Solar Radiation	…	Unsealed surfaces	Roof area	Façade greening area	Retention areas
Calendarday/solar angles		…	Built area	Green surfaces with/ without floor connection	Infiltration areas (through/ infiltration ditch)
Diurnal air temperature			Underbuilt area (incl. spill height)	Existing vegetation	…
…			Gross/ Net floor area	Number of trees	
			Private available free space	Canopysizeoftrees	
			…	…	
Derived KPIs	**Derived KPIs**	**Derived KPIs**	**Derived KPIs**	**Derived KPIs**	**Derived KPIs**
Apparent temperature – AT	Wind comfort	Degree of sealing	Floor area number	Green area factor	Blue area indicator (BAI)
Universal Thermal Climate Index – UTCI	Wind danger	Degree of building density	Building mass number	Extended Degree of sealing	Rain water management (RWM)
Surface temperature	Air quality(optional)	…	…	Biodiversity indicators	Discharge coefficient/water circle
…	…			Carbon capturing	…

Table 1: Overview and examples of indicators/KPIs that should be presented to assess the performance of a project

4.1.6 KPIs for the assessment

From the many variables and indicators that can be used to qualitatively and quantitatively describe and evaluate urban development projects, it is crucial to select those indicators most relevant for climate change adaptation. The selection of appropriate KPIs for the dashboard is critical to the effectiveness of the evaluation of different design and development options (De Marco et al. 2015). The KPIs should be

646

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

comprehensive, comparable and independent to avoid overlap. The indicators and further calculations should be easy to understand and should be able to provide information to address upcoming design or development issues. Current and historical data should be presented and available, e.g. wind statistics at specific times (Fernandes 2017).

In Table 1 the chosen indicators are listed, representing climate (temperature, wind), urban indicants (quarter, parcel, building) and green/ blue infrastructure. From these basic indicatorsand parameters further KPIs can be derived which enable a simple evaluation or comparison of different variants. The statistics on wind velocity and direction contribute to wind comfort and wind danger. The sealed surfaces add to the degree of sealing and degree of building density. The building height, façade area, roof area, built area and gross/net floor area conduce to the floor area number and building mass number. The green area factor (GAF), biodiversity indicators and the extended degree of sealing derive from the number of trees, façade greening, roof greening and green surfaces with or without floor connection. In the column of the blue infrastructure the natural waterbodies, retention areas and infiltration areas contribute to the blue area indicator, discharge coefficient and rain water management.

4.2 Requirements for the models

This chapter focuses on the necessary conditions and constraints for the models, with the aim of providing flexibility and ease of implementation. By keeping requirements to a minimum, it is easier to adapt and modify the model in the early stages of development. This flexibility allows better exploration of design alternatives and consideration of various factors that contribute to sustainable design.

4.2.1 BIM Model

In the early stages of an urban development project, not all information, both geometric (e.g. details of faced) and alphanumeric(e.g. data on the materials used), may be readily available. In addition, different development and design variants of the project are typically developed. Therefore, the BIM model is required to accommodate the different variants as well as a gap of detailed information. As the development process progresses and more dependencies are established, the complexity of implementing changes increases significantly. Therefore, by reducing the constraints on the model from the outset, it is possible to capitalise on the opportunity for sustainable and impactful changes in the early stages, when they are most feasible and affordable.

A key requirement is that the IFC model, which stores the architectural, technical and functional building data, has a closed surface. The closed surface requirement for the IFC model ensures that the model accurately represents the physical boundaries of the building. This information is critical for microclimate simulations and other analyses related to climate impact assessments. The ability to easily modify and adapt the model allows designers to iterate on different design options and evaluate their impact on sustainability. The second requirement is to assign accurate properties to the surfaces in the model to ensure that the microclimatic analysis properly accounts for the characteristics and attributes of the surfaces (see the next chapter for more information).

4.2.2 UHISolver – Microclimatic Simulation Model

The microclimate simulation model – OpenFOAM based UHISolver in this case – draws on mesoscale weather data usually but not necessarily for summer/hot-weather conditions. Input factors for the simulation domain are air temperature, direction and speed of wind, humidity and solar radiation, all of which need to be available in reasonably resolved time series over the 24 hours of a usual simulation. Typically, hourly values are used, but two-hourly values are also acceptable and even quicker simulations over just 1h are possible with some compromise on quality (for example, surface temperatures will not necessarily be accurate for simulations that only span a short time).

Buildings are included in the simulation with their albedo, thermal conductivity, thermal capacity and of course their geometry. At a minimum, building envelopes, including roofs, are resolved; depending on the requirements of the project, smaller details such as balconies, alcoves, passageways and shading structures may also be represented. The project also requires a geo-location and date so that solar angles can be accurately represented. For example, the DEEDS definition for heat wave days provides not only the daily and hourly input factors for the simulation, but also the annual day on which a heat wave day typically

occurs. If this information is not available, the summer solstice is often used (Xu et al. 2019; City of London 2022; Rheologic 2022).

Blue (water) and green (vegetation) infrastructure in the simulation domain can also evaporate water, converting sensible heat into latent heat trapped in moisture. Evaporation rates are set according to literature data.

4.2.3 Interaction of the models and representation in the interface/dashboard

By integrating data from the microclimate simulations into the 3D/BIM viewer, the web application enhances the viewer's capabilities by overlaying additional layers of information. By visualising these KPIs on the 3D model, users can easily understand the spatial distribution and variation of microclimatic conditions within the urban environment.

The interface should be designed with clarity and simplicity, presenting the data in a concise and visually appealing manner. Users should also be able to toggle information on and off – for example, to display certain variables (such as wind speed or air temperature) in the model. These variables are typically colour-coded on top of 3D surfaces. 2D representations fall short due to many of the variables not being projected onto simple z-normal planar surfaces, but onto more complex surfaces, that follow the elevation changes of the terrain, overlap (for example under bridges, on rooftops, in underpasses and thoroughfares) or are even completely vertical (for example wind speed over height). Without the ability to rotate, zoom and toggle, this information cannot be easily conveyed.

In addition to the spatial information users should ideally be able to see the temporal information too: for example, a colour-coded surface can show the air temperature at certain points in the geometry at one point in time (often 15:00 local time is shown, as this is often the hottest time). Ideally, a user should be able to select a point in the geometry and have the time information for that point – in this example, the temperature over 24 hours – displayed as a time series graph in a side panel.

4.3 Requirements for data preparation of input data

Data is the basis for the creation of the BIM model, the microclimate simulation and the calculation of the various indicators. In addition, a dashboard provides the ability to integrate and display existing data and indicators, for example about the location and mesoclimate.

4.3.1 Necessary input data for the BIM-model and the microclimatic simulation model

The basis for both models is terrain data and building cubature of the existing neighbourhood, as well as for the actual development project. In addition, microclimatic simulations need the implementation of (existing) green spaces and trees. In terms of buildings structure, the surrounding is used/necessary to show the "visual fit" of the new project to the neighbourhood. Concerning the microclimatic simulation, it is mainly necessary to evaluate the wind conditions for higher buildings.

As mentioned above, mesoscale weather data are necessary to set the correct input factors for the simulation. The time resolution should be at least 2 hours or better. A good data source for this data are the ERA5 or ERA5-LAND dataset published by the ECMWF. These data sets are available in hourly resolution globally. The spatial resolution is 0.25° respectively 0.1° (about 30km respectively 9km).

It is also possible to use data from meteorological weather stations, however due to the low height of these stations wind directions and velocities are often not representative. Using the high-quality data from the abovementioned re-analysis, high quality datasets that are error-corrected according to highest standards avoids that problem. It should be noted however that this synoptic wind is not influenced by small scale terrain, so the simulation model has to be tuned carefully to include enough terrain and surface features (buildings, forests, etc.) so that the simulated wind conditions at pedestrian height are accurate.

4.4 Application in different planning phases and for different stakeholder

The development of urban planning projects usually comprises several steps, which include both the area of development planning – i.e. open procedures as well as regulatory planning – i.e. legally binding planning instruments. A dashboard for assessing performance can be used in different phases and for different target groups. These are: (i) (landscape) planners and (landscape) architects, (ii) city executives and expert juries for urban development competition processes and possibly also (iii) laypersons like local or future residents.

The first step is usually the development of a basic urban planning model that serves as the basis for zoning and development planning, or builds on these existing planning instruments. Based on these, often master plans with detailed specifications and detailed qualities for the individual construction sites and public spaces are developed. The next steps usually include the preliminary draft, the design and the submission planning for the authorities before it comes to a detailed implementation planning for both the buildings and the open spaces (Reinwald et al. 2021a).

The use of the dashboard is particularly beneficial in the early phases of development, when there is still a great deal of design freedom and all the relevant parameters – building volume, building position, green space distribution, etc. – can still be modified to improve the project's (microclimatic) performance. Of course, it is also suitable for further planning steps and, above all, for quality assurance in the ongoing process, as there are often decisive changes in the project. Remastering the models according to nature-based solutions (blue/green infrastructure) is a great advantage of assessing the microclimatic effects of a project in early development stages. With regard to the different target groups mentioned above, it can be used as part of public relations work to inform local residents in general about the project. On the other hand, in the competition phase, it can be used by the expert jury to compare the submitted projects in terms of ecological parameters and thus select the submission with the most beneficial impact on the local microclimate and the best climate resilience. Depending on the target group, different modes are recommended/practical (basic vs. expert mode).

5 CONCLUSION – THE "GREENPLANOUT" DASHBOARD

This contribution aimed to describe the requirements, implementation perspectives and application possibilities of a web-based dashboard, which enables climate impact assessments ("climate check") on the basis of three-dimensional building models. The result is a conceptual architecture for the GREENplanout Dashboard (see Figure 1).

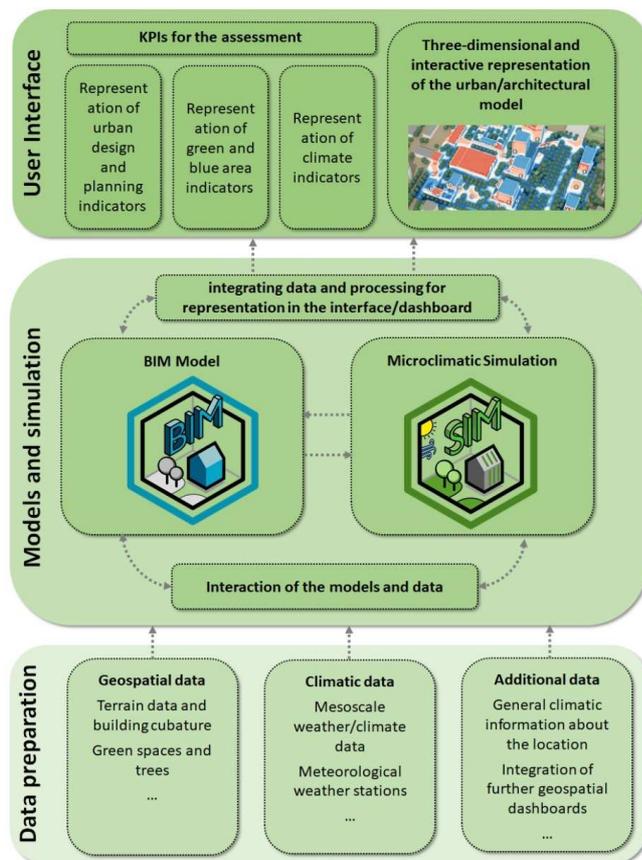

Figure 1: Conceptual architecture for the GREENplanout Dashboard

Requirements were analysed and collected for three areas: (i) Requirements for the user interface (ii) Requirements for the models and (iii) Requirements for data preparation of input data. The user interface should be accessibility for all users via a web portal that is easily readable/navigable by the user, since this

dashboard is aimed for various users from different professional backgrounds. To display information interactive display should be integrated. The user can click on a point in the geometry and an information window pops up with information, parameters and KPIs (see Figure 2). The displayed three-dimensional model is based on the interaction of two models used (BIM and UHIsolver) and the underlying data. These include geospatial and climatic data and can be enriched by additional data (e.g. general climatic information about the location).

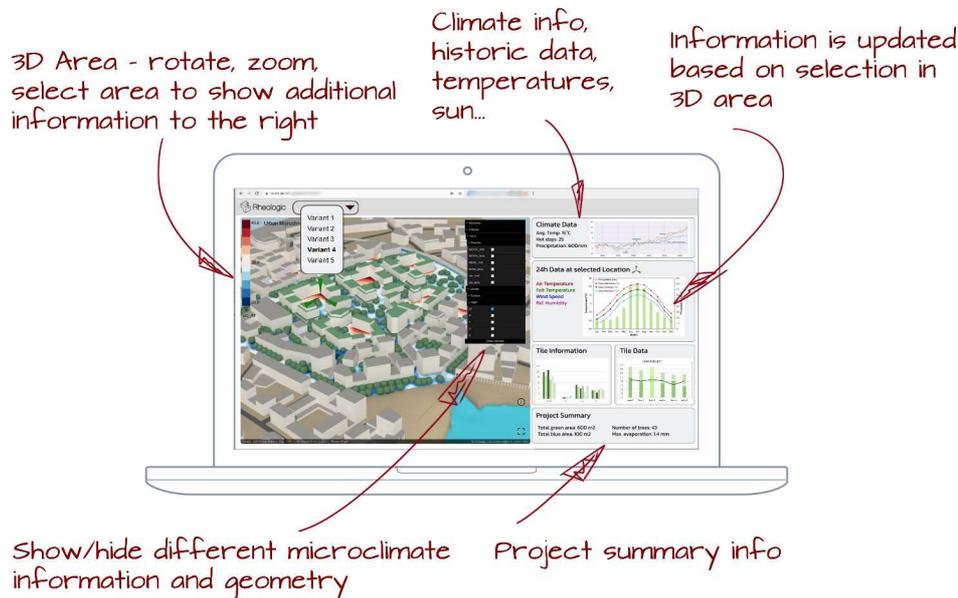

Figure 2: Mock-up of the planned dashboard. Based on the selected design variant the corresponding indicators like thermal load, wind speed etc. can be accessed via a selection menu (left side). Various KPIs allow an assessment of different variants and their performance in relation to the climate resilience of the building or neighbourhood (right side).

The interactive model and dashboard will provide much greater insight into the climatic "ground"-conditions than currently available synoptic weather and climate indicators can. From statistical weather data and meteorological models, it is only possible to indicate air temperature, radiation and humidity without the resolved influence of the built environment: on a shadeless, slightly rough plane without any obstacles. However, the built environment, that is often not resolved in meteorological models, has far-reaching and complex influence on the microclimate with large deviations in radiation (from trees and shading), wind velocity and direction (buildings), air temperature (conjugate heat transfer) and humidity (urban vegetation and water bodies). Insights into how, when and where these factors change allows urban planners to make much better-informed decisions throughout the planning process, ultimately resulting in a healthier, more resilient environment using best available tools. For the general public, it is an accessible way to become engaged in the design of public spaces already during planning, with the potential to foster increasing responsibility and a sense of stewardship for how we design urban space that is fit to the climatic challenges to come.

Especially for the greening building community (Enzi et al. 2021, Formanek et al 2020) this dashboard is very attractive, because the influence of green roofs and facades on the microclimate and the further effects of greening buildings (Mann and Mollenhauser 2021, Pfoser et al. 2013) such as biodiversity promotion, improvement of the albedo, production of evaporative cooling and stationary processes can be analysed and optimized. Greening thrives on visualization, and virtual models provide initial information about the possibilities, as well as a holistic view of radiative exchange in a neighbourhood network. In this way, the understanding of how to improve our future microclimates at specific locations and measures to improve climate protection can be promoted.

It should be noted that the dashboard primarily focuses on architectural or neighbourhood developments. How the object or the neighbourhood affects the surrounding neighbourhoods or the city as a whole can be analysed with other simulation tools that assess these larger-scale effects. A linkage of these levels is necessary to represent the interactions on a larger scale (Reinwald et. al. 2021b).

Research on Construction Method of Genetic Map for Rural Settlement Heritage of Ethnic Minorities in Guangxi, China

Xi Luo, Jianyun Huang

(Xi Luo, Shanghai Jiao Tong University, 800 Dongchuan Road, Shanghai, 1216862958@qq.com)
(Prof. Jianyun Huang, Shanghai Jiao Tong University, 800 Dongchuan Road, Shanghai, hjy2005@sjtu.edu.cn)

1 ABSTRACT

As the multicultural fusion area, Guangxi, China has twelve nationalities who live here for generations, including Han, Zhuang, Dong and Miao, etc. The cultural fusion among various ethnic groups is prominent, and has representative characteristics on multiculturalism and research value on rural heritage. As one of the carriers of culture, rural settlement heritage maintains the genetic characteristics of cultural "gene" in the process of inheritance. The laws are presented based on different expressions of material and non-material elements, and reflect the logic and order of the evolution of rural settlement heritage. Through the investigation of ethnic minority rural settlements in Liuzhou, Guangxi, this paper clarifies the construction logic of genetic map for rural settlement heritage. In addition, the excavation, identification, extraction of genetic elements and the construction of genetic map are carried out for representative rural heritage. Finally, this paper summarizes the research methods of rural settlement heritage genes in multicultural fusion areas of ethnic minorities. At the same time, it provides direction for the protection and sustainable development of rural settlement heritage, and guides the development of rural planning in some degree.

Keywords: map construction, multiculturalism, gene, rural heritage, rural settlement

2 INTRODUCTION

Based on the promotion of rural revitalization in the 14th Five Year Plan in China and the construction of beautiful village, many experts and scholars have carried out the research work on village, especially in some villages which are needed to be constructed because of serious problems. However, a complete system construction has not been formed in the research of rural settlement for ethnic minorities, especially that an in-depth study is lacking for multicultural fusion area of multiple ethnic minorities. The historical process of conflict, communication, integration and regeneration for ethnic culture is world-scale and generalized, and its influences are reflected on multiple domains, levels and perspectives. This has created cultural development opportunities for numerous nations, countries and regions, and brought unknown challenges.

Guangxi Zhuang Autonomous Region has diversified ethnic composition and cultural ecology, and Han, Zhuang, Dong, Miao, Yao, Mulao, Maonan, Hui, Jing, Yi, Shui and Gelao live here indigenously. Twelve nationalities form the multicultural fusion in Guangxi, including Baiyue culture, Miao-Yao culture, Central Plain culture and marine culture, etc. Liuzhou is in the north central region of Guangxi, and plenty of ethnic minorities live in mountainous and hilly areas, especially Han, Zhuang, Miao, Dong and Yao. The cultural fusion among different nationalities has representative characteristics and research value.

"Gene" as a biological concept, was proposed by Gregor Johnann Mendal, an Austrian scholar. This concept refers to a basic unit of biological heredity, as well as the carrier of genetic information, and genetic information can be passed on to the next generation through replication, causing the offsprings to show the same shape as their parents. As one of the carriers of culture, rural settlement heritage maintains the inheritance characteristics of their cultural "gene" in the process of inheritance. On account of the change in time and space, the genes of rural settlement heritage vary slightly in the process of inheritance. Thus, the variation of genes is a result of adaptation to the environment, which is not only the basic law of biological inheritance and propagation, but also the internal logic of the evolution and development of rural settlement heritage culture. Although "gene" and rural settlement heritage have different properties, they have similar inheritance principles [1]. The laws presented in genes reflect the logic and order of the evolution of the rural settlement heritage according to different expression patterns. Meanwhile, the exploration and integration of genes' internal logic and external expression is the process of constructing the genetic map [2].

In the investigation of 27 representative villages of ethnic minority rural settlements in Liuzhou, Guangxi, we also found that the heritage of these rural settlements has certain research value. Especially in these ethnic minority settlements, the cultural fusion and mutual influence are significant among different nationalities in the same region, or among different regions within the same nationality. At the same time,

cultural fusion has certain "gene" characteristics which can be excavated and identified both from the level of material culture and non-material culture. In the process of excavating, identifying, extracting and constructing these characteristics, we can find the direction of conservation and sustainable development of rural settlement heritage. In this way, the establishment of such a systematic framework can guide the future development of rural planning [3].

3 RESEARCH STATUS OF GENE FOR RURAL SETTLEMENT HERITAGE IN ETHNIC MINORITY

There have been many levels of research on rural settlements at home and abroad, these researches mainly focus on the evolution and development of rural settlements [4-7], the distribution characteristics and influencing factors of rural settlements [8-15], the reconstruction and optimization of rural settlement layout [16-17], as well as rural heritage protection [18-23], etc. These studies not only analyzed the spatial distribution and natural geographical causes of rural settlements, but also deeply analyzed the relationship between villages and natural and humanistic elements. In addition, the research work put forward the development direction and strategy for the revitalization and optimization of rural settlements.

Rural heritage is one of the important resources for rural development, and it is also the irreplaceable and irreproducible cultural heritage created by local people over thousands of years. In terms of rural heritage protection and inheritance, Zhou et al. [3] mentioned that villagers are less aware of the history and culture of their own villages, and villagers' senses of belonging to their own villages are gradually weakened. At the same time, the proportion of newly built dwellings in villages is increasing, while the new dwellings have no connection with the characteristics of traditional dwellings and even destroy the traditional features of villages. This phenomenon is widespread in many rural settlements, which brings numerous problems to the protection and inheritance of rural heritage.

The distribution of ethnic minorities in China is characterized by "Large communities, small areas", which means that China's ethnic minorities live together over vast areas while some live in individual concentrated communities in small areas. But the phenomenon of multiple nationalities living together is common in some ethnic minority settlements. Under the fusion of the multi-ethnic culture, rural settlements present the features of "material culture and non-material culture" and form a unique natural and humanistic landscape, among which rural heritage with research value is not lacking. For instance, the rural heritage includes layout features, traditional dwellings and architectural features of rural settlements, as well as the relationship between customs, beliefs, languages and totems. In addition, the symbiotic culture formed by mutual influence among different ethnic groups is also a type of rural heritage. Therefore, it is significant to study the rural settlement heritage in ethnic minority settlements which have the characteristics of cultural fusion.

In this research context, many scholars also suggested to take "gene" as the inheritance carrier of important information to study the landscape gene of a specific region. In addition, scholars regarded "gene" as a basic genetic unit to summarize the characteristics of regional cultural landscape. In 1979, Lewis proposed that the most essential difference between landscape interpretation and research is gene [24]. American scholar Taylor once proposed to apply gene analysis to find the rules of settlement space layout, or to find the most core common factor by comparing the spatial structures of settlements within a certain area, that is, to find genes [25]. In recent years, Liu [26] has carried out systematic and complete research on the landscape genes of traditional villages, using the "landscape gene method" to study the internal characteristics, external expression and inheritance features of traditional settlement landscapes. In the field of landscape genes of cultural heritage in traditional villages, Xiang et al. [27] analyzed the genetic map of cultural heritage landscape in the aspects of spatial sequence, distribution and pattern. Li et al. [28] summarized 13 villages of Dong in Hunan Province and studied the spatial genetic map of settlements, as well as the genes with cultural concepts. Qi et al. [29] identified and analyzed the landscape genes of Miao traditional settlements from the perspective of geography.

The minority areas studied in this paper are in Liuzhou, Guangxi, and many of them belong to multicultural fusion zones. At present, the studies of typical cultural regions are relatively mature, while those of multicultural fusion areas are still insufficient. In response to this situation, Meng reflected on the theoretical research (traditional dwellings and villages) and practical research (development of traditional dwellings) to provide ideas for the research on the development and evolution mechanism of traditional residential buildings in fusion areas [30]. In conclusion, some scholars have carried out researches on the genes of

ethnic minority settlements, but the research framework has not been established for multicultural fusion areas, as well as the inheritance and variation of cultural genes among ethnic minorities.

In this paper, typical rural settlements in Liuzhou, Guangxi are taken as examples to propose method to construct genetic maps of rural settlement heritage in ethnic minorities. In addition, relevant methods to extract and identify genetic elements in multicultural fusion areas are also proposed in this paper. This paper provides a framework for further research on the rural heritage of ethnic minority settlements in multicultural fusion areas, as well as the external representation and internal motivation of genetic inheritance and variation generated by the cultural fusion.

4 THE CONSTRUCTION LOGIC OF GENETIC MAP FOR RURAL SETTLEMENT HERITAGE

As an important part of rural genes, heritage elements of rural settlements would show different laws in different ways of expression, and this is also the expression of inherent laws for cultural heritage of rural settlements. In a word, the logical and ordered expressions of these genes are the processes of genetic map construction. Guangxi is the fusion zone of multiple ethnic groups, and genetic map can be excavated and constructed from three levels to study the fusion of multi-ethnic culture: diachrony, regionalism and confluence.

Guangxi is the confluence zone of multiculturalism. Firstly, the formation and development of multiculturalism can be explored from the perspective of synchronicity and diachrony. Synchronicity can present the symbiosis of different nationalities at the same time, while diachrony is the interpretation of the development of different nationalities in time and space. As a result, it is significant to discuss the cultural characteristics of each nationality in different historical stages from this perspective. Therefore, the relationship between synchronicity and diachrony is closely related to the research of multiculturalism in Guangxi, and is also the dynamic study of regional culture. Table 1 presents the process of demographic change and colony formation of various ethnic minorities in Guangxi from the Shang and Zhou Dynasties to the late Ming and early Qing Dynasties. Furthermore, Table 1 shows that the multicultural fusion among different nationalities was formed due to the regional change of indigenous nationalities and immigration of

Dynasty	Nationality
Shang and Zhou Dynasty (1766BC-255BC)	The three tribes of "Luoyue" in the Zuojiang River Basin, "Xiou" and "Cangwu" in the Guijiang River Basin coexist
Qin and Han Dynasty (211BC-AD220)	Part of the Han Chinese from the Central Plains moved to Guangxi,China,living together with ethnic minorities
Tang and Song Dynasty (618-1279)	After the differentiation and integration of the indigenous minorities, the Zhuang, Dong, Mulao, and Maonan nationalities were formed. At the same time, foreign minorities such as the Miao and Yao entered Guangxi.
Song to Ming Dynasty (1279-1368)	The Hui, Yi, Jing, Gelao, Shui and other ethnic minorities have gradually moved to Guangxi,China
Ming and Qing Dynasty (1368-1911)	A large number of Han people moved in during the Qing Dynasty, and some of the ethnic minorities moved to West Guangxi. The population of Han nationality in eastern Guangxi is larger than that of ethnic minorities, while the population of Han nationality in central Guangxi is increasing

Table 1: The vicissitude process of various ethnic groups in Guangxi

From the view of region, twelve nationalities who live in Guangxi for generations are composed of aboriginal and adventive nationalities, forming a multicultural pattern of "Large communities, small areas" with multiple nationalities living together. At the same time, multiculturism formed under the fusion of Baiyue culture, Central Plain culture and marine culture. Figure 1 shows the regional distribution of numerous nationalities and the pattern of ethnic communities in Guangxi [31].

Overall, the cultural tradition and lifestyles of aboriginal nationalities were generated by transition, differentiation and fusion, and diverse lifestyles and cultural symbiosis formed after the immigration of adventive nationalities. Figure 2 shows that the distribution of Han is wide, and the composition and origin of the population are complex, including three major factions of Guangfu, Hunan-Jiangxi and Hakka. The long struggle between Han and aboriginal nationalities caused the migration and reform of nationalities. Meanwhile, Miao, Yao and other ethnic minorities moved into Guangxi, and numerous characteristics of these ethnic minorities constitute the multiculturalism of Guangxi. In the process of influence and struggle, ethnic culture is affected by each other and crisscross and overlap are generated due to the continuous migration of various nationalities. As a result, the distribution pattern of various nationalities is also changing

constantly. In Table 2, the distribution of various ethnic groups has certain characteristics of fusion. The interaction effects of material culture and non-material culture contribute to the fusion of multiculturalism in Guangxi.

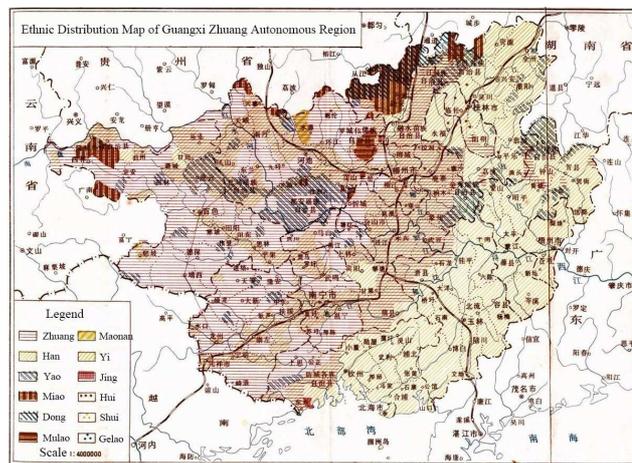
From the perspective of multicultural fusion in Guangxi, from the Paleolithic Age, aboriginal nationalities such as Xiou and Luoyue gradually turned into Zhuang, Dong, Mulao and Maonan with the development of history. These nationalities inherited Baiyue culture in some degree, including farming culture, production and life, Fengshui culture (Fengshui is a kind of traditional Chinese practice of determining the location of a house, tomb, or other items which are believed to have a vital effect on the fortunes of a family, owner, or user) and other aspects [32]. On the other hand, on account of political and economic factors, the Han gradually moved into Guangxi from Central Plains and Guangdong in different historical periods. In this way, multicultural characteristics of Lingnan (south of the five ridges, in south of China) Han were formed in the long-term life and fusion [33]. In addition, some ethnic minorities such as Miao and Yao, gradually moved to Guangxi later. Due to the weak economic status of these ethnic minorities, most of their settlements were in mountainous areas and mountaintops. Since these nationalities lived in the same geographical environment, the latter nationalities also kept the fusion with aboriginal culture and Han culture in Guangxi to ensure the continuation of the nationalities. Therefore, these latter nationalities have the cultural characteristics of "near Zhuang is Zhuang, near Han is Han". Therefore, multicultural fusion characteristics are presented in the dimension of time and space among multiple ethnic groups in Guangxi, which also provides the possibility for our future research.


Fig. 1: The regional distribution of nationalities in Guangxi [31].
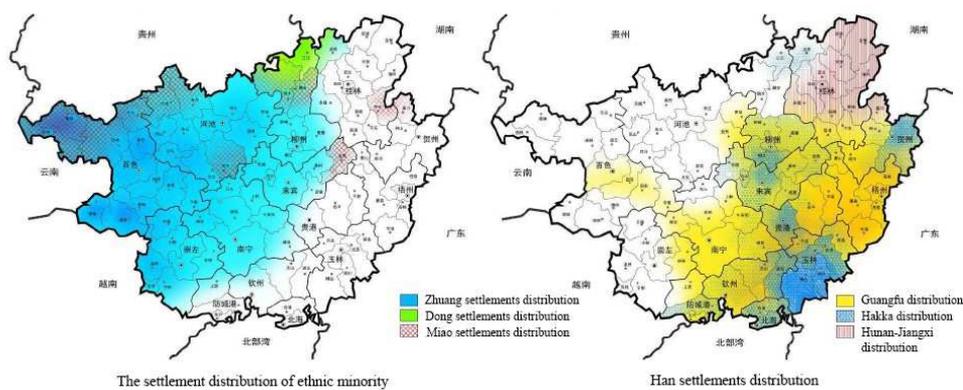

Fig. 2: The distribution of ethnic minorities and Han in Guangxi [31].

5 MATERIALS AND METHODS: CONSTRUCTION METHOD OF GENETIC MAP FOR RURAL SETTLEMENT HERITAGE

The rural settlements of ethnic minorities are characterized by clustering, centrality, defensiveness and respect of the environment. This paper focuses on the genetic identification of the rural heritage in ethnic minority settlements, and landscape genes of settlements have been studied already in the existing literature. However, there are both similarities and differences between this paper and the existing studies. Heritage

elements in rural settlements are significant in the inheritance of rural settlement heritage. They not only are the basic units to identify the "heritage" characteristics in rural settlements, but also reflect the external representation and internal development law of rural settlements.

Nationality	Main settlements
Zhuang	Zhuang residents mainly live in the six cities of Nanning, Chongzuo, Baise, Hechi, Liuzhou, and Laibin in Guangxi. The rest are scattered in 66 counties in the region.
Han	The residents of the Han are widely distributed, and they mainly live in the southeastern part of Guangxi.
Yao	Yao residents are mainly distributed in Duan, Bama, Jinxiu and Dahua in northwest Guangxi, Fuchuan and Gongcheng in northeast Guangxi, and autonomous counties of various ethnic groups in Longsheng.
Miao	Rongshui, Longlin, Sanjiang, Longsheng and other counties
Dong	Sanjiang, Longsheng, Rongan, Rongshui and other counties
Mulao	Luocheng, Yizhou, Liucheng and other counties
Maonan	Huanjiang, Nandan, Duan and other counties (autonomous counties) and Jinchengjiang District of Hechi City,China
Jing	Liwei, Wutou, Shanxin and other coastal areas in Jiangping Town, Dongxing City
Shui	Nandan, Rongshui, Yizhou and other counties
Yi	Longlin Autonomous County and Napo County
Hui	Guiling, Liuzhou, Nanning
Gelao	Longlin Autonomous County

Table 2: Main areas inhabited by various ethnic groups in Guangxi, China [31].

From the perspective of research classification, the studies of rural heritage genes discussed in this paper focus on material and non-material cultural elements with heritage value. Besides, the excavation and identification of rural heritage genes are carried out in multicultural fusion areas. Through the establishment of the genetic map, we can find out the generalities and individualities among different ethnic groups, to analyze the internal motivation of the long-term preservation of the "gene". Meanwhile, in the process of constructing the genetic map, the "genes" of rural settlements are compared longitudinally at different time periods and horizontally among different ethnic groups. Therefore, the cultural fusion areas can be found in the case of multiple nationalities living together, and some variant genes which are generated by long-term cultural fusion can be extracted.

5.1 Excavation and identification of genetic elements

The excavation and identification of genes for rural settlement heritage is a systematic and comprehensive process. Firstly, gene types can be classified according to the grade and importance of rural settlement heritage. In the identification of landscape genes in settlements, Liu classified gene types into main, attachment, mixed and variant gene to distinguish the settlement landscape types [1]. On this basis, the genes of rural settlement heritage studied in this paper focus on other aspects, and the importance of inheritance is combined with the classification of gene types. At the same time, the studies of mixed and variant genes concentrate on the composition and contrast of genetic elements in multicultural fusion areas (Table 3).

Classification standard	Category	Category explanation
Gene Type	Main gene	The core gene elements that occupy a dominant position in the heritage of rural settlements
	Attachment gene	Attachment genes are dependent on the main genes, but they are different from other rural heritage element genes with regional characteristics
	Mixed gene	A genetic element formed under the fusion of various factors in a specific rural settlement
	Variant gene	Due to special factors, genetic elements that have changed some genetic elements but are related to the original genes
Form of Expression	Dominant gene	Genetic elements with material form
	Recessive gene	Non-physical genetic elements
Identification Scale	Macro scale	Rural settlement heritage with regional spatial characteristics and block morphology
	Meso scale	Recognition of residential buildings, main public buildings and other architectural levels
	Micro scale	Material cultural elements such as detailed components and totem signs, as well as influential non-material cultural elements
Construction Method	Extraction element	Important identifiable elements of rural settlements
	Pattern extraction	Extract representative and special decorative patterns or meaningful patterns
	Structure extraction	Elements extraction of structural features such as buildings
	Meaning extraction	Regional expression and construction of non-material cultural elements
	Deduction extraction	Extraction of elements of logical deduction between material culture and non-material culture
Cultural Connotation	Monocultural gene	A rural heritage element that exists in a specific cultural background and has a specific cultural characteristic attribute
	Multicultural Compound Gene	The genetic elements formed by the fusion of diverse cultures and mutual influence

Table 3: Excavating and identifying methods of rural heritage genes in ethnic minority settlement.

Based on the genetic excavation of rural settlement heritage for ethnic minorities, we need to identify corresponding genetic elements. Material cultural genes in main identification methods include environmental factor, layout factor, main public building and residential building, etc. While non-material cultural genes include folk customs, clan culture, Fengshui culture, faith culture and so on. With the establishment of the connection between material cultural and non-material cultural genes, we can find out the logical relationship at different gene levels and deduce the external representation and intrinsic cause of rural heritage gene. So that this method can provide ideas for the construction of genetic map, as shown in Figure 3.

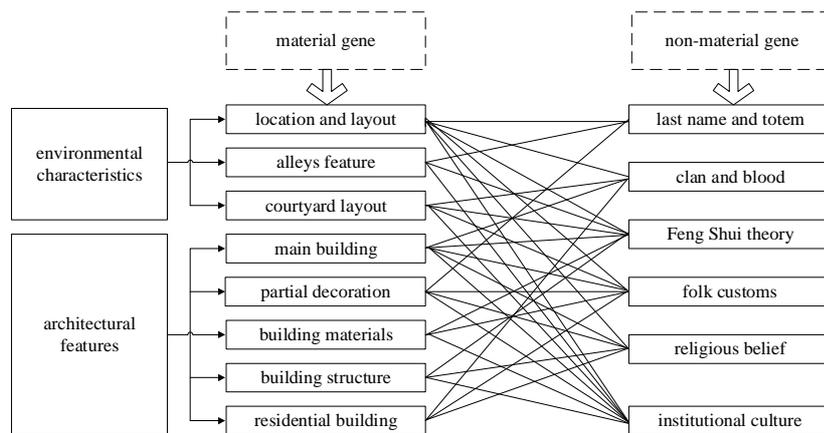
At the same time, gene identification will be carried out from the macro, meso and micro levels according to the scale range. The genetic information corridor was established for the elements with heritage value, and the rural settlement heritage elements were compared horizontally among different ethnic groups. So that we can analyze the genetic variation and genetic influence generated by cultural fusion among multicultural fusion areas, and this is the method of genetic excavation and identification of rural settlement heritage for ethnic minorities, especially the multicultural fusion areas, as shown in Figure 4.


Fig. 3: Logical relationship diagram of material and non-material cultural genes.
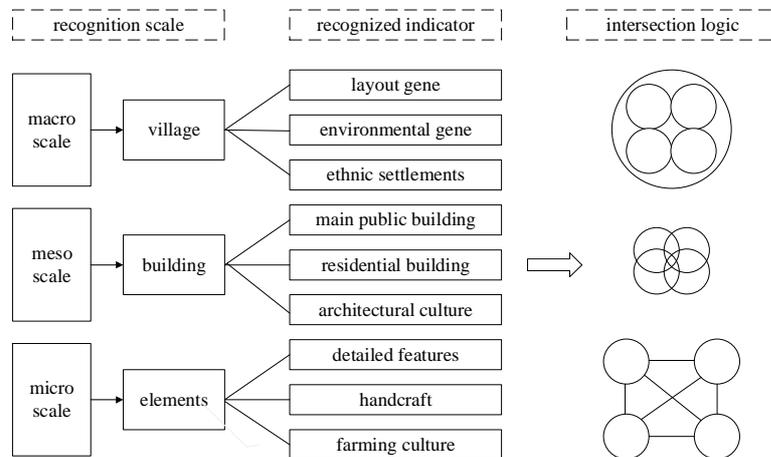

Fig. 4: The relationship between multicultural fusion areas reflected by gene identification at different scales.

In the investigation of rural settlements in Guangxi, we found that the rural population of Han, Zhuang, Miao and Dong is large, and the fusion characteristics among ethnic minorities are distinct, besides, the distribution of rural heritage with research value is wide in these nationalities. In the following sections, four representative villages of Han, Zhuang, Miao and Dong are taken as examples to analyze the important types of material and non-material cultural genetic elements (Table 4). After the analysis and comparison of these four different types of villages, ethnic minority rural settlements have the characteristics of strong centrality, living together in ethnic groups, and paying attention to the environment. At the same time, rural heritage genes retain some representative cultural characteristics, such as the courtyard-style buildings of Han, the phacelloid column square and hanging house (hanging house is a typical stilt style building and usually built on a steep hillside, with the main house on the ground and the other three sides hanging in the air) of Miao, the drum-tower and wind and rain bridge of Dong, and the stilt style buildings of Zhuang. In a word, all these

buildings have certain national characteristics. As various ethnic groups live in the same regional environment, cultural fusion and mutual influence also occur. For instance, Miao settlements occupy the major proportion of settlements in Rongshui Miao Autonomous County, but phacelloid column squares can also be found in some Dong villages due to the influence of Miao culture. In Zhuang villages of Rongan County, people gradually changed the traditional stilt buildings, and tended to build one-floor or two-floor courtyard buildings with cob walls.

Name of the village			Yajiao Village, Dongqi Township, Rong'an County, Guangxi, China	Dali Village, Liangzhai Township, Rongshui Miao Autonomous County, Guangxi, China	Pingmao Village, Gongdong Township, Rongshui Miao Autonomous County, Guangxi, China	Zhangkou Village, Rong'an County, Guangxi, China
ethnic classification			Hang	Miao	Dong	Zhuang
material cultural elements	village environment	location and layout	surrounded by mountains	harmony with site	living by the water	close to the water
		terrain	mountain topography	mountain topography	mountain topography	flat terrain
		landscape	ancient trees	ancient trees and wells	ancient trees	ancient trees
	layout characteristics	form	along the axis	branched form	centripetal form	ring form
		courtyard layout	courtyard style	corridor form	corridor form	corridor form
	architectural features and place	public space	ancient trees	phacelloid column square	phacelloid column square,drum-tower	agritainment
		other landmark buildings and places	watchtower	theatrical stage	Wind and rain bridge,watchtower	bamboo forest
	residential buildings	roof style	flush gable roof	gable and hip roof	gable and hip roof	flush gable roof
		gable shape	herringbone	herringbone	herringbone	herringbone
		decoration	stone carving	woodcarving	woodcarving	stone carving and woodcarving
		material	stone foundation and rammed earth wall	The main body of the building uses wood, but the bottom of the wall is gravel and blue bricks	wood,gravel	soil wall
		structure	courtyard style	Stilt style	Stilt style	courtyard style
		layout form	courtyard style and two floors	bottom overhead	bottom overhead	courtyard style and multi-storey
non-material cultural elements	language		Chinese	Chinese and Dong language	Chinese and Miao language	Chinese
	totem		dragon and phoenix	Miao embroidery	drum-tower	bronze drum
	handcraft		mason	fabric	spinning	brocade
	mode of production		forest fruit industry	agriculture and farming	agriculture	planting rice

Table 4: The identification of genetic elements in representative ethnic villages in Guangxi.

5.2 Extraction of genetic elements

In the extraction methods of genetic elements for rural settlement heritage, the existing studies classified gene extraction into element extraction, structure extraction, pattern extraction, meaning extraction and deduction extraction according to the principles of inherent-uniqueness, external-uniqueness, local-uniqueness, the overall advantages. Among the existing identification and extraction methods of genetic elements, some of the methods can be applied to the research of this paper on heritage elements of ethnic minority rural settlements, but some of them can still be improved. Taking the residential buildings of ethnic minorities as the example, many traditional residential buildings of Zhuang and Miao are mainly in the form of stilt, while hanging houses are more common in Miao settlements. The difference between two types of buildings lies in the extraction of building structure. If the above structure extraction method is used, the difference between two sides cannot be intuitively reflected. If the features of buildings are divided in detail,

local characteristics can be extracted more accurately. As shown in Figure 5 and Table 5, The extraction of genetic elements in residential buildings can be further carried out from the aspects of foot materials, the forms of doors and windows, partial decoration, building materials, roof style, plane structure and so on. In this way, the relationship of genetic elements in the dwellings of different nationalities can be distinguished.

For another example, in the extraction of elements, the unique landmark buildings and characteristic elements of some ethnic settlements will undergo the variation and interaction after cultural fusion, from this point, they cannot be regarded as the unique element features of the nationality. In our interview and research, Anning Village is a Miao village in Chang'an Town, Rongan County, but there is a wind and rain bridge at the entrance of the village. As the main landmark of Dong, the wind and rain bridge cannot be regarded as a sole national feature in such a region. Therefore, in gene extraction method, deconstruction of features can be carried out more meticulously, as a result, architectural, cultural and environmental features can be combined and analyzed in this element extraction method.

Fig. 5: Deconstruction of residential building features.

Serial number	Gene Type	Genetic characteristics
1	foot materials	blue bricks, red bricks, mud bricks, etc.
2	the form of doors and windows	brick carving, stone carving, wood carving, etc.
3	partial decorations	various patterns, decorations and symbols, etc.
4	building materials	crushed stone, wood, soil wall, blue brick, etc.
5	roof styling	Sloping roof, flat roof, gable and hip roof and flush gable roof, etc.
6	plane structure	Courtyard style, single row style, etc.

Table 5: The genetic elements and characteristics of residential buildings after deconstruction

5.3 Construction of genetic map

In terms of the construction of genetic map, it can be divided into plane and facade map, time and space map, entirety and segment map and other expression forms according to different gene types. The establishment of map can reflect the characteristics and laws of genetic elements in rural settlements more intuitively, and can be studied from macro, meso and micro levels. For example, genetic map can be established and studied at the level of rural settlements, villages' cultural heritage and residential buildings. The essence of this method lies in the map expression of genetic elements for representative characteristics after excavating, identifying and extracting the genes in rural settlements. So that we can further distinguish the differences and connections between rural settlements. In our investigation of minority villages in Liuzhou, Guangxi, the plane map was constructed for the representative residential layout among different ethnic groups (Table 6).

6 CONCLUSION AND DISCUSSION

The genetic research and genetic map construction of rural settlement heritage are important research methods for rural settlements in multicultural fusion areas such as Guangxi. This paper studies the logic of cultural fusion and construction method of genetic map for ethnic minority rural settlements in Liuzhou,

Guangxi, and interprets the research methods of rural settlement heritage. As for the actual investigation cases, we selected the representative rural settlements of Han, Zhuang, Miao and Dong to conduct the excavation, identification and extraction of genetic elements, as well as the construction of genetic map, in order to explore the research methods of rural settlement heritage in multicultural fusion areas.

Form	Map	Legend	Characteristic
semi-ring form	hall	hall	The bedroom surrounds the north and east sides of the hall, and the plan layout has a central axis symmetry.
side by side form	hall	hall	The bedrooms are located on the east and west sides of the hall.
open hall form	hall	hall	The open hall at the entrance is combined with the corridor and gatehouse. This is a flat layout formed in order to adapt to the terrain in the residential buildings of ethnic minorities.
Centered form	hall	hall	The main living and functional spaces in the plan are arranged in the center, and the surrounding areas are used as public activity space.

Table 6: The map of representative dwellings for ethnic minorities in Guangxi.

In the ethnic minority settlements of Guangxi, multiculturalism forms the cultural fusion among different nationalities, and forms cultural symbiosis in the same region or in different rural settlements. Thus, "gene" characteristics can be excavated and identified both from the level of material culture and non-material culture. This paper conducts a horizontal and longitudinal comparison of rural settlements. Through the logical and systematic construction of genetic map, this paper provides the direction for the protection of rural heritage and sustainable development of rural settlements, and guides the development of future rural planning in some degree.

This study deals with multicultural fusion areas and marginal rural areas influenced by culture, as well as the material cultural and non-material cultural heritage, and the system construction of the theoretical research involved in this paper still needs to be improved in the future. In practice, the extraction and organization of rural heritage genes contain plenty of contents and elements, and there are great differences among various types of villages. Therefore, the research scope of this paper is limited to a specific regional environment, and the study is conducted on villages that were formed under the multicultural fusion in Guangxi. Meanwhile, there are twelve ethnic groups living in Guangxi for generations. In this paper, four ethnic groups with large population and prominent fusion characteristics are selected as the examples, and the genetic map construction of rural settlement heritage in multicultural fusion areas for other ethnic minorities can be improved in the future.

1 ABSTRACT

In Italy, soil sealing is a major threats in terms of soil degradation and the loss of urban ecosystem services. The increase in new artificial surfaces or settlement areas at the expense of green and rural areas is intensifying the effects of climate change, in particular extreme weather events, such as the increase in intense precipitation and heatwaves. In this context, the Municipality of Padua is a paradigmatic case study. According to the Italian Institute for Environmental Protection and Research (2022), almost 50% of the municipal territory is completely sealed, making it the Italian city with the fifth highest values of soil sealing. To contrast the phenomenon, the EU soil strategy for 2030 suggested, among other strategies, the implementation of Nature-Based Solutions, strengthened with the participation and involvement of non-expert actors to be more efficient and effective.

This study was developed within the Living Urban Parks (LUP) project (Key Action 3, Erasmus + Programme EU) during two years of research and participatory activities (2020–2022) within the Municipality of Padua. It aims to involve youths aged 18–30 in a public process to reconceive of the urban green spaces of the city and to develop ideas and proposals for more sustainable urban planning, promoting participatory methodologies by using geographical tools (digital and traditional cartography).

More than 400 participants were directly involved in the project. All the ideas and proposals mapped during the seminars and workshops have been uploaded to the geoplatform Geocitizen. This geotool is usable on smartphones and tablets and, thanks to its interactive features and a geodatabase, allows the collection of georeferenced ideas, good practices and urban issues regarding green areas and parks. By the end of the project, 118 points had been collected on Geocitizen. Beyond the Geocitizen platform, the participants had the opportunity to test other geotools, such as Geopaparazzi and Google Earth Pro. In addition, the participants were able to present their ideas collected on the platform and directly interact with the local decision-makers who were involved to discuss and promote effective and efficient actions for the enhancement of the green areas and urban parks of the city. The use of different geographic technologies combined with participatory mapping approaches allowed an increase in the knowledge of the urban territory by making people more aware of the issue of soil sealing and urban regeneration opportunities. Finally, LUP allowed to reconception and design of green spaces to promote the restoration of degraded and abandoned areas and to propose the implementation of Nature-Based Solutions.

Keywords: geographical tools, green areas, participatory approach, Nature-based Solution, Soil sealing

2 INTRODUCTION

2.1 Nature-based solutions in the urban context: Strategiesto mitigate soil sealing

At present, soil sealing is one of the major threats in terms of soil degradation and the loss of ecosystem services in urban and rural contexts. It is considered one of the main forms of land take by the increase of new artificial surfaces at the expense of green and agricultural areas. This phenomenon is intensified by local

effects of climate change, in particular extreme weather events, such as intense rainfall and heatwaves. The scarcity or lack of permeable and vegetated surfaces can drastically affect the urban drainage systems and can exacerbate the urban heat island effects during heatwaves (Todeschi et al., 2022; Pappalardo et al., 2023). In addition, it decreases other soil functions and ecosystem services, for example, carbon sequestration, microclimate regulation, groundwater reserves, biodiversity and food production (Peroni et al., 2020).

According to the EU soil strategy for 2030, a hierarchy to contrast land take is identified in the pathway of four key actions: i) avoiding new soil sealing, ii) reusing surfaces and soil that are already sealed, such as abandoned or underused buildings and areas, iii) minimizing by using infertile agricultural areas and iv) adopting compensation or mitigation measures and strategies to reduce the loss of soil functions and its ecosystem services (European Commission, 2021). In addition to the four actions of the EU soil strategy for 2030, the adoption of mitigation measures to restore ecosystem services through the implementation of Nature-Based Solutions (NBS) is also encouraged. The strategy promotes cooperation with nature to address societal challenges and provides benefits for both human well-being and biodiversity by using, for example, green roofs, green facades, green buildings, urban forests and community gardens. Moreover, NBS could be utilised as a tool to restore urban brownfield sites by renaturalising or 'greening' these areas. Finally, the design and the process of the implementation of the NBS could be improved with the participation and involvement of citizens to be more efficient and effective. As reported by the European Environment Agency Report on NBS (EEA, 2021), some case studies present the co-creation of NBS by involving local communities and stakeholders, as, for example, the creation the green roofs in France and Germany. Thanks to citizen participation, the quality in urban NBS has fostered a higher degree of multifunctionality in the solutions than the NBS built by urban planners or architects.

2.2 Objectives

The study aims to test the participatory methodologies and technologies to involve youths and non-expert actors in re-thinking urban green spaces to identify abandoned buildings, brownfields and urban parks and to develop ideas and suggestions to restore these spaces by proposing NBS or other strategies. The participatory methodologies are based on the use of geographical tools combining digital and traditional cartography and mapping tasks on paper and in the field with Geoapp.

The specific objectives are as follows: i) to involve non-expert actors, in particular young people, in urban sustainability issues, such as soil sealing and in mitigation measures, ii) to spread the use of geotools for an increase in geographical knowledge of the urban territory and iii) to increase the empowerment of participants regarding their awareness of urban regeneration and planning.

2.3 The Living Urban Parks Project

This study was supported by the Living Urban Parks (LUP) project (Key Action 3, Erasmus + Programme EU). LUP was developed during two years of research and participatory activities between January 2020 and January 2022 within the Municipality of Padua. The project was implemented by the Italian NGO L'Osteria Volante in collaboration with the Municipal Administration of Padua and the research group Climate Change, Territory, Diversity, Department of Civil, Environmental and Architectural Engineering (ICEA) of the University of Padua. A participatory mapping approach was adopted to create a formative pathway and raise awareness among the participants regarding different issues (soil sealing, soil policy, climate change, NBS etc…). The results of the participatory mapping were shared with the different actors (NGOs and researchers) that are developing bottom-up designs and proposals to promote the implementation of NBS and sustainable planning in the green areas and urban parks. Moreover, LUP allowed the participants to have a greater knowledge of the importance of urban parks and green spaces in Padua through the use of geotools and urban walks and events within the parks and green areas. This paper is organised in six sections. The third section is an overview of the general aspects related to the participatory methodologies through the use of information and communications technology (ICT) and geotools, presenting their possible purposes in the context of sutainable urban planning and urban regeneration with the involvement of youths aged 18–30. The fourth section presents the geographical context and the methods and technologies employed during the project. The fifth section shows the results of the project and a critical reflection on the participatory process. Finally, the sixth section highlights some observations that can be takenfrom this study.

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

3 PARTICIPATORY METHODOLOGIES FOR THE IMPLEMENTATION OF NATURE-BASED SOLUTIONS (NBS)

Until recently, the main sources and producers of spatial data were governmental agencies, cartographic centers, private companies and local policymakers; indeed, high fees and copyright restrictions were a barrier to more widespread access to geodata (Arsanjani et al., 2015). However, in previous decades, the development of ICT and geomedia completely changed the methods of mapping and collecting spatial data, shifting them from a completely professional activity to one involving the engagement of non-experts (See et al., 2016). In particular, the emergence of open-source software and the lowered cost of the equipment played a key role in democratising the access to ICT (Gatti and Zanoli, 2022).

Hence, different terms have been created to refer to the involvement of citizens in the activities related to data collection and community participation, such as 'citizen science', 'neogeography' and 'crowdsourcing'. These terms are usually classified by considering the active or passive contributions from the citizens and the type of collected data, for example, spatial or no spatial data (See et al., 2016). In this context, citizen science is an umbrella term that refers to the involvement of non-expert audiences that contribute to research activities. In most cases, citizen science improves the research by increasing the amount of data collected or granting access to situated knowledge (Pristeri et al., 2019). Simultaneously, participants can increase their knowledge of specific research topics, learning the use of new tools, acquiring new skills, adding new value to the research and better understanding the scientific work in an appealing way. Hence, citizen science represents a unique opportunity to connect citizens to contribute to sustainable urban planning issues by collecting and analysing new data. For example, some studies have demonstrated how citizen science could contribute to the introduction, implementation, management and monitoring of NBS (Restemeyer and Boogaard, 2021).

Finally, if the collection of spatially explicit data is oriented for public purposes, the scientific community refers more specifically to the term Public Participation GIS (PPGIS), defined as the field within geographic information science that focuses on ways the public uses various forms of geospatial technologies to participate in public processes, such as mapping and decision making (Tulloch, 2014).

4 METHODOLOGY

4.1 Geographical Framework

The city of Padua is located in the Veneto region in the northeastern sector of Italy (see Figure 1). The municipal territory spans 93 km² with almost 210,000 inhabitants. Since the last decades of the 20th century, due to demographic growth and new needs linked to economic and industrial development, many low-density residential buildings sprawled throughout the urban core at the expense of green or cultivated fields, as in many other European cities (Peroni et al., 2020). This caused the spread of mixed rural-urban neighborhoods driven by the presence of industrial or commercial complexes and infrastructures. As a result, the Municipality of Padua reflects 49,6% of its territory covered by impervious surfaces (ISPRA, 2022). Among the various impacts of soil sealing, urban heat islands are becoming a serious risk for the local population, particularly the elderly (Todeschi et al., 2022). Moreover, there is also a scarce presence and unequal distribution of green and vegetated spaces. Indeed, only 10% of green areas are municipal and open and accessible to the public. In addition, studies report a low quality of the urban green spaces, with some neighborhoods with only 2.5 m² per capita (Pristeri et al., 2021).

4.2 The Participatory Mapping Process

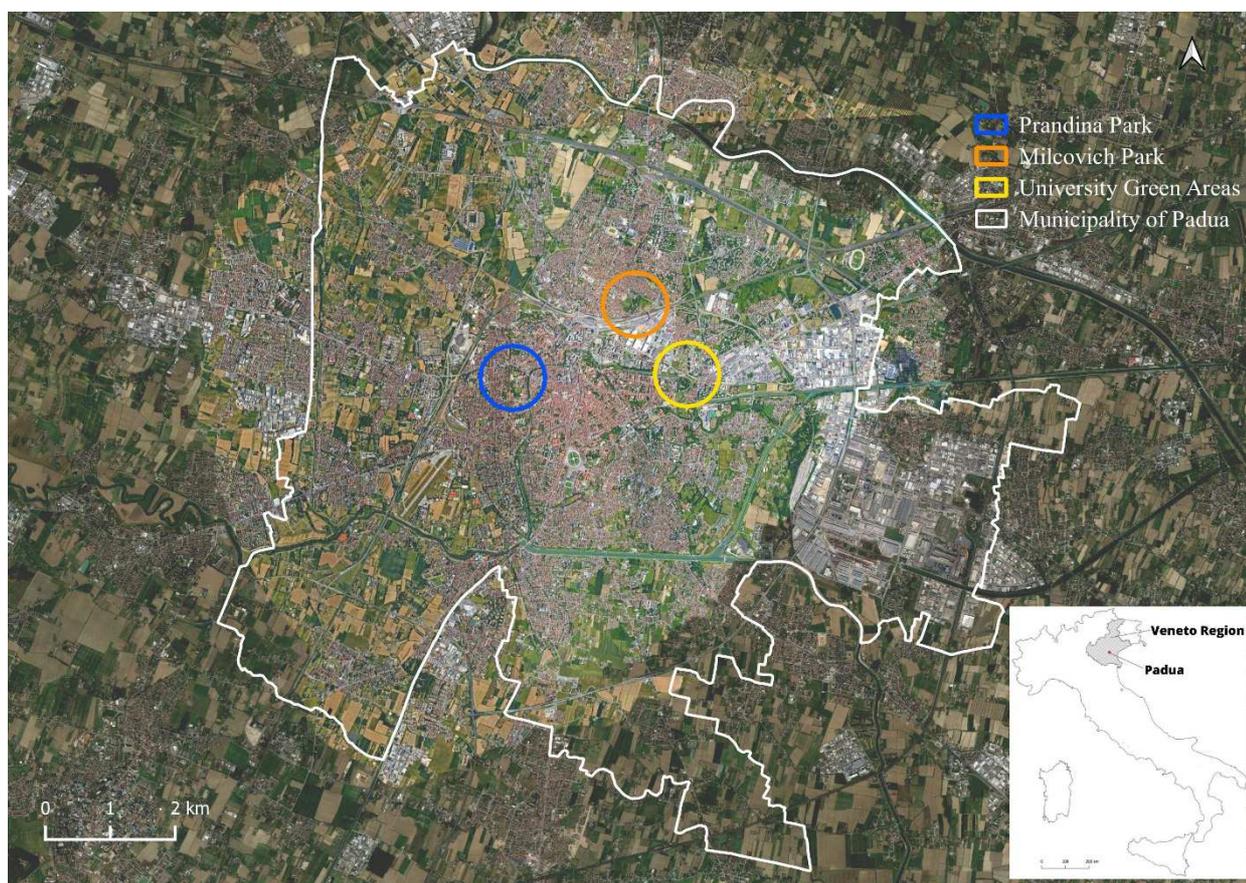
The involvement of young people was achieved by adopting different participatory methodologies with the contribution of some specific geotools: i) urban walks and in-site laboratories to know the territory of the city and to better understand specific urban management issues and ii) the geo-app Geopaparazzi and the geo-platform Geocitizen to map, collect spatial data and create ideas and proposals to implement and restore the degraded or underused urban green areas of the city.


Fig. 1: The Padua municipality with the three study cases thatadopted the participatory mapping process

The participatory mapping activities led by the researchers from the University of Padua were developed during nine events that were open to the public. Each event started with an in-site workshop focused on the LUP project, its importance in promoting urban sustainability and the design of possible NBS. The workshop also included a contextualisation of the area in which the activity would take place (usually an urban park) and, in some cases, an historical excursion. Each time, the participants received an introduction to the geographical tools needed. In addition, a test trial was carried out to ensure the capacity of the participants to use the geotools efficiently. Each workshop focused on one topic related to sustainable urban planning, such as soil sealing, climate change, the importance of the ecosystem services provided by the green areas and the possible restoration and implementation with NBS.

Six events dedicated their second part to the presentation of the Geocitizen platform and to the collection of data. The remaining three events had their second part dedicated to an urban walk with the participants through three different areas of the city: i) the university green areas in the Portello neighborhood, which is a key area for university students, ii) the Milcovich Municipal Park, located in the north sector of the city and closed to the train station and iii) the Prandina Park, in the city center (See Figure 2).

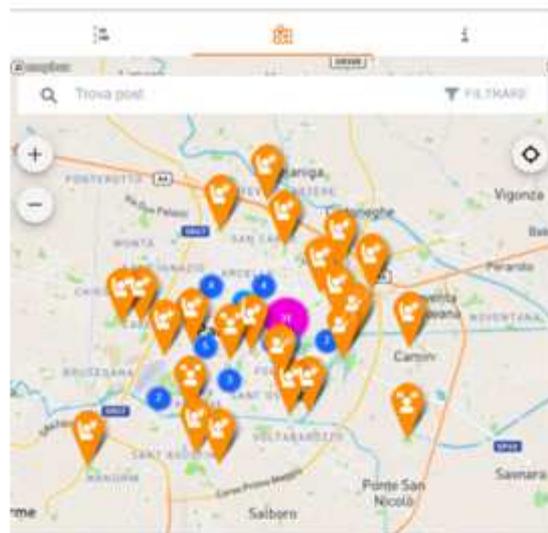
The first area was selected on the basis of the presence of a large number of young people, mainly students. They mainly live in this neighboorhood and are familiar with the area, its advantages and problems. This aspect is crucial to implement the effective and successful collection of proposals and ideas. The Milcovich Municipal Park was selected as a best practice location supported by the municipality. Indeed, years ago, good management and a dialogue with the public administration enabled the restoration of the area that was completely underused and now it is one of the most popular parks in the city and hosts various socio-cultural initiatives. The last area, the Prandina Park, an ex-military zone, at present hosts one of the few urban forests within the city walls. It was chosen as a location due to the intense public debate within the city regarding its future uses.

4.3 Geotools and methodologies for the participatory process

Urban walks are a well tested method in geographical research to support the sharing of people's perspectives regarding different aspects of the cities they live in (Husar et al., 2020). Walking through places

666

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Edoardo Crescini, ,Francesca Peroni, Francesco Facchinelli, Giuseppe Della Fera, Daniele Codato, Salvatore Pappalardo, Massimo De Marchi


allows discussion on the basis of a direct contact with spaces, integrating the stimuli of all the human senses. During the participatory process, urban walks succeeded as a way to collect data from the ground and as a method for the participants to elaborate and share their ideas. Notably, the two processes became intertwined, resulting in data collection that evolved and changed according to the proposals of the participants while they took part in the construction of the same proposal.

Fig. 2: Identification and geographical details of the three study cases selected for the PPGIS process

During the urban walks, the open-source and open-access mobile app Geopaparazzi was used. The app was developed in 2010 from HydroloGIS to facilitate GIS data collection (HydroloGIS, 2023). GIS data collection allows the user to access and edit spatial data during fieldwork with the support of smartphone GPS functionalities. Geopaparazzi was used to elaborate proposals on how to reconceive of the green spaces within the case studies by suggesting possible NBS. Finally, Google Earth Pro was used to visualise the collected data allowing a better understanding of the points' locations and assessment of their quality.

Geocitizen is a geotool that allows the implementation of participatory processing in which users can propose spatially referenced ideas and comment on the suggestions of the others participants. It is available both as an online platform and a mobile app and it was built in collaboration with the Fundación Centro de Competencia Educativa para Espacios Comunitarios (Ecuador). In the participatory process of the LUP project the Geocitizen platform (https://app.geocitizen.org/lup_padova) worked both as an informative tool that allowed interactive access to various cartographies of the Padua municipality as the main container of the mapped points and as a place to debate the suggestions among the participants through the comment function. The mapped points pertained to four different categories (or tasks) corresponding to: i) ideas to improve the urban spaces (idea task), ii) good practices carried out by the local population (good practices task), iii) existing problems within the spaces (problem task) and iv) questions for the local policy-makers (question task) (see Figure 3). As an online platform, Geocitizen collected data both from the youths who participated in the in-site laboratories and the urban walks and from a larger audience of users not directly involved in the activities but still interested in sharing their perspectives.

Fig.3:a) Screenshots of Geocitizen with examples of different tasks (idea, problems and best practices);b) a possible good practice to be implemented along the embankment of the San Benedetto Riviera for recreational and sports activities; c) a problem mapped near the station of a disused green area; d) and e)two ideas for using abandoned green areas, respectively the activationand promotion ofsocio-cultural activities, and the safeguarding of the riverbank biodiversity that presents several species of birds.

5 RESULTS

This study featureed a high participation of young people. More than 400 participants were involved and were able to approach and understand geographical concepts and issues related to sustainable urban planning. In general, the LUP project achieved two main results: the first concerns the use of geographical instruments and geotools by non-experts and young people to collect spatial data related to urban territory

668

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

and its green areas. From a practical point of views, the second outcome is related to the direct involvement in the participatory mapping process (PPGIS) of young people to address issues such as soil sealing, climate change and the possible measure and actions for more sustainable and inclusive urban planning focused on the improvment of green areas, including discussions with decision-makers of the municipality. Furthermore, the approach to the use of ICT and new geographic technologies allows participants to develop new skills and to explore the importance of geographical data in the perception of the territory and the creation of possible proposals to enhance its local context.

5.1 The Geocitizen Platform

The Geocitizen platform represents a useful and powerful tool for spatial data acquisition, providing to local decision-makers opinions and ideas from young people. In total, 118 points were collected and 97 were georeferenced. The majority of them are related to proposed ideas (83%), suggesting a desire to rethink the mapped urban spaces, for example, green areas, urban parks, empty or abandoned spaces and buildings, stream buffers or ecological pathways. The ideas and practices proposed by the youths in this task aimed to achieve a more sustainable city and developing NBS by introducing community gardens, food forests or bug hotels.

All the proposals are related to the improvement of the quality of life through the increase of different ecosystem services. The cultural and social services were the most cited, as well as the regulating and supporting ecosystem services. For example, one idea was proposed to deseal an empty space to create a green area and to implement different ecosystem services by introducing NBS. In addition, other ideas were related to the restoration of green spaces that are abandoned, badly managed or lacking basic equipment, such as benches, tables and drinking fountains. Moreover, the participants highlighted that these lacks often lead citizens to not frequent these areas and thus waste the green areas that could be used for both recreational and sporting purposes.

Many of the collected points concerned river banks or ecological corridors along the water network of Padua. These ideas emphasised the need to create health trails to improve and facilitate outdoor sports activities. Other ideas concerned the preservation of biodiversity, especially related to the avifauna that can be observed along the ecological corridors and canals of the city. The young people suggested restoring some buildings near these areas that could be transformed into birdwatching stations. This idea has a twofold function: the first is to bring citizens closer to the local fauna, which is often unknown, and to understand in a different way the importance of green areas in the city. The second is linked more to tourism as a natural attraction for visitors.

The category related to good practices, reporting virtuous experiences throughout the city, and represented 13% of all the mapped points. These examples allowed the effective and efficient valorisation of specific green areas of Padua with the help of civil society organisations, strengthening different ecosystem services. An example of good practices reported by the participants could be the presence of different agroecological farms in Padua or the requalification of green spaces promoted by different stakeholders and NGOs.

The points mapped as issues to be managed by public authorities (14% of the total) were mainly focused on proposals regarding the restoration of the urban parks and green areas that are totally abandoned, as well as agricultural fields. Another issue was related to the scant valorisation of the ancient city wall system of Padua that are an important cultural heritage and tourist attraction; the walls system includes green areas that are underused at present.

Finally, the last category concerns question tasks that were mainly directed toward knowing whether or not there are any projects to restore or rehabilitate various green areas or infrastructures located within the parks.

5.2 Urban walks with Geopaparazzi

During the urban walk activities, the collection of spatial data and the process of re-thinking urban green spaces were conceived through different geographical tools, from the use of cartography to the geo-technologies such as Geopaparazzi and Google Earth Pro. These geotools increased the engagement during the urban walks and stimulated the participants to use the 'eye-thinking approach' by adopting a double view of the study areas – from below through their own eyes and from the top through the use of cartography and aerial images (see Figure 4).

Fig.4: The photos show some examples of data collection usingGeopaparazzi and Google Earth Pro for the visualisation and the PPGIS activities

The first urban walk was performed in the Portello neighborhood within the university green areas. During the urban walk, the two parks closed to the university green spaces, the Parco Europa and Parco Venturini-Natali, were also crossed and surveyed. The proposals mapped by the young people during this activity mainly concerned the regeneration of the infrastructures and abandoned areas along the urban walk. In addition, a restoration of the Piovego canal banks was proposed with naturalistic dissemination paths presenting the flora and fauna. In addition, the possibility was proposed of transforming the area during the spring and summer seasons into a study area with the installation of temporary structures such as geodesic domes to encourage outdoor teaching activities.

Prandina Park is at the center of an important decision-making process, since the southern area of the park is now used as a car park; currently, the administration seems to be planning to increase the number of parking spaces in the next few years at the expense of the present green area. In this area, the participants proposed a series of very promising interventions for the management of urban greenery and ecosystem services. Among these, one of the most interesting included a redevelopment of the car park area with temporary architectural structures, such as exhibitions, art shows and local markets, in order to turn it into a place of

670

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Edoardo Crescini, ,Francesca Peroni, Francesco Facchinelli, Giuseppe Della Fera, Daniele Codato, Salvatore Pappalardo, Massimo De Marchi

aggregation for the city and to create new local economies. Moreover, the participants proposed to better equip the green area with benches, fountains and a dog area in order to transform it into a multifunctional space. Some ideas proposed to restore and safeguard the urban forest, with the involvement of the NGOs that are already active in the park, into a hotspot area with high biodiversity.

During the last urban walk, performed in the Milcovich Park, the participants developed proposals aimed at increasing the services and activities offered by the area. For example, an open-air cinema was proposed for the centre of the park, which is often not utilised. The creation of a bridge in the eastern sector would connect the park with the surrounding neighborhoods, allowing for greater attendance. Finally, the expansion of the area designated for urban gardens was also proposed with the possibility of creating an educational farm with the introduction of beehives.

5.3 Geographical Approach and Geotools in Sustainable Urban Planning

The use of different technologies allowed the understanding that geotools could be suitable according to the activity planned and the context in which it is used. For example, Geopaparazzi works very well for urban walks and less so as a point collection hub to support a dialogue with the public administration. The Geocitizen platform in that case is more effective, allowing social network interactions with reactions and comments and allowing the discussion of the different proposals directly online.

Furthermore, thanks to geotools, it is possible to strengthen the spatial skills and geographical awareness of the participants. In addition, this type of activity brought them closer to relevant topics, such as soil sealing and the importance of safeguarding and increasing the size and number of the urban green areas, while also presenting the guidelines that have been published and promoted by the EU as the EU soil strategy for 2030 and, thus, an acquisition of the geographical and notional knowledge that allows higher quality data collection.

Finally, this study emphasised the importance of developing and supporting such methodologies in the urban environment, not only to produce open-access spatial data and collect geographical information, but also to make the decision-making processes more inclusive and to turn non-expert actors into active participants who create data and participate in the rethinking of urban spaces. These practices also enable the development of more effective and efficient sustainable urban planning and the design of NBS with a variety of environmental and social benefits.

6 CONCLUSIONS

This study highlights the importance of the production of geodata through the implementation of citizen science and the PPGIS approach in an urban context to design and implement adaptation, compensation or mitigation measures in reducing the loss of ecosystem services mainly caused by the soil sealing phenomenon, and improve sustainability and well-being in the cities. The activities promoted in LUP through the testing of different geotools allowed the reconceptualization of some of the green spaces of Padua, promoting the implementation of NBS. Moreover, other ideas were proposed to realise the multifunctional green spaces directly by youths and non-experts actors. The LUP project is an attempt to enhance bottom-up participatory processes for the promotion of more inclusive decision-making processes that aim to involve local communities, their perceptions and visions in order to operate more effectively within the areas in which mitigation and adaptation actions are taken.

The Community Gardens and Kitchens, and their Contribution to the Social Development of the Marginalised Areas in Berlin: the Case Study of Beettinchen Community Garden

Hellen Aziz

(MSc. Hellen Aziz, Kassel University, Berlin, hellenaeem7@gmail.com)

1 ABSTRACT

Over history, food was an essential element in the cities' establishment, and it has had a huge effect on their location, urban context, culture, economy and social network. Urbanization facilitates and improves the physical access to food due to the efficient infrastructure, however the residents of the marginalized areas have vulnerable relationships with food, in addition to other socio-economic problems. That all increases the need for alternative food systems to reduce the distance between the producer and the consumer, and contribute to food security in those marginalized areas. These community food security projects, such as the community gardens and the community kitchens, have become a growing international movement, especially in the developed countries. They have been established, involved and managed by the community members, which followed the bottom up approach. They have been used by the state and civil society as activities to develop the marginalized areas. This paper aims to understand how community kitchens and gardens can be integrated as a vital element of urban development of the marginalized areas in Berlin, through analyzing the empirical aspects including the organization and the governance of these projects, the ownership of the used land, the motivation of the people who participate in these projects and to what extent they benefit from these projects, from the social aspects. The paper presents the case study; "Beettinchen" community garden in Märkischen Viertel in Berlin. The analysis is based on literature research, interviews, study visits and observations. This paper is a part of the author's ongoing PhD research about the community kitchens and gardens in Egypt and Germany, and how they can contribute to the urban development of the marginalized and vulnerable areas.

Keywords: marginalised areas, kitchen, garden, community, Berlin

2 INTRODUCTION

Food plays an important role in our life, not only through nutrition, but it contribute to the cities' development, including their urban context, culture, economy and social network, in addition to defining the urban layouts such as the internal land uses, roads, public spaces and buildings (Bricas and Conaré 2019; Salvador 2019). For example, the markets and slaughterhouses were located in the city centres (Bricas and Conaré 2019). However, this distance between cities and food increased over time because of globalization, and modern trade (Nuetzenadel and Trentmann 2008; Haysom 2015). Community gardens and kitchens are examples of the projects that follow the alternative food system, attempting to decrease the distance between the producers and consumers. Moreover, they are community based projects that focus more on community engagement, and participation. The paper aims to explore and understand the social contributions and effects of the community garden and kitchen projects in the marginalized areas, through analyzing the case study of Beettinchen community garden in Märkisches Viertel in Berlin, which is a neighborhood with large refugees' accommodation. As this paper is a part of the author' s PhD thesis "The community gardens and kitchens , and their contribution to developing the marginalized and vulnerable areas, in Germany and Egypt", it is exploratory research, and there will be a more structured follow-up research.

3 METHODOLOGY

This research is a part of the author's ongoing PhD research about the community gardens and kitchens and their contribution to the urban development of the marginalized and vulnerable areas in Egypt and Germany, under supervision of Prof. Uwe Altrock, from Kassel University, the Urban Development Department. This paper is based on a qualitative approach, aiming to understand the community garden and kitchen projects, and explore their impact on social patterns through analyzing case studies in Berlin. To identify the development patterns that include a local social perspective, a mixed-methods approach was applied.

First, reviews of secondary literature were used to understand the concepts of community gardens and kitchens, in addition to the food system in Berlin. Furthermore, Data collected from fieldwork, observation, interviews, and photography were utilized to analyze the chosen case study. The Beettinchen community

garden is chosen as an interesting case study due to many reasons, it includes different types of community gardens on the same land, as some people rent their own plot while BENN has two plots for the community to plant them together. In addition, it is a good example of a garden with a kitchen so it could help to understand the relationship between community garden and kitchen. Moreover, it is located in Märkisches Viertel, one of the 16 neighbourhoods with large refugee accommodations that includes BENN, Berlin Entwickelt Neue Nachbarschaften (Berlin Develops New Neighborhoods) program offices. BENN is a program of the Berlin Senate Department for Urban Development, Building and Housing to strengthen integration, neighbourly cooperation, social cohesion and participation (Senatsverwaltung für Stadtentwicklung, Bauen und Wohnen 2023).

Fieldwork included 5 site visits to the Beettinchen community garden in May and June 2023. Additionally, 12 semi-structured interviews were conducted to uncover the garden's governance system and organizations, the motivations of the users, and its impacts on their social life. The interviewees included the garden's tenants, visitors, and representatives from the involved organizations in the garden's management. The interviews focused on the garden's system, the users' motivation including the tenants and the users, their activities in the garden, and the governance system. Because the interviews consisted of open-ended questions, the duration was different from one interviewee to another but it was between 10 to 30 minutes.

One of this research's limitations is the time, as most of the community gardens and kitchens in Berlin are active only in summer starting in May due to the weather, and most of them only organize one event per month, which made it difficult to analyze a community kitchen example. Moreover, one of the case studies mentioned before in the submitted abstract has been excluded from this paper because through the analysis, the author discovered that the case study of the project "Make the neighborhood greener" in Beussel- and Huttenkiez in Moabit, Berlin, is about urban agriculture activities more than about systematic community gardens and kitchens which is the focus of this paper. Even with those limitations, the modified project framework produced relevant findings which are presented below.

4 LITERATURE REVIEW

4.1 Alternative Food Systems

Food System is a concept that illustrated all procedures involved in providing food for a population, including 5 stages : production - processing - distribution - consumption / food culture - disposal, beside the input-/output procedures and resource flows (Giseke et al. 2015; Kasper et al. 2017; Jennings et al. 2015). The alternative food system aims to improve the traditional food system through reducing the distance between the producers and the consumers (Campbell 2004). The alternative food systems include different aspects such as sustainable urban agriculture, local and regional food, and farmers' markets.

4.2 Community gardens

Community gardens are a type of urban agriculture's practices or activities. Urban agriculture is defined as "the growing of plants and the raising of animals for food and other uses within and around cities and towns, and related activities such as the production and delivery of inputs, processing and marketing of products." (Mougeot, 2005). Furthermore, the community garden is a plot of land in an urban area that is either communally or privately farmed by a group of residents from the nearby neighbourhood (Veen 2015), so food and plants will be grown on a shared setting. This concept of community garden first appeared in the United States of America in the 1890s due to an economic crisis. (McKelvey 2015; Grace 2022; Kurtz 2007), and it represents an important resource for food security during World War I and II (Grace 2022). Moreover, Europe has a long history of allotment gardens, which people rent as small plots for the purposes of food growing and recreation (Brown 2008), and they are considered a type of community gardens (Veen 2015). They started in the United Kingdom in the 18th century and in Germany in the 19th century (Keshavarz and Bell 2016; Drilling et al. 2016). In addition to allotment gardens, the modern community garden (CG) movement began to gain momentum in Europe in the mid- to late 1980s. In the 1990s, it also became widespread in Germany (Meyer-Rebentisch 2013).

Community gardens have a lot of social benefits as they are mainly built on engagement, and participation. (McKelvey (2015) and Firth, Maye, and Pearson (2011) stated that community gardens enhance the feeling of identity, ownership, and stewardship, since they provide a venue for people of all backgrounds to interact

674

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

and share cultural traditions. Moreover, they increase the sense of belonging, especially for newcomers and immigrants (Agustina and Beilin 2012).

4.3 Community Kitchens

Community kitchens are defined as "community-based cooking activities in which small groups of people meet regularly to prepare one or more meals together" (Tarasuk and Reynolds 1999). The community kitchens could be commercial or non-profit initiatives (Conservation Law Foundation, Dewey, and Fink 2018), and food there is usually produced in huge quantities by combining labour and resources (Tarasuk and Reynolds 1999). The community kitchens are different from food aid programmes because of their participatory structure and capacity to enhance mutual support (V. Tarasuk 2001). The concept of community kitchen was first initiated in Latin America (Kalina, Sheryl, and FoodShare 1993; Andreas 1989; Ripat 1998).

5   BERLIN'S COMMUNITY GARDENS AND KITCHENS

Berlin is a city with a lot of food activities, including community gardens and kitchens. Berlin has a long history of community gardens that spans more than 30 years, with a major grassroots movement that had its roots in the early 2000s (Beck 2021). There are 99 community gardens, mapped in Berlin in 2013 (Berliner GartenKarte 2023), as shown in figure 1, and they increased over the years as according to Beck (2021), the number of community gardens in Berlin reached more than 200 gardens in 2021.

Figure 1: the community gardens in Berlin in 2013 (source: Gartenkarte, 2023)

They have various scales, purposes, and organization systems. Regarding the scale, they vary from the large agricultural plots in the outskirts of Berlin such as the Bauerngarten in Pankow (Bauerngarten 2023), to the normal scale of neighbourhood community gardens such as the BrunnenGärten community garden (gruppe F 2023), and even to smaller scale community gardens that focus on the building or the block as GIDAK which is located in the courtyard of a former brewery site "GIDAK-Hof"in the middle of the cooperative at Saarbrückerstrasse as shown in figure 2 (Cityplot 2023). Moreover, the community gardens in Berlin have various purposes and aims. Some gardens focus on the environmental aspect and the ecological diversity,

while others focus on the educational aspect and how to share and transform knowledge and experience about agriculture, such as Maxim Climate-Garden for youth education in Pankow (Urban Abroad 2022). In addition, other community gardens are created because of social purposes, in order to create meeting points for the residents and to provide open space for newcomers and refugees such as Garden of Hope (Bustan El Amal) which is even named in the Arabic language (Grünanteil 2017).

Furthermore, in Berlin, there are a lot of initiatives related to community kitchens, which could be divided into collectives and projects (AWC SYLLABUS 2021). An example of the collectives is LebensMittelpunkte, which is a network that gathers 27 initiatives all over Berlin. These initiatives are locations with three categories of self-organized neighbourhoods' activities (LebensMittelPunkte 2023a):

- the "Depot" which focuses on storing and distributing food,
- the "Küfa" kitchen, which focuses on cooking together, and
- the "Kiez" neighbourhood, which focuses on empowering the people in every neighbourhood.

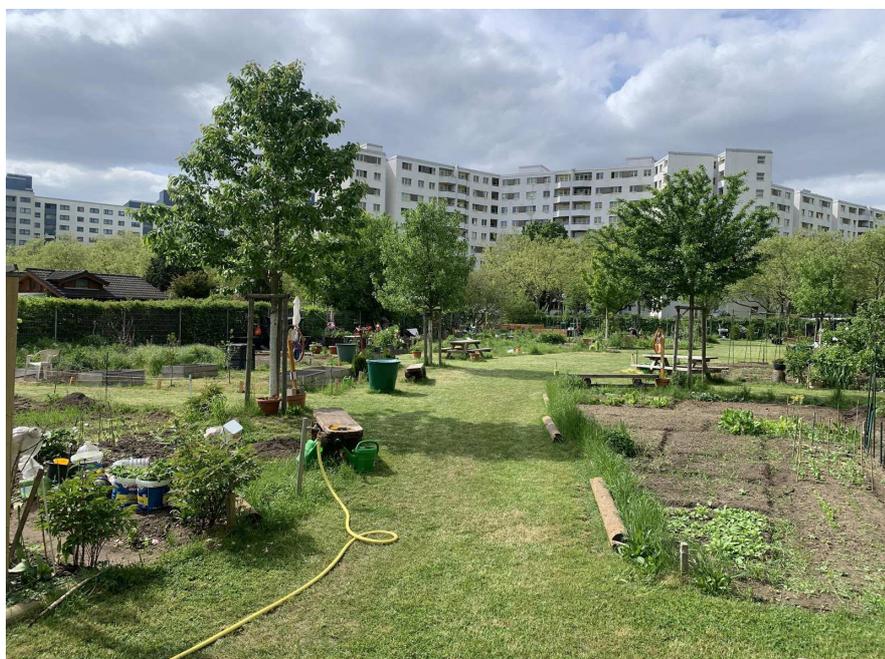
Four initiatives are regular "ready-to-use" food centre points in Mitte (LebensMittelPunkte 2023b). They are: "Baumhouse" in Wedding, "Offenes Wohnzimmer" in Moabit, Haus der Statistik", which is an old historical building complex, and "Culture Laboratory Trial & Error", and all of them offer community kitchen regularly once a month (LebensMittelPunkte 2023b). Moreover, Open Kitchen is shown as a great example of the community kitchen projects, as the Open Kitchen has been offering social cooking sessions on a regular, weekly basis in the form of a meet-up at Refugio in Neukölln since the summer of 2017 (Open Kitchen 2023). The Open Kitchen project focuses on cooking with refugees (Open Kitchen 2023), similar to other community kitchen projects in Berlin such as the "Refugees' Kitchen" which is a mobile kitchen, created through a partnership between artists and refugees (Refugees' Kitchen 2023). Furthermore, over the last few years, the connection between the community gardens and kitchens has increased, and there are many old projects of community gardens which have added the concept of the community kitchen to their structure. For example, the Prinzessinnengarten Café & Restaurant depends on the harvest of the community garden in addition to small local organic farms in Berlin. It is an example of the commercial community kitchen which stipulates that all its sales of food and drinks will go to the non-profit community garden project ('Garden Cafe | Princess Garden Collective Berlin' 2023)


Figure 2 : the plots of the garden and a path between them (source: author)

6 THE CASE STUDY: BEETTINCHEN COMMUNITY GARDEN

The Beettinchen community garden is an intercultural neighbourhood garden in the Märkisches Viertel in Berlin-Reinickendorf. It was founded in 2013 in the old location at Bettina von Arnim School. It relocated in 2021 to its current location at Treuenbrietzener Straße 32, next to the allotment gardens (Monzer 2023). The

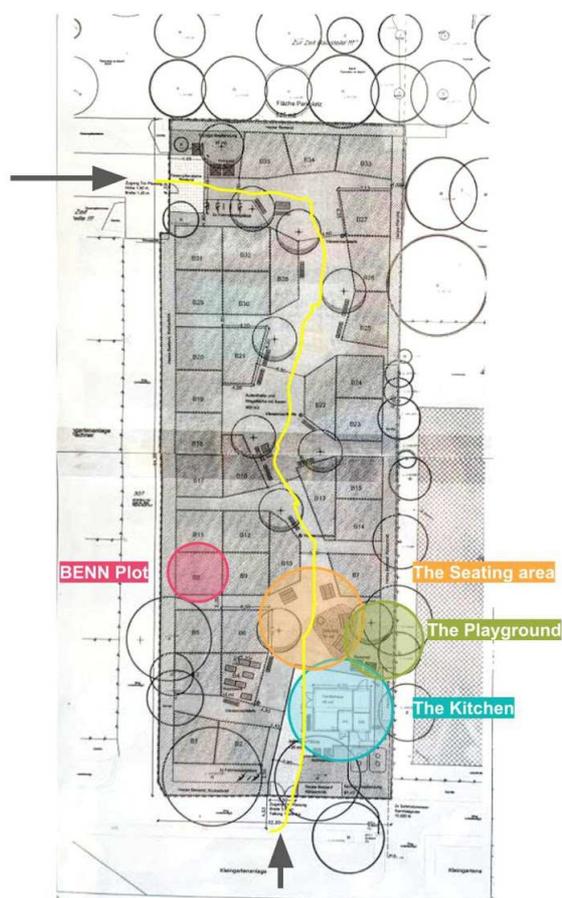
garden is easily accessible to the public because there is a bus stop just in front of it. The garden has two entrances, one from the parking spaces in the main street and another from the allotment gardens in the back. The garden has a total area of around 300 m2 (Skowronek 2023) and is divided into 35 plots, each of which is 39 m2 (Spremberg 2023), as shown in figure 2 and figure 3. The plots are rented out to tenants and there is a path between the plots. Based on the author's observations, there is a small kitchen facility which is usually opened for the tenants to use. Moreover it is used by the whole community in the grilling event organized by Albatros or in the summer harvest event in September by BENN. Furthermore, there are other facilities such as toilets, a small children's playground, and a seating area with 5 to 6 benches and tables next to the garden plots, as shown in figure 3 and figure 4.


Figure 3: the plan of the garden, illustrated the entrances, the path, the kitchen, the seating area and the playground (source: GESOBAU, 2018, edited by the author)

Figure 4: the seating area and the playground (source: author)

6.1 The Stakeholders Analysis

To understand the governance system of this community garden, the involved stakeholders are mapped and analyzed. The garden land is owned by GESOBAU AG, while MV. Albatros gGmbH is the operator of this

project (Monzer 2023; Sharaf 2023), which rents the whole land from GESOBAU.AG with a subsidized cheap rent, with an agreement until 2027/ After that, the garden could be forced to relocate to another place, according to GESOBAU's future plan for this land (Skowronek 2023). MV. Albatros gGmbH leases the 35 plots to tenants from the neighbourhood (Skowronek 2023). MV. Albatros gGmbH is a company that is interested in social work, especially in the districts of Reinickendorf and Pankow, within the context of district and neighbourhood work (Albatros gGmbH 2023). Since 2009, they have operated a multi-generational home in Reinickendorf and a community floor "Nachbarschaftsetage"in the Märkisches Viertel (Albatros gGmbH 2023). Their team has a weekly meeting in the community floor "Nachbarschaftsetage" to follow up and organize their projects including the garden, and the social manager from GESOBAU joins them once per month to check on how they work (Skowronek 2023).

Moreover, BENN, Berlin Entwickelt Neue Nachbarschaften, - which means Berlin Develops New Neighbourhoods - in Märkisches Viertel supports this garden; financially or through buying the needed materials, besides managing one plot in the garden (Sharaf 2023). BENN is a programme of the Berlin Senate Department for Urban Development, Building and Housing, which started in 2017, aiming to strengthen integration, neighbourly cooperation, social cohesion and participation in neighbourhoods with large refugee accommodations in 16 districts (Senatsverwaltung für Stadtentwicklung, Bauen und Wohnen 2023). The BENN team consists of 3 members, and they have their on-site office in Märkisches Viertel centre (Sharaf 2023). Moreover, BENN rents two plots from Albatros and they run it as a small community garden where all the neighboirs can come and join the gardening process (Sharaf 2023). One of the BENN team is responsible for this project, Mr. Khalil Sharaf, who has a Syrian background (BENN im MV 2023a), In addition atwo on-site workers are present in the garden, one Syrian, the other Kurdis who are responsible for the gardening, People from the neighborhood are allowed to participate in the gardening, and there are specific spots that are left for these people to grow their own plants, while other spots are specified for childrens to learn how to plant (Sharaf 2023). In the summer, starting from May, BENN organizes a garden cafe every Tuesday from 3 to 6 pm in the garden for all the neighbourhood. In addition to general gardening activities include sowing, planting, watering and harvesting (BENN im MV 2023b). Around 15 to 20 persons usually participate and attend this garden cafe (Sharaf 2023) shown in figure 5.

Figure 5: the garden cafe organized by BENN (source: author)

Regarding the tenants of the other plots, half of them are German and the other half are of different nationalities such as Arabic, Cambodian, Vietnamese, Turkish, Portuguese, according to the interview conducted with Volkmar (Spremberg 2023), who is one of the three on-site responsible workers for the garden on behalf of Albatros. One plot is rented by two women who share it and pay the rent together (Spremberg 2023). The tenants have a legal contract with Albatros and GESOUBAU with a cheap price of 240 Euro per year and they can pay by year or by month (Spremberg 2023; Skowronek 2023). This contract is automatically renewed every year and the termination of the contract is subject to a three months notice (Skowronek 2023). Moreover, Skowronek (2023) mentioned that there is a long waiting list of people who want to have their own plot in the garden, who are usually choose in a way that protect the garden's diversity and intercultural spirit, thus involving different nationalities and age groups. There is a house rule that states all the regulations and restrictions of using the gardens (Skowronek 2023) such as saving water and resources. For example, the tenants are not allowed to grill at any time for safety reasons and to avoid the noise and crowds in the garden. In addition, playing football is not allowed in the garden (Dubler, 2023).

Beside the regular tenants and BENN, there are other activities and projects that rent and use plots from the garden. For example, one plot is rented for free by Albatros by "Mobile Stadtteilarbeit" to establish raised beds for plants to be used by the wheelchair users, as shown in figure 6. They are getting plants for the raised beds for free, and they only pay insurance to get the keys of the garden and once they return it, they are getting the insurance back. In addition, they got funds from GESOBAU social organization to buy materials and build the structure of the raised beds for plants (Skowronek 2023). Another activity, which happened in one plot of the garden, is about ecological education. It is run by a person hired by Albatros, financed by BENN and it targets the youth and students (Fred 2023; Skowronek 2023; Spremberg 2023). Moreover, Skowronek (2023) mentioned that there is a plot of the garden rented to the Salam.ev. Initiative.

Figure 6: the raised beds for growing plants by the wheelchair users (source: author)

Figure 7 illustrates the mapping of the stakeholders and the actors involved in the garden and its activities, and their relations.

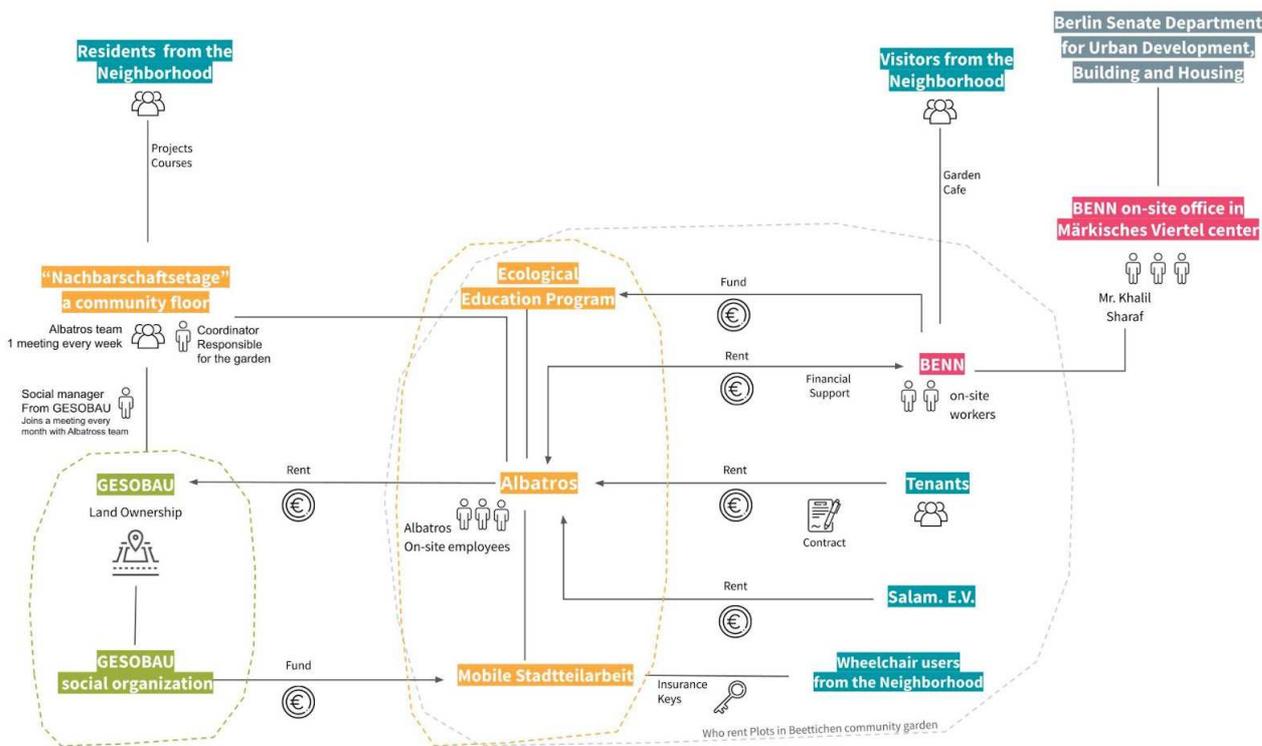

Figure 7: the stakeholders mapping (source: author)

6.2 The Garden's Activities

Regarding the garden's activities, the tenants are allowed to use the garden every day from 6am to 10 pm with their keys. while people from the neighbourhood can also come and many are sitting in the garden during this time (Skowronek 2023). BENN organizes a garden cafe every Tuesday in summer from 3 to 6 pm, and they offer drinks and snacks, in addition to helping in the gardening process (Sharaf 2023). The garden café's activities start with an event at the beginning of summer in May, when the neighbours participate in the decision making process. In addition, another event occurs in September at the end of the summer, and it is mainly about harvesting, then they cook together with fresh fruits and vegetables from the garden by using the kitchen in the garden (Sharaf 2023; Skowronek 2023). Beside the garden cafe, there are other activities organized by Albatros gGmbH, such as the grilling events, in which only the tenants can participate and grill their own food; and the clothes exchange event, a 'market' where people come to buy and sell old clothes (Spremberg 2023). Skowronek (2023) stated that they tried to organize a regular meeting for the tenants but it was not possible because it is difficult to find a day and time that is suitable for all of them. However, when there are events such as clothes exchanges, or fireplaces in winter, Albatros invites all the tenants and most of them usually join (Skowronek 2023). Moreover, there is an attempt from Albatros to move the activities that are used to be in the community floor "Nachbarschaftsetage" to the garden, especially in summer, such as the Turkish women cafe, (women gather every Wednesday at 2pm), Oma gegen Rechts (a programme about anti-racism), Energieschuldenberatung (a consultation on energy consumption and complaints), and a handcrafts course (Skowronek 2023).

6.3 The Interviews and The Social Relations

According to some open-questions interviews undertaken with anonymous tenants to discover the social life in the garden, a German retired man, stated that he knows a lot of people due to the garden, but he considers them as "bekannt" which means familiar not friends. In addition, he mentioned that sometimes they exchange products and food, and sometimes when he was sick, they used to water his plants for him. He comes twice per day to the garden to water the plants and enjoy the fresh air. Moreover, another German retired tenant woman stated that all the tenants mainly know each other as most of them come daily to the garden so they meet, say hi. This woman has one plot and her daughter has another plot and she mentioned that she comes everyday to water the plants of both plots. However her daughter, who lives in Friedrichshain (another district far away), comes on the weekend and during vacation with the grandchildren, and they play with the children of the Cambodian tenants who rent the adjacent plot. On the other hand, the woman mentioned that she cannot communicate with the visitors of the BENN garden cafe, as most of them cannot speak good German language. Furthermore, according to the interview done with Kristina Dubler, the manager of the community floor and the garden, there are problems and conflicts, sometimes happening between the tenants because of their different purposes and motives of using the garden, in addition to their different cultural background. For example, some of them have big families that cause some noise, while the others prefer the calm and rent their plot searching for relaxation. According to observation, it is noticeable that a lot of tenants come to sit in their plots to relax, read books and enjoy the sun. Despite the existence of a House Rule document, it is always difficult to deal with 35 tenants and their families in one piece of land, even though every tenant has a its separate plot, as there are no fences between them (Dubler, 2023).

The visitors of the BENN garden cafe are from various nationalities, such as German, Syrian, Egyptian, Kurdish. According to some open-question interviews done with the visitors of BENN garden cafe and the observations during the fieldwork, most of them know each other as they have a whatsapp group and they invite each other to this garden cafe. One German man who usually joins the garden cafe, mentioned that his motive is to help the immigrants who join the garden cafe through practicing German with him or asking him about any German procedures, for example, health insurance and searching for a job or apartment. Arab women mainly come to socialise and enjoy the sun and the good weather in the fresh air of the garden. Moreover, two women, one Lebanese the other Kurdish, mentioned that they used to celebrate their birthday and their kids' birthday in this garden by organising a party and inviting the people. The Arab women usually bring cooked food or snacks with them and enjoy chatting in the garden, and they use the planted mint and herbs in their teas. However, not all the people who come to the garden cafe participate the gardening, in particular, only a few men and kids participate in the gardening in the BENN plot, as shown in

680

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

figure 8. In addition, the garden cafe allows the kids from different nationalities; Syrian, Kurdish and German, to play together in the garden as shown in figure 9 and figure 10.

Figure 8: few men participate in the gardening activities (source: author)

Figure 9: the children from different nationalities play together (source: author)

Figure 10: the children from different nationalities play with the dog of the German retired tenant (source: author)

On 13 June 2023, during the author's visit to the garden cafe in the community garden, a group of 8 women from the sewing course by Albatros, most of them Iranian, Afghan and Kurdish, visited the garden with their instructor Eva. Although 6 of them mentioned that this is their first time to visit the garden as they did not

know about it before, they were interested in knowing all the activities happening in the garden and how to be involved in the future and 3 of them asked about the procedures to rent a plot.

7 DISCUSSION

The previous sections detailed the social patterns and the different activities of the Beettinchen community gardens. Through this analysis, it is noticeable that the Beettinchen community garden has a lot of opportunities to contribute in the social development of Märkisches Viertel, besides challenges.

Based on the interviews, the Beettinchen community garden is opening an opportunity for the locals to socialise, build their network through the garden cafe or other activities. For example, because of the garden cafe, they have a whatsapp group, where they get to know each other and invite each other to the garden cafe and the other events. The garden could be considered as their public space where they can gather and celebrate their birthdays. Moreover, the Beettinchen community garden offers a public space for people from different age groups. By providing a small playground children can play with each other; the retired tenants come to their plots daily to water their plants and to relax; other men and women join the garden cafe to socialise; the ecological education project which rents a plot in the garden targets youth; and the wheelchair users are also engaged in a plot which provides raised beds. As Märkisches Viertel is one of the neighbourhoods in marginalized areas, assigned to the BENN programme as a neighbourhood with large refugee accommodations, the Beettinchen community garden offers a great opportunity for cultural exchange smf for the refugees and the immigrants to integrate. It gathers different nationalities among the tenants and the visitors of the garden cafe or even through the visitors from the sewing course from the Nachbarschaftsetage. Although there are many stakeholders involved in the garden, having daily on-site employees by Albatros in the garden helps to organise the garden system and encourage this network. Having one of the BENN team responsible for the garden cafe from a Syrian background could help to engage more people from different backgrounds. Another potential opportunity for encounters is the kitchen which, despite being small is a good facility with needed equipment. It can be used in different ways that enable people to cook together and create more cultural exchange through organising more events regularly.

On the other hand, there are many challenges that face this model of community garden. As Kristina Dubler, the manager of the community floor and the garden mentioned there are a lot of problems and conflicts between the tenants due to their different motives and their different cultural backgrounds. In addition, language is another barrier. As the German retired tenant woman mentioned it is difficult to deal with the garden cafe visitors as not all of them can speak good German. Finally, the garden is threatened to be relocated, as the GESOBAU rents the land to Albatros only until 2027, and after that, no one knows what GESOBAU's plans will be for the future of the land.

8 CONCLUSION

Berlin is a big city with a lot of food activities that target the alternative food systems, as ways to reduce the distance between the producers and the consumers. These activities include many examples and models of community gardens and kitchens. This paper attempts to understand how community kitchens and gardens can be integrated as a vital element of urban development of the marginalised areas in Berlin, through analysing the case study of Bettinchen community garden in Märkisches Viertel, a marginalised area in Berlin, assigned to the BENN programme, as a neighbourhood with large refugee accommodations and requiring more social work to help the integration of the immigrants and refugees. While at this point the findings of this paper remain exploratory and a comprehensive study in the author's PhD will be necessary for conclusive findings, it is still obvious that the case study of the Beettinchen community garden offers a good opportunity for the people to socialise, integrate and exchange, in addition to considering it a public space for all age groups. However, it faces many challenges such as conflicts and problems between the tenants due to their different cultural background and diverse motives. Nevertheless, this paper argues the importance of the community garden and kitchen in the social development of the marginalised areas in Berlin.

1 ABSTRACT

Peri-urbanisation is a phenomenon taking place worldwide and affecting not only large cities but also smaller towns and settlements. The diverse set of activities, land uses and processes, which are characteristic for peri-urban landscape, are often poorly regulated and planned by the spatial planning and development policies. This may give way to interests of individual investors, which are rarely supportive of preserving green open spaces to serve the population for their leisure and recreational purposes. In this paper, we focus on the unbuilt spaces of the peri-urban landscape and their role for retaining a sense of place of local inhabitants who use this landscape for their leisure and recreational purposes. This study approaches the sense of place (SOP) as a category of the cultural ecosystem service framework. SOP has previously been highlighted as a specifically difficult category to be directly quantified and assessed with standardised procedures, and is therefore poorly integrated in landscape and management plans. Accordingly, this study is an attempt to set a basis for the SOP indicators development in the peri-urban landscape by (1) exploring and clarifying the notion and spatial characteristics of the peri-urban landscape, (2) identifying spatial planning actions and their influence on the peri-urban land use and functioning, and (3) exploring possibilities for the cartographic representation of SOP in the peri-urban landscape. We conducted a literature review, document analysis and spatial analysis in three case study cities in Slovenia: Ljubljana, Kranj and Koper. Then we developed a framework for peri-urban landscape characterisation and applied it to case studies. We compared results with the characterisation of the peri-urban landscape in formal documents and identified spatial actions and their influence on the peri-urban land use and perception. Finally, we evaluated whether the proposed framework could help in identifying areas according to their SOP potential and in developing SOP indicators for preserving peri-urban open spaces for its users. Our findings can facilitate incorporating information on SOP in a format that can be used by city authorities and spatial planners in the formulation of spatial planning measures and guidelines.

Keywords: cultural ecosystem services, sense of place, peri-urban landscape, mapping approaches, Slovenia

2 INTRODUCTION

Peri-urban landscapes, located at the city's edge, are a collection of ecosystems supporting biodiversity, wildlife habitat, flood protection, local climate regulation, oxygen production, recreation and other regulating, provisioning, supporting and cultural ecosystem services, as MEA(2005) defines benefits which are provided to humans by nature. There is evidence that people value these areas for various reasons, including the naturalness and spaciousness of peri-urban green open spaces (Neuvonen et al. , 2007), and leisure and recreation (Cadieux, 2008; Neuvonen et al. , 2007; Palang et al. , 2011; Tyrväinen et al. , 2007), which has become even more evident during the COVID-19 lockdown when people, measures allowing, fled to the semi-natural green spaces for outdoor recreation and leisure as a substitute for closed-down indoor recreation centres. In Slovenia, too, when the strictest measures limited people to movement inside the municipality of residence only, the semi-natural green spaces outside towns became popular destinations for outdoor recreation (Ugolini et al. , 2020; Žlender & Gemin, 2023). Clearly, people migrate from urban centres to urban edges to be closer to green open spaces (Piorr, Ravetz, Tosics, et al. , 2011). However, unless such actions are planned and regulated, they can lead to negative consequences such as overcrowding of green spaces for leisure use, diminishing peri-urban biodiversity and even accelerating peri-urbanisation.

This study is focused on the unbuilt spaces of the peri-urban landscape and their role in sense of place (SOP) of local inhabitants who use this landscape for their leisure and recreational purposes. It investigates SOP as a category of the cultural ecosystem service (CES) framework. SOP has previously been highlighted as a specifically difficult category to be directly quantified and assessed with standardised procedures, used for other ecosystem services (ES), and is therefore poorly integrated in landscape and management plans. To investigate the problem of poor inclusion of SOP in formal spatial plans, we set the following research question: Can characterisation of the peri-urban landscape help in recognising spatial patterns indicating valuable places for SOP as a CES category?

Accordingly, this study is an attempt to set a basis for indicating valuable places for SOP in the peri-urban landscape by (1) exploring and clarifying the notion and spatial characteristics of the peri-urban landscape, (2) identifying spatial planning actions and their influence on the peri-urban land use and functioning, and (3) exploring possibilities for the cartographic representation of SOP in the peri-urban landscape. We conducted a literature review, document analysis and spatial analysis in three case study cities in Slovenia: Ljubljana, Kranj and Koper. We then present the framework we developed for the characterisation of the peri-urban landscape and its application to the case studies, results obtained, and an evaluation of the proposed framework for developing SOP indicators of peri-urban open spaces. This paper is the first step in a project which will explore CES in the peri-urban landscape and develop a valuation framework for landscape planning and policy.

3 LITERATURE REVIEW AND RESEARCH APPROACH

3.1 Approaches to characterising peri-urban landscape

The peri-urban landscape is a complex and multifunctional system with specific features and several dimensions which should be taken into account in planning of this space (Filyushkina et al. , 2022; Gottero et al. , 2023). To achieve a clearer definition of the peri-urban landscape, scholars to date have explored issues of terminology and understanding the difference between different spatial entities (Simon et al. , 2006), the driving forces behind peri-urbanisation(Aalbers & Eckerberg, 2013; Piorr, Ravetz, & Tosics, 2011), the peri-urban issues occurring due to different stakeholders' interests, such as land ownership conflicts, land consumption, decreased biodiversity and lack of public services (Cattivelli, 2021; Dadashpoor & Ahani, 2019; Kristensen & Primdahl, 2020) and its low identity and recognisability (Qviström & Saltzman, 2008; Shoard, 2000). The latter, especially, is important for the exploration of sense of place of different stakeholders and its role in characterisation of the peri-urban landscape.

In the Slovenian context, Marušič et al. (1998) have prepared a division of the whole Slovenian territory based on landscape patterns, which reflect spatial units with relatively homogeneous landscape features. Their criteria were based on the level of nature preservation, variety of landscape features, spatial order and harmony. In their division, the peri-urban landscape is characterised as a "generic pattern, which has been altered by human interventions to the extent that it does not reflect any local specifics anymore"(Marušič et al. , 1998 p. 64). Reviewing further literature, different interpretations of the peri-urban landscape and approaches to peri-urbanisation can be found. Increasingly popular are studies which deal with defining physical boundaries. Scholars have taken different criteria to demarcate the peri-urban landscape, among the most popular being population density (Piorr, Ravetz, & Tosics, 2011), land use (Aguilera et al. , 2011), a combination of land use and population density (Gonçalves et al. , 2017; A. Wandl et al. , 2017) or an addition of several more specific criteria such as experts' opinions (Gottero et al. , 2023). It should be noted that consensus regarding such demarcation has not yet been reached and, according to Mortoja et al. (2020) is not even possible. Accordingly, we focus our efforts on characterising the peri-urban landscape in identifying patterns of peri-urbanisation rather than trying to fix its borders. Planning the peri-urban landscape greatly refers to planning its open spaces, which (will) form green infrastructures of cities and the production of goods and ES. These, together with planning of built-up tissue, require holistic policies and regulations (Gottero et al. , 2023). For these reasons, understanding, identifying and defining peri-urban spatial patterns through place-based approach is necessary to understand the complexity of peri-urban landscapes (Gottero et al. , 2023). Specifically, establishing land use rules for peri-urban areas is crucial for ES preservation. Accordingly, we developed a replicable method to identify peri-urbanisation in a spatial planning context of municipal and supra-municipal spatial planning.

3.2 Sense of place as a category of cultural ecosystem services

SOP has been suggested as a valuable approach to assess and understand the complex subjective relation between people and place (Stedman, 2016) and it has been proved useful in the exploration of peri-urban green open space users and SOP too (Žlender & Gemin, 2020). One of the most widely used definitions of SOP comes from Tuan(1977) who defined it as the meanings and attachments people attribute to place. It addresses the emotional, symbolic, and spiritual aspects of places. According to Relph (1976), SOP is about a person's understanding of a place; it involves experience and a subjective dimension. Conversely, Stedman (2003), Twigger-Ross and Uzzell (1996), and Hidalgo and Hernández (2001), among others, argued that the

construction of meaning is, beside individual, also a composition of social interaction and the physical characteristics of the environment. We propose the definition of SOP as a complex affective bond between people and a specific location. The specific location, the place, is determined by geographical location, material form and investment with meaning and value (Gieryn, 2000).

A number of factors can influence the formation of SOP and have been explored, among which the attributes of a place, such as (lack of) accessibility to a place and geomorphology (Koohsari et al. , 2023; Žlender & Gemin, 2020), arrangement of architectural elements in the streetscape(Hu & Chen, 2018) or level of shoreline development (Stedman, 2003). Other studies used different methodologies to measure people's attitudes towards planned changes in the landscape which can be negative or positive. Examples include coastal restoration(Hawthorne et al. , 2022), dam construction (Ganzevoort & van den Born, 2019), and changes in water quality (Mulvaney et al. , 2020).

The reviewed literature indicates the value of the spatial assessment of SOP for informing spatial planning of the peri-urban landscape. The integration of spatial, social and perceptual data into land use planning can enhance the understanding of reasons and impacts of change (Ryan, 2011) and improve people's pro-environmental attitude (Žlender & Gemin, 2020). Such information can thus help spatial planners to integrate social values in spatial planning, which is usually based on biophysical indicators (Gottwald et al. , 2021) and prioritises effective policy responses to ensure the sustainable future of the peri-urban landscape.

The ecosystem services framework is an attempt to introduce both biophysical and individual, subjective perceptions in landscape planning. Accordingly, some international classification systems, such as MEA (2005) or CICES (2013) include also CES which refer to the non-material benefits people obtain from ecosystems. Although the ES framework has been present in research and used in spatial planning and policy for a number of years now, the integration of CES categories in landscape planning and policy, especially categories such as sense of place, spirituality and identity, has fallen short, the main problem being the ambiguity and lack of clarity in defining these concepts (Cheng et al. , 2019; Feld et al. , 2010; Plieninger et al. , 2013). While acknowledging definitional vagueness as one reason for the neglect of some categories of CES, we suspect that the key reason is that many instances of CES cannot be directly quantified and assessed with standardised procedures and are therefore poorly integrated in landscape and management plans. The literature confirms the lack of quantifiable CES data, and that the small number of available indicators cannot be measured directly (Feld et al. , 2010; Layke et al. , 2012), with consequent difficulties for mapping.

CES has received even less attention in investigations of peri-urban issues, especially with regard to the attitudes of local users to peri-urban open spaces. The problem is compounded by the indeterminate character of the peri-urban landscape and the ensuing lack of interest in peri-urban issues. Previous research highlighted two difficulties that experts encounter in developing guidelines and policies in relation to peri-urban space(Žlender, 2021b, 2021a): the diversity of terms used to demarcate the peri-urban landscape, and the lack of knowledge of what is perceived as a transient landscape that will be developed in the future by the government, the planning profession and the general public. In combination with weak land use planning, the lack of interest in the current state of these spaces exacerbates the consequences of urban densification, as the shortage of ES in cities exerts increasing pressure on peri-urban landscapes.

In this study, we investigate SOP as a category of CES, but we do not emphasise the non-materiality, intangibility and subjectivity of CES which reflect the difficulty of incorporating CES into the ecosystem framework, where the use of quantitative methods prevails (Ryfield et al. , 2019). As emphasising this weakness may inhibit the ES framework as a decision-making tool, we focus here on finding different patterns and work towards defining a tangible and measurable component to understand the people-nature relationship(Gottwald et al. , 2021; Stedman, 2016). In developing our conceptual and methodological approach, we rely on the CES definition of Fish et al. as "a concept around which researchers and decision makers can understand ecosystems in terms of their life-enriching and life-affirming contributions to human well-being. . . encompassing a broad symbolic, experiential and virtuous realm of human interactions and understandings of the natural environment"(Fish et al. , 2016, p. 208). Accordingly, we examine SOP as a material phenomenon, which reflects the relationship between determining biophysical conditions of a particular location and social and cultural conditions of human habitation (Ryfield et al. , 2019).

Operationally, we do this by drawing upon the identification of land use characteristics, spatial patterns and planned actions in the peri-urban landscape, as described below.

3.3 Research approach

We built our methodology on three main steps. First, based on the predefined criteria, we identified patterns of peri-urbanisation in each of the case study cities and identified areas with different SOP. Secondly, we analysed the municipal spatial plans of each city to identify the peri-urban landscape and meaningful parts of the peri-urban landscape for its users and local residents. Finally, we compared the outcome and selected measures which can be useful in developing SOP indicators for each case study.

4 METHODOLOGY AND ANALYSIS

4.1 Case study cities

We selected Ljubljana, Kranj and Koper as all three cities have been previously identified as being affected by peri-urbanisation. Ljubljana is the capital and largest city of Slovenia, and a subject to peri-urbanisation due to in-migration and a consequent need for new housing, along with the expansion of economic activities and infrastructure on the city edges. The city-region is threatened by sprawled development and other negative effects of urbanisation and peri-urbanisation in the absence of comprehensive planning. Kranj and Koper represent average-sized Slovenian towns with a historical city centre and (sub)urban growth after the second world war. Both are considerably smaller than Ljubljana, but regional cores and thus important economic, cultural and social centres. Both Kranj and Koper are faced with housing and infrastructure development pressures, which mainly affect agricultural land (K. Nilsson et al. , 2013; Spyra et al. , 2021). All three cities have been also a subject to various projects investigating peri-urban issues (for details, see Piorr, Ravetz, Tosics, et al. , 2011; RENATUR: Improving Regional Policies to Better Protect Natural Heritage of Peri-Urban Open Spaces, 2023; Žlender, 2021a).

4.2 The content analysis of spatial plans

In Slovenia, the importance of recognising (C)ES in spatial planning and policy is stressed in several strategic documents on national and regional level. e. g. : Spatial Planning Strategy of Slovenia 2050; Regional Development Programme of the Ljubljana Urban Region, 2020; Spatial Planning Strategy of Slovenia, 2004, mostly in connection to green infrastructure and referring to EU Green Infrastructure Strategy (European Commission, 2013). In Slovenia, spatial planning on the local level is regulated with municipal spatial plans (OPNs). These plans should be prepared by each municipality and revised within certain time periods; however, a considerable number of municipalities is still without a valid OPN. In existing OPNs, the peri-urban landscape is rarely mentioned and (C)ES even less (Žlender, 2021a), despite above-mentioned strategic documents stressing the importance of recognising (C)ES in spatial policy. The problem often lies in lack of data and expert knowledge for envisioning long-term sustainable development. For the analytical purposes of this paper, we performed a content analysis of OPNs of all three case study cities.

4.2.1   Ljubljana

With 293,820 inhabitants (Statistični urad RS, 2023) the municipality of Ljubljana is the most populated Slovenian municipality, although geographically, most of its population is concentrated in the city of Ljubljana, while its eastern part is of rural character. The city of Ljubljana has a star-shaped morphology with development along the main roads and five green wedges in between, connecting the green hinterland to the city centre. Its structure reflects the historical development of the city, with visible traces on the urban structure and tissue of all main historic periods (MOL, 2010). Throughout the 1990s, Ljubljana has been subject to sprawled development, mainly in a form of large shopping centres, hypermarkets, outlets, leisure activities (multiplex cinemas, restaurants, specialised shops),housing and transport, due to the absence of yet to be established new spatial legislation and market-driven economy. Primarily affected were city-edge greenfield and arable land (Pichler-Milanović, 2005). The Municipal Spatial Plan (OPN)(MOL, 2010)entered into force in 2010. The OPN recognises several problems in relation to past sprawled development of Ljubljana, among which, most relevant for this study, are the loss of local and national identity of settlements due to new (sprawled) development that often ignores natural forces as well as

traditional settlement characteristics, together with privatisation of open space. The OPN specifies four peri-urban areas and their future development. First is the Sava river area, its hinterland and the Ljubljana plain, which, due to its role as a main air ventilation corridor of the city, should preserve its open space and limit the urban development. The development of recreation within the two green wedges located on this area, the preservation of the cultural landscape and the Zajčja Dobrava landscape park should be emphasised. Secondly, the use of Ljubljanskobarje (Ljubljana marsh) for (mainly extensive) agriculture should be preserved, and spatial interventions around solitary hills should be monitored since they are an important identity element of Ljubljanskobarje. Urbanisation should be limited, if not prevented. The development of the third area, Posavskohribovje, should be based on agricultural activities, alongside the development of tourism and recreation and new urban development should be limited. The emphasis on the agricultural development is foreseen also for the fourth area, the Polhograjskohribovje. It should be noted that terminologically the OPN understands the peri-urban landscape as the recreational and semi-natural hinterland of the city. Cultural landscape areas surrounding Ljubljana city, solitary hills, parks, Ljubljana circular path (PST) and water bodies are identified as elements and areas which should be preserved due to their important role for people's identity and sense of place.

4.2.2 Kranj

With its area of 151 km2 and a population of 56,780 (Statistični urad RS, 2023) the municipality of Kranj is the third largest municipality in Slovenia in terms of population. Around two thirds of its population lives in the city of Kranj. Its medieval town centre is laid out in a narrow area between the Kokra and the Sava rivers in a characteristic pyramidal shape and prominently planned height dominants. In time, the city has spread out towards the suburban settlements on the Kranjsko-Sorško polje (plain) east of Kokra towards the northeast and on the right bank of river Sava. The city is divided into several distinct areas due to the morphology of the terrain(MOK, 2014). The Municipal Spatial Plan of Kranj (MOK, 2014) understands the peri-urban landscape as a multifunctional space which accommodates both urban and rural uses. More specifically, the development of Kranjsko polje should be focused on the preservation of the cultural landscape by interlinking agricultural and forestry activities, and accommodating housing and commercial activities/The Sorško polje should preserve its peri-urban characteristics, which combine the distribution of smaller settlements with the interlinkage of arable fields and forests. Due to its vicinity to the city, the development should emphasise the recreational functions of Sorško polje. Škofjeloškohribovje should develop multifunctionally in the areas around the Sava river, while areas further from the city should preserve their rural character, alongside with the development of tourism, sports and recreation. The OPN does not mention any specific areas, elements or measures regarding the presence or importance due to sense of place or identity, but it does specify quality natural and cultural structures and elements which should be preserved. These pertain to the cultural landscapes of Sorško polje, Škofjeloškohribovje, and the northern part of Dobrave, cultural heritage of historical settlement cores, and natural preservation areas.

4.2.3 Koper

With an area of 304 km2 and a population of 53,440 (Statistični urad RS, 2023) the municipality of Koper is a coastal municipality surrounded by the Adriatic sea on its western side. The sea, the hills and the karst edge are important carriers of landscape identity and, alongside the geostrategic importance of the city of Koper, main factors to influence spatial development of the municipality (MOK, 2022; Pintar et al. , 2013). The city of Koper accommodates about half the municipal population and is characterised by a compact medieval town centre, historically dating from Venetian times, the port area and the former area of salt planes which were filled in between the wars to join the island town centre with the mainland. There has been high pressure for urban growth in the municipality due to the attractiveness of the coastal area and the presence of the port. The challenge is how to balance urban expansion and the protection of open space for agricultural and leisure purposes(Pintar et al. , 2013). Sub-urbanisation is most evident in the urban fringe and in settlements close to Koper, mainly due to lack of sufficient housing capacity, a higher living standard and a changing socio-economic situation in the urban zone. Conversely, the rural hinterland has been struggling with a shrinking population in settlements, abandonment of agricultural activities and consequent forest overgrowth (Pintar et al. , 2013). Within the PLUREL project, three main land use issues have been identified: land pressure due to housing and industrial development, pressure on agriculture from built development, and possible deterioration of high value nature areas (Pintar et al. , 2013). The recently

enforced OPN(MOK, 2022) divides the territory into three belts to direct future spatial development of the municipality. First is the urban belt, encompassing the city, its immediate vicinity and the coast. Second is the peri-urban belt, which should accommodate further development of housing, retail and industry, but also preserve agricultural activities and space for recreation. The third belt refers to settlements in the rural hinterland with lower density. The spatial and cultural identity of the municipality should be strengthened by preserving the cultural landscape, heritage and natural protected areas.

4.2.4 Summary

All three municipalities divide the space into three areas: city centre, suburban/peri-urban landscape with recreational hinterland, and countryside. In all three cases, the city centre is the most precisely defined area. Koper has the most precisely defined peri-urban landscape, but the terminology used is not consistent throughout the document and geographically some areas overlap. Both Ljubljana and Kranj define their peri-urban landscape as an area of settlements with denser development that has merged due to suburbanisation, and their recreational hinterland as an area with rural-urban functions with emphasis on the preservation of the cultural landscape. The recreational function coincides with agricultural and forest areas close to the cities, with emphasis on the importance of non-conflicting uses and ecological functions.

4.3 Spatial extent of peri-urbanisation

This study builds its methodology upon Žlender (2021b), Wandl et al. (2014) and Gottero et al. (2023), who had developed methodologies to delineate the peri-urban landscape. Their methodology is refined in this study and adjusted according to some specific spatial characteristics of Slovenia: e. g. , very high forest cover and Natura 2000 areas, high permeability (even in the cities), relatively low population density in comparison with other EU countries. Furthermore, actions of data combination were selected in line with the purpose of this study, i. e. , to identify spatial patterns with potential SOP of peri-urban landscape users.

The peri-urban landscape was spatially characterised in a multiple-step procedure. We developed it through GIS tools (QGIS Desktop version 3. 28), by overlapping, merging, weighting, and interpreting the most recent and openly accessible spatial data. In selecting data sources, we strived to use formally valid datasets, but due to lack of some information, we also used data from Open Street Map (OpenStreetMap Contributors, 2023). Before inputting data into the model, we inspected its quality and adjusted possible deficiencies such as coordinate system, spatial index, geometry. We also cleaned the data's inconsistencies and inaccuracies in data collection by excluding polygons of less than 10 m2. We processed this data using the "Query Builder" tool before starting the analysis. This tool provides an interface for defining filters to create feature subsets within a layer. The use of logical commands enables the construction of complex queries(QGIS project, 2023). Using this tool, we obtained refined data suitable for our analysis, thereby reducing the possibility of preserving methodological inconsistencies of the original data.

A pre-condition to the whole procedure was a grid creation. Based on Wandl et al. (2014), we divided the whole territory into a 500 m x 500 m grid cells. Then we applied all the data onto the grid layer. To eliminate methodological errors that occurred during the transfer of input data to the grid (the grid cut the input data, which resulted in the appearance of some very small polygons and lines), we first removed, within each cell, polygons with a size of less than 1% of the cell size and lines of less than 0,1% of cell size. We thematically generalised land cover datasets (e. g. , we combined all hydrological layers into a single "Water bodies" layer), which enabled the consolidation of data from different sources, simplifying the complexity of data sets, and facilitating spatial analysis of similar data.

We included data on population density, infrastructure network, current land cover, mix of the built and unbuilt areas, nature and culture protection regimes. In our selection of data sets, we attempted to capture the specific characteristics of the peri-urban landscape, such as the mix of urban and rural land uses, intermingling of built and unbuilt, the presence of specific land uses such as waste and sewage treatment plants, logistic centres and others. Accordingly, we grouped our data in primary and secondary conditions for peri-urbanisation. Primary conditions were: areas with population density of 150-500 persons/km2; areas with population density of less than 150persons/km2 which intersect with transport infrastructure (main roads and railway); and imperviousness density areas (European Environmental Agency, 2020) of less than 45%. As the second conditions, we added land cover classes, which we divided into two sub-groups: one encompassing land cover of predominately rural character – arable fields; meadows, pastures, and

grasslands, bare land or scarce vegetation, overgrown areas, wetlands, conservation areas, water bodies, forests; the other of predominately urban character - infrastructure nodes; mining and brownfield sites, artificial vegetation areas and paths, cultural heritage, power lines, other infrastructure, non-inhabitable buildings, but excluding multi-residential buildings (for more information, see Appendix 1).

In the first step, we selected grid cells indicating areas with population density of 150-500 persons/km2and added grid cells with imperviousness density areas of less than 45%. To this new layer we added grid cells indicating areas with population density of less than 150 persons/km2that intersect with transport infrastructure. In the second step, we calculated the sum of all grid cells indicating predominantly rural land covers and predominantly urban land covers, the condition being the presence of at least one layer with land cover for each urban and rural land cover in each cell. In the third step, we intersected primary and secondary indicators, to demonstrate main patterns of peri-urbanisation. Due to the latter action, the results were restrained to populated areas. To achieve a more continuous area, which would also include open spaces for leisure activities, accessible to people by foot from their residencies, we added a buffer to these cells indicating main patterns of peri-urbanisation. Finally, we aligned the resulting indications of the peri-urban landscape with a layer indicating peri-urban area as defined in the OPN of each case study municipality in locations where the differences were not great.

4.4 The spatial patterns of SOP

To define the spatial pattern for SOP denotation, we used the method developed by Burkhard et al. (2009), which proposes assessing the capacities of the various land cover types to provide ecosystem services. Apart from the land cover types, we included also natural and cultural regimes, which were found to be important for SOP development (Kopperoinen et al. , 2014). We scored the layers of cells with generalised land cover types and regimes from -3 to 3 according to their prerequisite of being either favourable or harmful to supply SOP for local users. The scale was developed and scores were given based on selected literature (Adem Esmail et al. , 2023; Campagne & Roche, 2018; Kopperoinen et al. , 2014; Luiza Petroni et al. , 2022; Ribeiro & Hribar, 2019; Zhang & Muñoz Ramírez, 2019) and expert assessment. The results are shown in Table 1.

Id	Generalised land cover types and regimes	Score given
1	Arable land (e. g. , fields, gardens, greenhouses, vineyards, orchards)	2
2	Permanent crops	2
3	Meadows, pastures and grasslands	1
4	Bare/sparse vegetation	-1
5	Overgrowth	-1
6	Wetlands (swamp, saltpans)	2
7	Water bodies (river, lake, sea)	3
8	Forest	2
9	Road infrastructure lines and nodes (roads, rail, airport, port)	-3
10	Energy and environmental infrastructure (areas of energy production, power lines, waste management areas, etc.)	-3
11	Non-inhabitable buildings and accompanying areas of exclusive use (industry, logistic, military, etc.)	-2
12	Non-inhabitable buildings and accompanying areas for wider use (retail, education, etc.)	0
13	Mine, degraded and brownfield sites	-3
14	Maintainedgreen areas and paths for public use (parks, leisure facilities, hiking and cycle paths, etc.)	2
15	Maintained green areas and accompanying infrastructure for sport and tourist use (sports facilities, stadiums, camp sites, hippodromes, etc.)	1
16	Predominantly residential and/or residential-agricultural compounds	0
17	Mixed use areas of housing and, services, retail, tourism, etc.	1
18	Nature conservation areas (Natura 2000, landscape parks, etc.)	3
19	Cultural landscapes (archaeological areas, cultural landscape, outstanding landscapes, monuments, etc.)	3
20	Cultural heritage settlements (historic cores of villages and towns)	3
Effect of land cover types and regimes on the prerequisites for potential SOP supply: 3 = very favourable; 2 = favourable; 1 = slightly favourable; 0 = no connection between the land cover type or regime, and the capacity to provide the SOP or no relevant capacity to provide the SOP; -1 = slightly harmful; -2 = harmful; -3 = very harmful		

Table 1: Potential SOP supply values.

5 RESULTS

5.1 The peri-urban landscape of Ljubljana, Kranj and Koper

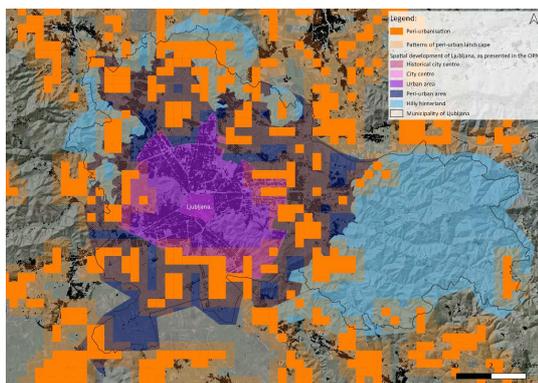
The images 1, 2 and 3 present the final output of spatial characterisation of peri-urban landscape. The newly defined peri-urban landscape coincides with the peri-urban landscape as defined in OPNs, but not always consistently. The results for each case are discussed below.


Fig. 1: The peri-urban landscape of Ljubljana. Data and background image sources: ARSO; DRSV; EEA; Geofabrik GmbH, OpenStreetMap Contributors; GURS; MK; MKGP; MNVP; MO Koper; SURS; Uradni list; ZGS

The results indicating the peri-urban landscape of Ljubljana coincide with the OPN's definition of the peri-urban landscape in the north, where the settlements of Šentvid, Polje and Črnuče are located, although our analysis indicated the extension of peri-urbanisation beyond the municipal border. The hills of Polhograjskohribovje on the west and Posavskohribovje on the east have restricted peri-urbanisation to spread to the west and to the east. Our results align with the OPN on the south, where peri-urbanisation occurs along Ižanskacesta (road), Tržaškacesta (road) and Črna vas (settlement). Barrier for peri-urbanisation on the south are hills Krimskohribovje. However, according to OPN, the peri-urban landscape covers the whole southern part of the municipality, where the Ljubljanskobarje (marsh) is located.

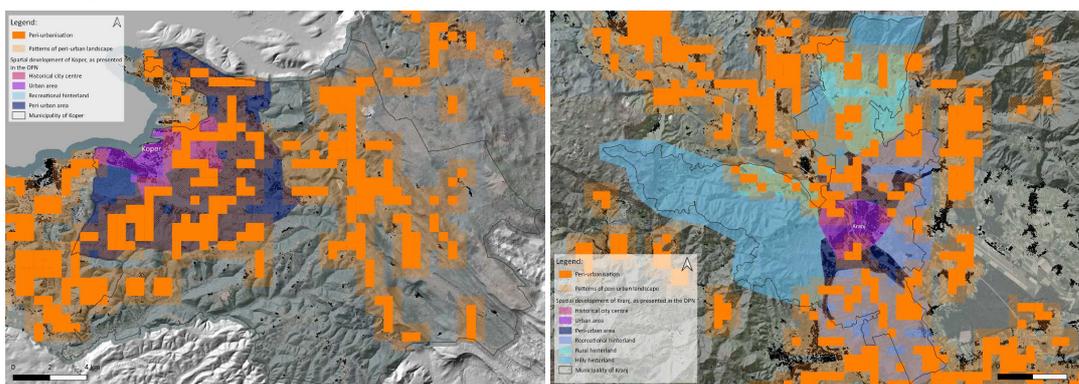

Fig. 2: The peri-urban landscape of Koper. Data and background image sources: ARSO; DRSV; EEA; Geofabrik GmbH, OpenStreetMap Contributors; GURS; MK; MKGP; MNVP; MO Koper; SURS; Uradni list; ZGS. Fig. 3: The peri-urban landscape of Kranj. Data and background image sources: ARSO; DRSV; EEA; Geofabrik GmbH, OpenStreetMap Contributors; GURS; MK; MKGP; MNVP; MO Koper; SURS; Uradni list; ZGS

Our results of the peri-urban landscape of Koper coincide with the OPN's characterisation of the peri-urban landscape in the north-eastern part which covers the settlements of Dekani, Pobegi, Sv. Anton and Škofije. The OPN indicates as peri-urban also Semedela and the Vanganel valley while our results indicate as peri-urban also the Šalara area and the coastal part towards the western side which belongs to the municipality of Izola.

In Kranj the analysis shows a tendency for peri-urbanisation developing along the main roads: to the north, in the thermal belt of Kranj below the mountains and around the highway junction, at train stops and the national airport. In the south, the whole plain (Kranjsko-Sorško polje) shows peri-urban characteristics, which is in alignment with the definition of this area in OPN as a multifunctional peri-urban area.

5.2 The spatial patterns of SOP provision potential in three case studies

In the three case studies, we identified spatial areas relative to the degree of SOP provision capacity by assigning scores of SOP provision capacity to various land cover types and protection regimes. Here it should be noted that we used the grid of cell size 100 by 100 metres because it showed better results as a grid of 500 by 500 metres cells. The images 4, 5 and 6 show results for each case study.

In the peri-urban landscape of Ljubljana, the resulting distribution of spatial patterns regarding SOP provision potential score from 'favourable' to 'slightly favourable' occurs in most of the open green land,

which aligns with green system hinterland from OPN. 'Very favourable' score was practically not present. Roads and larger settlements clusters exhibit 'no connection to provide SOP'. There are only few areas with a score of 'very harmful'. These are larger areas of built up and infrastructure use, such as the main shopping, business and leisure centre on the east (BTC City), mining areas and the city bypass.

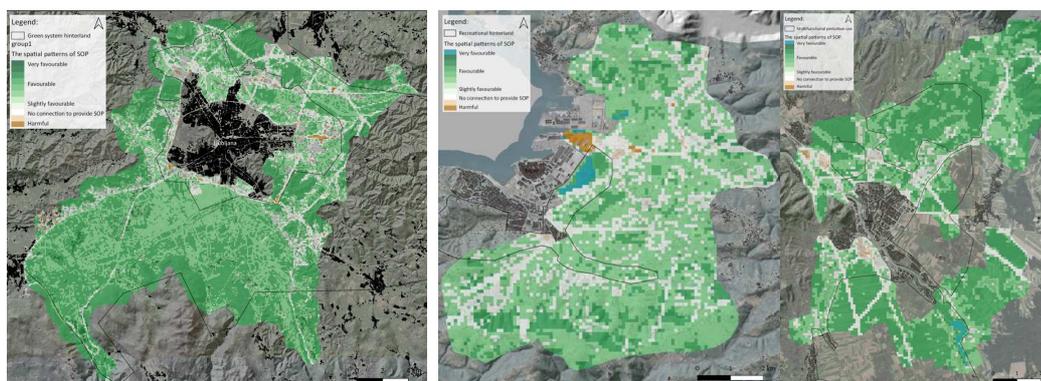

Fig. 4: The SOP provision potential map of Ljubljana. Data and background image sources: ARSO; DRSV; EEA; Geofabrik GmbH, OpenStreetMap Contributors; GURS; MK; MKGP; MNVP; MO Koper; SURS; Uradni list; ZGS. Fig. 5 and 6: The SOP provision potential map of Koper (left) and Kranj (right). Data and background image sources: ARSO; DRSV; EEA; Geofabrik GmbH, OpenStreetMap Contributors; GURS; MK; MKGP; MNVP; MO Koper; SURS; Uradni list; ZGS.

In the peri-urban landscape of Koper, the 'very favourable' spatial patterns occur in costal wetlands, especially in Škocjanski bay nature reserve. Spatial patterns of 'favourable' score are mainly exhibited along ridged hills and on the Karst edge. This is a very distinctive landscape because it is a geological and climatic border, where the Karst plateau turns into the flysch landscape of Slovenian Istria. Due to the scattered settlements, which show 'no connection to provide SOP', the border between 'very favourable' to 'no connection to provide SOP' is not clearly visible. Spatial patterns exhibiting the score of 'harmful' to 'very harmful' occur in the port of Koper and in industrial zones.

In the peri-urban landscape of Kranj, spatial patterns of 'very favourable' conditions can be observed on the lake Trboje on the south of the area. Spatial patterns of 'favourable' to 'slightly favourable' occur mostly on the open green land, indicating generally positive environmental characteristics. This evaluation aligns with green system hinterland from OPN. Railway, some small roads, transmission lines and settlements clusters show 'no connection to provide SOP'. Industrial, shopping, retail and leisure centres exhibit 'harmful' to 'very harmful' conditions.

In summary, we contend the analysis as being very illustrative of areas regarding their potential for SOP provision. We acknowledge that taking cells size of 100 by 100 metres improves the accuracy of the analysis (compared to taking cells size of 500 by 500 metres), since many land cover types are not necessarily large in size but can still have a distinctive effect on SOP. This may be especially relevant for identifying areas with 'harmful' conditions, which in none of studied cases appeared to be very extensive, when taking 500 by 500 metres cells. We also acknowledge that the use of different statistical analyses affects the results considerably. The summation method exposes water bodies, while the arithmetic mean method used exposes infrastructure and natural elements.

6 DISCUSSION AND CONCLUSION

6.1 Future actions for SOP in the peri-urban landscape

Taking the undetermined and ambiguous character of the peri-urban landscape as a challenge, our study demonstrated a scientifically guided method for indicating patterns of peri-urbanisation and assessing areas important for SOP of peri-urban landscape users.

Our results showed that the peri-urban landscape to support CES should not include only specific features such as population density or urbanisation, but also open spaces that have often multifunctional role in the peri-urban landscape. These open, unbuilt spaces therefore require unitary policies and integrated tools and regulation (Filyushkina et al. , 2022; Gottero et al. , 2023). We attempted to do this by including a variety of land cover types in the analysis and creating a buffer around the peri-urbanised areas to present peri-urban landscape more holistically.

Furthermore, our assessment of the potential of land cover types and regimes to provide SOP generated new insights into the spatial distribution of areas according to their SOP provision capacity, in three case studies. The used method allowed the presence of multiple land cover types and regimes in one cell. and the summed value indicated the interrelation of individual land cover types and regimes. We consider such an analysis more relevant in assessing SOP than the assessment of individual land uses, as suggested by Burkhardt et al. (2009)since SOP may be more likely manifested in a holistically perceived landscape(Ryfield et al. , 2019). This is especially relevant for Slovenia since finely structured land uses and covers are characteristic of the whole country's territory. Moreover, a mosaic of cultural landscapes of intermingling land covers and uses of arable fields, meadows and forest patches are recognised as valuable and a carrier of Slovenian national identity (Golobič & Lestan, 2016). This is emphasised also in the OPNs of all three case studies. Based on our results, we argue that the preservation of cultural landscape should be promoted due to its high potential for SOP capacity.

Our study provides valuable material for designing future policies with a direct impact on CES to enhance sustainable management of areas with high capacity to provide SOP. Of highest importance among them are the future regional spatial plans, as foreseen by the national Spatial Management Act (Uradni list 199/2021). The study can also be a starting point for a wider assessment of ecosystems and their services and consequent identification of land suited for future development based on its ES potential. That is to say that the peri-urban landscape is defined by high multifunctionality, thus not only conservation but also space for future urban development should be allocated there. The combination of different land cover types and regimes provides spatially explicit indication of meaningful places, which could be indicators of SOP (Knaps et al. , 2022). Spatial planners and managers can shape and foster place meanings by making these places accessible and allowing specific uses, thus encouraging the development potential of places to elevate their meaning and achieve more pro-environmental behaviour (Gottwald et al. , 2021; Žlender & Gemin, 2020). We are aware that not all land cover types or regimes within generalised land cover types and regimes support the same level of SOP. Assessing more specific land cover types and regimes, adding landscape features, points of interest and other elements may put additional values to the assessment of SOP provision. Nevertheless, we can evaluate the ecosystem service framework as having the capacity to capture evidence of SOP.

6.2 Evaluation of the methodological approach

This study was primarily scientist-driven and low stakeholder engagement is its main limitation. We are aware that the values used for the SOP supply assessment area theoretical estimation. However, we contend that the study contributes to much in demand capacity building. A natural progression of the study is the exploration of the perceptions of ES provision with the engagement of relevant stakeholders, to examine the extent to which the perceptions and opinions of different stakeholders may differ from each other, and compare those with literature-based values and those derived from modelling. Involving key stakeholders, especially the spatial planners and experts, collecting and confronting their opinions can culminate in producing more accurate assessments and new shared knowledge, which can elaborate an approach of both development and conservation plans and policies that build consensus among stakeholders, while supporting the concept of ecosystem services (Adem Esmail et al. , 2023; Filyushkina et al. , 2022).

Finally, we contend that the needs of peri-urban open space users and local residents are crucial in ecosystem management and spatial planning. In line with this, the actual supply of CES and use can be determined, rather than considering only the potential capacity. Thus, our future investigations will put efforts in engaging different stakeholders in our research of peri-urban landscape.

1 ABSTRACT

To further promote the share of cyclists in urban and rural areas, the focus lieson both improving objective road safety and increasing the subjective feeling of safety among cyclists. The subjective feeling of insecurity often forms a barrier to more frequent bicycle use for people who have so far cycled little or not at all, and who are therefore important for increasing the cycling share in urban and rural areas.

The focus of the research is to examine overtaking interactions involving bike and car traffic. Overtaking cars is one of the main causes of stress for cyclists. Not only does overtaking have physical suction and pressure effects on bike traffic because of air displaced by the car body, but also psychological stressors. There are proximity boundaries where people feel unsafe when someone does not maintain them, especially when imposed upon by large, fast vehicles. During overtaking interactions, there is no direct opportunity for communication due to the separation effect of the car body. The cyclist also cannot confirm that the driver is aware of their presence.

Since 2020, Germany has mandated that car drivers may only overtake cyclists on the roadway with a distance greater than 1.5 m in the inner city, and 2.0 m out of town. Other countries have similar regulations for overtaking interactions involving cyclists. France, Portugal and Spain have also adopted the 1.5 m law, in Australia, the distance is usually 1 meter on roads with speed limits less than 60 km/h and 1.5 meters on roads with higher speed limits. Distances set in the traffic regulations across different countries are primarily based on court rulings. Research is missing on which overtaking distance cyclists feel most safe and at which distance they are stressed.

This paper analyzes the effect of overtaking distances on cyclist stress. The research is based on test rides with 14 cyclists on urban streets. The bikes were equipped with sensors measuring the lateral distance between the bikes and overtaking cars. With the help of a stress-measuring method using medical fitness wristbands, stress-inducing overtaking interactions could be detected. The distance of the overtaking car and the stress events were compared by geometric and temporal coincidence. Through the Pearsons chi-squared test and the use of Cramer´s V, the results show a statically significant between closer overtaking distances and stress-triggering effects on cyclists: At distances under 1.6 meters, significantly more overtaking situations triggered stress.

The research has shown that the distance of cars overtaking cyclists has a big effect on the subjective safety of cyclists. The research also suggests that the 1.5 m approach is close to the measured "feel-safe" distance for cyclists and therefore supports regulations and enforcement around this value when planning streets to improve the safety of cyclists.

2 SUBJECTIVE SAFETY IN CYCLING TRAFFIC

2.1 Subjective and objective safety

The safety of cycling is composed of an objective and a subjective dimension and their interactions (Johannsen, 2013; Klebelsberg, 1982). Objective safety focuses on quantitative analysis of accidents and is usually based on an analysis of police accident statistics. Subjective safety looks at road users' emotional perception of the threat posed by a traffic situation (Fuller, 2005).

The term subjective safety describes the self-assessment of safety; i.e., how safe one feels in certain situations(Lange und Gasch 2006). From the Encyclopedia of Psychology of the scientific journal "Spektrum der Wissenschaft", subjective safety is described as a "typical experience-descriptive variable in the motivation theory-oriented research tradition on intraindividual conflicts and decisions" (Wenninger 2020). Thus, it is characterized by experiencesthat affect personal decisions (Jurczok 2019).

In road traffic, especially in cycling, the focus in recent years has been on objective safety. The goal is to use data to design the use and form of road infrastructure to prevent accidents or conflicts between road users. In recent years, however, the focus has increasingly turned to the "specific requirements and needs of local people and their perception of traffic"(Gehl 2018), hence subjective safety. The goal is now to incorporate aspects of subjective safety into the technical planning of transport infrastructure. The motivation behind the goal is to increase the acceptance of cycling in generalgeneral and thepotentialfor more frequent bicycle use. For many potential cyclists, a subjective feeling of insecurity is a barrier to more frequent use of the bicycle. In particular, for people who cycle infrequently – are also therefore highly important for increasing the cycling mode share - the subjective feeling of insecurity forms a barrier to more frequent cycling use (Aldred and Woodcock, 2015;Bill et al. 2015).

Since an objectively safer cycling infrastructure has no added value if it is not accepted by road users, cycling safety must be a combination of both subjective and objective road safety.

2.2 Factors of subjective safety in bicycle traffic

In recent years, the individual subjective feeling of safety among cyclists in Germany has grown steadily. This is shown, among other things, by data from the representative online survey "Fahrradmonitor" (Jurczok 2019), p. 48) conducted several times in Germany. A comparison of different years shows that the proportion of cyclists who feel "very/mostly safe" has increased from 53 % in 2017 to 63 % in 2021 (SINUS 2021, p. 48). This result shows that an improvement in subjective safety is achievable. In order to achieve an improvement in subjective safety, it must first be clear what stresses cyclists in traffic. In the study, dangers perceived by cyclists in the traffic flow are "too much car traffic," "no bike lanes," "inconsiderate behavior of other road users," "insufficient separation of bike lanes or bike paths from the lanes of cars" or "missing turn lanes". "Not sufficiently wide bike lanes or bike paths" tend to play a more subordinate role in the study (SINUS 2021, p. 121). Many of the stress triggers or uncertainty factors mentioned could also be related to overtaking: To much traffic means that cyclists are frequently overtaken. Reckless car drivers could be an indication of overtaking distance, and too-few separated bike lanes shows a clear general skepticism towards motor vehicle traffic.

A study by the Department of Transport (Gibbard et al. 2004) in Great Britain asked cyclists about elements that caused the most stress or feelings of vulnerability. Respondents perceive large roundabouts (36.4 %), fast traffic (11.2 %), a high proportion of heavy vehicles (17.8 %), and right turns in traffic (12.2 %) as most stressful or vulnerability-inducing. Many of the aforementioned points cover similar problems to the "Fahrradmonitor 2021" study. Due to the crossing of many conflict points when turning right - or, in countries with right-hand traffic, when turning left --it seems logical that cyclists tend to be more stressed than when riding through fewer conflict points.

In the study by Dennis Groß (2015), the stress of cyclists was made objectively measurable for the first time. By using a medical wristband, stress reactions of the human body were made visible. The evaluation of the study revealed a wide variety of stress triggers, which can be divided into three subcategories:

Horizontal effects are always related with the direction of travel of the cyclists. These include, in particular, intersections, merging into traffic, curves, road surface, obstacles, or narrow sections. Vertical effects involve the bicycle moving in a perpendicular direction. This is the case when cyclists ride over curbs, uneven pavement, or when the road has an incline or decline. Anthropogenic effects refer to all interactions triggered by other road users, such as an overtaking vehicle, oncoming traffic, pedestrians, or dooring. The various effects can also occur in combination, making it more difficult to identify the main trigger for the stressful situation. In addition, there may be other effects brought to the situation by the cyclist themselves (individual effects): Personal experiences and near-accidents at certain sections, but also the individual stress tolerance influences stress measurement (Merk 2019; Merk et al. 2021).

Another approach to measuring subjective stress is offered by the studiesof FixMyCity Team (2020)and Richter et al. (2019) about the safety and usability of cycling guidance. In both studies, cyclists were asked about their perception of safety when considering different traffic situations under variable infrastructure designs. The results of this showed that the street space design has a big impact of how safe cyclists feel on the street.

3 OVERTAKING INTERACTIONS INVOLVING BIKE AND CAR TRAFFIC

3.1 Legal Framework

Since 2020, Germany has mandated that car drivers may only overtake cyclists on the roadway with a distance greater than 1.5 m in the inner city, and 2.0 m out of town. Other countries have similar regulations for overtaking interactions involving cyclists. France, Portugal and Spain have also adopted the 1.5 m law.In Australia, the distance is usually 1 m on roads with speed limits less than 60 km/h and 1.5 m on roads with higher speed limits.

Distances set in the traffic regulations across different countries are primarily based on court rulings,such as the court decision from Hamm: "When overtaking, car drivers have to maintain a distance of at least 150 cm to the side and , when travelling above 90 km/h, they must maintain a 200 cm distance"(OLG Hamm, Az. 9 U 66/92).

However, no concrete justification forrecognizing these distances as "sufficient overtaking distances" (StVO, Germany) can be found in the technical literature.

3.2 Overtaking interactions in reality

Given that streets often have insufficient widths to allow for overtaking at a 1.5 m distance, many studies show non-compliance with prescribed minimum distances. Overtaking still takes place it is not legally permitted In the "SensorBike" project at the Karlsruhe University of Applied Sciences, only about 50% of recorded overtaking events had an overtaking distance of more than 150 cm (n=255 overtaking events). About 20% of recorded overtakes occurred at a distance of less than one meter (Röder et al. 2020). Other studies on overtaking distances also show corroborating results (Welz 2020; Baum 2019; Richter et al. 2019). Studies regarding overtaking distances under 150 cm in particular show that only about 50% of overtaking distances were greater than 150 cm in urban areas.

A closer look at the literature shows that the overtaking distances between motor vehicles and bicycles do not depend solely on the behaviour of the road users, but are influenced by the corresponding design of the road space. Although overtaking distances vary in different cities, the influencing factors are the same.

The lateral overtaking distance between motor vehicles and bicycles depends in particular on the width of the cycling infrastructure. A 100 cm wider cycling infrastructure leads to 33 cm wider overtaking distances. From a width of 1.85 m, cycling infrastructure leads to significantly larger overtaking distances than guiding cyclists in mixed traffic. Only the width of the cycling infrastructure is important, the type of cycling infrastructure is not decisive. If the width of the cycling infrastructure is smaller, the guidance in mixed traffic can lead to a smaller number of narrow overtaking distances. Thus, although overtaking does not occur at greater distances in mixed traffic, there are significantly more rejected overtaking manoeuvres than with cycling infrastructure under 1.5 m wide. In the case of cycle lanes or protective lanes less than 1.5 m wide, their benefits for the guidance of cycling traffic (e.g., recognisable guidance of cycling traffic, guidance in the field of vision of motor vehicle traffic, etc.) must be weighed against the lower overtaking distances compared to mixed traffic. It may be necessary to check whether a sequence of pictograms is suitable for the guidance of mixed traffic.

The width of the lane used by motor vehicle traffic also has an influence on the overtaking distances. Up to a lane width of 9.0 m, a widening of the lane results in an increase in overtaking distances. For every100 cm increase in lane width, the overtaking distances increase by 7 cm. Above 9.0 m, however, the lane width no longer has any influence on the overtaking distances. Overtaking by cyclists from oncoming traffic (encounter between car and bicycle) is rarely observed but is associated with narrow overtaking distances. On stretches of road with frequent overtaking manoeuvres with oncoming traffic, particular attention should be paid to ensuring sufficient overtaking distances. No influence on the overtaking distances between motor vehicles and bicycles was found for stationary traffic, the maximum permitted speed or the type of overtaking vehicle.

Objectively, motor vehicles overtaking bicycle traffic officially has only a minor negative influence on accidents. In accident statistics on cycling, overtaking rarely appears as a direct cause of accidents. According to a nationwide search engine query for online press reports of bicycle fatalities by Wordpress from early 2013 to 2018, only 6% of fatal bicycle accidents were due to ramming/striking with motor

vehicles(Wordpress 2018). The main causes of bicycle fatalities, according to this source, are solo accidents (32%) and right-of-way/crossings (28%). Other analyses of cycling accident statistics also assume a low direct involvement from overtaking motor vehicles(Peters 2010).

3.3 Potential factors influencing the occurrence of stress while overtaking interactions

Stress is generally understood as a reaction of the body to external or internal stimuli: so-called stressors. Stressors can be physical, psychological, or social. The body reacts to stressors when they disturb the balance in the body and the calmness of the person (Selye 1956). Stress can be seen as a type of adaptive response. As soon as a perceived stimulus is classified as relevant to the safety of the person, a protective mechanism takes place in the body through the release of hormones, such as adrenaline and cortisol, which puts the body on alert. A part of the autonomic nervous system, the sympathetic nervous system, is activated. The activation ensures "brain performance and behavioral responses of the body" (Zimbardo 1995). Evolutionarily, stress is a response that used to ensure human survival. The term "fight or flight," coined by the U.S. physiologist Walter Cannon (1915), plays a major role. By reacting to a stimulus with stress, the body was prepared for possible reactions necessary for survival and physical functions were ensured by hormones ("fight or flight"). Whether stimuli are perceived as threatening or irrelevant varies from person to person. The evaluation results from previous personal experiences, adoption of evaluations of others, change of knowledge and information, and personal theories (Tausch 2017). The subjective sense of safety starts here. Stress is seen as a reaction: the unsafe moments felt by each individual. In today's world, stress is mostly psychological in origin (Tausch 2017). In road traffic, however, stress can still be related to its former relevance. Thus, stress is mainly seen in pedestrian and bicycle traffic as a direct reaction to actual dangerous situations. Factors that function as stressors in everyday traffic are: Noise, proximity of stronger road users (fear of collision) or indirect factors, such as pressure or suction effects by other road users. All these stressors can be identified during (close) overtaking. For cyclists, potential stressors are triggered by their role as weaker road user on the roadway compared to motor vehicle traffic. Bicyclists, as weaker road users, are greatly outnumbered by faster motor vehicle traffic in a potential encounter and can thus feel a sense of being at their mercy. From the cyclist's point of view, this fear seems very understandable at first, but is not perceived as such by motor vehicle drivers. The car and the associated protective space act to separate from the real, threatening situation in possible collisions (Peters 2010).

A possible approach for maintaining sufficient overtaking distances can be derived from the four distance zones theory of ethnologist Edward Hall in 1982(Hall 1982). Hall assumes that every person allows certain distances to other groups of people without feeling uncomfortable. The intimate zone of a person or intimate sphere is reserved only for friends, family, or partners. It corresponds to an arm's length distance of60 cm. Strangers are perceived as threatening or intrusive in this zone their ejection of this intrusion can amass aggression ("stress"). The second zone is the personal zone, extending up to about 1.2m. Within this zone, only acquaintances or colleagues are tolerated. Sensory perception of these persons is already complete, but they are not perceived as directly unpleasant. In the social zone, people do not feel directly bothered or threatened by other people. In this zone, strangers are also tolerated; they are no longer fully perceived, sensory-wise. A direct threat or relevance for the well-being can be excluded. Overtaking can be assigned to this personal zone. Vehicles are therefore no longer completely sensory perceived from this distance and are therefore not seen as a nuisance or threat. With this approach, however, it must be considered that vehicles have a greater effect on cyclists due to their size, noise and other sensory perceptible influences and thus can still be perceived as threatening at distances beyond 1.2 meters.

So all in all overtaking by cars take a big role in the subjective safety of cyclists. There many reasons cycling people feels unsafe by big cars overtaking them real close. Also objective numbers show that there is no real reason to be really scared about. So what is the result of this inconsistency?: Is it really necessary to have rules which regulate the overtaking distances or is in the end the distance not that significant as it seems? These questions are to be investigated by the study of this work to increase the number of people cycling. In reality at least to enforce the rules you need more place for cyclists, otherwise near overtaking still will often take place on the streets. So the big question is has the overtaking distance impact on the stress occurrence of cyclists in urban areas and if so, at which distance the cyclists feel safe enough?

4 METHOD FOR DETERMINING STRESS PERCEPTION

4.1 Stress detection with the EmoCycling method

The EmoCycling methodology used in the project finds its origin in the "emotional cartography" initiated by Christian Nold in 2009. An essential component was the specially developed "Bio Mapping" device, which recorded biostatistical data in a georeferenced manner (Nold 2009). The recording of individual physiological responses is thus possible, with the individual acting as a "human sensor." Following a series of other research papers, Zeile et al. (Höffken et al. 2014) revealed the most common triggers for stress responses in cyclists using wearables, cameras, and smartphone-based applications. Specific traffic situations such as guidance patterns, high traffic volumes, dangerous overtaking, or the condition of the road surface were the most common stressors.

To measure the "stress level," the medical fitness wrist band "Empatica E4"is used(https://www.empatica.com/en-eu/research/e4/, 2020). The background use of this device is to generate real-time medical data for research purposes in order to perform analyses and visualizations. It records vitals data-- more precisely, the skin conductivity and temperature of the test persons during cycling -- and synchronizes the corresponding GNSS data to a smartphone. The basis for the recognition of moments of stress in the collected physiological data is done via a rule-based algorithm (Kyriakou et al. 2019). This assigns a stress moment when there is an increase in electrodermal activity (EDA) Activity (EDA) in conjunction with decreases in skin temperature values (ST).

When under stress, the human nervous system initially reacts with sweat production and an increased pulse. The sweat serves as a reaction to the imminent possible activation of corresponding body functions and the pulse is increased in order to supply corresponding body areas with sufficient blood. The extracted stress moments are each labelled with a timestamp and a geo-position so that they can be analyzed both spatially and temporally.

4.2 Structure and procedure of the study

When selecting the type of bicycle traffic routing, care is taken to select as balanced a proportion as possible of marked bicycle infrastructure (protective lanes/cycle lanes) and bicycle traffic routing in mixed traffic. For mixed traffic sections, both speed limits of 30 km/h and 50 km/h are included in the planning. Furthermore, when selecting the route, attention was paid to a clear course of the route, so that the route can be ridden by test persons without much prior knowledge. The test track has a length of about 7 km and leads across the inner city of Karlsruhe, Germany.

Fig. 1: Test Route in Karlsruhe, Germany

The test persons are selected according to two criteria. First, the subjects should have experience with cycling in urban traffic. Second, subjects should have a fairly homogeneous composition in terms of age and socio-cultural backgrounds. According to Geller's cyclist types, only people who can be classified as either

"Strong and the Fearless" or "Enthused and the Confident"are eligible for the survey. This grouping has already been used in several studies (Dill and McNeil, 2013, 2016; Portland State University et al. 2014) and are used as the basis for the present study.

The 14 test persons achieve good comparability within the group while controlling the study to focus only the effect of overtaking distances and the guidance of the bicycle infrastructure.

Test persons are equipped with anE4 to measure the occurrence of stress according to the EmoCycling method from Höffken et al. 2014. The bike is equipped with a OpenBikeSensor, cameras, and a GPS Tracker. OpenBikeSensor is an open-source project that has evolved over the last few years from a group of active everyday cyclists into an association. The goal of this project is mainly to provide and further develop a distance measuring sensor for the bicycle to record the lateral distance to other vehicles. It consists of ultrasonic sensors, an event trigger and GPS-recording.(OpenBikeSensor 2023)

In the present study, video recordings, distance measurements, and psychophysiological reactions of the test persons including GPS data are collected. In the analysis, the collected data is temporally connected to determine correlations between environmental parameters and overtaking distances and stress occurrences.

The processing and cleaning of the generated data sets of this research work is done by several steps:

First, the trips records from the camera are visually analysed for motor vehicle overtaking events. By overlaying the GPS points of the overtaking events and the distance data between bicycles and cars, a distance is assigned to each overtaking event. Since the GPS location of the distance data is sometimes very inaccurate, the overlay is verified using video time stamps and distance measurements. For this purpose, significant trip points such as the start and end of the test drive are overlaid with the respective time stamps.

The psychophysiological data of the fitness wristband are evaluated for stress moments by an algorithm based on the EmoCycling-method. Stress moments are identified and imported into a geographic information system using their GPS coordinates. By overlaying the stress moments with the overtaking distances, it can be determined in which overtaking events stress moments occurred. This results in a comprehensive data set with overtaking events, their lateral distance data, occurrences of stress, and other environmental parameters.

Statistical evaluation is performed using the chi-square test at the 95 % confidence level. Lower frequencies of expressions (n < 20) were not considered statistically, but only descriptively. The effect size of possible statistically significant parameters on the number of stress-inducing overtaking events is determined by the Cramer's V value. Additionally, two-step clustering is performed using the statistical software SPSS to identify possible groups of parameters "favouring" stress-inducing overtaking.

4.3 Results of the study

A total of 232 moments of stress were recorded in the study. These stress moments were first assigned to the overtaking processes and, in a further step, the remaining moments were assigned to other stressors through a second video analysis. With 42 %, the intersection aspect corresponds to the most stress occurrences. Overtaking vehicles occur as stressors in 28% of the assignable stress moments. At 11 %, slow vehicles ahead of the cyclist are a frequently occurring stressor in the study. The remaining stressors, including obstacles, bottlenecks, pedestrian traffic, oncoming traffic, and entering and turning vehicles, occur only sporadically as stressors. The classification of stressors according to Groß (2015)in the EmoCycling method, also used by previous studies, serves as an orientation. This first analysis shows that overtaking is the second largest stressor in this study.

A total of 226 overtaking events were recorded in this study. 38 (17 %) of the overtaking events can be attributed to a stress occurrence in the participants. 188 overtaking events are associated with no detected stress moments (83 %). Figure 17 shows the distances of all recorded overtaking events. The maximum overtaking distance is 230 cm and the minimum 70 cm. The 25 % quantile limit is at 130 cm and the 75 % quantile limit is 170 cm. Thus, the median 50 % of the values are between 130 and 170 cm. The median of all passing distances is 150 cm and the average of all passing distances is 152 cm. 50 % of the measured overtaking distances are above the often-used 150 cm and 50 % are below.

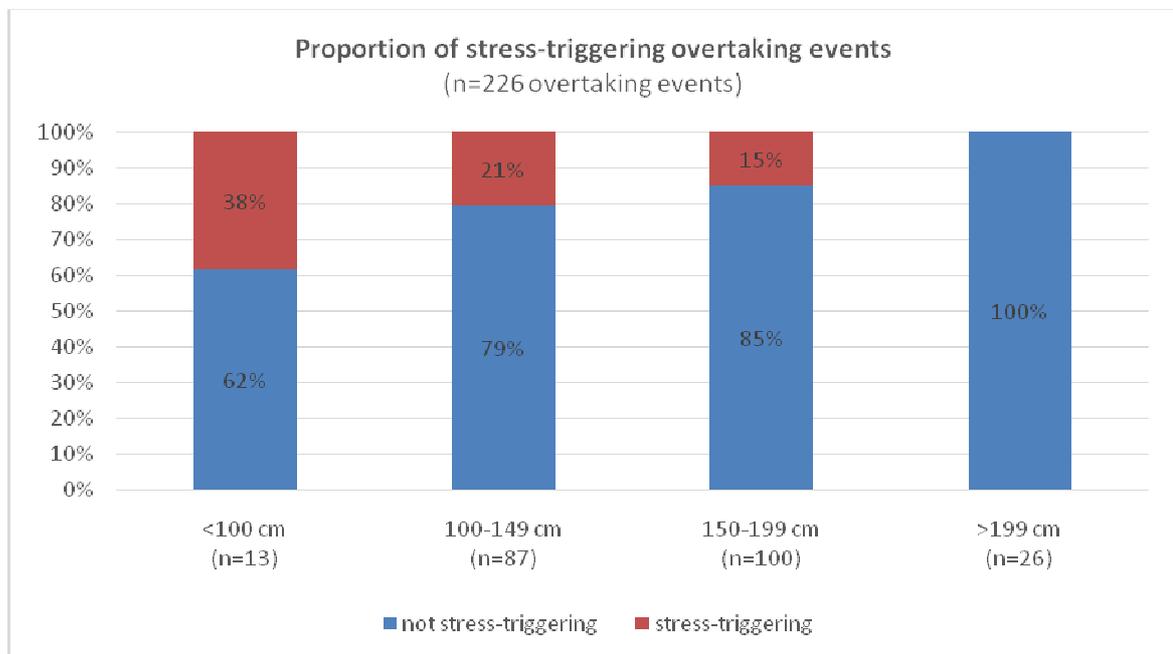

Fig. 3: Proportion of stress-triggering overtaking events

Using the Pearson's Chi-square test, the results show a statically significant between smaller overtaking distances and stress-inducing effects on cyclists:

For overtaking widths below 100 cm, the proportion of stress-triggering overtaking events was 38 %, for widths between 100-149 cm, it was 21 %, and for overtaking widths between 150-199 cm it was 15 %. At distances below 160 cm, significantly more overtaking manoeuvres triggered stress than at smaller overtaking-distances.

No stress-triggering overtaking events were recorded for overtaking events at distances above200 cm. However, the overtaking distances of the stress-triggering overtaking events above150 cm reveal that 13 overtaking events with a distance of 160 cm, 170 cm, and 180 cm were stress-triggering in certain cases (proportionately 15 %, 16 %, and 21 % of the overtaking events at these distances, respectively). These values indicate that, in these instances, the distance of 150 cm is insufficient or that perhaps other environmental parameters are responsible for the stress. 7 % of the overtaking events were thus still assessed as causing stress at overtaking distances greater than 160 cm.

Overtaking distances have a very large influence on the occurrence of stress among cyclists when overtaking by motor vehicle traffic. A statistically significant relationship between overtaking distance and the

frequency of stress-inducing overtaking was found for all distances below 160 cm. This relationship is most pronounced for overtaking distances less than 130 cm. However, overtaking events that did not have a stress-triggering effect also occurred below 130 cm and, at the same time, stress-triggering overtaking events occurred for overtaking events at a distance of more than 160 cm. These peculiarities are to be regarded as statistical outliers.

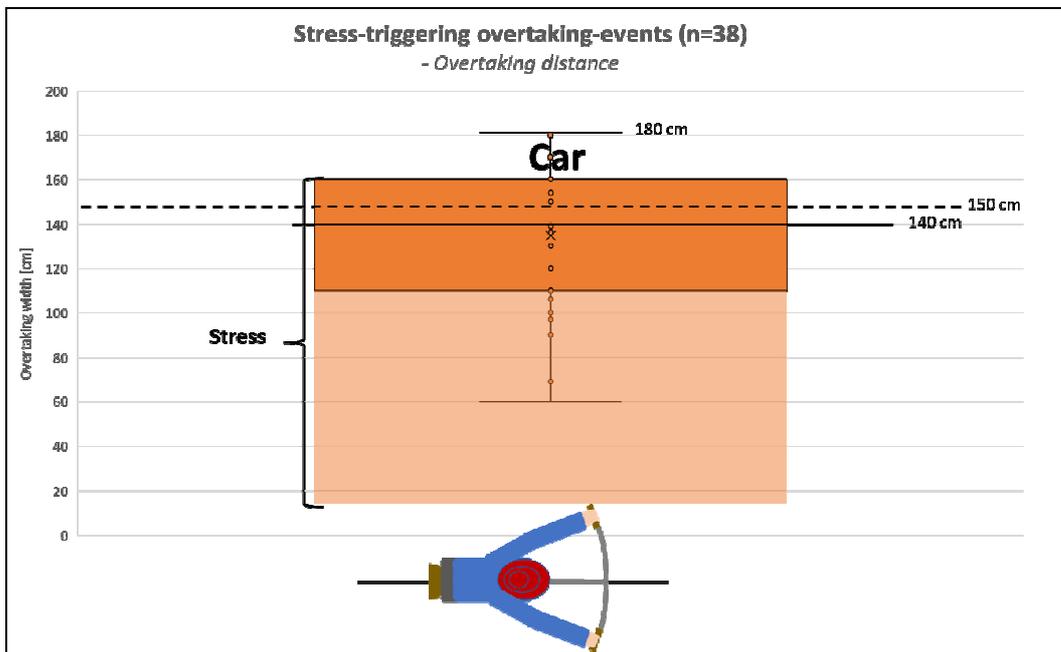

Fig. 4: stress-triggering overtaking-events depending on distance

Other environmental parameters did not provide any detectable influences on stress in the study: the influence of extra bicycle traffic guidance on the road such as protective lanes and bicycle lanes had no influence on stress occurrence. Also the difference between motor vehicle speeds of 50 or 30 km/h showed no influence in this study. However, these findings should not be considered definitive due to the small sample size.

5 DISCUSSION OF LOW-STRESS OVERTAKING INTERACTIONS INVOLVING BIKE AND CAR TRAFFIC

The present study shows that overtaking by motor vehicle traffic of cyclists has a measurable effect on objectively measurable subjective safety cyclists. Stressors such as crossing at 42% and overtaking vehicles at 28% occurred most frequently in the study. Stressors were measured in 17% of detected overtaking events. Thus, according to this study, motor vehicle overtaking events have a high influence on the occurrence of stress among bicyclists within urban areas.

The results show that the overtaking distance plays a decisive role: The larger the distance, the less stress was measured in motor vehicle overtaking events. Up to a value of 160 cm, a statistically relevant positive correlation was found between the small overtaking distances and the number of stress moments that occurred. For overtaking distances of less than 100 cm, the proportion of overtaking events causing stress was 38%, for distances between 100 and 149 cm it was 21%, and for overtaking distances between 150 and 199 cm it was only 15%.

In summary, the overtaking distances in overtaking events by motor vehicle traffic are most related to stress occurrences for cyclists. The overtaking distance of 150 cm regulated by, for example, the German Road Traffic Regulations (StVO) can therefore be seen as a sensible starting point for providing cyclists with sufficient subjective safety space. No negative or positive effect on the occurrence of stress among cyclists could be attributed to the environmental parameters of route type, bicycle traffic guidance type, maximum permitted speed for motor vehicle traffic, constricting elements in the right lane edge, and heavy traffic.

Measures should be taken to increase overtaking distances. Cyclists should be proclaimed to be respected on urban roads. The appropriate behavior of motor vehicle drivers should be encouraged through campaigns and notices. Some cities and states already launched campaigns to address the failure of motor vehicle traffic to

706

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

maintain the minimum overtaking distances with cyclists. In countries such as Switzerland, campaigns actively attempt to attract more attention to the issue of cyclist overtaking (Brenn 2021). The aim of these campaigns is to raise awareness of the current rules on minimum overtaking distance and to increase considerate behavior between motor vehicle traffic and bicycles. The long-term effects of these campaigns on overtaking are not yet foreseeable.

Another thing that derives from the study is that bicycle infrastructure must be built that promotes sufficient overtaking distances. In particular, sufficiently-large, on-roadbicycle facility widths of at least 1.85 m are important. If there is insufficient space for wide bike infrastructure, it should be checked whether mixed traffic on the roadway at low speed, possibly supported by pictogram sequences, present possible solutions. In some cases, a solution may be to prohibit overtaking of single-lane vehicles.

It is recommended to conduct further studies of this kind on a larger scale to make even more quantifiable statements. Additional factors, such as the influence of heavy traffic or the guidance of bicycle traffic on protected lanes on cyclist stress during motor vehicle overtaking events could be made. In addition, a further study should be conducted on the stress perception of cyclists when motor vehicles are following behind in order to be able to exclude potential stress occurrences for cyclists.

This research makes an important contribution towards determining the subjective feeling of safety of cyclists through an objectively-measurable method and therefore better understand the subjective safety of cycling. The statistical relevance of the overtaking distances with cycling traffic contributes to the so-far only partial implementation of minimum overtaking distance regulations and ultimately increases the subjective safety of cycling and promotes cycling in general.

The Impact of Free Municipal Wi-Fi on the Citizens' Right to the City, Good Governance, and Service Delivery in an African Context: the Perspectives of the Residents of Pretoria Central Business District (CBD) in the City of Tshwane, South Africa

Tlou Phillemon Mathane, Trynos Gumbo

(Tlou Phillemon Mathane, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, phillemonmathane@gmail.com)

(Prof. Trynos Gumbo, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, tgumbo@uj.ac.za)

1 ABSTRACT

Just after the year 2010, big cities in South Africa started to introduce programmes to provide free data, especially to their disadvantaged communities. This came in the context of a broader appreciation that access to data is no more a luxury, but rather a basic necessity for daily livelihood in the context of the fourth industrial revolution. The increasing explosion of the fourth industrial revolution is been driven partly by the pervasive digitization of things, which results in big volumes and a variety of data flowing from heterogeneous sources at increasing velocity. In this regard, all eight (8) metropolitan municipalities in South Africa (Buffalo City, Tshwane, Johannesburg, eThekwini, Ekurhuleni, Mangaung, Nelson Mandela Bay, and Cape Town) are currently implementing free Wi-Fi programmes to improve access to data. Some of the secondary cities in South Africa have also followed suit. Non-governmental role players have also started to provide free wireless internet sites as well. These efforts are most commendable in an African context, noting that the average internet penetration level in Africa is approximately 43.1%, compared to the global average of 66.2%. Significantly, these interventions are also commendable because they are in sync with the Sustainable Development Goal (SDG) 11, that of building sustainable cities and communities. However, from an empirical research perspective, the impact of such incredible initiatives on imperatives such as improving the citizen's right to the city, good governance, and enhanced service delivery in an African context is yet to be fully understood. So, the question is: to what extent can free municipal Wi-Fi to assist citizens to realize these three development imperatives, viz: realize their right to the city, good governance, and enhanced service delivery? To this end, this study empirically investigated the perspectives of the residents in the Pretoria Central Business District (CBD) in the City of Tshwane, South Africa. The City of Tshwane is the Capital City of South Africa. This study utilized a case study design and is qualitative in nature. Both primary and secondary sources were used. Fifty (50) residents in the Pretoria CBD responded to a randomly administered online survey. The results were analyzed by categorical aggregation and content analysis. The findings reveal that the Pretoria CBD residents feel that the Tshwane free Wi-Fi is making more impact in enabling the citizens to enjoy the informational right to the city and good governance, and lesser compared to improving service delivery. In conclusion, the researchers recommend an expansion of more free Wi-Fi sites in the Pretoria CBD to accommodate an increasing student population in the area, to make the Pretoria CBD more liveable, and sustainable, and to entrench social justice. However, the City of Tshwane would need to find an innovative funding model because the free Wi-Fi programmes are not cheap.

Keywords: Sustainable Development, Sustainability, Smart city, Free Wi-Fi. Tshwane

2 INTRODUCTION

In the past two decades, there have been different academic contributions on the role of smart technologies in cities and urban sustainability. One contribution is that smart city implementation reproduces the inequalities of marginalized people in the city (Willis, 2019). Another contribution is that smart cities do produce inequality (Caragliu and Del Bo, 2022). Yet another contribution is that the deployment of smart technologies makes cities/communities more sustainable (Hamza, 2021), thus bringing positive impacts on communities (Alavi, et al 2018). Yet, another contribution is critical to this notion (Hamza, 2021). So, despite all these diverse contributions, there are still some knowledge gaps. One of the gaps is that the majority of the studies are not based on empirical data. Another gap is that the majority of these studies are done in developed economies, and very few in the African context.

3 CONCEPTUAL FRAMEWORK

3.1 Framing the study conceptually

There are several conceptual constructs that the study engaged with. They are discussed below:

Figure 1: Conceptual Framework of the study: Source, Author (2023)

3.2 Sustainable development

The concept of sustainable development encapsulates the pillars of the economy, society, environment, and governance (Cecchin, et al. 2021). However, in the context of the fast-changing digital world and rapid urbanization, some scholars, e.g. Mondini (2019), posit that the technological pillar is very relevant. It is believed, at least by scholars such as Kopnina (2020), and Schopp, et al. (2020) that sustainable development is about raising the living standards of the next generations. Many other scholars agree that smart digital technologies tend to address urban management challenges in the 21st Century (Onyango, et al 2021). However, the empirical efforts to assess the efficacy of smart city interventions in Africa remain limited. In the context of the fast-changing digital world, the technological pillar is also relevant to the discourse of sustainable development (Mondini, 2019).

3.3 The Fourth Industrial Revolution

The Fourth Industrial Revolution (4IR) is challenging all fields of life all over the world (Korczak and Kijewska, 2019). It has made access to data and the internet lifestyle more popular. In countries such as China, digital technologies and the internet are vital for public involvement in planning and governance processes. This is positively associated with economic and social transformation. However, it is still acknowledged that the huge digital divide in communities creates unequal power relations (Zhao, et al., 2018). The 4IR (Industry 4.0) is about connections (Onik, et al. 2019). These connections affect how people live their lives (Xu, et al., 2018). The 4IR also incorporates things such as Artificial Intelligence (AI), advanced robotics, data analytics nanotechnology, 3D printing, the Internet of Things (IoT), blockchain neurotech, cloud technology, and biotechnology. These bring some sophistication in terms of how things are being done now (Korczak and Kijewska, 2019).

3.4 Smart and sustainable cities and communities

The creation of sustainable cities is one of the most pressing central challenges of this age (Yang and Taufen, 2022), especially due to increasing technological advances (Steputat, et al., 2020). There is a need for sustainable cities and sustainable communities, as espoused by Sustainable Development Goal 11 (Mondini, 2019). The notion of smart cities and their linkages to sustainable communities is prominent today in policy discourses internationally. Zielinska-Dabkowska and Bobkowska (2022) underscore the need to build sustainable cities and communities. Similarly, Yang and Taufen (2022) emphasize this in the context of the COVID-19 disruptions that have challenged the resilience systems of cities. So, the implementation of

modern digital technologies by municipalities must make cities and communities more sustainable (Hamza, 2021) because, today, like never before, cities face the challenges of being sustainable (Fell and Mattsson, 2021). The high rate of urbanization is adding to the sustainability challenges (Vaidya and Chatterji, 2020). There is also a broader realization and appreciation that what is needed is not just smart cities, but sustainable smart cities (Yigitcanlar, et al., 2019). Sustainable smart cities deploy digital technologies to improve the quality of life for residents (Zvolska, et al., 2019).

3.5 The right to the city

The concept of the right to the city is a sustainability question. This concept was inspired by Henri Lefebvre's work The Right to the City (1968). Influenced by the thoughts of Henri Lefebvre's work The Right to the City, Willis (2019) asks a question: "Whose Right to the Smart City?" Ben-Lulu (2021) asks an important question: who has the right to the city? Urban policies should promote the notion of citizenship for all (Borja, 2019). The right to the city is seen as an agenda for social change (Vergara-Perucich, and Arias-Loyola, 2019), especially in the context of smart cities (Van der Graaf, 2020). Smart cities are not just about data; but they are about citizens (Breuer, and Pierson, 2021). So, citizen participation is an essential element of the right to the city (Anastasiu, 2019). The citizens must be able to inhabit the city freely (Aquino, et al., 2020). In the context of smart cities, pertinent questions are asked about the right of citizens to apply their rights (De Frantz, 2021). The right to the city is about citizen-centric digital cities (Breuer, and Pierson, 2021), as it is also about citizens claiming their rights within a city (De Frantz, 2021). When the playground is unequal, the attainment of the right to the city becomes a difficult feat (Diaz-Parra, and Jover, 2021). Progressive social movements have placed inclusion (Hintjens, and Kurian, 2019) and social justice agenda at the center of the right to the city (Yang, et al., 2019). The right to the city is also about the informational right to the city. In South Africa, the Promotion of Access to Information Act (PAIA) is important in this regard. It reinforces the constitutional right of access to information.

3.6 Service delivery and good governance

Smart cities are perceived to solve a range of complex urban management challenges (Allen, et al. 2020) to offer value to residents (Timeus, et al. 2020). One of the value offerings is efficiency in the delivery of public services because smart cities must be citizen-centered (Yang, et al. 2019). Allen, et al. (2020) found that most citizens use e-government platforms for complex issues than for basic service delivery routine services. Whereas Gil, et al. (2019) found that digital platforms do benefit citizens, other scholars argue that it benefits most technology-savvy citizens compared to the poorest of the poor. Aurigi and Odendaal (2022) posit that the use of smart digital technologies should be context and place-based so that they enhance social sustainability. It has been found that e-platforms encourage more citizen participation, and also improve service delivery (Gil, et al. 2019). Smart city technologies can also save traveling costs and time (Jaiswal, et al. 2020). In addition, smart digital tools and platforms can be used by cities to strengthen governance systems (Rodríguez Bolívar, 2019). Information Communication Technologies (ICTs) can introduce some governance reforms to enhance accountability (Basu, 2019). Smart city technologies allow citizens to be engaged, and participate in public consultations (Gade, 2019). However, different planning cultures in cities do affect governance aspects (Lim, et al. 2022). It is also noted that the use of modern technologies tends to attract younger people more than older people (Kopackova and Komarkova, 2020).

4 METHODOLOGY

This research investigated the views of the residents in the Pretoria CBD and surrounding suburbs in the City of Tshwane, South Africa, as far as the impact of the Tshwane free Wi-Fi on the citizen's right to the city, good governance, and service delivery. The study used an online survey tool, which was administered to fifty (50) residents in the Pretoria CBD. A majority were from Hatfield (48%), Sunnyside (24%), and CBD (12%). The profile of respondents is quite mixed and dynamic. In terms of occupation, 53% of the respondents were students; and 30% were employed. In addition, 10% were unemployed graduates, and 6% were self-employed residents. As far as the age is concerned 90% are youth between the ages of 18 and 34, followed by 10% above the age of 45. The education level of respondents is also mixed: 42% with a 3-year post-matric qualification, 44% with an honors degree and above, and 14% with just matric. The voices of these residents were captured, synthesized, and analyzed. Surveys are popular for qualitative data (Mellinger

and Hanson, 2020). In addition, secondary sources (reports, academic journals, books, etc) were used. So, the research is qualitative in nature and was guided by the qualitative approach.

5 FINDINGS

5.1 Findings regarding access to free data in Africa

5.1.1 The politicization of data in Africa

The internet penetration level in Africa is 43.1%, compared to the global average of 66.2% (Internet World Stats, 2022). Some of the underlying causes of the slow digital uptake of ICTs in African countries are related to political interference and the sheer lack of political vision. The use of digital technologies to fight political battles is also a major factor of concern. For instance, in the Democratic Republic of Congo, reports of the government quelling civil unrest by suspending internet services - referred to as "blackouts" are common (Braun, and Buse, 2020). In Ethiopia, Tanzania, and Uganda the central governments tend to implement 'Internet Shutdowns' and "social media shutdowns". In Angola, authoritarian politicians use internet control to disadvantage political opponents (Garbe, 2021). Cameroon is also known for muzzling the digital rights of the residents due to the autocratic government's tight grip on the media (Murrey, 2022).

5.1.2 Best-case African models in terms of access to data

There are approximately five (5) African countries whose share of internet users exceeds the 50% population threshold. These are Morocco (84%), Seychelles (79%), Egypt (71%), South Africa (68%), and Tunisia 66% (Statista, 2022). An interesting observation is that although free Wi-Fi initiatives provide approximately 40% of data in the African continent (Danquah, Marful, and Duah, 2019), in these African countries, it is not easy to establish if the provision of free Wi-Fi is the key/main driver of higher levels of access to the internet. This is an area worth researching because academic and empirical research on the provision of free Wi-Fi initiatives is generally scanty in the African continent.

5.1.3 Worst-case African models in terms of access to data

There are African countries that need to, as a matter of urgency, do more in terms of reducing the digital divide through free Wi-Fi programmes. These include Sudan (only 10% of the population have access to the internet); the Democratic Republic of Congo (only 17% have access); Tanzania (25% have access); and Ethiopia (25%). The case of Ethiopia requires urgent attention because of Internet Shutdowns. Other stats looks as follows: Rwanda (26%); Zambia (only 28%); Uganda (29%); Zimbabwe (30%); Angola (35); Cameroon (36); Kenya (42%); Nigeria (51%); and Ghana (53%) (Statista, 2022). These countries need to galvanize the private sector, NGOs, CBOs, global multinational organizations, etc, to invest more in digital transformation. Of course, they need to improve financial management, root out corruption, and maladministration, to attract local and Foreign Direct Investments (FDIs).

5.1.4 Internet user gender gap in Sub- Saharan Africa: an overview

As far as the internet user gender gap between men and women is concerned, the situation in Africa calls for serious concern. Internet access for men is 33, 8%, compared to women at a meager 22.6%. This does not compare favorably with the world average, with access for men being 58, 3%, compared to women at 48.4%. Neither does it compare favorably with the developed economies (average), where access for men is 87, 6%, compared to women at 86.0%, whereas, in the developing economies (average), access for men is 52, 8%, compared to women at 40.7% (ITU, 2019). So, Sub-Saharan Africa has a lot to catch up on as far as access to the internet is concerned.

5.1.5 African Countries with more than 10 million internet users

The top 3 African countries with more internet users are Nigeria (109 million), followed by Egypt secondly (75 million), and South Africa third at 41 million (Statista, 2022). Morocco has 31 million internet users, followed by Ethiopia at 29 million, and Kenya at 23 million. Then follows Ghana (16 million), the Democratic Republic of Congo (16 million), Tanzania (15 million), and Sudan, Uganda, Angola, and Cameroon at 14 million, 13 million, 12 million, and 10 million respectively (Statista, 2022).

5.2 African Countries with less than 10 million internet users

There are several African countries with less than 10 million internet users by 2022. Cote d'Ivoire has 9, 9 million, followed by Senegal and Tunisia (8 million) and Mozambique at 7, 5 million (Statista, 2022). Some African countries with less than 7 million internet users include Mali (6, 3 million), Burkina Faso (5, 9 million), Zambia (5, 4 million), Zimbabwe (4, 5 million), and Benin, Rwanda, and Libya at 3, 6 million, 3.5 million and 3, 4 million respectively (Statista, 2022).

5.3 African Countries with a share of internet users exceeding 50% of their population threshold

There are also African countries with a share of internet users exceeding 50% of their population. Morocco leads (84%), followed by Seychelles (79%), Egypt (71%), and South Africa (68%). Tunisia follows (66%), then Mauritius (64%), and Gabon, Cabo Verde, Western Sahara, Botswana, and Algeria at 62%, 61%.9, 61.3%, 61%, and 60% respectively (Statista, 2022). Those whose share falls below 60% include Djibouti (59%), Ghana (53%), and Lesotho, Nigeria, Namibia, and Gambia all averaging around 51% share (Statista, 2022). It is important to juxtapose the statistics about the share of internet users with the statistics on the number of internet users. Table 1 present this kind of analysis. For instance, even though Nigeria leads in terms of the number of internet users, those only make up 51% of the share of internet users.

African Country	Number of internet users	Share of internet users
Nigeria	109 million	51.0%
Egypt	75 million	71.9%
South Africa	41 million	68.2%
Morocco	31 million	84.1%
Ethiopia	29 million	25.0%

Table 1: Juxtaposing the share of internet users with the number of internet users in selected African countries, Mathane (2023), based on Statista (2022).

The African country with a bigger share of internet users in Morocco, but in terms of the number of users, the country lies fourth at 31 million – less than Nigeria, Egypt, and South Africa. Interestingly, Egypt has the second number of internet users in the continent, and the share of internet users is also equally competitively high at about 72%, followed by South Africa with 41 million internet users with a share of 68%. This is an important point about the possibly institutionalized digital divide within African nations themselves.

5.4 African Countries with a share of internet users below the 50% population threshold

There are over 35 African countries whose share of internet users is less than the 50% population threshold This speaks to the direness of the situation of a digital divide in the African continent. The worst-case scenarios are found in countries like Chad, where 19% of the population has access to the internet. The Democratic Republic of Congo (DRC) is also battling, with only 17% of the population accessing the internet, similar to Burundi, Niger, and Somalia – all of which have 14% of the population accessing the internet. South Sudan is no better at 10%, similarly with Comoros and Eritrez at 8% (Statista, 2022). These are cases in the African continent where digital access must be addressed as a matter of urgency.

5.5 Arguments for decolonization (neo-liberalization) in the context of access to data in African cities

The implementation of free data programmes must appreciate the fact that African cities have their peculiar urban management challenges, socio-economic inequalities, governance failures, etc. So, the implementation must be rooted in the contextual realities of the cities (Bandauko, and Nutifafa Arku, 2022). Some scholars suggest that African cities should free themselves from reliance on neo-liberal policies crafted by the West. In this regard, they suggest that one way of doing this is for African cities to start investing in accessing free WI-Fi and internet services (Wissink, 2020). Indeed, other scholars call for decolonial thinking about technology, cautioning that if Africa continues to rely on foreign capitalist actors, this would endanger their well-being and sustainability (Oyedemi, 2021).

5.6 Findings regarding the free Wi-Fi in the City of Tshwane

5.6.1 SWOT Analysis of Tshwane free Wi-Fi

Table 2 below shows Ramokgopa's (2018:226) insightful thoughts about the SWOT analysis of free Wi-Fi in Tshwane. From the perspective of strengths, strong executive commitment, coupled with administrative and technical internal competency in the area of ICT is a must. From a Business Continuity Management (BCM) perspective, it is also commendable that when the Democratic Alliance (DA) took over governance in the CoT, this programme was continued. From the perspective of weaknesses, the fact that the city does not own bandwidth is one of the strategic risks which should be managed judiciously. It can also be added that the fact that the City of Tshwane has not yet found a sustainable solution for theft and vandalism constitutes a weakness within the CoT management ecosystem. Another major weakness relates to the lack of clarity on the funding model.

STRENGTHS	WEAKNESSES
- Executive Leadership is committed to the programme. - Internal CoT ICT technical team. - Partnership model with competent service providers.	- The funding model is not yet clarified - Lack of CoT ownership of bandwidth - Lack of specialized and experienced legal team for contract management
OPPORTUNITIES	**THREATS**
- Increased smartphone usage in CoT. - Universal access to the internet - Increasing education levels of CoT residents - CoT enjoyed first-mover advantages - Online learning opportunities in CoT. - Revenue generation opportunities - Internet-based businesses can grow. - More private-sector investments - Increases engagements between city management and communities - Real-time communication	- The perception that the internet is a luxury can result in unfavorable funding decisions. - CoT can face possible litigation by some private sector internet providers. - Likely to commit mistakes as first movers - Negating the potential scale benefits. - Financial unsustainability. - Cyber security risks - Delayed legislative clarity because municipalities are not designated as internet service providers. - Impersonal community interactions

From the perspective of opportunities, there are many positives – increasing internet access, accelerating usage of smartphones, internet-based and/or online learning for teachers and learners, as well as opportunities for local online businesses Ramokgopa (2018). However, there are also missed opportunities currently, including opportunities for the CoT to partner with CBOs, NGOs, and the residents themselves. Opportunities for crowd souring funding also need to be explored. The City is not optimally pursuing raising its revenue (monetizing) with this platform. From the perspective of a threat, some of the key challenges include cyber security risks and financial unsustainability. At the level of social justice, the rate at which the CoT would engage citizens in impersonal ways would increase. Significantly, lack of legislative clarity considering that municipalities are not designated as internet service providers; including the fact that free data is not yet gazetted as a basic function of municipalities in South Africa is one of the strategic threats affecting free municipal Wi-Fi in South Africa as a whole. Policy and legislative lethargy and procrastination in this regard need to be corrected, particularly in the context of coalition politics, which have proven rather unpredictable.

5.6.2 Tshwane free Wi-Fi and the right to the city

The right to the city is a loaded and multilayered concept. So different aspects of this concept were dealt with in the survey. For instance, the respondents were asked their opinion regarding the Tshwane free Wi-Fi's contribution to enhancing the capacity of residents to exercise their informational rights to the city of Tshwane. In this regard, a majority of respondents (42%) felt that the free Wi-Fi is making a modest contribution, followed by 30% who believe that it is making a lot of contribution. About 22% felt that the contribution is there, but very modest in terms of impact. The respondents were also asked their opinion regarding the Tshwane free Wi-Fi's contribution to enhancing social justice in Tshwane. In this regard, 76%

agreed (of these, 56% just agreed, whereas 20% strongly agreed). Only 20% were not sure, and just 1% disagreed. The respondents believe that a significantly high proportion of Tshwane residents (80%) rely on the Tshwane free Wi-Fi to engage on social media platforms. However, only 32% of the respondents indicate that they use the Tshwane free Wi-Fi to engage on social media platforms. More respondents (46%) use their private data and use the Tshwane free data when their private data is exhausted. This means that a lot of the students (53%) tend to use private data first before they use Tshwane's free Wi-Fi.

The respondents were asked their opinion regarding the Tshwane free Wi-Fi's contribution to enhancing spatial justice in Tshwane. In this regard, 72% agreed. However, 18% disagree, and only 10% disagree. In addition, the respondents have diverse views about the Tshwane Free Wi-Fi serving all people of Tshwane equally well irrespective of their geographic location. About 48% agree, and 20% disagree. About 18% were not sure, and 14% strongly disagree. In terms of accessibility, 40% of the respondents feel that the Tshwane Free Wi-Fi accommodates all people (accessible for all), followed by 30% who disagree. In addition, only 46% of the respondents believe that in its current format, the Tshwane free Wi-Fi responds to the local contexts of communities. About 38% are neutral, whilst 26% disagree with the notion. Rather surprisingly, 60% of the respondents believe that the Tshwane Free Wi-Fi is directly informed by the socio-economic needs of the community. A small percentage (9%) disagrees, whilst 28% is neutral. As far as traveling inconvenience/costs are concerned, 62% of the respondents believe that since the introduction of the Tshwane Free Wi-Fi, some people no longer have to travel to the central city/town to do things that can be done through digital platforms. About 26% disagree, and 12% are neutral. The respondents were asked their opinion regarding the Tshwane free Wi-Fi's contribution to enhancing economic justice in Tshwane. In this regard, 44% of the respondents believe that the Tshwane free Wi-Fi makes a good contribution to enhancing economic justice in Tshwane. About 20% are of the view that the contribution is modest, and 22% believe that the contribution is low. On another factor, 78% of the respondents believe that many residents in Tshwane rely on the Tshwane Free Wi-Fi for economic opportunities such as job applications and business transactions. Only 10% disagree with this notion.

In terms of stakeholder analysis, the respondents were asked their opinion regarding whether the Tshwane free Wi-Fi implementation embraces partnerships and contributions. In this regard, 62% agreed, and 28% were not sure, whilst 9% felt that there is no involvement of external partners. Similarly, the respondents were asked their opinion regarding whether the Tshwane free Wi-Fi implementation embraces community involvement. About 64% agree, and 24% are neutral, whereas 9% disagree with the notion. As far as private sector involvement is concerned, 60% feel that there is adequate involvement, followed by 26% who are not sure; and 14% don't agree with the notion. The involvement of organized civil society formations also attracted diverse opinions; with 58% agreeing that there is adequate involvement of civil society groups in the conceptualization and implementation of the Tshwane Free Wi-Fi. However, 26% were not sure, whilst 16% disagreed with the notion.

5.6.3 Tshwane free Wi-Fi and service delivery and governance

Similarly, the respondents were asked their opinion regarding the Tshwane free Wi-Fi's contribution to enhancing service delivery in Tshwane. In this regard, 36% feel that a lot of contribution can be seen; whilst 32% believe the contribution is modest. About 26% of the respondents are not sure, whilst only 6% disagree. Nonetheless, approximately 44% of the respondents believe that many residents in Tshwane rely on the Tshwane Free Wi-Fi to engage the city on service delivery matters. About 34% are not sure; whilst 22% believe that generally, Tshwane residents prefer traditional (non-digital) ways of engaging the city. Similarly, about 22% of the respondents indicated that they are part of the Tshwane residents who use Tshwane Free Wi-Fi to engage the city on service delivery matters. Interestingly, 42% indicate that they use Tshwane free data for service delivery engagements only when their private data is finished. The rest (22%) indicate that they prefer residents prefer traditional (non-digital) ways of engaging the city.

The respondents were also asked their opinion regarding whether many residents in Tshwane rely on the Tshwane Free Wi-Fi to pay their bills, check statements, etc. Nearly half of the respondents (46%) believe that many Tshwane residents use the Tshwane Free Wi-Fi to pay their bills, check statements, etc. And, 12% believe that residents still prefer the traditional (non-digital) ways of paying their utility bills. Approximately 42% were not sure. Respondents were also asked if they are part of those Tshwane residents who use Tshwane Free Wi-Fi to pay their bills, check statements, etc. Interestingly, 42% of the respondents indicate

that they always use their private data. Another 42% indicate that they use Tshwane free data when their private data is finished. The rest (16%) indicate that they prefer residents prefer traditional (non-digital) ways of engaging the city. Finally, the respondents were asked to share their opinions regarding whether the Tshwane Free Wi-Fi is contributing to allowing residents to participate in governance processes in the City of Tshwane. Some 36% of the respondents feel that the Tshwane free Wi-Fi is making a lot of contribution in this regard. However, another 36% believe that the contribution does exist, albeit just modestly. Some feel that free Wi-Fi is not contributing in this regard. They make up 20% of the respondents. Finally, only 8% feel that the free Wi-Fi program is not making any contribution whatsoever in this regard.

6 CONCLUSIONS AND RECOMMENDATION

There are compelling reasons for African cities to deploy digital technologies so that they are not left behind as global cities are now more than ever before heavily influenced by intelligent technologies to interact directly with people. Africa is expected to reach a population of about 2.5 billion in 2050 (INED, 2019). This would be the fastest growth rate in the world. So, the deployment of sustainable and free Wi-Fi systems in African cities is more urgently needed (Ndiaye, et al 2022). The underlying problems causing poor access to internet connectivity in Africa have less to do with a lack of infrastructure, but more to do with a lack of commitment to good governance. African leaders and authorities need to do away with the politicization of data. This is untenable from a sustainable governance point of view. As far as the City of Tshwane Pretoria CBD case study is concerned, a majority of respondents agree that the Tshwane free Wi-Fi is greatly assisting in improving the citizen's right to the city. In terms of good governance, the study concludes that the Tshwane free Wi-Fi is also greatly assisting in entrenching social justice. However, when it comes to improving service delivery access and quality, the Tshwane free Wi-Fi is found to be used by fewer residents. In conclusion, there are some implications for the future. This means that cities can no longer approach planning from traditional planning approaches. Data is more than an essential need today, than it was in the pre Covid period. For the longer term, access to data will occupy similar position of significance as basic services such as water electricity, santiation, etc. Acces to data may even be a human right. Should such an eventuality arise, from a legal perspective, municipalities may not longer have an option of providing free access to data voluntarily, as this could be a Constitutionally mandated basic service. Cities should proactively plan for such eventualities, and partner with private and non governmental stakeholders to piggy back on therigh strenths and unique capabilities. past as well as projected future ones for the use of free wifi and its rolling out pace. In the case of Tshwane, the researchers recommend an expansion of more free Wi-Fi sites in the Pretoria CBD to accommodate an increasing student population in the area, thus increasing the possibilities of making the Pretoria CBD more liveable, sustainable, and entrenching social justice. However, the City of Tshwane needs to find innovative funding models because the free Wi-Fi programmes do not come cheap.

1 ABSTRACT

The liveability in urban neighborhoods partially depends on the living conditions in the residential environment (Die Bundesregierung 2016: 3). These include the supply of goods and services as well as their quality and accessibility. The infrastructures that influence the liveability in urban neighborhoods vary depending on the age, social status and life stage of the residents. These include educational, administrative, health, cultural and recreational facilities. Reasonable accessibility may also be perceived very differently by young adults without children, families, baby boomers or the elderly. According to Prof. Carlos Moreno's model of the "15-minute city", each trip should have a maximum walking or biking distance of 15 minutes (Moreno 2021). However, the model of the 15-minute city does not specify speeds, i.e. what distance is achievable within the travel time. This can differ depending on the target group.

The focus of this paper is on the spatial analysis of factors that determine the quality of life of baby boomers (birth cohorts 1955-1969)[1] in urban neighborhoods in terms of infrastructure provision. It is likely that some existing infrastructural facilities will necessarily have to be maintained at the location, e.g. some educational institutions or large recreational, cultural and sport facilities. Others, however, could function in the future via delivery systems. Particulary in view of digital developments, some systems and offerings are outdated in their current form or need to be restructured and adapted. The question also arises as to what need there is for new infrastructure offerings.

In this context, this subproject of the research project "Ageing Smart – Intelligent development of spaces", which is funded by the Carl Zeiss Foundation, examines the following research question using the city Jena as an example: Which infrastructures condition a high liveability in urban neighborhoods and how must they be accessible? The results of the accessibility analysis can be overlaid with the population data of the city of Jena on the basis of selected infrastructures. In the next step, it is examined how many of these infrastructures can be reached by baby boomers within a reasonable distance in 15 minutes by foot and by bike. Based on this analysis, it will be discussed where infrastructures need to be supplemented or digitally substituted in order to promote a high quality of life for Jenas population – especially for baby boomers – or where accessibility on foot and by bike needs to be increased.

Keywords: livability index, accessibility, social infrastructure, 15minute city, walkability

2 THE CONCEPT OF THE "15 MINUTE CITY" AS A BASIS FOR ACCESSIBILITY ANALYSIS

A variety of uses can be found in urban neighborhoods. In addition to residential use, these include especially services, stores, businesses as well as social and technical infrastructures. The scope of the facilities is primarily determined by demand. This varies depending on the resident structure. The goal is to reach all necessary facilities through active mobility. This reduces motorized individual traffic so that air quality improves, noise is reduced and space is created.

The concept of the 15 minute city, first mentioned by Prof. Carlos Moreno, concretises the guiding principle of the city of short distances. In the "city of short distances", the aim is to reduce motorized private transport and increase the proportion of distances covered on foot, by bicycle or by public transport. It is backed up by the Leipzig Charta, a guiding document of national urban development policy, that also calls for "[...] compact, socially and economically mixed cities with well-developed infrastructures [...]" (BMI 2020: 3).

The goal of the 15 minute city was formulated as follows: "[...] all residents are able to access their daily needs (work, housing, food, health, education, and culture and leisure) within the distance of a 15-minute walk or bike ride." (Moreno 2021) Short distances covered through active mobility contribute to climate protection as well as to improving air quality in cities. In addition, city inhabitants save time and are

---

[1] As defined in the research project "Ageing Smart – Designing Spaces Intelligently", funded by the Carl Zeiss Foundation.

physically active, which can have a health-promoting effect. Neighborhoods can be strengthened and space in public areas can be saved and reallocated by reducing stationary traffic.

The concept reduces the guiding principle of the city of short distances by public transport and specifies a specific time in which the infrastructures are to be achieved. Regardless of Moreno's definition, many accessibility studies based on that concept also consider accessibility by public transit. It only describes a tangible idea of how cities should be equipped. It is not universal and does not take into account that the walking distance is significantly less than bicycle distance. In addition, it does not take into account walking and cycling speeds. Different population groups move at different speeds. As a rule, the average walking speed is between three and six km/h. The average cycling speed is usually 15 to 20 km/h. Furthermore, not all urban inhabitants are able to get around by bicycle.

Accessibility models based on the 15 minute city concept only take into account whether there is a corresponding infrastructure within the radius. The different lifestyles of city inhabitants are not taken into account. Accordingly, it is quite possible that a resident can already find very good infrastructure facilities in their neighbourhood according to the analysis, but does not use them for various reasons. The concept of the 15 minute city can therefore be seen as merely a basic idea, which is further substantiated by the Liveability Index.

3 CONCEPTUAL MODEL: CONCEPTION OF A "LIVEABILITY INDEX" BASED ON THE ACCESSIBILITY OF SOCIAL INFRASTRUCTURES IN URBAN NEIGHBOURHOODS

In order to concretize the idea of the 15 minute city and to investigate the accessibility of infrastructures as part of the liveability in urban neighbourhoods, an index has to be formed. This index consists of different variables – in this case different infrastructure facilities. It forms a theoretical construct to measure the accessibility of infrastructures as a precondition for liveability of the inhabitants of urban areas.

The different variables can be weighted or combined according to their target group-specific importance. This procedure creates additional scope for decision-making for municipalities, as they can individually adapt each variable and their weighting to the demands of the resident structures in different urban neighbourhoods. By combining the variables, it is possible to examine how well the residents are equipped with infrastructures of general interest. In addition, two further options for action can be explored. On the one hand, the accessibility analysis based on the index shows deficits in infrastructure provision. On this basis, location decisions can be made regarding supplementary infrastructures in order to improve the liveability at the target groups' residential locations. On the other hand, this method can be used to identify residential locations that have a high liveability according to the variables examined. This can potentially trigger relocation chains that can counteract a housing shortage.

Public infrastructures as well as privately provided ones in urban areas that are periodically visited (see Table 1) and can only be provided digitally or as a delivery service in part or at considerable expense are examined. The distinction between public and private providers is important because the municipal options for action are very limited in the case of private infrastructures.

Approximation of a Liveability Index based on the accessibility of infrastructures

The social infrastructure in municipalities forms the basis of services of general interest. This includes "retail and everyday supply/local supply, education, social services, health and medical care, emergency services, disaster control and fire protection, leisure facilities, community facilities"." (Beirat fuer Raumentwicklung 2011: 4). These services are supplemented by "public and private local and long-distance transport" (ibid.). Specifically, according to the Academy of Spatial Development (ARL), the public social infrastructure essentially includes primary and secondary schools, universities, the library system, childcare, youth care and youth psychological services, care for the elderly, health care, sports and disaster control (Winkel 2018).

Local supply as well as restaurants, pharmacies and general practitioners are provided by private parties and can hardly be controlled by municipalities, they are part of the private infrastructure. The Land Use Ordinance does allow areas to be designated for these purposes. However, occupancy depends on private individuals, so these facilities are usually only available if they are economically viable. Vacancies can't be completely avoided by the municipality.

Areas for local recreation, sports facilities and public transport stops are usually provided by municipalities. The possibilities for planning and implementation are limited on the one hand by the availability of land. On the other hand, these usually are non-economic infrastructures whose operation and maintenance must be ensured by the municipalities. Thus, the financial resources of the municipalities are also decisive for their quality and quantity.

Local infrastructures whose daily or at least regular accessibility can significantly influence the liveability are selected here as examples for further investigation. Infrastructures that are visited only rarely or only by small parts of the population on a regular basis, such as universities, museums and churches, are excluded, as are the emergency services and services that are nowadays regularly perceived digitally, such as banking and postal services.

Public Infrastructure	*Private Infrastructure*
Public transport - Bus stops - Tram stops - Underground stops	Local supply (goods for daily needs): - Discounters/Supermarkets - bakery, butcher, drugstore (in close proximity) - Shopping centres with appropriate assortment
Environment and local recreation - Green spaces - Parks - Local recreation areas	Medical care - General practitioners - Pharmacies
Sports facilities - Sports halls - Sports fields - Other sports facilities	Gastronomy - Restaurants - Cafés - Bars
Child and youth care, schools - Day nurseries/kindergardens - Primary schools - Secondary schools - Playgrounds - Youth centres	

Table 1: Examples of local infrastructures whose accessibility can significantly influence liveability

To make the indicators measurable, the accessibility must be quantified. There are several ways to do this. Based on the concept of the 15 minute city, the assumption can be made that all variables are equally weighted and fulfilled if they are reached within 15 minutes on foot or by bicycle. However, due to the points listed in chapter 2, this approach is not meaningful. Based on this, further concretisations are made.

Therefore accessibility is classified in a three-stage evaluation scheme (very good, good and acceptable). For this study, an acceptable walking distance is assumed to be 15 minutes at an average walking speed of 5 km/h. Accordingly, a distance of five minutes is considered very good and a distance of 10 minutes is considered good.

Furthermore, the individual elements of the infrastructure are weighted, whereby the weightings can vary greatly depending on the cohort considered. As an example, a weighted scheme could be structured as below (table 2).

4 CALCULATION IN GEOSTATISTICAL GRIDS

To apply this research approach methodologically and to make the site assessment manageable, the results are aggregated in grid squares. The weighted accessibility values of the individual infrastructures are then summed up into an index value for each grid square. In the case study the 1 ha INSPIRE grid (100m x 100m grid cell) by the European Commission is used. This format was established by the Statistical Office of the European Union (eurostat) with the goal to provide comparable statistics at the EU level (Eurostat/European Union, n.d.). The datasets are based on surveys, the current one is from 2011. In 2022 the census was surveyed again, the data is expected to be available from March 2024 (Statistische Aemter des Bundes und

der Laender 2023). Usually the survey interval is every ten years, in this case eleven. The processing of the results takes an additional one to two years.

The advantage of this approach is to obtain a uniform and sufficiently accurate spatial comparison framework for the calculation of the index without having to take individual local conditions into account. It is also advantageous that data is increasingly being collected and evaluated in geostatistical raster form in order to have a neutral, comparable spatial basis on the one hand and to ensure data protection on the other.

	very good / x3	good / x2	acceptable / x1
Public Infrastructures			
Public transport - Bus stops - Tram stops - Underground stops	3	2	1
Environment and local recreation - Green spaces - Parks - Local recreation areas	3 6 6	2 4 4	1 2 2
Sports facilities - Sports halls - Sports fields - Other sports facilities	3 3 3	2 2 2	1 1 1
Child and youth care, schools - Day nurseries / kindergardens - Primary schools - Secondary schools - Playgrounds - Youth centres	6 6 3 3 3	4 4 2 2 2	2 2 1 1 1
Private Infrastructures			
Local supply (goods for daily needs): - Discounters / Supermarkets - bakery, butcher, drugstore (in close proximity) - shopping centres with appropriate assortment	9 3-9 9	6 2-6 6	3 1-3 3
Medical care - General practitioners - Pharmacies	6 3	4 2	2 1
Gastronomy - Restaurants - Cafés - Bars	3 3 3	2 2 2	1 1 1

Table 2: Example of a weighted scheme to to make the influence of various indicators measurable

5 CASE STUDY: LIVEABILITY FOR BABY BOOMERS IN THE CITY OF JENA

As an example, the conception of an area-wide Liveability Index for the population group of baby boomers in Jena is presented. The city of Jena is located in the federal state of Thuringia. The population includes 110,502 people (31.12.2021, Thueringer Landesamt fuer Statistik 2022a) on an area of 11.477 ha (31.12.2022, Thueringer Landesamt fuer Statistik 2022b).

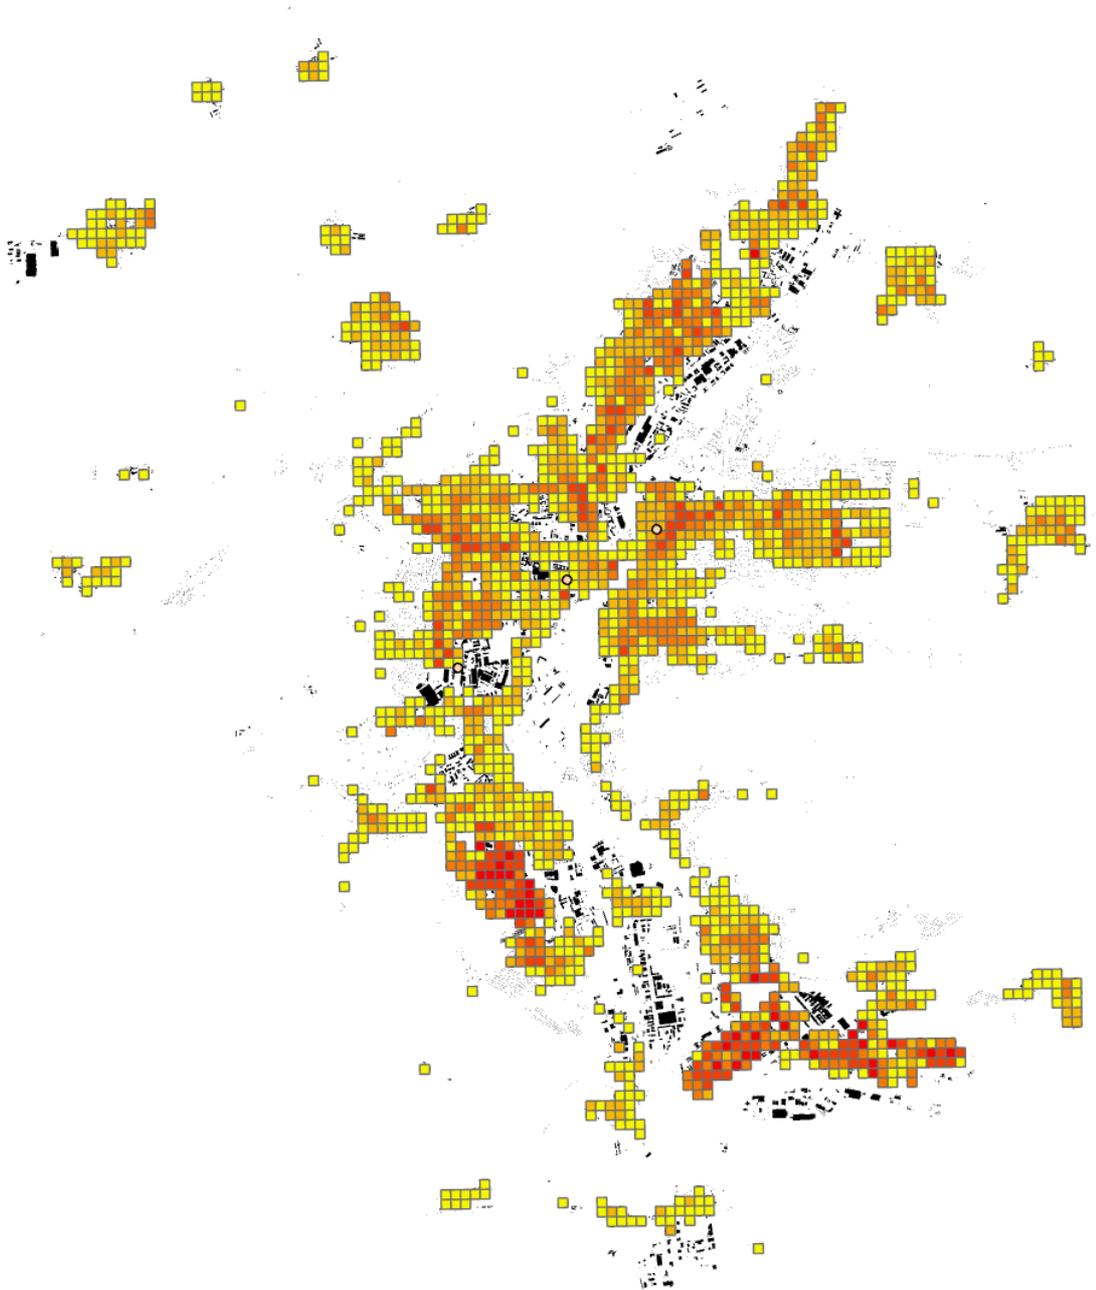
The data basis for the example of Jena was partly provided by the city of Jena within the framework of the above-mentioned research project. The points of interest (POI's) were taken from Open Street Maps (OSM), the accessibility analyses were carried out with ArcGIS Pro.


Fig. 1: Distribution of the total population in Jena (red many, yellow few)

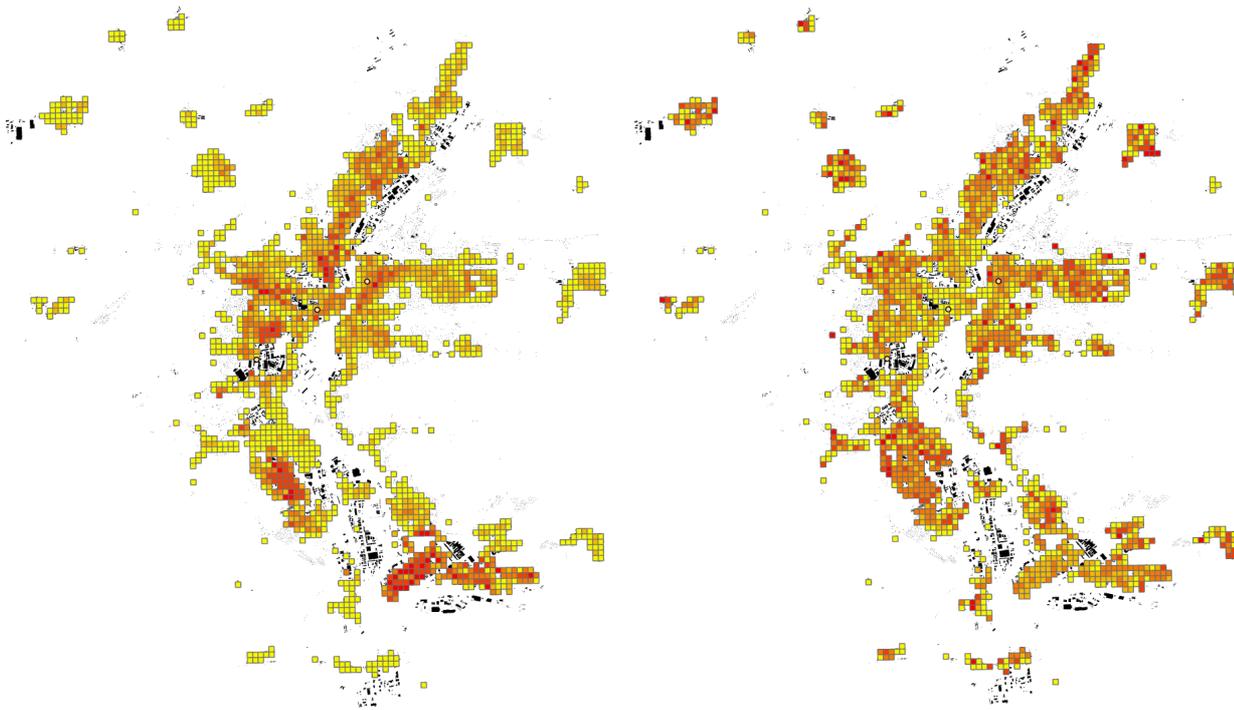
The population density is particularly high in the large structures in Jena-Lobeda in the south (average age: 44.9 years) and in Jena-Winzerla in the southwest (average age: 46.8 years) (see Fig. 1). In addition, it is higher in the terraced housing west of the Saale. The population density is correspondingly lower in the districts with more dispersed building structures around Jena.


Fig. 2: Distribution of Baby Boomers in Jena – Absolute (red many, yellow few). Fig. 3: Distribution of baby boomers in Jena – Proportion of total population (red many, yellow few)

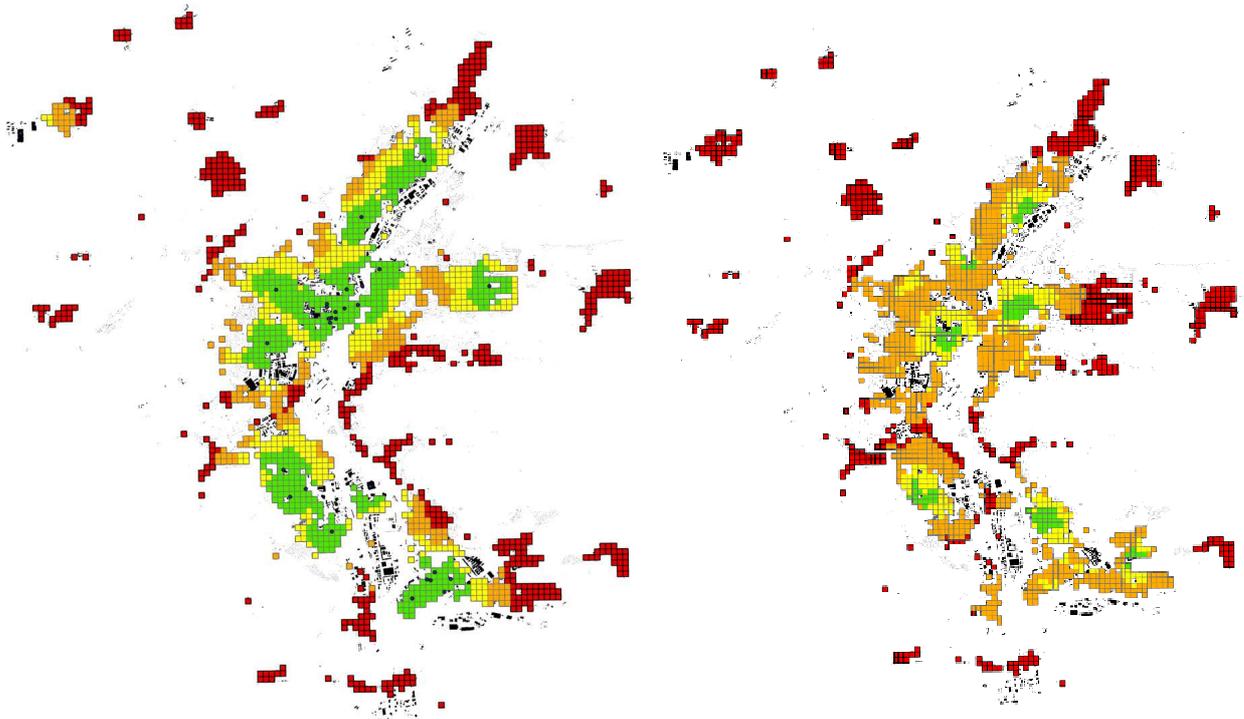
In absolute numbers, the baby boomers are distributed largely in line with the total population (Fig. 2). When looking at the distribution of the baby boomers as a proportion of the total population, it can be seen that the baby boomers make up a moderate to high proportion of the total population and are relatively evenly distributed in the urban area (Fig. 3).

The list of indicators presented above needs to be adapted for the specific study group. For example, childcare facilities and schools are rather irrelevant for the cohort of baby boomers.

The accessibility model is also specified. For this, a walking speed of 5 km/h is assumed, and accessibility by bicycle is not included because it is assumed that a relevant part of the group can no longer use a bicycle as they get older.

In the next step, the accessibilities for the individual infrastructure sectors are determined for the walking times 5, 10 and 15 minutes. As an example, a representation follows for the supermarkets available in Jena, which have a very different coverage of the populated urban area. While in central areas larger parts of the population live within the 5-minute range of one or more supermarkets, in decentralised parts of the city there are whole districts that lie entirely outside the 15-minute range.

In the next step, the accessibilities determined by network analysis are transferred to the inhabited grid squares of the city and the respective index value is stored.


724

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Fig. 4: Rasterized index "supermarkets" (green: <5 min, yellow: <10 min, orange: <15 min, red: >15 min). Fig. 5: Rasterized index "general practitioners" (green: <5 min, yellow: <10 min, orange: <15 min, red: >15 min)

The network analysis and transfer of the index values to the population grid is then repeated for each infrastructure sector. The accessibility of supermarkets with a full range of groceries (Fig. 4) and of general practitioners. (Fig. 5) is shown here as an example. Due to the different number of locations and differences in the choice of location, there are large variations in accessibility. In general terms, it can be said that significantly more people in Jena live in the immediate vicinity (5 min) of supermarkets than of general practitioners. The part of the city area that does not have a doctor's practice within a 15-minute walking radius is also larger.

There are smaller areas in the city centre and around district centres that have excellent accessibility in (almost) all criteria. However, this is not the rule. Urban areas dominate in which accessibility is heterogeneous across infrastructures. There are also urban areas in which the infrastructure is mostly well accessible, but in which one or a few sectors are missing. The methodological handling of such cases must be discussed. Should these areas still be considered as 15-minute cities, or should exclusion criteria be set here? These considerations are essential when it comes to quantifying the theoretical and general model of the 15 minute city.

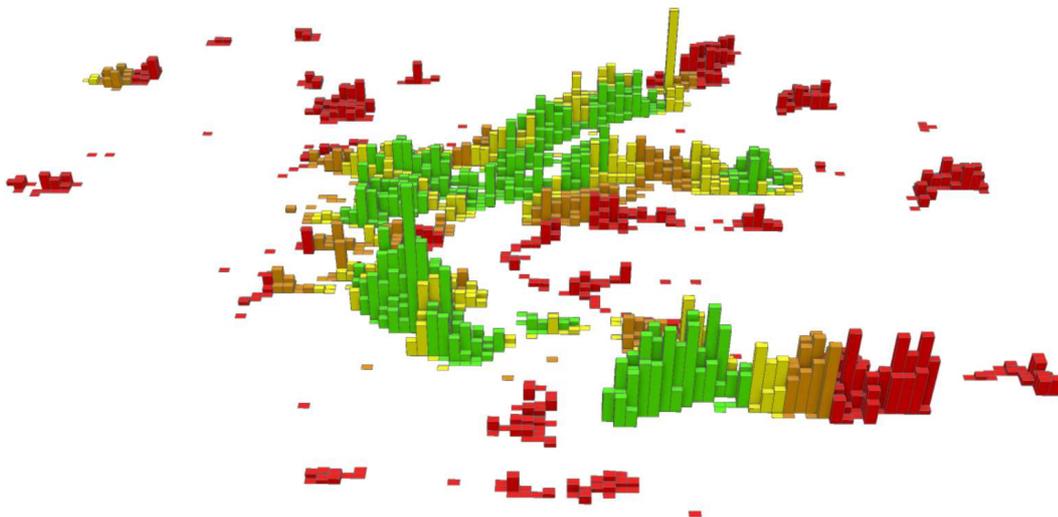


Fig. 6: population-weighted accessibility (green: <5 min, yellow: <10 min, orange: <15 min, red: >15 min)

In a last step the results of the accessibility analysis are overlaid with the population data of the city of Jena on the basis of selected infrastructures.

Various conclusions can then be drawn from this. On the one hand, it can be determined what proportion of the population lives in a "15 minute city" tailored to the needs of its age group and where this is the case. At the same time, deficits in the municipal and private infrastructure can be identified.

6 CONCLUSION

The concept of the 15 minute city is a very interesting approach to liveability in cities, but it has some gaps. For accessibility analyses, it can only be used in a highly concretized form. Parameters such as walking and driving speeds must be differentiated and defined. By concretizing the concept, it can serve as a framework for a Liveability Index. When creating this index, it is imperative that the responsible planners and decision-makers agree on comparable criteria and quality levels. In addition, the target group must be defined.

The hectare grid represents a good reference size for accessibility analyses. The spatial reference value is sufficiently concrete to show resilient decision options. Especially since spatial planning is already imprecise to a certain degree anyway due to assumptions and scenarios. If the above points are taken into account, the Liveability Index can be a good evaluation and decision-making aid.

In the next step the index is comprehensively applied to Jena as an example. Based on the results, recommendations on potential weightings and their consequences in the location analysis can be shown.

The Planning and Utilisation of Green Spaces in South Africa: Potchefstroom as a Case Study

Zaakirah Jeeva, Trynos Gumbo

(Zaakirah Jeeva, University of Johannesburg, Town and Regional Planning; Johannesburg, South Africa, zaakirah.jeeva@gmail.com)
(Prof. Trynos Gumbo, University of Johannesburg, Town and Regional Planning; Johannesburg, South Africa, tgumbo@uj.ac.za)

1 ABSTRACT

Public green spaces, commonly known as parks, play an important socio-psychological, physical and ecological role within cities. They support active lifestyles, promote citizenships, reduce air pollution, decrease heat island effects and support environmental sustainability. However, previous studies have found that the quality of parks within settlements fluctuates depending on their location relative to the Central Business District (CBD) and wealth of residents. This variation in quality (supply of park area or facilities) effects the utilization (potential demand) of parks, which in turn reduces the benefits, derived from these spaces. This paper sought to investigate the quality and utilization of parks in Potchefstroom, South Africa. It explored 3 different parks in 3 suburbs on the basis of the wealth and racial history of the suburb. Qualitative data was collected at each park through semi-structured interviews to determine its utilization, and an observation study was used to determine the park quality. The analysis indicated that there are marked discrepancies in the quality of neighborhood parks between suburbs previously designated for different racial groups. However, the utilization was not determined by the quality of the neighborhood parks, with poor quality parks in previously disadvantaged areas being used more frequently. The study"s findings shed light on the green inequality of South African cities and calls for further intervention to bring in green equality.

Keywords: Green Inequality, Green spaces, Distributional Justice, Sustainability, South Africa

2 INTRODUCTION

Academically, public green spaces are defined as open areas, which are primarily covered by vegetation and which are provided and maintained by the local authorities. These open green spaces come in various sizes and are commonly known as parks. From a planning perspective, parks serve multiple functions and offer citizens social, psychological and environmental benefits (Rojas- Rueda et al., 2019). As a result, the World Health Organization considers green open spaces to be essential for the physical and emotional wellbeing of citizens.

However, research conducted in Australia, South Africa, Spain and America have all found that lower income residential areas or minority racial group suburbs within cities have less access to green spaces or street trees than more affluent areas (Astell-Burt & Feng, 2019). In the case of South Africa, the planning and design of public green spaces has been more complex due to its political history as well as the unique ways in which parks are used in the country. Neighborhood parks in South Africa are planned to provide recreational and cultural services (Shackleton et al., 2018). However, these public open spaces are also utilized by the public to address their individual needs which come from high poverty levels and African identity or spirituality (Khumalo & Sibanda, 2019). These aspects are culturally opposing at times and deter the traditional utilization of parks. Consequently, research conducted in South Africa found that although there are many parks in the cities, only the well maintained parks close to the CBD and affluent areas are utilized, while the others were simply ignored. However, Das and Honiball (2021) add that the underutilization of South African low-income neighborhood parks is attributed to the lack of amenities, inappropriate location, lack of attractiveness, lack of accessibility, no interest, and crime. This generates a vicious cycle in the level of green spaces and infrastructure provided (supply) by the government and the low demand of green spaces in these suburbs.

This paper seeks to engage the first dimension of environmental justice - that of distributive justice, which addresses fairness in provision of public spaces and related resources within the South African context (Low, 2013). In light of this, the paper examines the quality of parks and their utilization in three different suburbs located in Potchefstroom South Africa (Harnik, 2009:6). The paper starts by providing a brief backdrop of South African cities and their relationship with public green space planning. It then describes the methodology, discusses findings and draw conclusions. The next section provides a background to the study.

3 BACKGROUND

The South African apartheid city stands out as an extreme example of urban social engineering (Seekings, 2011:532; Venter et al. ,2020:106). Its spatial morphology was based on racial segregation and hierarchy that systematically disadvantaged those who were classified as „Coloured", „Indian/Asian" or „Black". During this period people of color were forcibly removed from urban areas and moved to „group areas" s located far from urban amenities. Within the apartheid city, White"s lived in high-income urban neighborhoods with good quality infrastructure and urban amenities, whilst South Africans classified as Coloured or Indian lived in lower class rural neighborhoods with poor services and no urban amenities. African"s or Blacks lived in townships that had minimal infrastructure and services (Seekings, 2011:540). Each of these group areas were then treated as separate local administrations, and infrastructures such as highways, industrial zones, and buffer zones were used to create physical divisions along the lines of race. Furthermore, regulations were put in place to control social interaction between racial groups in public spaces (Seekings, 2011:538). This created exclusion, spatial fragmentation and high levels of inequality in the country (Lehohla & Shabalala, 2014:501). In an analogous fashion, the environmental policy of apartheid South Africa was as cruel and perverse as the spatial one.

Under the colonial and apartheid governments, thousands of Black South Africans were forcibly removed from their ancestral lands to make way for game parks, and billions of Rands were spent on preserving wildlife and protecting wild flowers, while people in "townships" and "homelands" lived without adequate food, shelter, and clean water. The Whites-only policies in national parks meant that black South Africans could not enjoy the country"s rich natural heritage, and draconian poaching laws kept the rural poor from desperately needed resources (Kuruneri-Chitepo & Shackleton, 2011). A study conducted by McConnachie and Shackleton (2010) found that there was less public urban green infrastructure and fewer parks in the poorer neighbourhoods (African, Indian and Coloured residents) than the more affluent ones (White residents). The same was found with respect to the provision of street trees, with many areas in poorer neighborhoods having no street trees at all (Gwedla & Shackleton, 2017). Consequently, Black South Africans (and anti-apartheid activists in general) paid little attention to environmental debates during the apartheid era since the environment was seen to be a white, suburban issue of little relevance to the anti-apartheid struggle.

However, the liberalization of South African politics in the late 1980s created a discursive and institutional space for the rethinking of environmental issues, and a vibrant debate began on the meaning, causes, and effects of environmental decay. The most fundamental outcome of these developments was the broadening of the definition "environment" in legislation to include the working and living space of Black South Africans. Subsequently, a wide range of trade unions, non-governmental organizations, civic associations, and academics adopted the new environmental discourse. Within a few short years these bodies began to challenge the environmental practices and policies of the past, with the hope of bringing in environmental equality and distributional justice (Ramphele and McDowell 1991).

In 1994, the African National Congress (ANC) came into power and realized that social, economic, and political relations were also part of the environmental equation. As a result, the ANC pledged that environmental inequalities and injustices would be addressed as an integral part of the party"s post-apartheid reconstruction and development mandate (ANC, 1994: 38). Accordingly, in 1996 the South African Constitution granted all South Africans the right to human dignity, equality and freedom. In terms of the right to equality: it stated that everyone is equal before the law and has the right to equal protection and benefit of the law. In order, to promote equality, the Constitution put in place a number of legislative measures that could be adopted to protect the rights of people who were disadvantaged by unfair discrimination. In section 24 the Constitution further adds that all citizens have a right to an "environment that is not harmful to their health and well-being" and that development should be "ecologically sustainable". When these rights are read together it becomes clear that environmental justice is part of a larger social justice paradigm, which seeks to transform the lives of people for the better.

Consequently, over the past 29 years (1994-2023), numerous policies and legislation were passed in post-apartheid South Africa, including the   Reconstruction and Development program (RDP), Spatial Development Frameworks (SDF), Development Facilitation Act (Act 76 of 1995), Habitat and Local Agenda 21 initiatives, the Green Paper on Development Planning (1999), the National Environmental Management Act (Act 107 of 1998) and National Spatial Planning and Land Use Management Act (SPLUMA, Act 16 of

728

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

2013). All of these made provision for equitable green space planning. However, before any decisions could be made on the implementation by the local authority, a broad framework of stakeholders was engaged. This included public participation and several objectives were met to ensure that what was required was implemented. This often resulted in the approval of green spaces having to continuously be balanced against other urban land-uses such as housing, infrastructure, economic and business development (Cilliers, Diemont, Stobbelaar & Timmermans, 2011: 695-698). As a result, parks were not prioritized practically and this is deeply felt in everyday life for South Africans (Makakavhule & Landman, 2020). This is especially, true in government-built social housing areas, where environmental justice, sustainability and quality of life aspects have been neglected (Chishaleshale et al., 2015).

However, to provide a perspective on the scale of the neglect, a study conducted by Venter et al. (2020) found that there is environmental inequality and distribution injustice in 49 out of the 52 district municipalities. With white urban households living within 700 m of a public park, whilst African households have to walk, on average, 1.7 km (Venter et al., 2020). Furthermore, Lategan and Cilliers (2016:13) found that the more affluent suburbs, which are primarily populated by whites, have the lowest housing density but more green space per capita. This can be compared with the new low-income housing suburbs, which are primarily populated by poor Black South Africans, having the highest housing density but the least green space per capita. Despite this, little empirical research has been conducted to examine the physical attributes of neighborhood park contexts and the correlation with utilization. This additional insight could assist in understanding the differences in quality and utilsation as well as provide insight into the level of inequality on a neighbourhood level. The next section provides brief descriptions of the methodology followed to determine the quality (supply) and utilization (demand) of neighborhood parks in Potchefstroom by analyzing the parks in three different suburbs within the city.

4 METHODOLOGY

Over the last decade there have been several urban ecological studies in Potchefstroom which have focused on urban biodiversity, ecosystem services, green spaces and green economy (Cilliers, 2010a; Cilliers et al., 2013). However, these projects were focused on parks within high- and middle-income areas, and they did not provide insight into the quality distribution of parks within the city. Consequently, this research sought to address the shortcoming by investigating the correlation between the quality of neighborhood parks and the utilization of these parks in Potchefstroom, South Africa (Brasington & Hite, 2005:4).

The study area was comprised of: Area A- Botanical Gardens in the Built area (High Income), Area B- Hospital Park in Baillie Park (middle income) and Area C- Ikageng park in Ikageng (Low Income) (see map below).

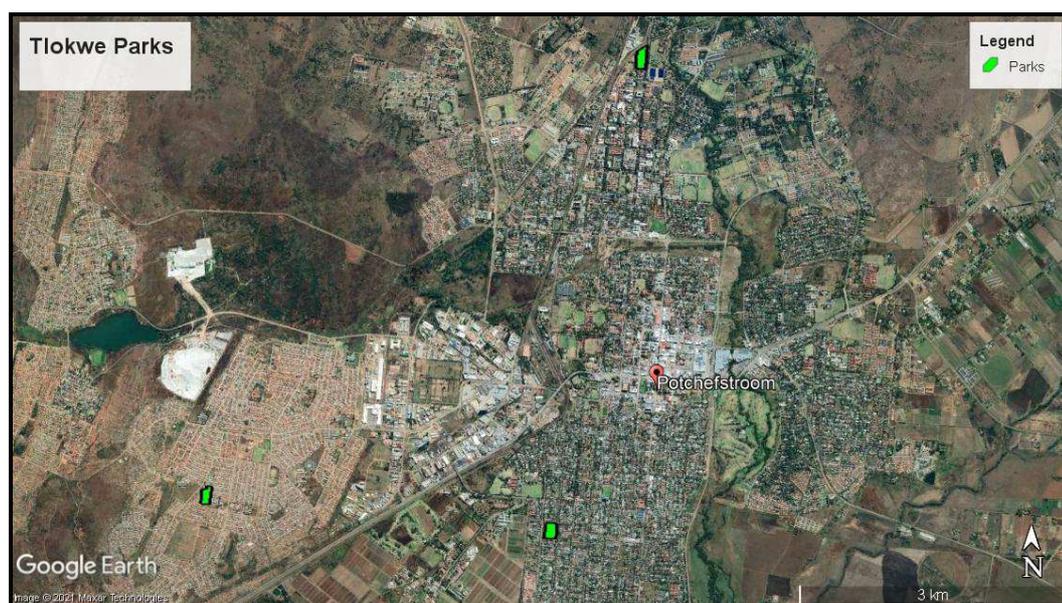

Fig. 1: Location of the three parks in Tlokwe local municipality (Source: Own composition)

These parks were chosen due to their location in the different suburbs and distance from the CBD. The researcher sought to determine if quality and utilization is affected by distance from the CBD . At each of these parks the researcher conducted semi-structured face to face interviews with randomly chosen participants from different ages, genders and races. In total 30 Interviews were conducted between 19/07/2021-22/07/2021. Responses were documented and analyzed. The next section discusses the key findings from the empirical study on the utilization and quality of parks in Potchefstroom.

5 RESULTS

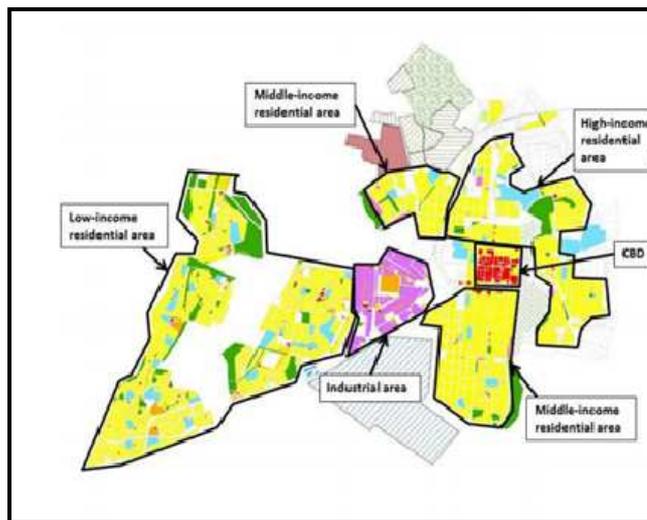
There are 79 Parks in the Tlokwe Local Municipality (Potchefstroom) according to the Integrated Development Plan (IDP). Of these, 44 are considered developed, 6 semi-developed and 27 underdeveloped (JB Marks Local Municipality, 2018:246). The local municipality classifies developed parks as having green infrastructures which are regularly maintained, whilst underdeveloped parks are seen as not having adequate green infrastructure. The figure below illustrates all the open green areas around Potchefstroom.


Fig. 2: Green spaces in Potchefstroom (Source: Authors Own)

Fig. 3: Location of Case study relative to CBD (Authors own)

Morphologically the map illustrates a typical Apartheid city model, and the green markings illustrate the neighborhood parks. High income localities are located in the North of the city and the lower-income residentss in the South, close to the industrial area. Analysis of the map reveals that green spaces across Potchefstroom are unequally distributed, with more green spaces in the low-income residential areas than the high-income residential area.

This finding was confirmed by the local IDP which also added that most of the "underdeveloped parks" are predominately located in the low-income residential and middle-income residential areas, while larger more well-developed parks are located in the higher income areas(JB Marks Local Municipality, 2018:246). According to the IDP the two of the three randomly chosen parks for this study that were categorized as "developed parks" (i.e Botanical Garden and Petersen park) and one of the parks was an "underdeveloped park" (i.e Ikageng Park). The next section captures the key findings on the quality of these parks (supply).

5.1 The quality of the parks

According to Urban Land Institute (2021), high quality parks have five key characteristics: 1.Are in excellent condition and are well maintained, 2. Accessible to all potential users, 3. Provide positive experiences for park users, 4. Are relevant to the communities they serve, and 5. Are flexible and adaptable to changing circumstances. In order to evaluate the quality of parks in Potchefstroom and to capture the quality of the parks, each park will be discussed under separate headings according to the above criteria and findings are motivated with images. The map below provides perspective on distance of the parks from the CBD.

A. The Botanical Gardens

The NWU Botanical Garden which is situated in the high income area was opened to the public in 1982. It is situated 4.1 KM North from the Potchefstroom CBD and covers 3ha. It has more than a 1500 plant species and provides a habitat for a variety of animals and insects. There is a variety of vast open spaces where people can come for recreational purposes and the paved footpath can be used for physical exercise (see Images below). The park also has lights, trash cans, restrooms and benches all along the paved footpaths. The park is maintained by the University but open to the public at no cost.

Fig. 4: Pictures of the Botanical Gardens (Source: Own Compositions)

This park is located in the former white suburbs and is considered to be a developed park by the Integrated Development Plan.

B. Hospital Park

This park is centrally located opposite the public hospital and is 2.7 km from the CBD. The researcher"s first observation of the park was that there is no parking available on the property and there was no fence around the park to ensure safety. The park also looked run-down, with the paving being uneven and the paint fading on buildings. The tennis court is also dilapidated and converted into a skateboard park. The restrooms are also neglected with several broken windows and no doors. While the park has various trees, many branches were cut (for fire wood) and the grass was over grown (see figure below). One of the participants also rightly pointed out that there are no benches, street lights and trash cans on the property, and as a result litter is scattered everywhere (see images below).

Fig. 5: Pictures of Petersen Park (Authors Own)

This park is considered to be developed by the Potchefstroom IDP.

C. Ikageng Park

Ikageng Park is located 7km away from the CBD in a suburb that was the former African township. At this park the researcher found that there is no parking and it could only be accessed by foot. The park has no grass and no infrastructure such as restrooms or play facilities (Swings, see-saws or jungle-gyms) lights, trash cans, benches and footpaths. The only infrastructure this park has is a set of goal posts. There is no maintenance in the park and the people of the neighbourhood use the open land to dump their trash (see figures below). Whilst the researcher was at the park there was not a lot of activity going on in the park, but those who were there stated that young boys use the park to play soccer in the afternoon and older people come to watch them play.

Fig. 6: Pictures of Ikageng Park (Source: Own Compositions)

732

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

This park is considered to be under developed by the IDP.

In light of the above findings, one could conclude that the Botanical garden situated in a built area which is 4km from the Potchefstroom CBD offers the best quality green spaces, since it adheres to all 5 of the quality criteria (see table below). Both the hospital park and the Ikageng park are not considered to be high quality parks since they adhere to 0 of the five quality criteria (see table below).

Quality	Ikageng	Hospital	Botanical Garden
Distance from CBD	7km	2.7 Km	4.1 KM
Well Maintained	No	No	Yes
Accessible	No	No	Yes
Positive experience	No	No	Yes
Relevant to local community	No	No	Yes
Flexible and adaptable	No	No	No

Furthermore, the study found that the quality of parks did not depend on the distance from the CBD but rather the wealth of residents. With the hospital park, this is closer to the CBD but is of a poorer quality compared with the Botanical garden. However, parks located in the poorer area and former black townships are still found to be the least developed. The next section unpacks how each of these parks are used.

5.2 Utilization of the Parks

Utilisation can be defined as the manner in which the public use a particular space. The study found that the Botanical Garden which is located adjacent to the University had a lower utilization rate than the Hospital Park which is located opposite the hospital and the Ikageng Park in the low income area. The respondents (10) claim that they visit the botanical garden once a month, while those interviewed at the Hospital park (13) and Ikageng Park (7) claim to visit the parks daily.

The motivation for the frequent visits to the Parks (Hospital and Ikageng) was that they were easily accessible and that they offered space for recreation and exercise. However, the Botanical garden was not as frequently used due to time access restrains (8am to 4pm) and the distance from home. Additionally, many (6) respondents from the botanical garden stated that they have large gardens of their own and do not find the need to visit a park as often. Respondents from Ikageng (7) and Hospital Park (6) state that they have small gardens or no gardens and are dependent on parks for recreational space. The table below captures main findings.

Criteria	Botanical Gardens	Hospital Park	Ikageng Park
Income Group	High Income	Middle Income	Low Income
Frequency of usage	Once a month	Every day	Every day
Purpose of usage	Recreation	Recreation	Recreation
Like about park	Accessible and clean	Quiet, spacious and near home	Meeting place and soccer field
Dislike about Park	Lack of maintenance	No maintenance and insufficient infrastructure	No grass, litter everywhere, no facilities and no lights

Table 2: Findings on the utilization of Parks in Potchefstroom (Authors own)

Analyzing the responses, one finds that the botanical garden was found in the high income area and people liked it because it was accessible and clean, however, some respondents still did not like it because it was not "well maintained". However, Hospital Park which was located in the middle income area and closer to the CBD was favored since it was " Quiet, spacious and near their home". However, they also pointed out that the park was not well maintained and did not offer sufficient infrastructure such as parking, toilets, and playing facilities. On the other hand, people who used the Ikageng park claimed that they liked it because it offered them a common meeting place to play and watch soccer.

One of the main findings from the semi-structured interviews was the manner in which recreation was defined. Respondents, who were white and young (20-30 years), from the botanical garden stated that they used the park to walk, run and picnic. However, respondents who were mostly Black and middle aged (30-40years) from the hospital park used the park for recreation, but defined recreation as "sitting in the sun", "children skating" and "socializing". Some (2) stated that they use the park to sort out recycling material, since they have nowhere else to sort it. On a Sunday, if one was to drive past, one could also notice a group of people in white clothes who use part of the park, for "worshipping" purposes. On the other-hand the Park in Ikageng was used to play soccer, and the community uses it to socialize during these matches.

The main finding for the researcher was that parks offer a "sense of place", and the likes and dislikes are subjective. The researcher further asked each of the respondents if they visited any of the alternate parks in

Potchefstroom, to which they all stated that they don"t ever use other parks since they are not as accessible, and some just simply never thought of visiting parks in other suburbs.

The next section discusses the key finds to determine if there is equality of green spaces and if quality effects utilization.

6 DISCUSSION AND FINDINGS

In 1996, a one-city one tax base principle was implemented, which meant that all citizens in the city should be treated equally. This also meant that all suburbs within the city should have equal access to amenities, services and facilities- green spaces included. However, access in this case was not just about facilities being open for everyone to use, but it also meant that the quality of facilities within the city should also be the same throughout the settlement. Unfairness of distribution would foster conflict and undermine cooperation, furthermore the inequality of services would mean that some citizens would have greater benefits and a better quality of life in comparison to the rest. The section below discusses the key findings of the paper.

6.1 Inequality in green spaces

Not all impacts or benefits can be measured in monetary terms. Neither can all types of neglect and inequality be expressed in words, but some things have to be experienced first-hand, therefore the researcher attempted to capture images to provide undeniable insight into the reasons for inequality.

The study found that even though there are no restrictions on movement, the apartheid city model still has an effect on how cities look and are utilized today. The research revealed that many respondents live on city perimeters which are either due to self-limitation or economic barriers. Many low-income residents cannot access facilities within the city solely due to transportation costs, even though these facilities are free. High-income residents on the other hand have self-limitations due to "fear of others" or lack of interest, and this restricts them from exploring the poorer end of the city. Regardless, of which barrier is analyzed, we find that there are two different realities for people living within a 10 km radius in the same city. So, even though there are facilities and amenities in the city, they are only accessed by a few who live close by.

The study further found that, although GIS maps within policy documents claim that there are 79 Parks within the city, most parks are located in the former non-white areas (Ikageng, Promosa and Mohadin). However, when the researcher drove around in the vicinity to determine the utilization and quality of these parks, most of them were non-existent to an extent. "Parks" in these locations were merely open plots with no infrastructure, and were similar to the Ikageng Park. According to the inhabitants these open spaces have always been there and they were unaware that it was actually earmarked to be a park.

On paper, in 2013 the Ikageng park was supposed to be developed and its purpose was to provide the local low income residents of the community with much needed recreation facilities. It was also supposed to include multi-functional courts, a children"s play area, picnic and braai facilities and a large outdoor amphitheater. It was to have essential infrastructure such as lights, dustbins, grass patches and paving (See figure below).

However, nine years later in 2021, one can see the disparities between what was sold to the public and what was actually provided. Upon interviewing the persons within the municipality, no one could say why the project was not seen through and what happened to the money. This also brings into question the distributional injustice that children experience in the city. Children in the North (High-income) are exposed to 1500 different plants and species in the Botanical garden, while children in the South (low-income) have dirt patches, rubbish dumps and broken goal posts. The core notion of distributional justice in South Africa could therefore be questioned 30 years later.

However, the inequalities are not just spatial but they are environmental, socio and psychological. This is demonstrated through the parks in the south being poorly maintained, lacking infrastructure and not providing even grass for citizens to relax on. These green spaces which are supposed to be used for psychosocial and ecological benefits are instead being used to dump rubbish, accommodate homeless people and graze animals. It is clear that the benefits that green spaces ought to provide are not being provided in the low-income areas.

Figure 7: Ikageng Community park concept plan (Outlining landscape architecture, 2013)

6.2 Does Quality affect utilization of Green Spaces?

Parks are recognized as key public spaces that offer social value to adjacent neighborhoods. In these spaces, safety, infrastructure and maintenance are important measures of ensuring utilisation. However, the study found that these factors are not the only ones affecting the utilization of parks. The study found that the participants from low-income areas (Ikageng Park) use parks more often than the middle-income (Hospital park) and high-income participants (Botanical garden) (McConnachie & Shackleton, 2010:248). However, the question of who was utilizing the parks and for what purpose provides valuable insight into the social dynamic experience in the city.

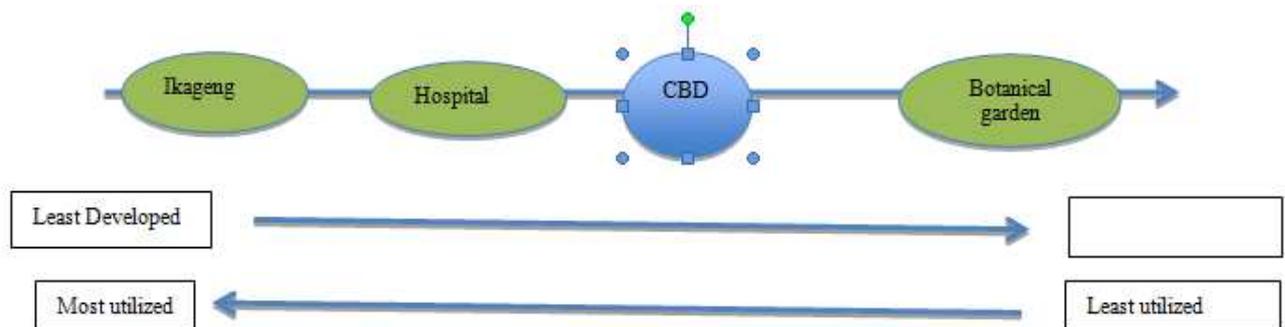

Figure 8 : The Quality vs Utilisation of Parks in Potchefstroom (Authors own)

In light of this, an article published in the local newspaper "The Herald" in August 2021, reported that homeless people live in the Hospital parks" bathrooms, and thieves, drug addicts and prostitutes loiter in the park during the day. Furthermore, the study also found that local recyclers also use the parking lot to collect and sort recyclables outside the park. As a result, local residents claim that the park is more of a stress to the local community then a recreational area. Consequently, the public has requested the municipality to demolished the park and replace it with an indoor gymnasium.

However, for the purposes of this study, it was revealed that the Hospital park and Ikageng Parks both do not have the best quality infrastructure or could be considered to be a high quality park. Nevertheless, they are still being utilized in an alternate fashion and they still offer unconventional benefits to the public. This shows that there is a difference of opinion about acceptable usages and there is still a fear of others.

In conclusion, the study found that the quality of the parks does not affect utilization; however utilization could influence the quality of the park and the neighborhood. It further revealed that the unconventional utilization of Parks deters investment, and the vicious cycle of inequality continues.

7 CONCLUSION

The study found the Apartheid city model still impacts how cities look in South Africa today. This was verified with the unequal distribution of green spaces and green infrastructure across Potchefstroom. It also found that high-income residential areas have fewer parks which are better maintained but rarely used, whereas low-income residential areas have more underdeveloped parks with almost no green infrastructure and maintenance but are used the most often. However, the less developed parks are utilized in an unconventional manner but still provide benefits to the public which include an area to socialize, graze animals, sort out recycling material, accommodation for the homeless and garbage disposal. It could be agreed that this inequality does not allow inhabitants to have the full benefit from green spaces and questions the provision of these spaces. The paper recommends that further research be conducted on the socio-psychological inequalities created by the lack of adequate facilities in the poorer neighborhoods.

8 RECOMMENDATIONS

8.1 Public awareness

There are various policies in place to support environmental equity, and the local municipality does have funds allocated to develop the underdeveloped and semi-developed parks. Nevertheless, the practical aspect is not that easy because funds are allocated according to need and officials indicate that the patching of potholes and provision of houses with water and electricity is more important than parks. That could be true and reiterates the lack of interest in green spaces. However, if the benefits of green spaces could be realized and the importance inculcated, the significance of these spaces might be realized. In light of this more public awareness and environmental knowledge is required to really bring in change.

8.2 Avoid Blue Print

Parks throughout the world have similar plans, structures and infrastructure. This structure paints the idea of high-quality parks which are implemented regardless of culture. The study has alluded to the idea that South African parks are not really considered a big deal in the higher income areas since building density is much lower and most houses have private gardens. However, parks are more valued in the lower income areas since houses and gardens are small and the needs of lower income individuals differ from high income individuals. As a result, it is important to conduct to participative planning in order to understand the needs to the community. For one, the community needs space to "worship" on a Sunday and to gather and socialize in the sun. Another need identified is for people to have space to organize their material recycling activities, and to skate. Although all these needs might not easily be accommodated within a traditional green open space, it is the requirement of the public. Therefore, planners should be innovative and willing to break from conventional blue-print development.

8.3 Access to Justice

On paper at least, South Africa"s constitutional provisions on equality, justice and freedom rank among the most progressive in the world. However, at a more practical level, many people in South Africa do not have the financial means to actively pursue costly court proceedings; especially those including environmental inequality and distributional injustices. The study has revealed the initial plan and the reality of the Ikageng park, however, the citizens of the community do not have the financial muscle or the funds to open a court case against the municipality to ensure justice.

As a consequence, public interest law firms and civil societies are required to look at cases such as Ikageng, and seek justice and equality for those who cannot achieve it themselves. If local government is not held accountable for empty promises, the vicious cycle of inequality will continue.

1 ABSTRACT

There are many forms of NBS for contemporary urban challenges that reflect individual elements or facilities in urban space, but a systematic and comprehensive implementation of NBS in urban planning documents has not yet been observed. In this paper, we use unaltered native habitat types (HTs) as innovative forms of NBS that originate from the natural or semi-natural environments of the same region as the targeted urban environment, which is the subject of urban planning. We draw on a planning approach that attributes added value (a function in addressing urban challenges such as air pollution, noise, stormwater management, and urban heat island) to HT, thus linking the concepts of NBS and HT in an innovative way to integrate them into urban planning. Based on a qualitative content analysis of spatial planning documents in the case of Slovenia, the paper presents a proposal for the inclusion of HTs as NBS in spatial planning documents at national, regional, and local levels. It was found that strategic spatial planning documents are suitable for defining the concept of NBS as a way of addressing urban challenges, while key to integrating HT as NBS into existing spatial planning practice are the spatial implementing document sat national and municipal levels, as well as the Urban Development Concept as a mandatory technical basic document for these acts.

Keywords: spatial planning documents, habitat types, nature-based solutions, urban challenges, environment

2 INTRODUCTION

The concept of nature-based solutions (NBS) is firmly established in European urban policy, but its systematic and integral implementation in urban planning documents is yet to be observed. NBS are based on natural or nature-mimicking processes with the aim of solving social challenges (Cohen-Shacham et al., 2016; European & Directorate-General for Research and, 2015; Goličnik Marušić et al., 2023). We focus on NBS in urban areas. The most typical urban challenges to which NBS can respond are mainly particulate and gaseous air pollution, noise, stormwater runoff, and urban heat island (Ferrini et al., 2020; Raymond et al., 2017).

There are many forms of solutions to urban challenges in the literature, referred to as nature-based solutions, that reflect individual elements or facilities in urban spaces (e.g., green roofs, urban gardens, rain gardens, permeable paving, urban woodland, vertical greening systems, open green systems, constructed wetlands, river floodplains). In this paper, we used unmodified natural terrestrial and freshwater habitat types (HTs) found in Europe as forms of NBS for urban challenges. HTs as NBSs originate from the natural or semi-natural environments from the same region as the targeted urban environment that is the subject of urban planning. HTs are notable spatial units for conservation practice and their spatial definition can be directly represented graphically in spatial planning documents. Recognizing their ability to effectively solve urban challenges such as temperature reduction, stormwater management, noise reduction, air quality improvement, and CO_2 concentration reduction through their ecosystem processes (such as evapotranspiration, shading, water purification, water retention, noise attenuation, particle deposition, carbon sinks) gives us the opportunity to treat them as NBSs represented directly in spatial planning documents. The following characteristics, defined by Dremel et al. (2023),represent a basic starting point for understanding natural HTs as NBS:

(a) They do not require (extensive) maintenance (e. g. supplemental watering) and are self-sustaining, unlike agricultural and urban Hats'

(b) They are more resilient to pests, weather and climate conditions, and other disturbances than HTs of non-native species.

(c) They contribute to the biodiversity of native species.

This paper focuses on the pilot attempt to integrate HTs as NBS in spatial planning documents, from the strategic and national level to the implementation level and the local level. The aim of the paper is to present a proposal for the inclusion of HTs as NBS in spatial planning documents using the example of spatial planning in Slovenia. The result of the pilot test is a conceptual proposal that shows how HTs can be included in binding spatial components that are NBS and not only as spatial units for nature conservation in mandatory spatial planning documents relevant for nature conservation.

In Slovenia, the urban environment faces the following urban challenges that could be addressed by the implementation of HTs and on which our research focuses:

(a) urban heat island (Cerar, 2020; Darko & Krevs, 2015; Komac et al., 2016) and thus the need to reduce surface temperature, especially during hot summer weather.

(b) urban pluvial flooding (Klemen et al., 2020; Krajnc, 2019)and thus the need for efficient stormwater management to regulate urban surface runoff.

(c) noise pollution from road and rail traffic (Cegnar et al., 2022; Prislan & Kvasič, 2021) and therefore the need for noise reduction.

(d) particulate matter (PM10) air pollution, mainly from traffic and small wood-fired biomass combustion plants (Cegnar et al., 2022; Koleša, 2021), and therefore need for air quality improvement.

2.1 Spatial documents in the planning system in Slovenia

The overarching law for spatial planning in Slovenia is the Spatial Management Act ("Zakon o urejanju prostora (ZUreP-3)", 2021). It defines in detail the objectives, principles and rules of spatial planning, actors, spatial planning documents and procedures for site selection, detailed planning and approval of spatial developments of national importance, as well as other spatial measures, instruments, monitoring, operation of the spatial information system and issuance of certificates in the field of spatial planning. Spatial planning is implemented through the preparation and drafting of spatial planning documents and national spatial planning procedures. A Spatial Management Act defines the spatial development of the country, regions and municipalities (strategic spatial planning documents), and determines the implementation of spatial regulation (spatial implementation documents). In addition to main spatial planning documents, all the mandatory documents under the ZUreP-3, which directly affect their preparation, are also important and are therefore also the focus of the study.

Spatial planning documents are both strategic and implementing. Strategic documents take precedence over the implementing documents and are coordinated so that the implementing documents do not conflict with strategic documents. In Figure 1, the strategic spatial planning documents are shown in the left column in the middle box and the spatial implementing documents in the right column in the same box. The central frame in Figure 1 also shows the relationships between them and the level of responsibility for their preparation (State, Region, Municipality).

In addition to the hierarchy and typology of spatial planning documents, Figure 1 shows that the overarching framework for spatial planning, which includes the approval and implementation of spatial planning interventions and the implementation of other spatial planning tasks, is the National spatial order (DPR) (represented by the outer frame surrounding the central framework of spatial planning documents), and the documents that are mandatory for certain spatial planning documents, which influence their preparation and approval (the list of documents is shown outside of the frame).

3   METHODOLOGY

To assess the potential of including HT as NBS in spatial planning documents that influence spatial planning in Slovenia, or in spatial planning instruments at the national, regional, and municipal levels, we developed a set of criteria for qualitative content analysis. Each document was evaluated according to the following three criteria:

 (1) Determination of the status of HTs and NBS participation in the document: in order to determine the situation, we analysed documents whose orientations are defined for the entire country of Slovenia, and which were therefore analysed in terms of their content objectives, recommendations, orientations, etc. When analysing each document, we asked whether it in any way involves HT and the NBS, or, if the NBS is not explicitly mentioned/referred to, whether the document's guidelines are consistent with the NBS concept.

740

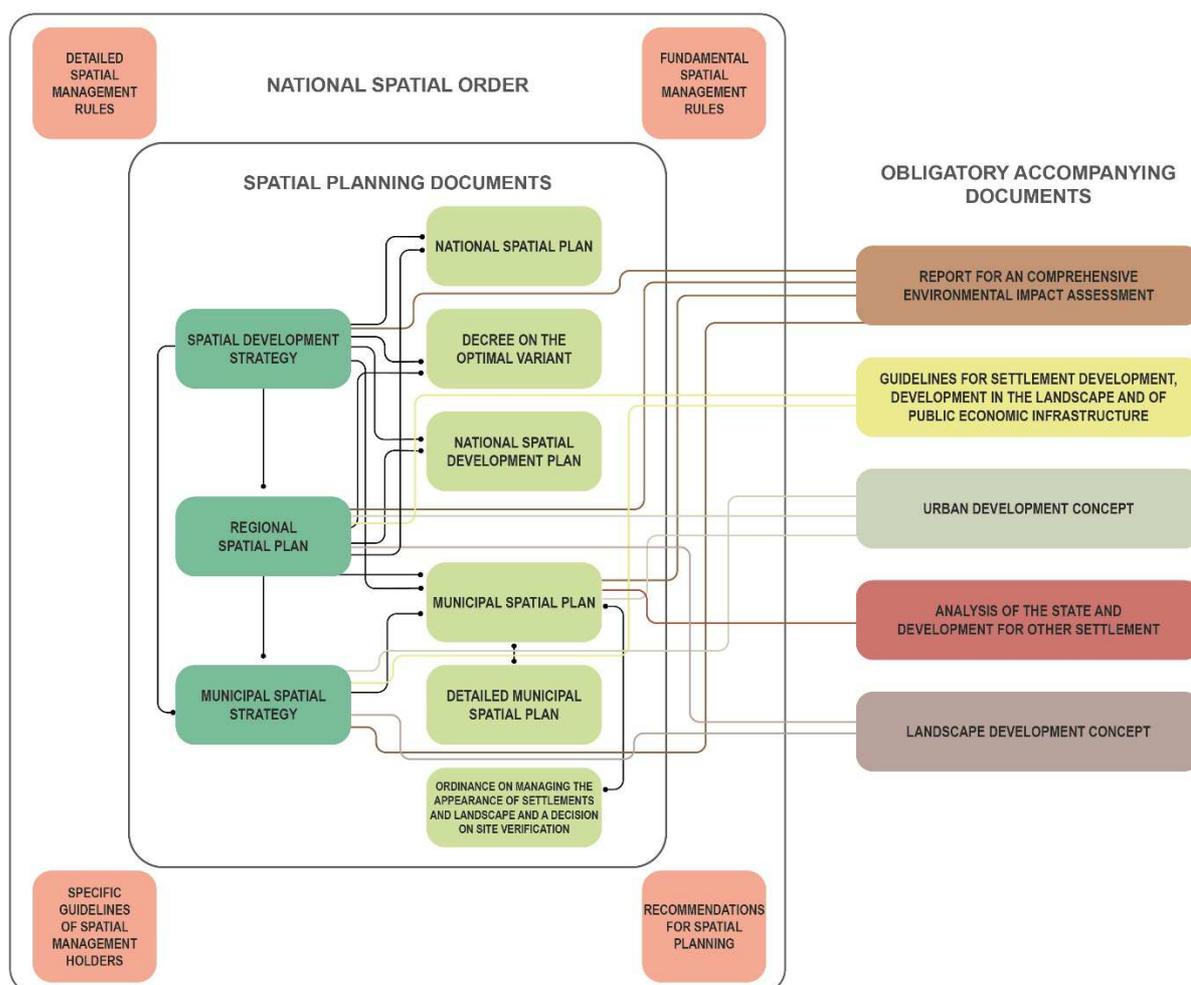
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Figure 1: Spatial documents and their links under the Spatial Management Act (ZUreP-3)

The following documents were analysed for content: Draft Spatial Planning Strategy; Specific guidelines of spatial management holders of National spatial order, National spatial order (DPR) and DPR recommendations for spatial planning. For the spatial planning documents prepared for individual areas (Regional Spatial Plan (RPP), National Spatial Plan (DPN), Municipal Spatial Strategy (OPP),Municipal spatial plan (OPN),Detailed Municipal Spatial Planning Plan (OPPN), and mandatory background documents, we examined their drafting instructions, which are mainly contained in the Spatial Management Act (ZUreP-3) or in specific publications.

(2) Rationale for including NBS and HT as NBS in the documents: This was justified based on our knowledge of the concept of NBS, the content included in spatial planning documents, their scale, and their impact on lower-level spatial planning documents. In some documents, we acknowledged the reasonableness for including NBS as a concept, while in others, primarily the implementing documents, we fleshed out NBS as HT.

(3) Possibilities and opportunities to include NBS and HT as NBS in the planning document: These were identified primarily in the way each document is created to integrate with established spatial planning practices, rather than adding new procedures or documents.

Based on Criteria 2 and 3, if we have determined that it is appropriate to include HTs as NBSs or there are possibilities and/or opportunities for their inclusion in the graphic and descriptive parts of the relevant spatial planning document, we have proposed for each document how HTs can be included as NBSs.

4 RESULTS

4.1 Status of the inclusion of HTs and NBS in spatial planning documents

The results show that there is no analysed spatial document that explicitly refers to the NBS concept, but in terms of knowledge about NBS and urban planning, we were able to identify different paraphrases and terms in the documents that lead to the same goals as the implementation of NBS.HT as a spatial unit is mentioned only where the analysed document refers to nature conservation and thus understands and considers it in terms of limiting interventions in space.

4.1.1   Strategic spatial planning documents

The Draft Spatial Planning Strategy and Regional Spatial Plan (RPP) and the Guidelines for the preparation of Strategic Spatial Documents at the regional and municipal levels do not directly address the NBS concept. They focus only on green spaces, green infrastructure, and the region's green system. This is likely due to the fact that green infrastructure is a very strategic approach to planning and NBS can also be seen as a tool to implement green infrastructure principles and are therefore more applicable at other planning levels.

The Draft Spatial Planning Strategy identifies green areas as effective means of addressing urban challenges, as the goals and implementation of the Spatial Development Strategy of Slovenia(SPRS) concept includes efforts to address urban challenges through vegetation (e.g. preservation and creation of floodplains, and a greater proportion of well-managed and maintained green areas to mitigate extreme events and heat islands) or recognizing the value of vegetation and water bodies in general, which are the beginnings of the introduction of the NBS concept. The Regional Spatial Plan(RPP) emphasises the importance of the region's green system for ecological connectivity of ecosystems and creating conditions for their conservation, but does not recognise the importance of these areas for addressing urban challenges. Strategic spatial plans do not address HT, but efforts to conserve habitats in general can be recognised. The spatial scale of the maps in the strategic spatial planning documents is not detailed enough to show individual HTs for urban challenges.

4.1.2   Spatial implementing documents

The analysis shows that spatial implementing documents for individual areas are prepared according to guidelines that do not include the NBS concept. As for the HTs, only those that are relevant for nature conservation are addressed. For example, the National Spatial Plan (DPN)addresses HT in the planning of nature conservation areas established by the state and in the environmental reports for each plan if there are HT of nature conservation importance in the area of the proposed development. The Decree on the optimal variant(UNV) and National Spatial Development Plan (DPUN) also address the nature conservation importance of HT as a constraint to development. The spatial scale of implementation planning at municipal level (Municipal Spatial Plan and Detailed Municipal Spatial Plan) is suitable for highlighting HTs and addressing specific urban challenges, while the Municipal Spatial Plan (OPN) and Detailed Municipal Spatial Plan (OPPN), together with the Ordinance on Management of the Appearance of Settlements and Landscape(UONK), are key documents for permitting, promoting, or preventing certain interventions in the urban environment.

4.1.3   National Spatial Order (DPR)documents

Based on the content analysis of the National Spatial Order(DPR) documents, we note that the concept of NBS is implicit or potential in the guidelines documents from the field of settlement space, protection from natural and other disasters, energy, water management, and nature conservation, while HT as a spatial unit of nature conservation importance is included only in the Guidelines for Nature Conservation. The recommendations for spatial planning, as presented by Šuklje Erjavecet al. (2020), and Čufer and Ribič (2021), indirectly refer to the concept of NBS, but do not mention it explicitly and do not address HT or define green areas in relation to HT.

4.1.4   Obligatory accompanying documents

All obligatory accompanying documents to spatial planning documents or their drafting instructions address nature conservation-related HTs as constraints on spatial interventions, but the NBS concept is not found in them. We identify the Urban Development Concept (UZ) and Landscape Development Concept (KZ)as relevant for the NBS and HT, which provide an interdisciplinary and comprehensive expert basis and have

742

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

the status of obligatory accompanying documents, and therefore focused only on these two documents in the further analysis of the accompanying documents for strategic and implementing spatial planning documents. For the urban challenges considered here, the Urban Development Concept, which targets urban areas, is more relevant than the Landscape Development Concept, which targets areas outside the built-up area.

4.2 Rationale and possibility to include NBS and HT as NBS in the documents

	Docume nt	Explanation of reasonableness and possibility	
		NBS	HT as NBS
Strategic Spatial Planning Documents	Spatial Develop ment Strategy of Slovenia (SPRS)	Development documents by area and sector must not contradict the strategy. Therefore, it is essential for the introduction of the NBS concept at the local level that these documents recognise it as an appropriate and effective way to address the challenges.	As we look for ways to use HTs to create a better quality of urban living environment, the scale of spatial planning at national level is too high for them and therefore it does not make sense to include HTs in the graphic representations of the SPRS. In the descriptive part of the SPRS, individual HTs in urban areas should be understood as smaller spatial units than green spaces and blue spaces or their individual elements that also occur in other areas, such as residential areas. The conservation or restoration of HTs in urban and periurban environments should be argued not only in terms of biodiversity, but also in terms of their direct contribution to solving urban challenges. The SPRS provides an opportunity to include this understanding of HT into the orientations for achieving the SPRS objectives, while also including it in the indicators for monitoring the implementation of the SPRS.
	Regional Spatial Plan (RPP)	Areas identified in the RPP as important for nature conservation should also be identified based on their functions in addressing societal challenges, making them part of the environmental infrastructure (and not just nature conservation). The NBS concept provides an opportunity to develop this kind of understanding of the region's green system. NBSs as means of addressing urban challenges should be identified and presented a guiding principle in the report. Prior to developing the RPP, urban challenges need to be well defined, especially those whose impact extends beyond municipal boundaries or need to be addressed on an inter-municipal level. In addition to the defined challenges, the RPP expert base can use the NBS concept to propose appropriate solutions. This can provide space for appropriate solutions already at the regional level and be can be directly transferred to the OPN.	The planning scale is too small to show in the graphic part the positioning of specific HTs to address urban challenges, which requires a scale of 1:5000.
	Municipa l Spatial Strategy (OPP)	The OPP should follow other national development documents and EU development objectives, including the NBS concept. As the OPP is prepared for urban communities, consideration of urban challenges (already in the expert bases) is even more important than in the regional plan. The OPP spatial scale may already be relevant for NBS planning for specific urban challenges.	The OPP shows the layout of the planned networks (e.g., municipal infrastructure, green system), so it is not yet a suitable spatial document for locating specific HTs as NBS. As it defines the areas for which the UZ or KZ is to be elaborated, HT as NBS can be considered as NBS within these two expert bases.
Spatial Implementing Documents	National Spatial Plan (DPN) Decree on the optimal variant (UNV) National Spatial Develop ment Plan (DPUN)	In the context of national spatial planning, NBS can serve primarily to mitigate the negative impacts that new planned elements cause in space (e.g., noise reduction, particulate matter deposition and thus air quality improvement, stormwater retention, etc.).	These spatial planning laws define the spatial implementation laws of the municipalities, so it is important that HT is provided as NBS in these documents. It is important that HT be more specifically defined as a form of NBS in the UNV, as this draft provides space for planned spatial development. A detailed graphic representation of the planned/warned HTs as NBS at a scale of 1:5000 is reasonable in the DPUN.
	Municipa l Spatial Plan (OPN)	The OPN is referred to as an important spatial planning tool for the introduction of the NBS concept in urban areas(especially for the settlements for which no UZ is prepared). However, it is important that the urban challenges and their management are defined in the development programmes and do not contradict the orientations in strategic documents.	HT can be mapped in the graphic part and presented in the descriptive part, while the content is transferred in more detail to the subordinate documents (OPPN and OUNK).
	Detailed	As a municipality can change the land use or spatial	HTs may be presented in the OPPN as NBS in

	Municipal Spatial Plan (OPPN)	implementation conditions through an OPPN without first changing the OPN, this spatial planning tool is particularly suitable for urban areas with an already defined OPN.	appropriate detail.
	Ordinance on managing the appearance of settlements and landscape (OUNK)		How HTs implemented in the urban environment to act as NBS are managed can be written into the OUNK.
National Spatial Order (DPR) documents		As spatial planning documents are prepared based on and in accordance with the various recommendations, the NBS concept should be properly identified, interpreted and recommended within the DPR, in particular in the recommendations in the areas of settlement development, water management, nature conservation, energy, protection and safety, sustainable mobility, road and rail transport and motorways. There is also an opportunity to develop specific spatial planning recommendations for the NBS concept.	An important improvement would be to start to identify existing HTs that are important for the quality of the living environment, in addition to HTs that are important to conservation, and to protect them accordingly.
accompanying Obligatory documents	Urban Development Concept (UZ)	The development of UZ is based, among other things, on spatial solutions that arise from the challenges of the settlements. It therefore makes sense to incorporate NBS in UZ to address urban challenges by addressing challenges and solutions in a holistic and systemic manner at the whole settlement level. NBS as a mean to address challenges should be defined in the development vision and professional backgrounds of the UZ. In this way, UZ can provide an important professional basis for the implementation of NBS in the preparation of RPP, OPP and OPN.	In IP/UZ, as an expert base, the NBS can be concretized by placing appropriate HTs.

Table 1: Spatial documents in which it makes sense to involve NBS and/or HT as NBS to address the urban challenges

The spatial documents that have proven to be suitable for the integration of HT as NBS for the urban challenges in their graphic and descriptive parts and in their elaboration procedures are the spatial implementing documents:

- at the level of national spatial planning, the National Spatial Plan (DPN), the Decree on the optimal variant (UNV) and the National Spatial Development Plan (DPUN),

- at the level of municipal spatial planning, the Municipal Spatial Plan (OPN) and its subordinate Detailed Municipal Spatial Plan (OPPN) and Ordinance on managing the appearance of settlements and landscape (OUNK),

- and Urban Development Concept (UZ) as an expert study for the OPP, OPN and/or RPP.

4.3 Proposal for how to include HTs as NBS into spatial planning documents

In the following, we make suggestions for the inclusion of HT as NBS in the existing components of the implementing spatial planning documents of national and municipal spatial planning, as well as UZ as expert studies that have proven to be relevant spatial planning documents for the inclusion of HT as an NBS.

4.3.1 Inclusion of HT as NBS in spatial implementation acts of national spatial planning

In developing the DPN, we suggest that expert studies identify and map HTs (especially bypasses, forest, wetlands) that already function as NBS and protect them in the same way as HTs of nature conservation importance (e.g., by prohibiting construction or creating alternative HTs). At the same time, the placement of appropriate HTs should be required to avoid negative impacts from development. This could be the subject of a separate expert study from the environmental report, as it is important to include the concept of NBS and HT in the initial stages of the developing potentially viable options, rather than in the evaluation of the selected option. HTs would be shown on maps at 1:5000 scale or smaller, depending on the size of the planned or protected area, or they would be shown in the descriptive part of maps at a larger scale, e.g., a specific (named) HT is established in a specific dry reservoir.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4.3.2 Inclusion of HT as NBS in spatial implementation documents of municipal spatial planning

We suggest that in the development of the OPN, the assessment of the situation and future needs of the area identifies the urban challenges that can be solved by the NBS and proposes solutions to them in the expert studies by locating or protecting the corresponding HT at a scale of 1:5,000 or more detailed. This is crucial in the initial phase, in particular for dividing the area into the corresponding spatial planning units, determining the corresponding land use designations, and the spatial implementation conditions. As the division of the OPN area into spatial units should be based on the specificity of the urban space and may also be determined by specific protection regimes (e.g., water resources, Natura 2000) and not necessarily by infrastructure corridors, the space could be subdivided according to urban challenges and designated or protected HTs. Currently, the most characteristic spatial morphological units of unified spatial planning are land use zones such as single-family houses, dense (closed) housing, historic settlement core, production areas, green areas, economic zones, etc., which means that they are mainly defined by activities and facilities. For the areas where NBS interventions are foreseen, the OPN must provide for the preparation of an OPPN, since the OPPN, among other things, presents in more detail the technically justified spatial arrangements for the implementation of environmental and nature protection measures. Planners of the OPPN can either preserve the HT or create a new one through provisions on a specific parcel. It is important that, in addition to the existing HTs that are important for nature conservation, HTs that are important for maintaining a high quality living environment are identified and mapped, appropriately protected, and the possibility to use these areas is established.

In the already adopted OPNs, it is useful to identify urban challenges within specific spatial planning units, as these allow for different types of actions in the area. A single HT as NBS should not be equated with a land use designation when drafting or updating new spatial planning legislation, as they can occur in small areas within different land uses, e.g., within residential areas, economic zones, transport infrastructure areas. However, where larger contiguous areas of HT are envisioned to address challenges (flat ground occurrence of HT), it makes sense to provide for a separate, more detailed land use designation. Considering the existing types of basic and detailed land use designations, we suggest that the larger areas of HT be placed in one of the following detailed land use designations:

- other maintained green areas which, according to the regulations, are green belts with a protective or other function;

- wooded areas in the case of forest HT;

- water areas on land in the case of inland or marine water HT or water infrastructures, so that their ecological function can be specified, e.g., for water purification or water retention;

- areas related to protection against natural and other disasters for HTs that contribute to protection against natural disasters such as floods, landslides and fires;

- areas of environmental infrastructure if HT, which has an identified important function e.g., wastewater treatment, water retention for later use, etc., were defined as public economic infrastructure, which would require modifications in legislation to recognise the broader, not just nature conservation, importance of HT.

To address the challenges posed by HTs, it is important that their location or protection is adequately defined in the spatial implementation conditions, as these directly determine the design of spatial interventions. In a specific spatial planning unit, specific HTs, their uses (accessibility, types of recreation, etc.)protection regimes, specific restrictions and requirements should be defined. Within these provisions, there is an opportunity to understand and predict the occurrence of HT also on green roofs and vertical greening types, and not only on flat and paved surfaces. This will require further interdisciplinary research. HTs to be provided or protected should be shown in detail on the site.

For HTs that allow other land uses for residents in addition to their primary function as NBS (e.g. recreation), it is important that the established allowable land use of the particular spatial planning unit is appropriate for their placement in the spatial planning unit (allow for sufficiently large areas). In our opinion, HTs that do not serve recreational use for the population cannot be counted towards the absolute area of open green or other areas that serve the common use of the population. However, in addition to the so-called

required absolute area of open green spaces, it would also be useful to define the absolute area of specific HTs to address a specific urban challenge within a given spatial planning unit.

The OUNK provides the opportunity to define the appearance of HTs, their allowable or minimum size, design requirements, etc., which may vary from settlement to settlement, depending on their distinctive characteristics and identity. Care must be taken to ensure that the design of HT does not take precedence over its NBS function. As the decree aims to improve the quality of the environment and mitigate the effects of climate change, the municipality may include in this spatial planning document (which may be merged with the OPN) a requirement to implement NBS for certain spatial interventions, e.g., construction of rain gardens, green roofs with/or appropriate HTs.

4.3.3   Inclusion of HT as NBS in Urban Development Concept (UZ)

The UZ should identify HTs that are already part of the city's existing green system and have an important NBS function (e.g., flood protection, cooling of the surrounding area). Such areas should be given a conservation value and protected at a scale of 1:5,000 on a unit basis. In addition, their integration with urban functions (accessibility, recreational opportunities, sustainable mobility routes, etc.) should be determined. The determination of what percentage of the urban area should be occupied by HTs should be considered on a unit-by-unit basis and determined based on expert evidence on the effects of HTs.

5   CONCLUSION

In this paper, the concept of NBS and HT as a form of NBS is applied to the case of the Slovenian planning system, with the proposal to integrate it into the existing spatial planning documents and place it in the scope of spatial planning. Based on a systematic review of spatial planning documents, we found that in strategic spatial planning documents and national spatial planning documents, especially in the spatial planning guidelines for sectors and spatial planning recommendations, there is an opportunity to define the concept of NBS as a way to address the upcoming urban challenges, thus defining NBS as a vision and goals for spatial development. The key to the integrating HT as NBS into existing spatial planning practice is spatial implementation documents, both at the national and municipal levels, and UZ as the mandatory expert basis for these documents. Understanding and translating the concept of NBS from EU-level policy documents into national, regional and local strategic documents will be the key to their widespread adoption. However, further research on the performance and environmental requirements of HTs, with an emphasis on interdisciplinary and multi-criteria evaluation, is needed to promote a planning approach that spatially locates appropriate HTs as NBS for urban challenges.

The Potential of Bio-Based Insulation Materials for Healthy Living Spaces and Sustainable Architecture

Sandra Böhm

(Dipl. Des. Sandra Böhm, KIT, Faculty of Architecture, Institute of Design and Building Technology IEB, Sustainable Construction, Englerstraße 11, 76131 Karlsruhe, sandra.boehm@kit.edu)

1 ABSTRACT

In Germany, 30 % of CO_2 emissions and 35 % of final energy consumption are due to the operation of buildings.[1] The building sector must therefore make an intensive contribution to the energy transition. In addition to the requirement to operate every new heating system with 65 % renewable energies from January 2024, the energy-efficient refurbishment of existing buildings, for example by installing new windows or upgrading thermal insulation, is to be massively promoted in order to reduce energy consumption and emissions. The renovation of the building stock should contribute significantly to the EU's goal of climate neutrality by 2050. In order to achieve a climate-neutral building stock, the operating energy and in particular the non-renewable share of primary energy must be drastically reduced and the remaining energy demand must be covered predominantly with renewable energy sources.[2] A large part of the operating energy of buildings is due to the heating or cooling systems in living spaces. Appropriate building insulation, especially in existing buildings, can save energy at this point. Do we want to continue this energy upgrade of our buildings with synthetic materials from finite resources, some of which have been proven to endanger our health, or will we succeed in the biological insulation turnaround that would bring energy-efficient, sustainable and healthy living spaces? With a view to the desired climate neutrality of the EU, is it not a logical conclusion to refurbish the building stock with insulation materials that consume as little energy as possible in their production, while causing virtually no emissions?

In answering these questions, it is important to consider the potential of biological insulation materials. What raw materials are available? What are the manufacturing processes? How are the material properties and durability of biological insulation materials to be assessed?

The paper examines biological insulation materials and their use for creating healthy living spaces in a sustainable architecture. It focuses on the raw material base, which often consists of residues and by-products, the construction-relevant properties and aspects of material health. Depending on the results of this analysis, the aim is to define the use of biological insulation materials as part of a sustainable resource management in the building sector, which can be understood as a Nature-Based Solution. According to the definition of the International Union for Conservation of Nature (IUCN) Nature-Based Solutions (NBS) are described as measures for the protection, sustainable management and restoration of natural and modified ecosystems.[3]

The following explanations are intended to show that the replacement of synthetic insulation materials, some of which contain substances that are harmful to health, with 100 % bio-based insulation materials can help to conserve non-renewable resources and thus combat the scarcity of resources. The mostly very environmentally damaging mining methods of non-renewable resources could be greatly reduced and, in this way, ecosystems could be protected. In addition, the increased use of renewable resources could positively address other challenges within the construction industry, such as the need to create healthy living spaces and drastically reduce emissions from the production of building materials.

Keywords: sustainable architecture, renewable raw materials, alternative resources, healthy building materials, bio-based insulation materials

2 INSULATING MATERIALS ON THE MARKET

A survey by the Agency for Renewable Resources (Fachagentur Nachwachsende Rohstoffe e. V., FNR) identified the market shares of the most commonly used insulation materials. Insulation materials based on fossil raw materials had the largest market share of insulation sales in 2019 with 48 %. Mineral insulation materials had a share of 43 %. Insulation materials made from renewable raw materials were only sold at 9 % in 2019 (2 % more than in 2011). However, manufacturers are noticing an upward trend.[4] Finally, the topic of sustainable construction has also arrived in society, so that more and more building owners are making a more conscious choice of materials when building a house or renovating an existing building.

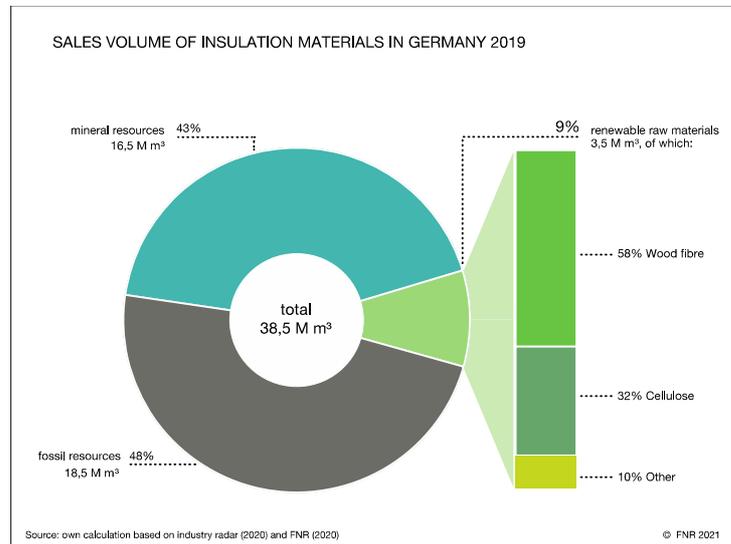

Fig. 1: Sales volume of insulation materials in Germany 2019. Source: Fachagentur Nachwachsende Rohstoffe e. V., FNR (Agency for Renewable Resources): Aktuelle Nachricht, 24.02.2021. Translated and traced by Sandra Böhm and Luca Diefenbacher

In 2017, Pforzheim University published a market and social research study on the very low market share of insulating materials made from renewable raw materials, but also on their potential for further development. The Pforzheim University of Applied Sciences summarises the results of the study on its website and addresses a change from the "attitude-behaviour gap" to the "producer-people gap".[5] In the past, building owners often had a positive attitude towards bio-based insulation materials, but did not act on their attitude. Today, however, according to the study, they would very much act according to their attitude and buy insulation materials made from renewable raw materials, but they are prevented from doing so by a lack of supply on the market. The main focus was on bio-based façade insulation, for example from wood fibres, cellulose or hemp. This study on "Renewable raw materials in the industry" is based on 340 interviews with private building owners, specialised companies, authorities, traders and architects.

A statement on the study emphasises the special role of architects as independent, advising and competent protagonists of the building sector. However, the manufacturing companies should lose their shyness about investments in research and development of insulating materials made from renewable raw materials, as the insulating materials sector plays a decisive role for the "ecological development" in Germany.[6]

The desire for more ecological insulation materials on the part of building owners is therefore present. The range of products on offer in the trade should be expanded accordingly. Some biological insulation materials already exist, some of them have been used for centuries, but they have been pushed out of the market by the development of modern synthetic materials. Today we realise that these synthetic materials are not the solution in the long run. The corresponding resources are coming to an end and their disposal is partly highly problematic - to name only two aspects relevant for the life cycle. In the following, exemplary insulating materials on a biological, synthetic and mineral basis will be presented and comprehensively compared with each other. The aim is to obtain an initial overview of possible potentials of biological insulation materials.

2.1 Origin and availability of raw materials and the production of insulation materials

2.1.1   Biological insulation materials from residues and by-products

Insulation materials made from renewable raw materials should be produced from domestic or regionally available resources in order to keep transport costs and the associated CO_2 emissions as low as possible. In addition to the main raw material, however, different and partly synthetic additives are also added to bio-based insulation materials. These are intended to improve fire protection, prevent mould or pest infestation or stabilise the fibre structure of the insulation material. In order to obtain a recyclable biological insulating material, however, it is essential to do without such additives during production. If the insulation materials are 100 % biological, they could be composted in one's own garden.

In addition to the flawless processing of renewable raw materials into building materials while avoiding harmful and/or synthetic substances, the efficient use of these raw materials is particularly relevant in protecting our ecosystems. Even renewable raw materials are not available in unlimited quantities. The raw material base of bio-based insulation materials consists, for example, of wood chips, flax fibres, cellulose flakes, straw, seaweed or cork scrap. These are residual materials and by-products from other material flows. Flax short fibres, for example, are a by-product of the textile industry. Seaweed accumulated on the coast is often removed at great expense and disposed of in landfills, as it is considered a nuisance on the beaches, which are mostly used for tourism, and is regarded as waste. However, these residual materials, which accumulate anyway, can be further processed into pressure-resistant boards, flexible mats, blow-in or plug-in insulation and used for building insulation.

Fig. 2: Accumulated seaweed in the Baltic Sea. Source: Lübecker Nachrichten: Seegras war früher ein Nebenverdienst für viele Fischer. URL: https://www.ln-online.de/lokales/nordwestmecklenburg/seegras-war-frueher-ein-nebenverdienst-fuer-viele-fischer-ESLCPAW7PUEGKZWUAEHEBMBWS4.html [Accessed: 14.06.2023], Copyright Foto: Maik Freitag.

In addition to the raw materials and additives used, the primary energy used in the manufacturing process plays a decisive role in assessing the sustainability of building materials. The use of insulation materials should reduce energy consumption in the use phase. With regard to the overall energy balance, it also makes sense to use insulation materials that are produced with as little energy as possible.

The following will discuss these aspects in more detail based on the selected insulation materials. Wood fibre insulation boards, a cellulose fibre blow-in insulation material, insulation fleeces made of flax and hemp are being compared with rock wool as a representative of mineral insulation materials and foamed polystyrene and PUR rigid foam insulation boards as representatives of fossil-based insulation materials. In addition, seaweed is presented as a niche product within the insulation industry.

Wood fibre insulation boards are made from residual wood from the sawmill industry. An insulation board consists of at least 80 % wood fibres.[7] It has a thermal conductivity of 0.040 W/(mK) and building material class B2, normally flammable. The wood information service describes the production of wood fibre insulation boards using the wet process as a process in which no additional binding agents are needed, as only the wood's own binding forces in the form of lignin come into play. The wood fibres are first thermo-mechanically broken down and finally set under heat. Wood fibre insulation boards are dried at 160 and 220 °C. Additives containing resin or bitumen are added to individual products to improve their strength, for example.[8]

The process data set of wood fibre insulation board (wet process) of Ökobaudat, refers also to the use of various additives, e.g. to PVAC (polyvinyl acetate), a plastic used in glues. Paraffin is also mentioned, which is used in special products to produce a water-repellent layer. So, you have to look closely and consider additives product by product. The recycling of residual materials, in this case wood chips, into a high-performance insulation material is particularly useful, but the total non-renewable primary energy demand (PENRT) in the production (module A1-A3) of wood fibre insulation boards from the wet process is very high (through the drying process) at 1823 MJ per m3 compared to other bio-based insulation materials.[9]

Cellulose insulation flakes are produced from waste paper with comparatively little manufacturing energy. The total non-renewable primary energy demand (PENRT) in production (module A1-A3) is 94.79 MJ per m³.[10] The insulation material has a thermal conductivity of 0.037 to 0.045 W/(mK) and is normally flammable (building material class B2). If the cellulose insulation is properly and tightly stuffed, a dense structure is created which prevents the spread of fire and on which a protective layer of carbon is formed.[11] Nevertheless, borates are added to the recycled fibres for fire and glow protection. Boric acid and borax were classified by the European Commission in 2010 as toxic to reproduction and as a substance of very high concern.[12] If the mixture contains more than 5 % borax or boric acid, it would ultimately have to be classified as well. The quantities actually added are even higher, for example 12 % borax and 8 % boric acid.[13]

When installing the flakes, a high dust load can occur, which is why work should only be carried out professionally with appropriate equipment and comprehensive cleaning of the construction site afterwards. There is no special occupational safety labelling for cellulose fibres, but the added borates are also contained in the dust. In the meantime, more compatible flame retardants are used, such as ammonium polyphosphate, which is classified by the Federal Environment Agency (Umweltbundesamt, UBA) as unproblematic in application.[14] With regard to the availability of the raw material, the relatively simple production and the physical building properties, blow-in insulation made of cellulose flakes is a good alternative to established synthetic insulation materials. However, they should not be used carelessly and special attention should be paid to professional installation and, if possible, borate-free mixtures should be used.

Flax insulation boards or flax fleece consist of short fibres of the flax plant. These short fibres are a by-product of the textile industry. The cultivation of flax is in sharp decline in Germany, but is being further expanded in neighbouring countries. The cultivation and harvesting of flax are labour-intensive, but almost all parts of the plant can be processed into different products.

Flax insulation boards have a thermal conductivity of 0.040 to 0.045 W/(mK) and are classified as normally flammable (building material class B2). The fibres are glued with starch or mixed with bicomponent plastic fibres. These bicomponent plastic fibres consist of either petroleum-based plastics or bioplastics. As with insulating materials made of cellulose, fire protection is also achieved by adding ammonium polyphosphates or borates. In some cases, soda ash is also used as an alternative.[15] In principle, the composition must also be taken into account, depending on the product. Against the background of recycling or possible later composting, insulation boards mixed with plastic should not be used. However, it can be said that a residual material that is available anyway is put to a sensible use. Some manufacturers take back the insulation boards after use for reuse or recycling. For example, material that is not damaged or soiled can simply be reused or processed into stuffing wool.[16] Loose flax insulation materials are also offered without additives and can be used as insulation material without any problems. They are naturally resistant to pests and resistant to mould.

Hemp insulation mats or hemp fleece consist of various parts of the hemp plant, especially the hemp fibre, have a thermal conductivity of 0.040 to 0.045 W/(mK) and are classified as normally flammable (building material class B2). The fibres are mixed with bicomponent plastic fibres. In some cases, supporting fibres made of starch are also used, but this process is still very cost-intensive. For fire protection, ammonium polyphosphates or soda are added. If handled properly, the flame retardants are considered harmless, but there is still potential for savings here. Material that has been used purely for this purpose is sometimes taken back by the manufacturers to be used in the production of new boards or stuffing wool. Undamaged mats can simply be reused.[17] The availability of hemp fibre from Germany is currently very limited, as the cultivation of hemp fibre has only been permitted under strict conditions since 1996. In the meantime, however, one can observe an upward trend in the expansion of cultivated areas for this undemanding and versatile plant.[18]

Despite the still limited availability of hemp and flax products in Germany, these rapidly renewable fibre plants should not be underestimated. Due to the versatility of the high-performance fibres, they will certainly play a greater role in our country again in the future. What is striking about both products is the high non-

renewable primary energy demand in production (module A1-A3) with about 1500 MJ per m³.[19] There is certainly still potential for savings here.

Jute insulation boards are made from old cocoa or coffee sacks that were previously used to transport goods to Germany and may not be used again for the same purpose.[20] They have a thermal conductivity of 0.038 to0.041 W/(mK) and are classified as normally flammable (building material class B2). Up to 10 % biopolymeric support fibres are added for stabilisation and up to 5 % soda ash for fire protection.[21] The soda is already used for cleaning the shredded fibres. The insulation boards can be installed very easily and quickly by the user without special protective clothing. The boards can be assembled by the customer or delivered prefabricated. Like many natural insulating materials, jute insulation boards have a high absorption capacity and can compensate moisture well due to this property. After absorbing moisture, they do not lose their function as long as the moisture can be released again.[22] In addition, they offer particularly good heat protection in summer.

Naturally occurring residues that do not come from agriculture or an already existing production lines represent further interesting resources for material recycling. Seaweed is also such a natural residual material, particularly well suited for the production of insulation materials. However, insulation materials made from seaweed have been used by the local population for a long time and are naturally suitable for use in the construction sector they are still absolute niche products.

Two different species of seaweed are used for the production of insulation materials. Common sea grass (Zostera marina) grows at a depth of 14 m in the form of meadows along the Baltic Seacoast. The blades of grass die in autumn and are washed up on the coasts in large quantities. Due to its availability and beneficial properties, it has been used for centuries for upholstery, roofing and insulation. It does not rot, does not mould and is resistant to vermin due to its high silicate content. The dried seaweed is used without any other additives. The long seaweed fibres have a pleasant paper-like appearance in their feel and can be stuffed by

hand. The thermal conductivity is0.043 to 0.045 W/(mK). The insulation material has building material class B2.[23]

Neptune grass (Posidonia oceanica) can also be used to make insulation material. Plant remains are used here, which are formed into spheres by the movement of the waves after they die. These balls can be found on beaches throughout the Mediterranean, where they are removed and disposed of at great expense.

An architect from Karlsruhe carried out initial tests with these balls a few years ago. He was particularly struck by the very good fire behaviour. Today, the balls are processed into stuffing wool and sold as insulation material. Although the raw material is transported from the Mediterranean region to Germany, very little energy is needed for the entire further processing. In a simple mechanical process, the fibres are prepared and the sand is sieved out. No additives are necessary. The material is naturally mould-resistant and normally flammable (building material class B2). It is not attractive to vermin and has a thermal conductivity of 0.039 to 0.046 W/(mK).

These two positive examples show that it is entirely possible to use natural resources that are 100 %natural for building insulation. In the case of the previously described insulation materials made of wood, cellulose, flax, hemp or jute, synthetic fibres are currently too often added for stabilisation or borates as flame retardants. However, there are corresponding biological and sustainable alternatives that manufacturing companies should focus on in the future. because this is the only way to produce sustainable building materials that can be recycled or composted again and again for a closed-loop system as we need it.

2.1.2 Insulation materials from petroleum-based or mineral raw materials

Extruded polystyrene foam boards (short: XPS insulation boards) consist of polystyrene, a petroleum-based plastic. They have a thermal conductivity of 0.035 to 0.040 W/(mK) and building material class B1, flame retardant. XPS insulation boards are resistant to moisture and do not rot. The insulation material is repeatedly criticised because of the flame retardants and blowing agents used. Some of the blowing agents are extracted during production, some remain in the insulation material and are released into the ambient air over years when installed.

In addition, flame retardants and other synthetic additives are used.[24] The flame retardant Hexabromocyclododecane (HBCD) is no longer approved. However, it was used for many years and is therefore still found in large quantities in existing buildings. Until 2017, corresponding products were allowed to be installed in Germany, although the toxic effect was already proven in 2008 and the substance was classified by the EU as being of extreme concern.[25] The substance, which is difficult to break down, has already been found in breast milk, fish, marine mammals and birds of prey in Arctic regions.[26] Furthermore, the dismantling and especially the disposal of thermal insulation systems made of XPS containing HBCD is complex and associated with high costs, as the ingredients of concern may only be disposed of in special incineration plants.[27] In the meantime, for example, brominated polymer is used as a flame retardant, which is non-toxic and non-bio-accumulative. In addition, however, a TBBPA derivative (Tetrabromobisphenol A) is also used, the effect of which is currently being investigated by an EU programme. Like HBCD, it is also

said to be bio-accumulative, persistent and hormonally active in vitro.[28] There are numerous other variants of flame retardants and blowing agents that are used in XPS insulation materials and whose effects cannot be described here in individual cases. However, we have learned from the past that substances once considered unproblematic later turned out to be problematic in terms of environmental and health aspects, for example the CFC-12 blowing agent that was used in the past.

According to Ökobaudat, the total non-renewable primary energy demand (PENRT) in the production (module A1-A3) of XPS insulation materials is 2839 MJ per m³.[29] This is a very high energy demand that cannot be justified, considering the mass use of XPS in building insulation and numerous other applications, for example in the packaging industry. For PU insulation boards made of slab stock foam, the total non-renewable primary energy demand (PENRT) in production (module A1-A3) of 325 MJ per m² is given in the Ökobaudat dataset.[30] Using the layer thickness of 0.12 m given in the data set, this value can be converted to P 2708, 3 MJ per m³.

PU insulation boards made of slab stock foam or polyurethane rigid foam boards are petroleum-based rot proof products that are created in a chemical reaction, with the help of the blowing agent pentane. HCFC-141b was also used as a blowing agent, but has been banned in Germany since 2004. Furthermore, the Ecological Building Material Lexicon (Ökologisches Baustofflexikon) lists many other formerly and currently used blowing agents, flame retardants and additives, some of which have been banned over time and then replaced by alternatives. Polyurethane rigid foam panels are considered harmless to health when installed, but during production employees come into contact with numerous toxic substances. Subsequent outgassing of the blowing agents can also be assumed. In addition, the plastic may only be disposed of in small quantities and is therefore incinerated, producing toxic hydrochloric acid. The insulation value of rigid Polyurethane foam boards with a thermal conductivity of 0.025 to 0.030 W/(mK) is particularly good. In addition, depending on the product, building material class B2 (normal flammability) or B1(low flammability) is possible.

Fig. 7: Installation of PU rigid foam panels as above-rafter insulation. Source: Baustoffwissen, RM Handelsmedien GmbH & Co. KG: Dämmstoffe, Einsatzbereiche von PU-Hartschaum. The possible building material class B1of XPS insulation boards or rigid Polyurethane foam boards is certainly an advantage. However, if a fire does occur, the fire behaviour is very dangerous. Rigid

Polyurethane foam boards burn with a strong formation of smoke, which makes orientation and escape in the burning building difficult and can lead to health damage. XPS insulation boards are suspected of emitting toxic gases in case of fire. The question arises as to what risks we should accept for a good insulation value. The Ecological Building Material Lexicon (Ökologisches Baustofflexikon) points out that these insulation materials should only be used from an ecological point of view if their efficiency (very good insulation value, thus thin component layer) is absolutely necessary and no other insulation material can be used accordingly.[31]

As an example of the mineral insulation materials, the most important aspects of rock wool are explained below. Its thermal conductivity is 0.035 to 0.040 W/(mK). Rock wool is considered non-combustible with building material class A1. It consists of artificially produced mineral fibres based on sedimentary or magmatic rocks. Binding and water-repellent agents are added as additives.

A mixture of the rock, coke, recycled wool and lime is prepared for the melting process. Binding and impregnating agents are used when the threads are pulled out of the molten mass. The binder polymerises in the curing oven. The fibres of rock wool can cause irritation of the respiratory tract, itching and reddening of the skin if they come into contact with it. Mineral wool fibres were classified as suspected carcinogens in the 1980s. The so-called WHO fibres, dust fibres of a certain size and geometry, are respirable and therefore banned.[32] Products available on the market today no longer contain respirable fibres. In terms of non-renewable primary energy demand (PENRT) in production (module A1-A3), rock wool with a value of 1137MJ per m³[33] is better than XPS insulation (2839 MJ per m³) and wood fibre insulation board from the wet process (1823 MJ per m³).

The recycling of clean used rock wool is possible, but the take-back options by manufacturers are still in their infancy and are only offered sporadically, especially for the commercial sector. The lamination of rock wool with paper, aluminium or plastic film further complicates or prevents recycling. This example again clearly shows how important it is to use pure building materials that can be reused or recycled accordingly.

With regard to the total non-renewable primary energy demand (PENRT) in production (modules A1-A3), the values of bio-based insulation materials are mostly in the lower range, provided that the processing intensity is relatively low or if residual materials were recycled anyway, as in the case of jute or seaweed, for example. Overall, it can be said that little-processed bio-based insulation materials or recycled insulation materials have the best values here and the energy requirement is amortised in less than one year.[34] Insulation materials from renewable raw materials also offer the advantage that the raw materials store CO_2 during the growth phase, i.e. during the production of the insulation resource, while CO_2 is already released during the production of the basic materials for the synthetic insulation materials.

2.2 Building physical properties and material health of insulation materials

The data on thermal conductivity in W/(mK) differ slightly in the third digit after the decimal point. This minimal distinction is due to the production by different manufacturers. According to Table 1, the values in the preceding text from the Ecological Building Material Lexicon (Ökologisches Baustofflexikon) are in part minimal worse in terms of insulation value than the data from the Agency for Renewable Resources (Fachagentur Nachwachsende Rohstoffe e. V., FNR). In summary, it can be said that the values of petroleum-based and mineral-based insulation materials turn out to be somewhat more advantageous than the values of biological insulation materials.

Table 1: Overview of the most important technical values for insulation materials. Source: Fachagentur Nachwachsende Rohstoffe e. V., FNR (Agency for Renewable Resources): Marktübersicht. Dämmstoffe aus nachwachsenden Rohstoffen. 10 überarbeitete Auflage (2019), Gülzow-Prüzen. Table translated by Sandra Böhm.

The bio-based insulation materials can score points with regard to other building physics properties. Materials with a low water vapour diffusion resistance factor are able to transport moisture that has penetrated the material and allow it to dry out again elsewhere. The mostly different sized pores in natural insulation materials lead to the fact that the moisture first migrates through the small pores while the effectiveness of the larger pores for the insulating effect is maintained. In an insulation material with uniform pore size, this effect does not occur. In Table 1, the very low water vapour diffusion resistance values of most bio-based insulation materials are striking compared to the values of extruded polystyrene. This absorption behaviour of biological insulation materials has a regulating effect on the humidity level of indoor spaces and is particularly advantageous for a pleasant indoor climate in today's increasingly airtight residential buildings.[35]

The specific heat capacity refers to the thermal protection in summer. Materials with high values offer better thermal protection here, as they pass on incident heat only very slowly. In the summer heat, the high heat storage capacity of natural insulation materials means that the absorbed heat is only released with a long delay, i.e. during the night, and not in the afternoon, as is the case with synthetic insulation materials, for example.[36]

Such beneficial properties of natural insulation materials have already been proven in studies. In contrast to mineral and synthetic insulating materials, natural insulating materials can compensate moisture fluctuations to a certain extent and thus have a positive influence on the indoor climate, which is particularly beneficial for allergy sufferers. The fire behaviour should also be mentioned again. The bio-based insulation materials burn rather slowly and only a small amount of smoke is produced. As long as no chemical components have been added, it can also be assumed that no toxic smoke gases are produced. Rigid foams, on the other hand, melt, drip burning and burn very quickly overall; this is accompanied by strong, dark smoke formation.[37]

For special applications, insulation materials such as XPS or PUR insulation materials are still justifiable to a certain extent, for example, in areas exposed to moisture, e.g. as perimeter or base insulation, inverted roof and terrace insulation. It is always necessary to weigh up which insulation material is best suited to which application in order to use the appropriate products in a targeted manner and to reduce building materials from finite resources as much as possible. The goal should therefore be to establish pure insulation materials from renewable raw materials (NawaRo) on the market and to use them on a broad scale. However, this will

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

only work if we use these raw materials efficiently, for example the residues and by-products from already existing material flows, and exclusively in a closed-loop system.

Looking at the material health of 100 % biological insulation materials, it becomes clear that their use in living spaces could be of outstanding importance especially for vulnerable population groups. In the future, the need for housing and care facilities for the elderly and those in need of care, as well as childcare facilities in our communities, will increase. In planning these facilities, material health will play a huge role in improving the quality of life and well-being of these target groups, rather than compromising them. Natural building materials, including biological insulation materials, which positively influence the indoor climate and do not emit pollutants, will be increasingly in demand.

The people who work in the production of insulation materials should not be ignored. Particularly in the production of synthetic insulation materials, there is a great potential for health hazards that must be minimised as far as possible through appropriate alternatives.

3 CONCLUSION

The petroleum-based insulation materials, e.g. XPS insulation boards, or the mineral insulation materials, e.g. rock wool, undoubtedly have very good technical properties and a high insulation value. However, if one considers ecological and health-relevant aspects, they are no longer convincing. If one looks at the long lists of ingredients of synthetic and mineral insulation materials, they are not an alternative from an ecological point of view. Crude oil as the raw material basis for synthetic plastics can possibly only be used for a few more decades. According to Wecobis, coal is an alternative base material, also a non-renewable raw material, the processing of which would require even more energy – from an ecological point of view and, with a view to our descendants, also from a social point of view, thus not an alternative either.[38] Some of the numerous additives are considered worrying or even toxic. This also makes disposal time-consuming and expensive, recycling difficult or impossible – depending on the condition of the used insulation materials. Land filling is usually no longer permitted because toxic substances are contained and landfill space is running out. In addition, toxic substances are produced when some synthetic insulation materials are burnt. We must realise that we owe it to future generations not to produce more hazardous waste that will sooner or later end up in the environment.

The renewable raw material base of NawaRo insulation materials speaks for itself. Of course, biological insulation materials are not free of concerns. Here, too, additives are mixed in that could either have health effects (borates) or interfere with recycling or composting (bicomponent support fibres). However, these additives are used to a much lesser extent. In addition, alternative flame retardants and biological support fibres are already available. With insulation materials made from seaweed, there are even products that manage entirely without additives. Insulation materials made from renewable raw materials are usually easier to reuse or recycle at the end of their life cycle and can be thermally recycled without any problems. Ideally, they are even compostable.

Insulation materials made from renewable raw materials are convincing overall because of their contribution to healthier living spaces, if they are installed on the inside of the room - for example, in the case of retrofitted insulation in an existing building. Due to their natural properties, they contribute to moisture regulation in this case. In addition, they have a higher thermal capacity than mineral or synthetic insulation materials and are therefore particularly advantageous in terms of heat protection. Even if the insulation values are sometimes somewhat lower than those of mineral wool and co., they are still convincing due to their overall balance with regard to their renewability, CO_2 storage during growth and the advantageous properties with regard to heat protection, room climate regulating properties and easily assessable fire behaviour.

The sourcing of raw materials plays a major role in ecological considerations. Of course, it makes no sense to transport coconut fibres halfway round the world to insulate our houses with them, but there are exceptions such as seaweed from the Mediterranean region and many domestic alternatives. The seaweed insulation materials, jute insulation mats or cellulose insulation materials also require relatively little

---

[38] Wecobis (Hrsg.): Polyurethan-Hartschaum (PUR/PIR), Lebenszyklus, Rohstoffe, Verfügbarkeit. URL: https://www.wecobis.de/bauproduktgruppen/daemmstoffe/aus-synthetischen-rohstoffen/polyurethan-hartschaum.html [Accessed: 07.06.2023]

manufacturing energy. However, softwood fibreboards from the wet process, for example, are an exception, because a lot of energy is used for their drying process. Such production processes worsen the ecological balance and counteract CO_2 storage during plant growth.

The demand for insulation materials will rise sharply in the near future due to climate change and the new directives and laws. All in all, it will be worthwhile in the future to use insulating materials made from renewable resources that are 100% biological if possible. Only in this way will we be able to combat the already existing scarcity of resources. The use of renewable raw materials and in particular the full use of biological residues and by-products will conserve the non-renewable or only very slowly renewable raw material sources of our earth.

In order to meet the responsibility of the building sector towards climate, environmental and nature protection, it is necessary to establish a sustainable resource management in the building sector (Nature-Based Solutions, NBS) in order to coordinate the material flows better. In this context, the availability of renewable raw materials must be recorded and monitored across all sectors. This is an important basis for the development of new alternative building materials and thus also for the development of sustainable biological insulation materials. After all, what use are new products if their production has to be stopped again due to a shortage of raw materials?

In building practice, sustainable resource management would lead to building materials being used efficiently and individually adapted to their application. Building materials from renewable raw materials produced according to certain ecological, economic and social criteria should always have priority. Building materials from finite resources should only be used in exceptional cases. The guidelines for such sustainable resource management would be based on the principles of recyclability, renewability, health and environmental compatibility and, of course, the necessary technical properties.

Numerous research projects continue to work on the development of new, efficient insulation materials from renewable raw materials. For example, a team of researchers from Osnabrück and Hamburg is developing an aerogel insulating material made of lignin, which is a residual material from paper production. Aerogels consist almost entirely of air, i.e. of very many microscopically small pores, which is why heat is conducted extremely poorly in them. The size of the pores in the nano-meter range is the decisive factor in comparison with other insulation materials such as Styrofoam, whose pores are around 200 micrometres in size.[39] Aerogels have been around for a long time and are used in the aerospace industry, for example. Until now, however, they were mostly made of plastics or silicates. Mark Fricke, who was also involved in the development of the "conventional" aerogels, has now developed the innovation from renewable raw materials with his team. Mark Fricke considers the potential of the new insulation material to be particularly high. Large quantities of lignin are available as residual material and due to the particularly good insulating value, the insulating material can be installed in a material-saving and thus very versatile way. The team is currently still working on market readiness.[40]

This example shows that it is possible to produce bio-based and sustainable insulation materials that have no limitations in terms of technical properties compared to petroleum-based insulation materials. Currently, the great potential of bio-based insulation materials is that they are renewable, often produced with low energy consumption, and that biogenic residues are used as a resource within a biological cycle-based system - i.e. without the use of synthetic additives or substances that are harmful to the environment and health. In the future, it is essential that all information about all additives and substances used in production be disclosed. Such full declarations are a prerequisite for the use of building materials in a cycle-based system.

The advantages of biological insulating materials with regard to their physical properties, in particular summer heat insulation and the regulating properties on the indoor climate, as well as the assessable properties in case of fire, were made clear in this paper. It aimed to show that the origin of the raw materials, the production, the properties during use and disposal of biological insulation materials are advantageous for environmental protection, the fight against climate change, the conservation of resources and the creation of healthy living spaces.

The Potentials of Digital Tools to Contribute to Spatial Transformations – the Example of the Digital Twin of the City of Helsinki

Jonas Pauly, Karina M. Pallagst

(MSc. Jonas Pauly, RPTU Kaiserslautern-Landau, jonas.pauly@ru.rptu.de)
(Prof. Dr.-Ing. habil. Karina M. Pallagst, RPTU Kaiserslautern-Landau, karina.pallagst@ru.rptu.de)

1 ABSTRACT

Spatial transformations are a key challenge for communities and regions. The term is rooted in the assumption that in the Anthropocene era, human ways of life and modern economic systems have led to an unsustainable consumption of natural resources and a failure to adhere to planetary limits, which ultimately endangers the natural basis of human life (Engel and Knieling 2018, WBGU 2011).

Nowadays we see, in particular with the example of climate change, how environmental threats of different types and intensities affect cities and regions. It creates a strong demand for action. Cities and regions are thus directly affected by transformations. At the same time, they define the spaces where approaches of action and implementation of instruments of spatial planning have the chance to make cities more sustainable and resilient to risks. Thus, active processes which include the whole society are required (Engel and Knieling 2018).

Such proceses as is likely to present many municipalities with a major challenge with many difficulties, which raises the question of what options there are for providing them support. The mega-trend of digitalization affects almost all areas, including spatial planning (Pallagst et al. 2022). It can be observed that digital tools have been increasingly used in spatial planning in recent years, offering new technical possibilities. The paper will look in particular at the digital twin of the city of Helsinki and its relevant fields of application. The city faces a variety of different risks in terms of climate change (City of Helsinki 2019). Recent research by the authors investigates which potentials the digital twin of Helsinki offers to support the necessary transformative processes and triggers potential changes of strategies and methods in spatial planning.

In order to measure spatial transformations, various theories and multi-level perspective approaches from transformation research are already available (Zolfagharian et al. 2019, Bauknecht et al. 2015, Engel and Knieling 2018). On this basis, the paper discusses to what extent digital tools, can be applied in order to support transformation processes. In addition, the paper intends to contribute to a methodology for comparative case study research.

Keywords: Digital Twin, Digital Tools in Spatial Planning, Spatial Transformation, Helsinki, Climate Change Risks

2 INTRODUCTION

The Digital Twin of the City of Helsinki is a digital 3D model that can be enriched with various sectoral data. As a tool, it has already been established in urban development in Helsinki and is used, among other things, for the visualization of planning scenarios, specific analyses and public participation (Hämäläinen 2021, Tuukkanen 2023, City of Helsinki 2022, City of Helsinki 2023).

Finland is one of the leading countries when it comes to digitalization and the development of technological innovation. (Edquist and Hommen 2008).

Transition Theory teaches us that technological innovation in the social system is created at a niche level by pioneers of change. In the case of sudden shocks, crises, but also slowly advancing mega-trends, pressure is exerted on the socio-technical regime. As a result, the mainstream becomes more open and technological innovations have the opportunity to get established in the mainstream (Engel and Knieling 2018, WBGU 2011, Geels 2011, Grin et al. 2010).

Such mega-trends or crises very often have a large global relevance. In the case of Finland, these include dealing with risks related to the effects of climate change, ageing of society, social disparities, but also digitalization itself. (Cit of Helsinki 2017, Purkarthofer 2023).

These issues have a direct spatial reference and impact on regions and cities. Spatial planning bundles the instrumental possibilities to design the space in a way that is necessary to deal with the challenges of mega-trends and crises.

In terms of spatial transformation, climate-related challenges, especially decabonization and adaptation to changing conditions, are particularly relevant (Engel and Knieling 2018, WBGU 2011).

The question therefore arises to what extent such new technological innovations, such as the digital twin of the City of Helsinki, that are being used in spatial planning have the potential to support transformative processes and contribute to this.

This paperfirst deals with the theory of spatial transformation, digitalization in spatial planning, and planning cultures as an important contextual field of research. It then looks specifically at the digital twin of the City of Helsinki. Among other things, it will be shown how this tool is used in planning and it will be analyzed to what extent a contribution to spatial transformation is made by the digital twin. On the basis of the knowledge gained, the conclusions are discussedthat can be drawn from this for the methodological approach. The steps that need to be taken into account in order to be able to measure a contribution to transformation processes are identified. For the purpose of future comparative case study research, a standardized procedure is proposed.

3 THEORY BASED CONSIDERATIONS

3.1 The Phenomenon of Spatial Transformation

The term transformation goes back to the reflections on the Great Transformation. In Karl Polanyi's 1944 book of the same name, the term is used in connection with the processes of change in society related to the changing conditions of the economic system during the Industrial Revolution (Ebner 2017). However, the terminology "Great Transformation" is still used today and usually describes processes of change in society starting from mostly global mega-trends or crises. An example of this can be the mega-trend of digitalization. The social process of change that goes hand in hand with this would therefore be digital transformation in this context. The goal of the transformation can be seen here as sustainable establishment. Transformation research describes the examination of change processes of social systems towards more sustainable structures as well as their support from a scientific perspective (translated from Wittmayer and Hölscher 2017).A strong interest in the research of transformation is emerging, driven among other factors by the dramatic sociocultural, political, economic, and technological challenges society faces (Pereira et al. 2018, Bruns 2022).

Despite its applicability to many different topics and trends, the discourse as a whole is very much dominated by the topic of the environment as a resource and basis of human life. In Germany, it is the "Wissenschaftlicher Beirat der Bundesregierung Globale Umweltveränderungen" (translated: Scientific Advisory Council of the German Federal Government on Global Environmental Change) that enjoys great attention in the scientific discourse with its publication on the Great Transformation and sees decarbonization as the main task here. The currently prevailing modern economic forms and consumption practices in the world are seen here as the main triggers for above all climate- and environment-related mega-trends and crises of today. One of the triggers identified is that resource consumption is not regenerative and planetary boundaries are not respected. Against the backdrop of the Anthropocene era, it is therefore humans themselves who are having a negative impact on the environment and thus endangering their own basis of life. On the other hand, the humans themselves also have the influence to react to the dangers with a process of change. One can differentiate here, whether this reaction from a pure survival will and danger defence happens, or whether it is an active process carried into the society, in which the change is arranged in a union of the people. The latter is seen as the actual transformation process, since it is assumed that such processes can only take place and succeed at the level of society as a whole (Engel and Knieling 2018, WBGU 2011).

Transition Theory aims to describe and explain the societal processes within the scope of transformation. The theory is based on the assumption that innovations arise primarily in niche areas through so-called pioneers of change (Engel and Knieling 2018, WBGU 2011). It goes back to Grin et al. 2010, who proposed a multi-level perspective approach to the question of how to be able to understand the process of change. The considerations in this regard have already been discussed and modified several times in the literature, for

764

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

example by Geels (2011) and by WBGU (2011). According to this theory, transformation is understood as a comprehensive change of socio-technical systems. In the theory, the dominant socio-technical regime is the meso-level. Above this is the macro-level and below it is the micro-level. Both levels affect the socio-technical regime. The macro-level forms the external context, meaning overarching themes from which mega-trends are derived (Engel and Knieling 2018). The macro-level thus influences the events of the socio-technical regime and puts pressure from it (Geels 2011). From below, on the other hand, the micro-level affects the socio-technical regime. This is the niche level. Here, the so-called pioneers of change act and develop technology and innovation outside the mainstream of the meso-level (Engel and Knieling 2018).

According to the theory, the actual process of change occurs at the moment when, at the level of mega-trends, sudden shocks or long-term but fundamental crises put the socio-technical regime under such pressure that a restructuring of the system is forced. At this moment, the socio-technical regime opens up to the developments of the niche level and enables technological innovation to become established in the mainstream (Engle ans Knieling 2018).

Transition Theory with its Multi-Level Perspective approach "serves as a middle range theory" (Zolfagharian 2019). Transition research relies on creative interpretation of the result obtained through the Multi-Level Perspective method, making it clear that despite the attempt to quantify, qualitative methods have an important place (Geels 2011, Zolfagharian 2019).

The concept of spatial transformation is directly related to the great transformation and transfers the level of consideration to the spatial context. Sustainable development plays a key role in urban and regional planning (Knieling and Kreschmann 2016, United Nations n.d.). The establishment of sustainability as a planning principle, often also defined as a principle in legal documents, can be observed worldwide. However, the relevance of the spatial perspective also stems from the fact that threats directly affect spaces and create direct pressure for taking action among cities and regions. At the same time, the administrations and organized civil society have the possibility and competence to shape the space at the respective administrative level, e.g. of a city, in such a way that necessary steps to cope and manage change can be implemented. Cities or urban spaces in particular have a special potential to foster exchange between different groups and movements and thus have a particularly inventive and experimental power to develop innovations (Engel and Knieling 2018, WBGU 2011). Possible courses of taking action for municipalities include the adaptation or creation of necessary infrastructures, spatial development adapted to new needs, the adaptation or creation of new governance processes, governance structures and working methods, and an adapted prioritization of financial support and investments.

The spatial scope in the study of transformation has an important meaning in transformation research. According to Engel and Knieling 2018, transition theory raises the question of concrete spatial conditions. They identify a further need for spatial research here.

3.2 Topical Planning Cultures and digitalization in spatial planning

Pallagst et al. investigated shrinking cities as a window for possible changes in planning cultures in the frame of the EU project PlanShrinking (2010-2015). In order to derive a typology of planning cultures applicable for the context of shrinking cities, the authors modified Othengrafen's culturized planning model (Othengrafen 2010) describing the general context of planning cultures towards shrinkage (see figure 1). Figure 1 demonstrates general criteria of planning culture, supported by a specific criterion for shrinking cities: shrinkage context. "Societal context" displays the "backbone" of a planning culture with a range of more general understandings, "planning context" describes the beliefs of the planning profession, and "planning toolset" refers to the methods at hand. The category "shrinking context" comprises those aspects which might trigger change in planning cultures due to shrinkage and its implications on urban development and planning reactions.

In addition, the PlanShrinking research traced several preconditions for the joint research of planning cultures and shrinking cities:

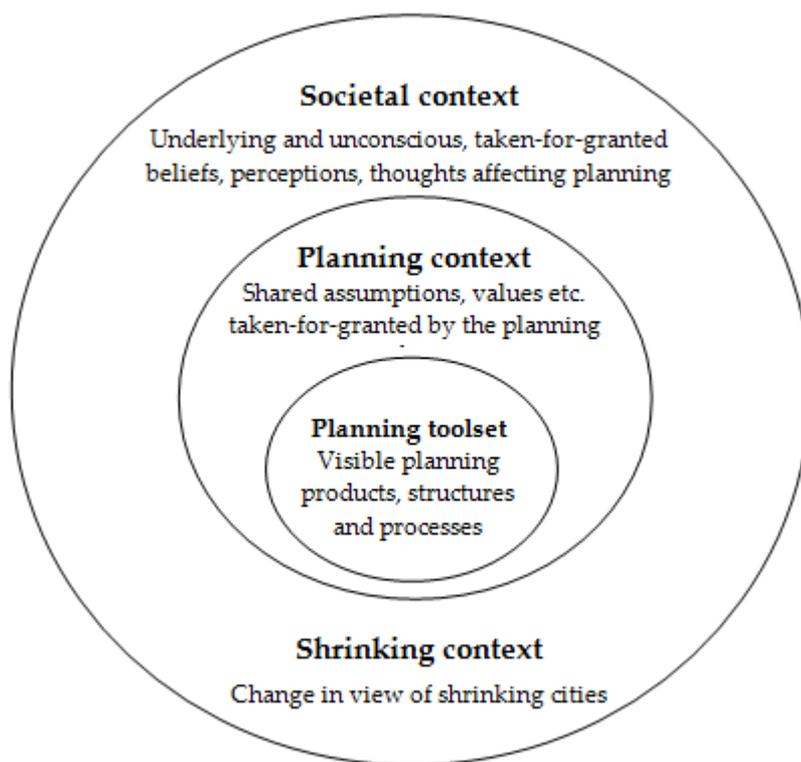
Both topics -- planning cultures and shrinking cities -can be labelled emerging topics in spatial planning. Just like planning cultures, shrinking cities have been widely underrepresented in international comparative urban and regional research.


Figure 1: Facets and layers of planning culture with reference to shrinking cities, Source: Pallagst et al 2013.

The shrinking city phenomenon is a multi-dimensional process, comprising cities, parts of cities or metropolitan areas that have experienced dramatic decline in their economic and social bases. Urban decline and the loss of employment opportunities are closely linked in a downwards spiral, leading to an out-migration of population (Pallagst, 2008). However, despite the fact that globalisation is a trigger for urban shrinkage, economic transformations do not affect all cities in the same way; on the contrary, shrinkage can show very different characteristics depending on national, regional and local contexts (Cuningham-Sabot and Fol, 2007). Research on planning cultures is usually attributed to a national context of a planning system – however, this also involved different levels of planning (from national to local).

Planning cultures serve as an academic concept which is lacking an evidence base, whereas shrinking cities is a planning challenge vividly engaging practitioners and academics likewise in search of urban or regional solutions.

The author's previous research on shrinking cities made clear that planning cultures can be investigated by evidence based research utilizing the shrinking cities phenomenon. Nonetheless, planning offers a plethora of topics potentially serving as windows of investigation for planning cultures – one of them being digitalization. Research by Sorensen (2015) further underpins this argumentation: He suggests that planning cultures might change when faced with as he calls it "critical junctures of institutional change and innovation in planning systems" (Sorensen 2015). One of these critical junctures might be the context of digitalization.

Thus one of the aims of this paper is to shift the window of investigating planning cultures from the evidence base of shrinking cities towards the realm of digitalization. The following paragraphs will make a first attempt in order to derive preconditions from shrinking cities research for the field of digitalization.

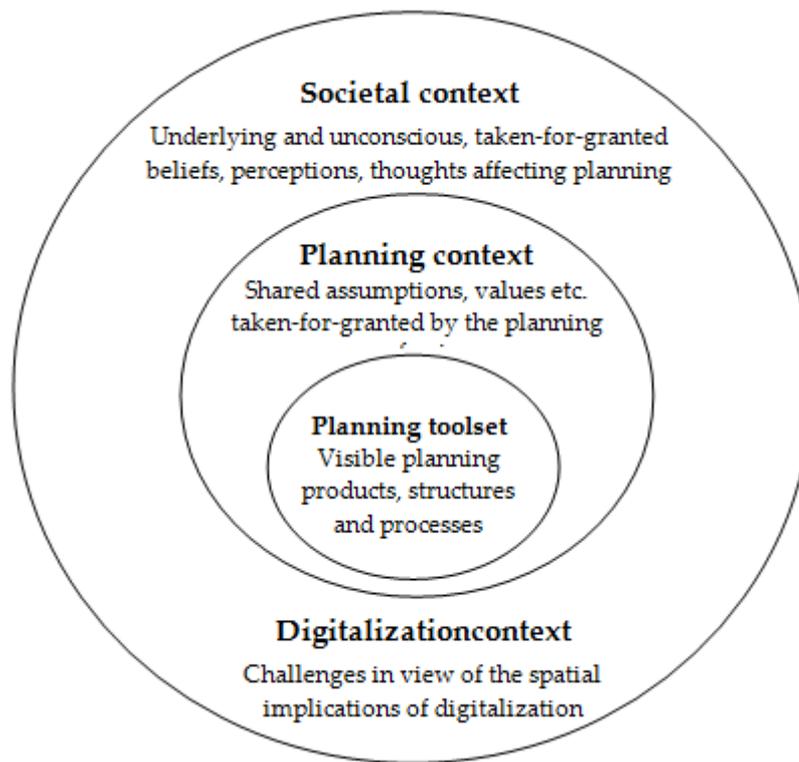
In a first attempt to conceptualize planning cultures and digitalization, the author suggests a research frame (see figure 2) derived from the facets and layers of planning culture in terms of shrinking cities (see figure 1). This research frame (figure 2) adds digitalization as a new component to the planning cultural context.


Figure 2: Facets and layers of planning culture with reference to border regions, Source: Own design based on Pallagst et al., 2013.

Pallagst et al. (2022) framed first ideas for an operative definition of planning culture. Accordingly, planning cultures are defined as follows: "Planning cultures encompass the societal aspirations towards planning – its processes and its outcomes. It refers to the values and shared beliefs of stakeholders involved in planning, and the methods and tools they are applying and producing. Planning cultures are not static but constantly evolving in line with societal changes or planning related challenges. Planning cultures as we see it can be attached to specific territorial entities, be it nations, sub-nations, regions, or cities – most likely but not necessarily within administrative boundaries. In addition, they can be attributed to cities or regions having to face specific planning problems".

The research on changing planning cultures in view of digitalization will certainly add to the notion of topical planning cultures.

Digitalization has been a field of action in spatial development for quite some time. Building on the digitalization trend and starting from the approach of digital and networked smart cities, the synopsis of networked digitalization and spatial development has been planned and researched since the turn of the millennium (Hollands 2008). At the core of this is more efficient management but also a broader understanding of sustainable and more efficient urban development (Leitheiser and Follmann 2019; Herrschel 2013). In the highly competitive segment of smart cities, standardized platform solutions from large international IT or consulting firms are often implemented (Hollands 2015). Furthermore, an international discourse has been established in research that critically reflects the smart city movement (Grossi and Pianezzi 2017). Smart cities also continue to be an issue in German urban development policy, as manifested, among other things, in the Smart City Charter presented in 2017 (BBSR 2017). Accordingly, digital development should take place in the sense of sustainable and integrated urban development.

Digitalization has an impact on spatial planning and development in various fields of action (Spellerberg et al. 2021). With regard to services of general interest and the centrality of settlements, this enables a new perspective on the principle of equal living conditions. Likewise, the use of different digital tools such as Artificial Intelligence, visualizations and platform solutions poses new requirements for the design of planning, decision-making and participation processes. This, in turn, has consequences for the planning tools and the competencies of spatial planners and other actors in the planning and development process.

While smart cities as a concept have been widely researched, there is a lack of references and answers with regard to the design of the nexus of digitization and spatial planning and development for resilience, sustainability and transformation.

Furthermore, there is still limited research on the transformative forces of these concepts for the development of cities and regions. There is a lack of fundamental research on the effectiveness of smart tools, concepts and applications. Questions that such a conceptualization of smart spaces should encompass include:

To what extent can cities and regions use the digital transformation as an opportunity for spatial development?

What is the role of model projects? What are the spatial effects of these concepts, and where are the opportunities and limitations?

Whether and to what extent are methods, instruments and paradigms of spatial planning changing in this context in the course of digitization?

While not all of these general research questions can be covered in this paper, the following paragraphs will shed light on the digital twin as a potential tool of fostering spatial transformations with the example oft the city of Helsinki.

4 THE DIGITAL TWIN OF THE CITY OF HELSINKI

4.1 Planning cultural Context of Helsinki and Finland

Helsinki is the capital city of the Republic of Finland and is located in the south of the country on the coast of the Gulf of Finland of the Baltic Sea. Administratively, it forms the Finnish capital region together with the cities of Espoo, Vantaa and Kauniainen. The cities are strongly intertwined spatially and together form a large-scale agglomeration with approximately 1.2 million inhabitants (Statistics Finland 2023a). The city of Helsinki is located in the centre of this region and has a population of just over 660,000 (Statistics Finland 2023a).

About 5.5 million people live in the entire Republic of Finland (Statistics Finland 2023a). In Finnlad, there are a total of 293 municipalities (Purkarthofer and Mattila 2023). In terms of administrative tasks, many areas of competence lie with the municipalities. The local identity of the people is therefore mostly strongly related to the municipality. At the medium administrative level in Finland, the country is divided into 18 regions, in which the respective municipalities are organized into regional councils on the one hand, and 15 Centres for Economic Development, Transport and the Environment on the other hand. The Swedish-speaking Åland Islands are excluded from the above stated administrative structure. They have an autonomous status and have an independent administrative structure (Purkarthofer and Mattila 2023).

Finland is very rural overall and extremely sparsely populated, especially in the northern municipalities. Overall, the country has a population density of only about 16 inhabitants per square kilometer (Statistics Finland 2023a, NLS 2018). This contrasts sharply with the highly urbanized capital region with 1,533 inhabitants or Helsinki alone with 3,073 inhabitants per square kilometer (Statistics Finland 2023a, NLS 2018). In terms of Finland's demographic structure, it is noticeable that the population is ageing. This can also be seen in the population projections. For example, the population in the 0 to 44 age groups is expected to decline by 2040. This contrasts with the population group of 75-year-olds and older, where a very strong increase is forecast. Here, too, the capital region stands out from the statistics for the country as a whole. Although the older population cohorts are also expected to increase here, at the same time there is no discernible downward trend among the younger cohorts (Statistics Finland 2021). Overall, Finland is experiencing increasing immigration from other countries, but this is most visible in the more urbanized areas, such as the capital region. At the same time, in the context of intermunicipal migration movements in Finland, it can be observed that many people move from rural areas to urbanized areas (Statistics Finland 2023b, Statistics Finland 2023c). Finland is characterized by a rural exodus.

In terms of the economy, industry and services both play an important role in Finland. In urbanized areas, however, there are particularly many employees in the service sector. In rural areas, agriculture, forestry, wood production and paper production can be identified as important in the industrial sector, in contrast to urban areas. In these areas, there are particularly large numbers of employees on the rural side (Statistics Finland 2022).

Culturally, Finland is characterized by a self-image as a country with a geogrpahically and politically peripheral location (Purkarthofer 2023). It can be assumed that in this context, a social sense of duty to adapt to global political and economic trends and movements on the one hand and personal responsibility with

regard to growth and prosperity on the other hand lead to a country with a certain openness with regard to a culture of learning from failure, trial and error and innovation. The country's technology and innovation policy deliberately creates an environment to link science, industry and administrative authorities and to strategically promote start-ups in the innovative technology sector. Since the mid-1990s, Finland has experienced a strong economic upswing with this strategy and is considered one of the world's leading countries in terms of innovative strength (Edquist and Hommen 2008). In this context, Finland is also seen as a model country with exemplary function in the field of digitalization.

This cultural background also plays an important role in spatial planning and illustrates the mindset behind the approach of meeting solutions to existing tasks with new technological possibilities and a willingness to experiment. Furthermore, the historical background of Finland also influences the planning cultural context. In this context, the era in which Finland belonged to the Swedish kingdom and the era in which Finland was a grand duchy in the Russian Empire should be mentioned in particular (Purkarthofer 2023). Despite the country's independence since 1917, influences from both eras can still be found in culture and architecture today. Linguistically, for example, Swedish is still a widely spoken language in Finland. As a country with a very rural landscape and hardly populated areas, a close relationship to nature plays an important role in society, despite the noticeable urbanization and rural exodus since the 1950s. The contrast between the traditionally rural structures on the one hand and the modernization and investment developments in the urban areas on the other hand often leads to conflicts in society. In addition, social disparities, both within urbanized areas and between urban and rural areas, also cause tensions in society. Finland is traditionally a welfare state. The fact that the state provides for the economic security of the individual is an important value. Against this background, the aforementioned social disparities trigger social and political discourse (Purkarthofer 2023). These spatially relevant issues are crucial in the context of capturing the planning context.

On the other hand, environmental issues should not be underestimated when examining the key challenges of spatial transformation. In a publication, the City of Helsinki has analyzed how it is affected by climate change. Among the important factors identified are the risk of flooding due to rising sea levels and storms with heavy rainfall, as well as the general increase in precipitation in the winters, which can lead to dramatic amounts of snow or a high safety risk in road traffic as temperatures rise and hover around the freezing point more frequently than before. However, rising temperatures in summers are also increasingly perceived as a problem, both as a health risk for people and as a threat to native species of flora and fauna (City of Helsinki 2019). In planning, on the one hand, there is a general awareness of the need to make decisions that take the dangers into account (City of Helsinki 2019) and, on the other hand, sustainable urban development and mobility as a specific set of issues (Purkarthofer 2023).

In terms of systematizing the cultural factors mentioned, these can be applied to the extended theory according to Knieling and Othengrafen described in section3.2. Additionally it includes the context of the spatial transformation.The following table summarizes some important factors.

General Context	Societal context	• Self-image as peripheral geographical and political location of Finland • Rural character and closeness to nature • Experimental mindset with an open culture of learning from failure and innovation • Welfare state
	Planning context	• Rural exodus and urbanization processes • Sustainable urban development and sustainable mobility • Rather low understanding of overall planning and stronger focus on single object development with focus on design and architecture
Specific Context	Spatial transformation	• Dealing with risks associated with climate change impacts • Ageing society • Social disparities
	Digitization	• Good digital infrastructure • High social relevance • High level of innovation through exploitation of digital opportunities

Table 1: General and Specific Context aplied to the case of Helsinki, Finland

When dividing the various factors into the individual fields of context, it becomes clear that some points cannot be clearly assigned in terms of content and that a different division would also be conceivable. It is important to remember that the Specific Context is a more concrete part of the Planning Context and that the Planning Context is a more concrete part of the Societal Context. In the case of spatial transformation, for example, all points also fit into the planning context. Therefore, it is necessary to analyze beforehand which of the points that play an important role in connection with the planning context also represent a central mega-trend in society, and especially in world politics.

According to the theory of Knieling and Othengrafen, the planning artifacts are still missing for a complete consideration of the planning cultures. Here, the planning system is considered in particular. Especially the different administrative levels, relevant legal documents, formal planning instruments and plans with their legal effects, and relevant actors are to be considered. This structure is also followed by the so-called "Country Profiles" of the Academy for territorial Development in the Leibniz Association. In special cases, it may also be necessary to deal with exceptional informal planning instruments or working methods. The following explanations are taken from the "Country Profile" for Finland by Purkarthofer and Mattila 2023.

In the case of Finland, the relevant levels are the national level, the regional level (in particular the 18 regions with the regional councils) and the municipal level. The legal basis for the planning instruments at all these levels is the Land Use and Building Act of 1999. At the national level, there are the "National Land Use Objectives". These are general, central issues for which corresponding goals are formulated. The Finnish federal government, in particular the Ministry of the Environment, is responsible for this. The defined objectives must be observed and taken into account at the regional planning level. At the regional level, the "Regional Land Use Plan" is the central instrument. Here, non-parcel-specific representations of linear and areal structures are mapped on topics such as infrastructure routes, protected zones, settlement areas and development areas. The Regional Council is responsible for this. The plan has legal force for the development of plans at the Municpal level. At the Municipal level, there are two different formal planning instruments. First, there is the "Local Master Plan." This maps similar issues to the plan at the regional level, but has a higher degree of detail due to its scaling for only one municipality at a time, and also performs the function of zoning the various land uses. Here, the development visions of the municipalities are presented, which have a legally binding effect on the second instrument at this level, the "Local Detailed Plan". This plan has the purpose of developing a specific area within a municipality. It can define, among other things, permitted land uses, number of stories, building heights, certain design regulations, and other prohibitions and restrictions. It forms the basis for building permits for structures. The Municipal Council is responsible for both the Local Master Plan and the Local Detailed Plan (Purkarthofer and Mattila 2023).

Despite the structure of the planning system, in which specific sectoral planning topics are integrated in the sense of integrated planning, especially in the "Regional Land Use Plan" or the "Local Master Plan", the understanding of planning is rather less coordinative but more strictly local and design-oriented (Purkarthofer 2023).

In the specific case of Finland and Helsinki, in addition to the formal planning tools, it is necessary to mention that innovative digital possibilities are increasingly being applied and tried out in planning and are now established as a working method in many Finnish cities. Among these, the case study considered here, the digital twin of the City of Helsinki, should be mentioned. It will be explained in more detail in the next two sections.

4.2 Development and Technical Issues

Digital twins as a tool or software program have their origins in the industrial sector, where they are used in manufacturing to increase productivity and efficiency and are used in the fields of "designing/planning, optimization, maintenance, safety, decision making, remote access, and training, among others" (Singh et al. 2021). It is a "dynamic digital representation of a 3D-designed product or solution which, in the most optimal cases, represents the same features and provides the same information as its physical counterpart" (Hämäläinen 2021). Applied to the context of the digital twin of a city it is thus a 3D city model of the physical city. But it is a "solid data infrastructure forms the foundation for [...] digital twins" and has to be enriched by "city data, such as energy consumption or traffic data" (Hämäläinen 2021).

The beginnings of the City of Helsinki's digital twin go back to considerations in the 1980s. At that time, the city had seen the need to simplify processes related to road maintenance and construction. The many different departments responsible for different technical infrastructure, such as telephone, water pipes or electricity, was identified as a problem, as each department only had its own data available. The idea was therefore to share and connect these data with each other. This provided a first use case. However, in the early stages of development, it was a simple 2D basemap that was developed, but digital and therefore flexible in terms of how the map could be used to map data. Over time, more and more use cases were added and the map has finally evolved into a 3D model of the city (Tuukkanen 2023).

Important actors in the development of the digital twin of the city of Helsinki were and are the City Survey Department of the city administration and also the private sector. The City Survey Services of the City of Helsinki have the responsibility to provide the basic data for the creation of the model, so in particular the modeling of terrain, to map the topography, as well as the built environment. This involves, for example, taking measurements, but also flying over the built environment from various perspectives. The private sector with companies in the field of software development play an important role in the technical development of the tool, since here the City of Helsinki can access the necessary expertise and resources. In addition, however, individual pioneers or visionaries with the relevant competence function are also important in order to be able to implement existing ideas. In the case of the city of Helsinki, a mayor at the time provided the necessary budget for development due to his personal affinity for architecture and urban planning. The main user of the digital twin is the Urban Planning Department of the City of Helsinki, which uses the tool in urban development. However, there are other city departments that interface with and use the tool. Citizens also use the digital twin, on the one hand for public services and on the other hand within the context of participation processes initiated by the Urban Planning Department (Tuukkanen 2023).

The digital twin of the City of Helsinki was built specifically for the needs of the city. Two basic digital models have been created. On the one hand, there is the mesh model, which does not contain exact geodata, but offers a more detailed modeling and is therefore mainly used for visualizations, and on the other hand, the GML model, in which each object has an exact geoinformation, which can be stored with data, and in which measurements can also be performed. Therefore, the GML model is usedmainly for analytical use. In particular, the terrain, building bodies, but also partly underground areas and the interior of buildings are modeled. Each object in the model has a uniquely assigned ID. This makes it possible to bundle data from different departments in the same model. The digital twin is thus also a platform for data collection and links the various application areas and users, enabling coordinated collaboration. Points, lines, surfaces and volumes in the model can be used to visualize the data. The digital twin is also linked to the portal for openly accessible data, the "Heslinki Region Infoshare" (Tuukkanen 2023, City of Helsinki 2022).

4.3 Application in Urban Planning

The digital twin of the city of Helsinki is used by the city administration for urban planning and has already established itself here as a tool and working method in spatial planning (Tuukkanen 2023).

Many different functions can be used in planning. In traditional urban development, the plans for their implementation lead to a Local Detailed Plan. In the preparatory planning process, however, the drafts are visualized with the help of the digital twin. This makes it possible to compare different planning scenarios with each other and also to use them in the context of public participation integrated in the tool (City of Helsinki 2023). At the same time, urban planners can use basic functions of the GML model, such as taking different spatial perspectives, shading at certain times of the day and year, and measurements (City of Helsinki 2022). As a result, the digital twin of the city of Helsinki is a kind of new and innovative informal planning tool that can be used as a multifunctional tool.

The tool is not only mutlifunctional, but also multisectoral. There are many different use cases for special topics in spatial planning. On the one hand, these can be used within the specific spatial planning sector, but on the other hand, they are also available to planners for coordinated planning, e.g. for the development of new urban areas. Planners can thus map different thematic analyses into the model and superimpose them as needed to make data- and fact-based decisions. This has happened, for example, in the development of Helsinki's Smart City lighthouse project, the revitalization of old harbour areas to develop the Kalasatama urban district (Hämäläinen 2021).

The city of Helsinki presents some of these sectoral use cases on its website (City of Helsinki 2023). These include, for example, the visualization of data on offers and possible plans in the field of mobility analysis, the visualization of radiation on building surfaces for the analysis of solar energy potential, the visualization of technical infrastructure for the optimization of maintenance and planning and execution of construction works, the modeling of inner-city trees, the so-called Urban Tree Database, for use in the maintenance of the tree population, but also in the preparation of necessary environmentally relevant documents in permit procedures in urban planning, as well as the projection of heat islandsin the city, which also makes use of weather data (City of Helsinki 2023, Tuukkanen 2023).

Not all of these use cases are openly accessible. Especially in the case of data on critical infrastructures or sensitive information to which individual people could be linked, the city is the exclusive user of the tool. Despite the numerous possibilities offered by the tool, it is currently still mainly used for development and planning, especially the visualization of planning scenarios, analytical sectoral factors and citizen participation. Not yet strongly used are the possibilities in the daily city operations, which can be implemented with the help of technologies such as sensors, machine learning and artificial intelligence. In this area, the tool offers much more potential and could be the next step in the tool's development (Tuukkanen 2023).

5 CONTRIBUTION TO SPATIAL TRANSFORMATION

In order to be able to make a conclusion about the contribution of the digital twin of the City of Helsinki to spatial transformation, the first question to be asked is which transformative process exactly is being considered here. In addition to the core topic of spatial transformation, the management of issues relevant to climate change, there are other mega-trends, such as demographic change or digitalization, that are relevant in the context of societal transformative processes.

It can be stated without a doubt that the digital twin of the city of Helsinki makes an important contribution to climate-related issues related to global warming and the goal of decarbonization and adaptation to the changing conditions cities are confronted with.

There are many use cases of the Digital Twin where planning decisions are supported by data, analyses and visualizations of planning scenarios with regard to sustainable urban development. For example, the tool's application functions have the purpose of highlighting potentials for the development of emission-free energy production. The projection of heat islandsin the city makes it possible to recognize where intervention is needed, for example, to create more resilient spaces with greening. Mobility analyses enable the strategic planning of sustainable mobility offers and promote therefore sustainable urban development.

The contribution to coping with a spatial environmental transformation process is definitely given, however, the impact on the consequences of the mega-trend of climate change is not extraordinarily high, and can also be compared with other projects that have a similar output without using digital twins. On the other hand, the digital twin as a technological innovation in spatial planning makes many processes easier. Considering the enormous challenges faced by municipalities, the tool offers enormous advantages and puts the City of Helsinki in a privileged position here compared to other cities. The administration of the City of Helsinki is responsible for tasks that other cities in the world are responsible for, too. In the era of crises, digitalization and increasing regulation of public tasks and competencies, the City of Helsinki has a tool in the form of the digital twin that takes away some of the complexity and enables the city administration to work more efficiently. Ultimately, this also benefits efforts to achieve sustainable and resilient urban development.

When considering digital transformation, the contribution to the transformative process can also be confirmed. Both the transformation in terms of climate change-related issues and digitalization demonstrate a direct connection with the functions and effects of the tool on the working methods in the city. Particularly with regard to the digital transformation, it can be seen that the impact is extraordinarily high, as the public tasks from different areas and departments are functionally linked with each other and the work becomes more efficient. The digital twin of the city of Helsinki is thus a project that is driving digitization in the city very strongly and has the potential of having an influential impact on other cites as well.

6 CONCLUSION FOR METHODOLOGICAL CONSIDERATIONS FOR FUTUR RESEARCH

From the example of the Digital Twin in Helsinki, it is possible to reflect on the methodological approach to analyze the contribution of an innovatiove digital tool used in spatial planning to spatial transformation processes.

Transition theory can be used in transformation research to identify transformative processes as such and to trace their development and course. It is important, however, that the specific element to be measured is no longer in the realm of the niche, but has already established itself at the regime level.

It is important to clearly define a coping and management objective for the mega-trend or crisis, as this is the only way to check whether the development of the niche innovation and its establishment at regime level will contribute to fulfilling the coping and management objective. The goal here should not be to fully achieve the coping objective. Since spatial transformation can be a very long process that is usually approached from many different directions, it is unlikely that the contribution of a single aspect alone will achieve the complete coping and management.

However, when comparing the impact of an innovation established at regime level with a potential contribution to a defined coping and management objective, the question arises as to its quantifiability. In order to assess the existence of a contribution, only the general knowledge of solution approaches to the mega-trend or crisis in question prevailing at the time of the analysis can be applied. This results in the necessity of naming the corresponding solution approaches in advance, at least roughly and with reference to the specific topic of the innovation. In the case of climate change, for example, a solution approach according to the prevailing current state of knowledge would be the creation of inner-city green spaces. If the impact of an innovation, such as a tool that identifies green space potentials, is matched with its contribution to addressing climate change, the contribution can be confirmed by this finding. However, the expression of a contribution can vary widely even when it exists. Therefore, it is recommended to categorize the contribution, based on different levels of expression. Possible categories could be:

- only an indirect contribution
- direct contribution with low or no extraordinary impact on the mega-trend
- direct contribution with extraordinary impact on the mega-trend

This categorization in turn creates quantifiability to a certain degree.

When considering an innovation, however, it can happen that the contribution of different sub-aspects, such as different functions of a ditial tool, are also assessed in different ways. Therefore, care must be taken in the procedure not to combine different aspects to be distinguished in the investigation.

The following figure summarizes the considerations regarding the methodological approach.

Figure 3: Proposed methodological approach to analyse and evaluate the contribution of a technological innovation in spatial planning to a transformative process by making use of the Multy-Level Perspective approach of transition theory; own design

However, it also became clear that for a holistic view of a technological innovation in spatial planning, further components must support the analysis. This includes, in particular, the identification of the planning culture context, taking into account the specific context of digitalization and the relevant mega-trend or crisis.

Another component to be added is the observation of the digital tool itself. Development, functions and actor structures must be identified. The technical dimension plays a particularly important role here. The methodology proposed so far is not yet able to accomplish enough in this regard. With the goal of applicability for future case study research, a standardised research grid is needed in this area that can measure technological, functional and data-based factors. There is a need for further research in this area.

1 ABSTRACT

Electric cars, also known as Electric vehicles (EVs), possess a smaller ecological footprint compared to traditional internal combustion engine vehicles (ICEVs). While certain aspects of their production may have comparable, reduced, or different environmental impacts, they have the advantage of emitting minimal to no tailpipe emissions. Furthermore, they help reduce reliance on petroleum, decrease greenhouse gas emissions, and mitigate the health effects caused by air and environmental pollution. In recent years, there has been a noticeable research focus on incorporating EVs into smart cities, as they offer a means to reduce urban carbon dioxide (CO_2) emissions. Consequently, a limited number of studies have sought to enhance the widespread integration of EVs in order to promote environmental sustainability and contribute to the advancement of the built environment. Consequently this study aims to explore existing literature pertaining to the impact of electric vehicles in promoting a sustainable urban transportation system and fostering an environmentally friendly ecosystem. To accomplish this, the study will employ the Prisma methodology, which involves extracting relevant information from peer-reviewed journals and conference papers. The outcomes of this research endeavor will yield valuable policy implications, aiding policymakers and decision-makers in their efforts to combat climate change and enhance the efficiency of the electric vehicle market.

Keywords: Electric Vehicles, Transport Planning, Smart Cities, Sustainability, Mobility

2 INTRODUCTION

Transportation stands as a pivotal pillar within modern civilization, serving as both a catalyst for economic progress and a generator of employment opportunities (Krishna, 2021). Yet, despite its undeniable significance and the advantages it brings, the observations of Ritchie (2020) underline an alarming reality: the transportation sector emerges as one of the largest and swiftest contributors to carbon dioxide emissions, accounting for a substantial 16.2 percent of the total global CO_2 emissions in 2020. This disconcerting trend exacts a toll on human well-being and the environment, as highlighted by Degirmenci and Breitner (2017).

In response to this pressing challenge, Sendek-Matysiak (2019) emphasizes the necessity of addressing air pollution concerns and reducing the overreliance on crude oil for road transportation. Achieving this transformation necessitates the adoption of innovative mobility concepts aligned with principles of sustainable socioeconomic advancement. On an international scale, countries grapple with the imperative to curtail carbon emissions originating from the transportation sector. Alternative energy sources have emerged as promising candidates to supplant fossil fuels, which currently power nearly 92 percent of transportation fleets/vehicles (Khalili et al., 2019).

Within this landscape, electric vehicles (EVs) emerge as a beacon of promise, providing nations the opportunity to shift away from fossil fuel-dependent vehicles towards more environmentally friendly energy alternatives like electricity. By doing so, they effectively address the adverse consequences of climate change that grip the global stage. Sun et al. (2023) underscore the predominant focus on limiting climate change to below 2°C, spurring nations to enact transformative measures. To significantly reduce greenhouse gas emissions, including CO_2, a widescale embrace of low-carbon technologies across all sectors becomes paramount (Lamb et al., 2021). While progress strides forward in certain sectors such as electricity, the transportation domain confronts formidable hurdles (Xu et al., 2021). Research by Hao et al. (2016) accentuates road vehicles as the primary emissions source, projecting a doubling of the passenger vehicle fleet by 2050. As all energy sectors grapple with the demand for decarbonization, addressing emissions in transportation emerges as particularly pivotal, given its substantial contribution to greenhouse gas emissions. Consequently, adopting alternative modes of transport like electric vehicles, which do not rely on fossil fuels, becomes a compelling imperative.

An electric vehicle (EV) is characterized by its dependence on one or multiple electric motors to propel it, drawing power from stored electrical energy within batteries or alternative storage systems (Rudatyo & Tresya, 2021). With the potential to address mounting environmental, economic, and energy challenges within transportation—ranging from air quality to climate change and urban expansion (Haddadian et al., 2015)—electric vehicles stand out for their minimized emission of greenhouse gases and pollutants in comparison to traditional gasoline or diesel vehicles (Ehrenberger et al., 2019). Moreover, the integration of electric vehicles holds the potential to bridge the divide between the energy and transportation sectors. This integration generates a wealth of data within smart cities, ushering in fresh prospects and business models for forward-looking enterprises. Thus, companies embracing EVs not only enhance their competitive edge but also fortify their strategic standing. The crux of our study revolves around dissecting the role of electric vehicles in sustainable planning, while simultaneously pinpointing the barriers obstructing their triumphant integration.

3 CONCEPTUAL SYNOPSIS

In recent years, a discernible research trajectory has emerged focusing on the integration of Electric Vehicles (EVs) within smart cities. This strategic movement stems from the potential of EVs to contribute significantly to the mitigation of urban carbon dioxide (CO_2) emissions, thus aiding in the reduction of environmental impact.

3.1 Historical Development of Electric Vehicles

In the study conducted by Anderson and Anderson in 2005, the evolutionary trajectory of electric vehicles (EVs) becomes apparent, tracing their development as a collaborative endeavor involving diverse scientists, each contributing significantly to their progression. The historical timeline of EVs can be segmented into three distinct periods: an initial era spanning from 1890 to 1929, marked by their early dominance within the market from approximately 1895 to 1905; an intermediate phase from 1930 to 1989; and the contemporary years from 1990 to the present day. The origins of EVs are rooted in the emergence of batteries, which marks the inception of their early history. In 1821, the English chemist Michael Faraday introduced the world's inaugural electric motor, followed closely by the practical application of Faraday's motor to rotate a wheel by the English mathematician and physicist Peter Barlow in 1822. The creation of "the Faraday disc," the world's pioneering dynamo by Faraday in 1831, laid the foundation for generating electrical energy through mechanical means.

This forward momentum persisted with notable innovations such as the construction of an electric motor-powered drifter in New England, United States, in 1835, and the introduction of an electric locomotive to the public in 1838. In 1841, Davidson devised the larger Galvani locomotive; however, due to the prohibitive cost of disposable batteries and resistance from railroad workers, the invention failed to thrive. Concurrently, between 1832 and 1839, Robert Anderson conceptualized a battery-powered horseless carriage. Regrettably, the absence of rechargeable batteries hindered this invention from reaching the market. A pivotal breakthrough arrived with the efforts of Dutch chemistry professor Sibrandus Stratingh, who developed a more efficient and practical battery-powered carriage. While it displayed enhanced performance, issues like noise, smoke, and discomfort persisted. Over time, Belgian scientist Gaston Plante addressed the challenge of recharging batteries, effectively overcoming the limitation of their inability to recharge post-depletion. This led to the successful creation of the first EV powered by rechargeable batteries in 1881.

Thus, the evolution of electric vehicles (EVs) encompassed a series of crucial contributions from scientists and inventors, culminating in the realization of rechargeable battery-powered automobiles. In 1881, Gustave Trouve introduced a three-wheeled EV to the public in France. Subsequently, in 1882, an English company emerged to produce rechargeable batteries, while Thomas Edison in America worked on an innovative battery type employing nickel-iron. Between 1910 and 1925, substantial advancements in battery technology materialized: battery storage capacity increased by 35%, service life improved by 300%, and maintenance costs plummeted by 63%. EVs proved to be cleaner, odorless, quieter, easier to initiate, less intricate, and more convenient in comparison to horse-drawn carriages or internal combustion engine vehicles (Burton, 2013). In 1894, the collaboration of Henry Morris and Pedro Salom yielded an "electrobat," a two-person transportation vehicle. Recognizing its potential, Isaac Leopold Rice, president of the Electric Storage Battery Company of Philadelphia, proposed a joint venture with Morris and Salom. Subsequently, the

778

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Electric Vehicle Company (EVC) was established, concentrating on the manufacture of both batteries and EVs. The first commercially viable EV was produced at the Columbia factory in Hartford, Connecticut, and unveiled in May 1897. Shortly after, a service station for charging infrastructure was inaugurated in Newport. From 1897 to the summer of 1899, Columbia manufactured several hundred EVs for both domestic and international markets.

3.2 Overview of Electric Vehicle Adoption in the Developed and Developing Countries

Lambert (2022) posits that the advancement of electric vehicles is gaining momentum across the majority of developed nations worldwide. Presently, the global roads host a fleet of over 16 million electric vehicles (EVs), with a predominant 90 percent concentration observed in China, Europe, and the United States. Notably, various countries, particularly those classified as developed, have demonstrated remarkable progress towards the widespread adoption of EVs. Fortuna (2019) identifies the leading 15 nations in terms of EV market share, all of which are European countries. Norway emerges at the forefront with an impressive 82.7 percent market share in the first half of 2021, followed by Iceland (55.6%), Sweden (39.9%), Finland (28.3%), Denmark (26.8%), Germany (22.1%), Netherlands (19.7%), Luxembourg (18.3%), Switzerland (18.2%), Austria (17.2%), France (15.5%), Portugal (15.4%), Belgium (15.3%), the UK (14.9%), and Ireland (13.4%). While the United States (US) does not claim a spot within the top 15 countries in terms of EV market share, it stands as the third-largest market, trailing behind China and Europe. Notably, by 2020, Europe has superseded China, holding the consistent record of dominating the global electric vehicle market in terms of sales growth since 2012 (Perkins, 2021).

Furthermore, the transition from internal combustion engine vehicles (ICEVs) to more ecologically sustainable EVs has gained acceptance in numerous developed nations across the globe. Scholars such as Carranza et al. (2014), D'Egmont (2015), and Olson (2018) conducted studies on EV adoption in Norway, revealing that while the country faced obstacles such as elevated EV costs relative to ICEVs and insufficient charging infrastructure, these challenges could be surmounted through strategic incentives and a well-defined plan for establishing adequate charging networks. In a study exploring electric mobility in Europe, Biresselioglu et al. (2018) identified impediments to widespread EV adoption, including a dearth of charging infrastructure, escalating electric vehicle prices, extended charging durations, heightened electricity consumption by EVs, and scarcity of battery raw materials. Greene et al. (2014) delved into the transition to EVs in the United States and concluded that factors inhibiting the shift included uncertainties surrounding EV technology and the limited influence of governmental regulations. They also emphasized the importance of forthcoming studies to address EV-related uncertainties, thus providing a foundation for policy formulation. Vassileva and Campillo (2017), in their analysis of EV adoption barriers in Sweden, deduced that the absence of a robust incentive structure acted as a potential hindrance. Overall, the trajectory is clear: the majority of developed nations are embarking on the path of adopting electric vehicles as a prominent alternative to fossil fuel-dependent vehicles.

3.3 Electric vehicles adoption in the Developing countries.

Between 2015 and 2020, the market share data concerning new electric vehicle (EV) sales in "other countries" (excluding China, Europe, and the United States) remained below 2%, underscoring the prevalent challenges that many countries, particularly those in the developing sphere, continue to encounter in their quest for EV adoption (IEA, 2021). The insufficiency of a well-established market structure, network infrastructure, and robust economy stands as the chief explanation for the lag in EV adoption within developing nations, as elucidated by Asif et al. (2021).

Prakash et al. (2018) delved into the impediments faced by India, a developing country, regarding widespread EV adoption, identifying barriers that encompassed, among other factors, inadequate charging infrastructure, absence of governmental incentives, and customer traits. Similarly, Asadi et al. (2021) undertook a study exploring factors influencing EV adoption, revealing that range anxiety, post-sales support, and a dearth of charging infrastructure were the principal roadblocks to progress in Malaysia's EV adoption journey. Bigot (2020) turned attention to Russia, uncovering the slow integration of EVs, primarily attributed to the elevated cost of EVs, harsh winter conditions, and a deficiency in charging infrastructure. Encouragingly, Bigot also revealed a promising trajectory, as Russia's charging infrastructure is expanding, poised to surmount this barrier in the future.

Habich-Sobiegalla et al. (2018) concluded a study probing the intentions behind EV purchases in Brazil, pinpointing the elevated cost of EVs relative to internal combustion engine vehicles (ICEVs) and the inadequacy of public infrastructure to support their deployment. Moeletsi (2021), in a survey examining EV barriers in Gauteng, South Africa, brought forth the primary factors contributing to people's reluctance in acquiring electric vehicles—namely, the elevated purchase price and steep battery expenses.

However, although the pace of EV adoption in developing countries is arguably sluggish, with research in this domain still scarce (Asif et al., 2021), several developing nations have set ambitious targets and long-term strategies for EV integration. For instance, India has set an audacious goal to replace all ICEVs with EVs by 2030 (Chhikara et al., 2021; Das et al., 2019). Malaysia aims to establish 125,000 charging stations by 2030, while Thailand has laid out an extensive EV policy with the objective of having 1.2 million operational EVs and 690 charging stations by 2036 (Schröder et al., 2021). In Africa, South Africa is ambitiously targeting to account for 1% of global EVs (Wilberforce, 2021). To conclude, it is evident that the pace of EV adoption within developing countries lags behind that of their developed counterparts, although various initiatives and strategic plans have been set in motion to bridge this gap.

4 METHODOLOGY

The review on the role of electric vehicles (EVs) in environmental sustainability and their potential barriers to adoption was conducted using the Prisma approach. To gather comprehensive information, the study drew upon the latest academic literature on the topic and supplemented it with case studies from selected countries. These case studies served as crucial sources of information for defining the methodology and identifying the main application testbeds. The primary objective of the proposed multilayer approach was to assess the impact of EV adoption compared to vehicles reliant on fossil fuels, specifically focusing on its contribution to maintaining and achieving a greener environment. Additionally, the study explored the prospects of EVs while also identifying the obstacles and challenges that hinder their widespread adoption.

5 FINDINGS

This section presents information on the contributions of electric vehicles to the environment, its prospects and challenges.

5.1 Prospects of Electric Vehicles in Greening the Environment

Climate change and greenhouse gas emissions have become increasingly serious in recent years and transportation has been identified as one of the greatest contributor to this menace. While transportation is an integral part of any country, it cannot be denied that it is also a significant contributor to greenhouse gases. Based on this, there is need to identify ways of curtailing these, especially in cities and countries with great automobile dependance. One of the ways of the ways of reducing the reliance on cars that uses fossil fuels which is one of the greatest contributor to environmental problems and increasing the greening of the environment is the use of electric vehicles. Below are some of the Pros/ Prospects of Electric vehicles in achieving a green environment.

- Energy Savings: Electric vehicles are particularly effective in conserving energy at lower speeds and in situations that involve frequent changes in driving dynamics. This characteristic makes cities an ideal target market for their adoption. As the generation of electricity is expected to become greener in the future, electric vehicles have the potential to significantly reduce greenhouse gas emissions. Given the ongoing global discourse on climate change, this becomes a crucial consideration. Notably, the transportation sector accounts for over a fifth of the European Union's greenhouse gas emissions and is the only sector experiencing emission growth. While there is still potential for reducing emissions per kilometer driven through improvements in internal combustion engines, achieving emission reductions beyond 50% necessitates the implementation of new technological solutions like electric vehicles. Compared to conventional vehicles, electric vehicles exhibit approximately 50% lower emissions based on the current average electricity supply. Moreover, additional environmental benefits can be realized as the carbon intensity of power generation continues to decrease through the integration of greener and renewable energy sources.

- Societal and environmental cost: A report by Tseng et al. (2013) stated that the overall emission costs associated with the lifetime of a car encompass three primary sources of emissions: upstream

production and disposal of car components, tailpipe exhaust, and upstream energy production. Collectively, these three categories of emission costs are commonly referred to as the societal and environmental cost over the vehicle's lifespan. Specifically, tailpipe emissions during the driving cycle contribute to the release of air pollutants that have detrimental effects on human health. A comprehensive study conducted by Michalek et al. (2011) focused on vehicular emissions across a wide range of vehicle types based on gasoline consumption. The study revealed that, except for electric vehicles (EVs), tailpipe emissions of greenhouse gases (GHGs) constitute more than 50% of the total lifetime GHG emissions for most vehicle types. Furthermore, these emissions have a significant impact on health outcomes, including mortality and morbidity, as well as adverse effects on the environment such as reduced visibility, crop loss, forest degradation, depreciation of natural resources, and material depreciation. Hence, the electric vehicle is considered accounts for the least in terms of societal and environmental cost.

- Reductions in Noise Pollution: According to the research conducted by Hatt et al. in 2020, electric vehicles (EVs) offer distinct advantages over gas-powered (internal combustion engine) vehicles, providing benefits to their users. Notably, experts in transportation and electricity, as highlighted by Noel et al. in 2018, have identified noise reduction and improved performance as the top three advantages of EVs.

One significant benefit is the reduction in noise levels associated with EVs. This attribute contributes to a more pleasant driving experience for individuals and helps maintain low noise levels within communities. By minimizing noise pollution, EVs offer a quieter and more peaceful environment for both drivers and nearby residents.

- Lower Maintenance: Electric vehicles offer significant advantages compared to vehicles that rely on fossil fuels, including reduced maintenance requirements and economic savings. Studies by Egbue and Long (2012) and Noel et al. (2018) highlight these benefits. According to Lin and Sovacool (2020), users of electric vehicles have reported lower maintenance needs and reduced operating costs, primarily due to the absence of fuel expenses and the availability of inexpensive electricity.

When electric vehicle owners were asked to assess the advantages of their ownership, "less maintenance" emerged as the second most popular benefit, as it translates to both monetary and time savings (Egbue & Long, 2012). The reduced need for maintenance not only contributes to financial savings but also allows owners to allocate their time more efficiently. From the foregoing, it can be asserted that electric vehicles is very vital in achieving a green environment through the reduction in various environmental problems such as pollution and overall improvement in human health.

5.2 Barriers to the use/adoption of Electric Vehicles

Despite the role of electric vehicles in greening the environment, there are numerous barriers in both the developed and the developing countries of the world militating its effective adoption. Below are some of the barriers to its use:

- High Cost of Acquisition: The substantial initial purchase cost stands as a major deterrent to the widespread adoption of electric vehicles (EVs) across a global spectrum of countries. To illustrate, Sidabutar (2020), in a study focusing on electric vehicle utilization in Indonesia, highlighted that the typical purchasing capacity for cars in the country rests around 200 million Rupiah. Comparatively, the most affordable electric vehicle available in Indonesia, the DFSK Gelora E, carries a price tag of 480 million Rupiah—a sum surpassing the average car purchasing power by more than 200 percent. Consequently, this fiscal discrepancy compels consumers in Indonesia to lean towards internal combustion engine vehicles as their preferred choice. The elevated cost of EVs primarily emanates from the lofty battery prices, particularly pronounced in developing nations that often rely on battery imports from China— a pivotal constituent in EV manufacturing (Umah, 2021).

- Insufficient amount of charging infrastructure/ stations: The absence of a robust charging infrastructure constitutes a substantial barrier to the widespread adoption of electric vehicles, as underscored by Raksodewanto (2020). Serving as the bedrock for providing the primary energy source for electric vehicles, charging stations play an indispensable role in facilitating their adoption. However, the existing infrastructure remains far from attaining the envisioned goal of 25,000 gas

stations by the year 2030. Presently, a mere 200 operational charging stations exist, revealing a stark disparity due to the elevated installation costs, particularly prominent in most developing countries, with Indonesia serving as a prominent example.

The twin challenges of range anxiety and the dearth of adequate charging infrastructure frequently engender stress and unease among electric vehicle (EV) owners. The prospect of undertaking long-distance journeys amplifies these concerns, especially when navigating areas beyond urban domains, a concern illuminated by She et al. in 2017. The predicament intensifies when EV owners must rely on unfamiliar sites, such as hotels, often necessitating appeals for access to charging facilities, thereby compounding stress and uncertainty. In the context of Indonesia, the installed charging infrastructure remains notably inconsequential in comparison to the sheer volume of gas stations. This imbalance prompts prospective Indonesian electric vehicle buyers to deduce that the nation is yet to establish a comprehensive preparedness for transitioning to electric vehicles (Jati, 2021).

- The safety and performance of the lithium ion battery used in EVs are both notable barriers to purchasing and present a challenge once the EV has been purchased. One particular aspect that raises concerns among individuals is the performance of lithium-ion batteries in electric vehicles (EVs), primarily due to the lengthy charging time compared to the quick refueling process of gas-powered vehicles (Lin and Sovacool, 2020). Charging a battery in an EV may require several hours, posing a potential inconvenience to users. In addition to the charging time, safety represents another significant apprehension associated with the adoption of EVs, primarily due to the inherent risks of battery-related incidents. Instances of battery fires or explosions, particularly in the event of an accident, have been identified as valid safety concerns (She et al., 2017; Hatt et al., 2020). Ensuring the safety of EVs and their battery systems remains a key consideration for widespread acceptance and adoption.

- The performance and reliability of an EV once purchased are also a major barrier barriers to the widespread adoption of EVs. For example, one aspect that has raised concerns among electric vehicle users and experts is the durability of the battery and the potential need for replacement, particularly considering the high cost associated with replacing the lithium-ion battery. In relation to this, Lin and Sovacool (2020) highlighted the issue of reliability, particularly during the winter season, as the battery might require more frequent charging and longer charging times.

- Lack of model diversity: Studies have shown that electric vehicles face limitations in terms of price range and available features, leading to a lack of diversity. The options for consumers to customize their EVs according to their specific needs are limited. For instance, certain EV models may be too small and impractical for individuals with families, failing to meet their requirements. Additionally, there is a noticeable absence of functional diversity, particularly for those who require towing capabilities, as there are no current EV truck models available (Haddadian et al., 2015).

5.3 Sustainable Urban Mobility

Crafting a sustainable urban transport system encompasses the enhancement of multiple facets, including but not limited to mobility, accessibility, affordability, social equity, efficiency, safety, security, convenience, low carbon footprint, comfort, and harmonious coexistence with both people and the environment. Achieving this vision necessitates a comprehensive approach to address diverse challenges, which collectively encompass: the mitigation of urban air pollution, grappling with climate change, curbing the toll of road accidents, taming excessive motorization, bolstering public transportation services, fostering pedestrian and cycling culture, and acknowledging the distinct requirements of marginalized urban populations, women, the elderly, individuals with disabilities, youth, and children.

It remains pivotal to recognize that urban transport, or mobility, transcends mere isolation; its dimensions are intricately intertwined with various other aspects of urban existence. United Nations Environment Programme (UNEP) (2010) underscores that the transport sector stands as the second-largest contributor to global carbon dioxide (CO_2) emissions stemming from fossil fuel combustion. Of this share, a significant 23 percent of CO_2 emissions emanate from transportation, with road transport constituting a substantial 73 percent, trailed by international shipping and aviation. Paradoxically, transport's role in global climate change mitigation initiatives remains disproportionately limited in comparison to other sectors. Among the

782

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

prominent environmental concerns, urban air pollution emerges as a pervasive hazard, casting a shadow over numerous locales.

Table 1: Air pollution in selected cities. Source: World Bank, 2009

Table 1 presents the World Bank's comprehensive assessment of air pollution levels across select cities in both developed and developing countries worldwide. A striking trend emerges from the data: cities in developing countries consistently exhibit higher levels of various air pollutants in comparison to their developed counterparts. Despite this observation, only a handful of cities manage to adhere to the recommended thresholds established by the World Health Organization (WHO) to ensure air quality. Across the global landscape of cities, the road transport sector stands out as the primary contributor to urban air pollutants, alongside elevated levels of carbon monoxide and hydrocarbons, among other noxious substances. Consequently, these emissions play a substantial role in triggering an array of respiratory and cardiovascular afflictions. An array of epidemiological investigations have unequivocally linked pollutants stemming from transportation to ailments like asthma, bronchitis, heart attacks, and strokes. Those particularly vulnerable to the perils of urban air pollution include infants, the elderly, and individuals afflicted by chronic respiratory ailments. For instance, as reported by Majumdar (2010), a staggering 25.6 percent of children in Bangalore, India, experienced asthma between 1999 and 2009. Furthermore, according to the World Health Organization (WHO) (2008), air pollution is implicated in nearly 2 million premature fatalities globally, with road transport emerging as a substantial contributor to this grim toll due to its role in exacerbating outdoor air pollution.

To effectively combat these issues, it is imperative for cities to recognize that concerted, collective actions are essential, aligning with global mitigation objectives. Adopting a diversified array of measures rather than relying solely on a single approach yields manifold advantages. This multifaceted strategy encompasses:

Push and Pull approach:

Examining the predicament through the lens of "where" individuals should position themselves in the realm of transportation—effectively where to "guide" them—and discerning which modes warrant their engagement, constitutes a methodological perspective referred to as the "push and pull" approach. This approach underscores the necessity for urban transport strategies to not only incentivize the public to opt for public transport and nonmotorized alternatives but also to devise tactics that gently nudge them away from the confines of automobiles and analogous modes of transport. Attaining the "pull" dimension entails delivering a commendable standard of service within public transport, erecting robust infrastructures catering to public and non-motorized modes, and implementing policies that enhance the usability of these modes. Concurrently, achieving the scenario where individuals are "restrained from car usage" necessitates the enactment of policies designed to discourage vehicular reliance. Such policies encompass the termination of fuel subsidies, the establishment of fees associated with automobile ownership and operation, and a comprehensive implementation of measures that escalate the overall costs incurred by utilizing these modes. Critically, the revenue generated from these charges should be channeled to reinforce the sustainable urban transport alternatives.

Public Transport, Non-motorized transport, Transport demand management, and Transit oriented development: An alternative perspective on implementing sustainable urban transport hinges upon the utilization of the four delineated measures. Public Transport represents a pivotal dimension of this approach, necessitating the creation of robust public transport systems, encompassing the establishment of comprehensive mass transit networks. Within this ambit, the Bus Rapid Transit (BRT) system has emerged

as a favored solution in recent years, celebrated for its moderate implementation costs, expedited setup, exceptional service quality, and impressive passenger capacity, thereby translating to diminished vehicular congestion. Additionally, other rapid and ecologically benign urban passenger transport systems such as subways and light-rail configurations ought to be embraced as supplementary transport modes, thereby encouraging the establishment of multi-modal transport systems.

For instance, a notable 116 cities, predominantly situated in industrialized nations, operate their own metro systems, catering to an estimated daily ridership of 155 million individuals. Furthermore, approximately 400 light rail systems operate worldwide, with a staggering 200 additional systems currently in the planning phase. Many burgeoning megacities in developing nations are also directing investments toward the establishment, enhancement, and expansion of urban light-rail networks. Despite the formidable construction and maintenance expenses associated with metro and urban light-rail systems, they offer substantial, far-reaching benefits across the economic, social, and environmental spectrums. Non-Motorized Transport, alternatively labeled as "Active Transport," encapsulates pedestrian and cycling modes, as well as their associated infrastructure, policies, and educational initiatives. In recent times, these modes have gained notable traction due to their pronounced merits in curbing transport emissions and bolstering human well-being (Godefrooji et al., 2009).

Transit Oriented Development: This concept pertains to an urban design strategy characterized by policies that endorse intensified urban development along mass transit corridors (Cervero, 1998). The underlying logic driving this approach is rooted in the potential for substantial gains in energy efficiency and transport efficacy achieved through urban layouts in which mass transit networks enable swift connectivity to key urban hubs encompassing residences, workplaces, educational institutions, recreational venues, and healthcare facilities.

Avoid, Shift, Improve Framework:

- Avoid: The initial strategy centers on curtailing unnecessary travel and minimizing trip distances. This entails seamless integration of land use and transport planning, the promotion of mixed-use developments, and leveraging information and communication technologies (ICT) to curtail individual travel frequency. Strategic implementation can effectively augment accessibility, curbing travel distances and durations. Achieving proximity between residences, workplaces, and commercial centers through comprehensive urban development master plans is a pivotal facet. Furthermore, this approach capitalizes on the potential of ICT to replace activities previously mandating physical travel. Given its potential for profound social, economic, and environmental benefits, the "Avoid" strategy takes precedence, as its comprehensive application can significantly transform urban transport dynamics.

- Shift: The subsequent strategy is dedicated to facilitating a transition towards more sustainable transportation modes. This entails encouraging automobile and motorcycle users to pivot towards public and non-motorized alternatives. Leveraging an array of travel demand management tools, the strategy orchestrates an enhanced development of both inter-city passenger and cargo transport. Moreover, it cultivates an environment that retains existing public and non-motorized transport users, acknowledging their role in promoting sustainability. Properly executed, the "Shift" approach ranks as the second most potent avenue for instating sustainable urban transport. When Avoid and Shift strategies synergize within a city, the foundation for transformative change is laid, although continued enhancements remain feasible.

- Improve: The final strategy revolves around policies that seek to elevate transport practices and technologies, embracing a technological perspective to address urban transport challenges. This encompasses refining fuel quality, enhancing vehicle fuel efficiency standards, instituting vehicle emission regulations, introducing vehicle inspection and maintenance (I&M) protocols, and transitioning towards "intelligent transportation systems" capitalizing on information and communication technologies for enhanced transport management. This strategy also underscores the urgency of refining freight transport technologies and logistics for comprehensive transformation.

Overall, even though the success rate of electric vehicles in achieving sustainable transportation planning is enormous, there is a need to explore other measures which will promote sustainable planning, especially in the developing countries of the world where the rate of adoption and utilization of electric vehicles is low.

6 CONCLUSION

Transportation stands as a pivotal conduit linking individuals, locations, commodities, and services, fostering community growth, augmenting quality of life, and nurturing economic vitality. However, it concurrently serves as a noteworthy contributor to greenhouse gas emissions. In response, the global arena is actively endeavoring to address these challenges by pivoting towards greener energy sources and transitioning from fossil fuel-propelled vehicles to electric alternatives. Nevertheless, the widespread adoption of electric vehicles (EVs) remains an intricate challenge, particularly in developing nations. Obstacles encompassing inadequate charging infrastructure, elevated EV costs, and limited public awareness collectively hinder the swift embrace of EVs. By discerning the paramount catalysts and impediments in electric vehicle adoption, these nations can strategically chart pathways to surmount these barriers and bolster the integration of electric vehicles into their landscapes. Additionally, alternative sustainable transportation methods such as such as integration of all modes of transport such as the use of active travel/public transport in combination with other modes such as road, rail and air. Also, it is pertinent that to avoid total eradication of vehicles that use fossil fuels on our roads, there is a need to generate ways to adapt fossil fuel vehicles to use of renewable energy. This will allow road users/motorists to focus on diverse options instead of a single track which is not beyond human ingenuity.

1 ABSTRACT

The South African government has set up sound governance structures to respond to growing demands for services since 1994. Although the country has functional institutional structures and is one of the largest economies in the African continent; the healthcare system was substantially impacted by the outbreak of the global Covid-19 pandemic. As with countries around the globe, South Africa struggled to devise timeous response strategies to the pandemic resulting in huge losses of lives and depressed socio-economic activities. As co-members of the BRICS power bloc, the South African and Chinese economies share commonalities. This paper therefore draws some significant lessons from China's experience in managing the epidemic, while also taking account of uneven social and economic impacts. Chinese experiences of good governance systems and meaningful capacities to engage in trial-and-error responses to the pandemic resulted in the containment of the disease. A systematic analysis of literature was conducted to answer clearly formulated questions. This research adopted a case study design together with a qualitative research approach. The results reveal that there are weaknesses in South Africa's constitutional democracy with a three-tier system of government and an independent judiciary. This aggravated the severity of Covid-19 which negatively impacted the people and put more strain on the healthcare system and the economy. The governance structures' late response to adjust led to losses of lives and the rapid spread of the virus, which resulted in the implementation of strict lockdown measures. On the contrary, the Chinese government's robust global governance structures enhanced its ability to promulgate laws and guidelines which informed rapid changes across all aspects of its functions. This resulted in the swift implementation of initiatives that ensured strict safety protocols to reduce the spread of Covid-19 and generated advanced analytical technological systems and created new markets for new technologies. As a result, of the global phenomenon, South Africa has learnt from Chinese experiences as the largest developing economy in the world. In view of the findings of the study, it is recommended that South Africa collaborates with other countries to facilitate real-time information and skills transfer and to avoid being left behind. As part of the proactive measures to enhance emergency responses to pandemics, commitment to planning and implementation of long-term strategies is required to circumvent future pandemics. In conclusion, the study reveals that governance system reforms are needed to improve and strengthen primary healthcare and to ensure that government processes and systems foster good governance. The paper further suggests that South Africa should consider investing in competent skills, technology and adequate budget to ensure good governance systems, as well as actively conducting research studies in preparation, responding to any future infectious diseases.

2 INTRODUCTION AND BACKGROUND

The era of the Covid-19 pandemic has had a severe impact on the global economy and social well-being of many people, both from the physical and mental health viewpoints, with regard to how global-geo-politics affects national systems of governance. Clearly, South Africa was not prepared for the COVID-19 pandemic. In fact, the 2020 report of the Global Preparedness Monitoring Board concluded that the majority of countries were unprepared for COVID-19 because "our understanding of pandemic preparedness has been inadequate" (GPMB, 2020). In some cases, preparedness was understood too narrowly. For example, some countries laid in stocks of PPE but failed to complement this with a robust testing system to identify infected people. They also did not build community-level systems for handling outbreaks (GPMB, 2021).

The Covid-19 pandemic was regarded a global public health emergency; the first case was reported in the City of Wuhan, and Hubei Province in China in 2019. These patients most notably presented with clinical

symptoms of dry cough, dyspnea, fever, and bilateral lung infiltrates on imaging. Cases were all linked to Wuhan's Huanan Seafood Wholesale Market, which trades in fish and a variety of live animal species including poultry, bats, marmots, and snakes. Subsequently China cautiously informed the World Health Organization (WHO) given that many of the Chinese's reported cases were from vendors at sea point and poultry amongst others. The spread of the disease to other countries including South Africa prompted the WHO to declare a global pandemic in March 2020. This resulted in China declaring "peoples war" against the virus and adopting a model which became a Chinese Covid-19 diplomacy and policy instrument which set the global political agenda (Nian, 2021).

This paper, therefore, draws some significant lessons from China's experience in governance and policy perspectives in the fight against the Covid-19 pandemic. The Chinese model is a very useful benchmark for policy instruments and sets a political agenda for the effective implementation of governance systems. The Chinese government understood that in order to successfully conquer the Covid-19 pandemic, it was imperative to strengthen its power relations and maintain cordial ties with neighbouring countries to improve and restore its national image, given that the first victim of Covid-19 was detected in China (Nian, 2021). Nian further reveals that the dynamics and changing power relations as a result of the Covid-19 pandemic have reshaped China- Southeast relations in the political ties, and economic co-operation in the immediate and long term. For instance, Singapore drew a valuable lesson from China's experience to combat the spread of the pandemic. Once the virus was detected, it expanded its screening process to all checkpoints including airports and sea points.

Compared to China, which is the second-largest economy, the African continent has been dealing with a rapidly changing global environment since the early 90s. These changes have major implications for the continent's future development. However, they are also a part of an era of greater global structural weakness, which has posed complex challenges for the continent, and where the spectra of global marginalization has always loomed large. In this regard, steering mechanisms of global governance take on added meaning in the African context. These evolve "through the sponsorship of states, and the efforts of actors other than states at the transnational or subnational levels, or through states and other types of actors jointly sponsoring the formation of rule systems" (Rosenau, 2009).

As an example, the threat of avian flu led to calls for "pandemic preparedness," but readiness entails preparation of a certain kind (Buck & Ghiglione, 2020). This became evident in the context of the current pandemic. The European countries had enough ventilators to meet the challenge related to coronavirus except Germany, which had to order an additional 10,000 ventilators from a domestic supplier. Another example was the Global Outbreak Alert and Response Network (GOARN) developed in 2000. This is a global partnership among public health institutions, laboratories, NGOs, and other organizations designed to observe and respond to epidemics. The WHO provides much of the staffing and assistance for GOARN but does not directly fund it, and there are currently proposals to enlarge and strengthen this network so that it can engage in emergency interventions at the local level, where the WHO is not designed to assist (Obstfeld, 2020).

Global governance offers an alternative perspective from which to reimagine the world order. As it becomes a serious contender for explaining how we see the world, it is guiding us in legitimizing our actions in the world.

The erratic workings, inadequacies, and flaws of institutionalized structures, rule systems and norms of global governance have conspired to bring Africa to a critical juncture. This is compounded by the view that global governance is devoid of any grand logic, made up as it is of a borderless web of interactions by formal or informal institutions, states, markets, and citizens. This multiplication of spheres of authority gives global governance its myriad of control mechanisms which derive from "different histories, goals, structures, and processes". Thus, the " global Covid-19 pandemic health emergency crisis brought into unambiguous relief the magnitude and scope of the challenges that the world should confront". In this regard, the world found itself in a storm which was the novel coronavirus epidemic (Global Preparedness Monitoring Board, 2020).

This paper examines the role of the global governance system during the Covid-19 outbreak, and the experiences in South Africa in the context of learning from the Chinese, model and public policy discourse. The paper further provides an argument and a deep sense of reflection on South Africa's response to the Covid-19 pandemic, and whether it had a mechanism in place to mitigate the spread of the disease, in

particular since the pandemic's emergence in early March 2020. The pandemic further provided an opportunity for researchers to understand that the global response to the infectious Covid-19 pandemic would play a very critical role in improving future policy discourse and governance systems in the management of public healthcare systems. The impact of the pandemic exposed some existing socio-economic inequalities in developing countries including policy gaps in both public and private healthcare systems.

In essence, the pandemic has widened the existing gap between the rich and the poor, and the urban and rural communities. Hence, Fourie and Lamb (2023) argue that those who lived in developed countries and in the past had access to adequate health care facilities including regular income found themselves to be living in the best times during Covid-19. This paper further provides an overview analysis of how South Africa, the African continent, and the world have responded to diseases and pandemics that had a much more severe impact on the global economies of scale and healthcare systems. The paper also provides significant opportunities for natural and social scientists, as well as researchers to learn more about the pandemic and future healthcare emergencies.

The paper depicts how the Covid-19 pandemic disrupted the world economy and led to public health fatalities and increased mortalities. It negatively impacted the country's gross domestic product (GDP) leading to a high rate of unemployment arising from strict lockdown measures which were imposed to mitigate the spread of the disease.

3 CONCEPTUAL SYNOPSIS

3.1 State governance

The notion of global governance is referred to in the context of the movement towards political cooperation amongst transnational actors, aimed at negotiating responses to problems that affect more than one state or region. Studies show that a global governance perspective helps elucidate how scale mattered in relation to the Covid-19 crisis. For instance, Rosenau and Czempiel (1992) view Global Governance "as a process of confluence and cooperation among multiple actors, state, and non-state actors". However, Weiss and Wilkinson (2014) stress that the unevenness of power has always been present in global governance, where some states have been far more capable actors than others, and non-state actors. In order to deal with such unevenness's, the South African government has adopted its long-term National Development Plan 2030. This unpacks the role of different sectors of society in contributing to the achievement of its desired long-term goals. In shaping its global governance, however, compared to the development plans of other countries such as China and their strategies of bi-lateral and multi-lateral institutions, the South African plan places a great deal of emphasis on good governance as part of the non-physical infrastructure that must be developed to support socio-economic change. Thus, South Africa has determined its critical role to participate in the global governance space.

In South Africa, the case of the Covid-19 pandemic had far reaching implications for all sectors of society across all spheres including at the global level. Its impact was mostly felt in the health sector, as it had to respond to the growing pressure of the virus and ensure that the health facilities were not overrun and consequently health services did not collapse. South Africa consequently adopted a governance approach in managing the pandemic and understanding the role of the cities and patterns of human behavior during the outbreak.

3.2 Political system

In this discussion, it is necessary to reflect on reasons why China remains the second largest economy and continues to pursue the dominant player in global and political governance. This can simply be tracked to the fact that the Chinese firmly believe that the political system must first be founded on a sound system to ensure political stability in the country. This can be traced back to the generation of leadership in China since the founding of the Republic of China in 1949. The Chinese rise to global economic power can also be attributed to its huge growing population and its rapid implantation of reforms, particularly in the economic sectors (Zhu, 2019).

Furthermore, it should be noted that China's political system is socialist and pursues a state governance system under the Communist Party of China (CPC). This focuses on developing a sound system for the

party's visionary leadership. It gives priority to developing the economy, stable politics, its culture and society and the military as well as foreign affairs to enhance state governance. According to Zhili and Juan (2020), the Chinese state governance model has led China to be relatively successful in the implementation of policy instruments and economic development since its reform to achieve developmental goals. It is therefore the reason why China's foreign trade policy remains significant in the country's integration into the global economy. Hence, China plays a dominant role in or is party to many treaties and institutions involved in the Group Twenty (G20).

This phenomenon was proved sound when China was faced with the mammoth task and responsibility to contain the spread of the very first difficult global public health emergency Covid-19 pandemic in modern history.

The notion of global governance provides a better understanding of the various practices that fall within the concept of globalization. Hence, Lederer and Muller (2005) state in more practical terms that global governance combines both domestic and international institutions, which includes both political and economic power relations as determined by the process of globalization. This provides a much broader interpretation and understanding of the concept of global governance and political economy which in essence includes how political choices can shape patterns of economic integration and development.

4 STUDY AREA

The paper sketches the challenges faced during Covid-19 with a focus on all nine provinces in South Africa. In response to the global and domestic challenges confronting the provinces, the government has committed to the plan which reflects a collective vision for the city region in a decade's time and beyond. The plan seeks to address the fundamental problems of unemployment, poverty, and hunger, as well as health, inequality as a consequent effect of the pandemic. Hence in the main, South Africa has committed to rebuilding its economy after the devastating effects of the coronavirus pandemic.

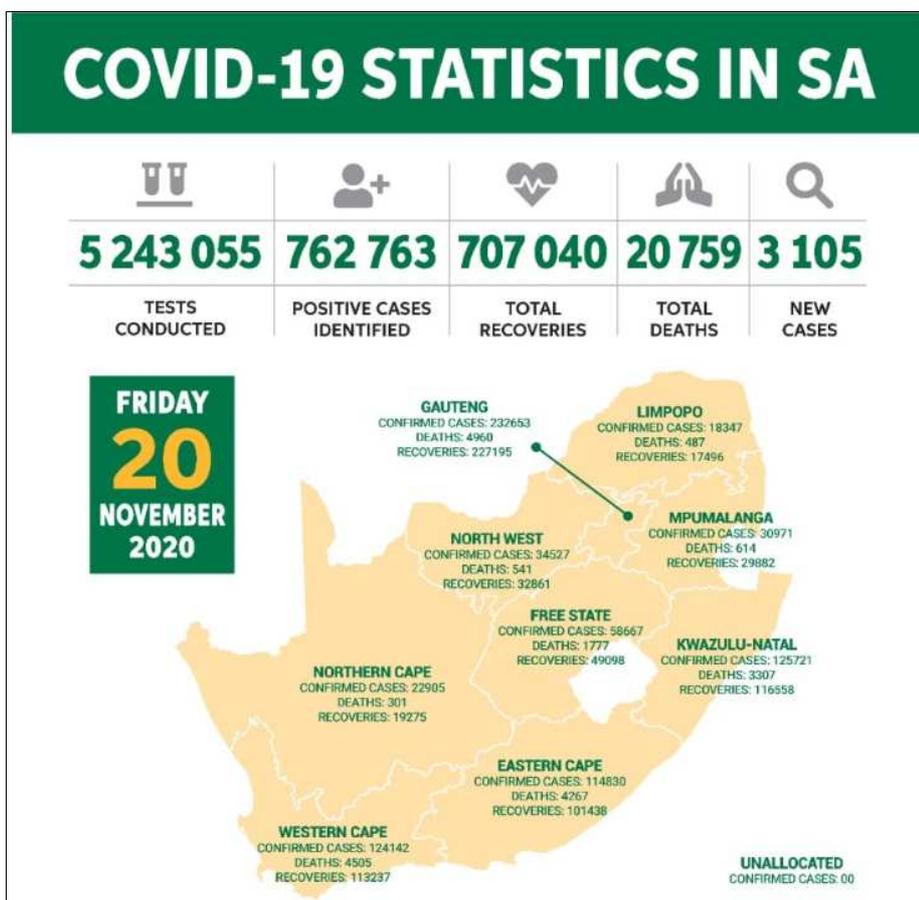

Figure 1. Reported cases in South Africa by November 2020, across all nine (9) provinces. Source: https://sacoronavirus.co.za/2020/11/20/update-on-covid-19-20th-november-2020/

The Covid-19 pandemic has given impetus to efforts in adaptive governance which have existed since South Africa achieved democracy, given that all measures had to be put in place to collectively achieve a cooperative system across all spheres of government. At the helm of these collaborative efforts to address the pandemic government announced a solid governance structure and systems intended to coordinate decision-making processes faster, as well as enhancing the flow of information and responsiveness.

According to the World Health Organization, by November 2020 the number of Covid infections had sharply increased, leading to more deaths reported. This negatively impacted social wellbeing, and created economic pressure thereby increasing the current material conditions of inequality and unstainable infrastructure. South African Covid-19 Statistics for 2020 reveal that South Africa remained one of the 20 most infected countries with a high rate of reported Covid-19 cases. Figure 1 below shows the extent of reported cases in South Africa by November 2020, across all nine (9) provinces.

The severity of this Covid-19 outbreak resulted in it being declared by the WHO as a global pandemic. This prompted the South African government to declare a national disaster, and to establish a command council to coordinate South Africa's response to the Covid-19 challenges (Government Gazette, 15 March 2020). The command council announced measures to combat the pandemic including a nationwide lockdown for 21 days with effect from 26 March until 16 April 2020. This meant that all South Africans had to stay at home except for health workers in the Public and Private sectors, Security Services, as well as those in the categories deemed to be providing essential services. According to Beaubien (2020), Covid-19 was a global phenomenon, considering the rapid chain of events, and it seemed that the lockdown model allowed governments throughout the world to act decisively and effectively from both a public health and governance perspective. The turn to lockdowns also highlighted the prominence of centrally driven or 'centre of government' (CoG) arrangements to coordinate the government machinery to respond to a pandemic (Kunicova, 2020). An over-arching lesson was gleaned from how various countries employed CoG mechanisms to fight Covid-19. This was that trans-national learning that feeds into 'good practice' is a necessary but insufficient marker of success – the structure and character of CoG mechanisms must also demonstrate 'good fit' with individual country contexts. Good practice features might include hands-on executive leadership, clearly defined roles, responsibilities, and interfaces between policy command and operational structures, as well as public awareness campaigns. Figure 2 below shows South African demographics for all nine provinces, and their reported Covid-19 cases by June 2021.

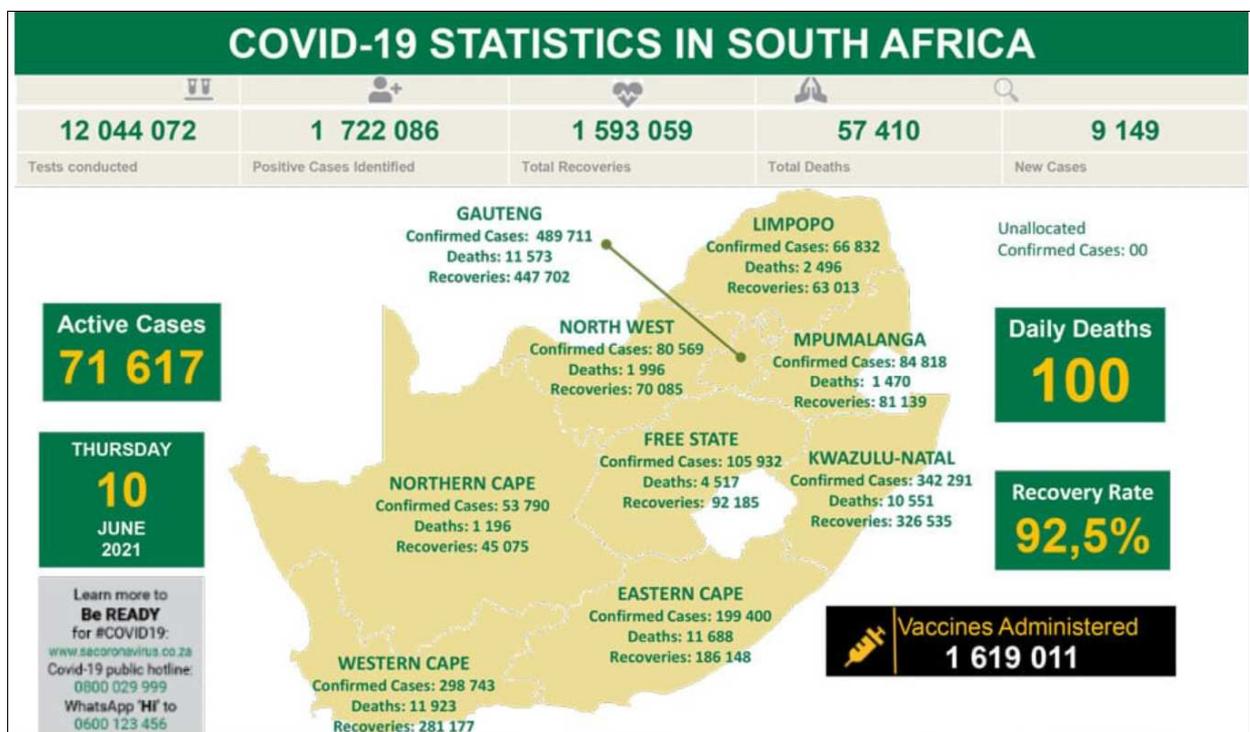

Figure 2. South African demographics for all nine provinces and their reported Covid-19 cases by June 2021.Source:http://sacoronavirus.co.za/2021/06/10/latest-confirmed-cases-of-covid-19-in-south-africa-10-june-2021/

4.1 Significance of Data Management in Decision-Making Process and Governance

An effective integrated model of governance required coordinated efforts in ensuring that the quality of information flowed properly through the system. This denotes that a proper structure was required to provide a synoptic view of the progress of the pandemic ranging from the collective planning of responses and interventions including monitoring of the effects of the pandemic.

The Chinese government has played a critical role in ensuring epidemic prevention and control, thereby leveraging the digital data platform. Digital technology is a very important means of communication, and it should be noted that China is largely a mobile society with many of the Chinese community using smart technology. Hence, China became the first country to use artificial intelligence data to meaningfully fight the Covid-19 pandemic. The key lesson to be learned from the Chinese governance system was their investment in digital platforms and data. This played a very critical role during the prevention and control of the Covid-19 epidemic, as it is said that every Chinese app had some added features for a dedicated hub specific to the coronavirus.

This app played a crucial role in helping both the urban and rural communities get updates on developments during the pandemic. More importantly, the Chinese app helped many people in rural communities to reduce their travelling patterns to the cities, through usage of "We Chat" for the collection of necessary medicine for their well-being. Even truck drivers made great use of the app in terms of becoming "solidarity social forces" during the lockdown period.

The positive spin for these Chinese initiatives is that South Africa had to adapt to changing demand in technology and subsequently initiated its own mobile app to fast communicate messages and data related to the impact of the Covid-19 pandemic. Thus, it was able to reach millions of South Africans including those in the rural areas who might not be privy to news broadcasting.

4.2 The Impact of the Pandemic on the Economy

The Covid-19 outbreak had a severe impact on the global economy and the ability of countries to trade in view of the lockdown measures which were implemented. This was also seen in China, wherein the first quarter of its economic performance declined and was resuscitated through business resumption and economic recovery after the lifting of the lockdown. The Republic of China's strategy has been to focus on the domestic market economy whilst pursuing to maintain and expand its international markets domination and in that way remaining the second-largest economy.

In South Africa, the implication meant the rising rates of unemployment and poverty as businesses were now faced with severe pressure to close down leading to the financial markets and the banking system opting for the introduction of relief funds for business. To mitigate the dire economic consequences arising from these lockdown measures, the South African government adopted a 'risk-adjusted strategy' with five different levels of lockdown.

The introduction of the framework for the risk-adjusted strategy provided guidance to different sectors of the economy to return to economic activities using a phased approach. This, however, was done to ensure that the WHO safety protocols were adhered to and were ultimately mandatory for all citizens. These protocols related to social distances, regular hand washing and sanitizers, wearing of face cloth masks, as well as reducing social public gatherings including limiting the number of people attending funerals. These measures were applicable until the lockdown restrictions were lifted, and the economy was fully reopened.

The South African government further advocated for the provision of social grant relief packages and support of households through the distribution of food parcels and vouchers to the poorest communities, as well as relief packages for firms or businesses in distress. Central to that was the allocation of the Covid-19 budget to support health workers through the procurement of personal protective equipment (PPE's), surgical masks, ventilators, and oxygen equipment to support Covid-19 patients. Covid-19 revealed that the focus on WHO as the sole instrument of global health governance may have been misplaced. A pandemic creates problems of scale, and many of these require international cooperation. However, many of these may not be resolvable by an international organization, no matter how broad its reach. This pandemic has reinforced the message that stockpiles of PPE need to be preserved and updated at regional, national, and subnational levels (Feinmann, 2020).

4.3 Impact of Pandemic on Mental Health and Depression

The Covid-19 virus spread like wildfire across the world in a very short space of time. The high infection rate and associated health risks prompted the world to impose restrictions which had a major effect on people's mental health, causing fear, depression and anxiety (Oman et al., 2022). This is attributed to a lack of income and social support, as well as access to social amenities. A study by Oman et al. (2022) in Malaysia revealed that the psychological effect of the pandemic placed tremendous emotional stress on people. The rising death toll from Covid-19 also instilled more fear within people of losing their loved ones, their income and the possible next wave of the Covid pandemic.

5 METHODOLOGY

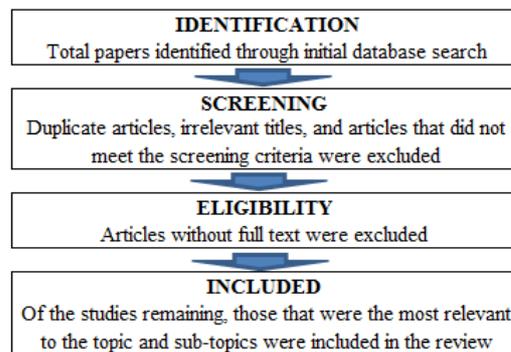
The authors analyzed literature by using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) tool, specifically adopting guidelines in the PRISMA flow diagram and PRISMA checklist. PRISMA helped to pinpoint and review research relevant to the role of global governance systems in shaping responses during the pandemic. The papers found were screened for relevance using a selection of defined criteria including the number of citations and the journal impact factor. The authors used the PRISMA checklist to assess the quality of the identified sources and only the most relevant papers were included. A variety of filters was also applied to the search to narrow the results, such as eliminating articles that fell outside a specified timeframe. Both journal and non-journal articles were included. The PRISMA flow diagram below (Figure 3) shows the four criteria which were used to guide the authors in their research: identification, screening, eligibility, and inclusion.


Figure 3. Simplified flow chart showing the selection process for the articles

6 RESULTS AND DISCUSION

This paper illustrates the value of global governance systems for South Africa in shaping responses during pandemics, and lessons leant from the Chinese Covid-19 experiences. The research strategy for this paper involved a number of case studies to achieve its desired outcome. The study used data from books, conference papers, articles, and journals mapped in the form of tables and figures, as well as lessons learned.

Covid-19 created a sharp focus on the existing structural inequalities and institutional weaknesses in the Public Health sector in South Africa. Whilst the country had made tremendous progress in ensuring the quality and access to healthcare facilities for numerous people who were unable to afford private healthcare, studies still show that the healthcare sector had been under severe strain even prior to Covid-19.

This study focuses particular attention on the nine provinces, in South Africa, as shown in Table 1 below, Stats SA Mid-Year Estimate Population (2021) reflects the densely populated provinces in South Africa due to high in-migration. This required a swift response and effective management to reduce the increasing number of Covid-19 infections.

The outbreak of the Covid-19 pandemic in South Africa necessitated the health system to have adequate capacity to be able to deal with the emerging crisis. This meant that South Africa had to adopt a multisectoral and multidisciplinary approach at the political and leadership level in order to save lives and livelihoods. The comprehensive health plan response was also prepared to ensure that health facilities had enough beds, particularly in the public sectors so that patients diagnosed with Covid-19 could access basic health facilities. Figure 4 below illustrates the daily infections and active cases in South Africa experienced during the third wave.

Nine Provinces in South Africa	2021 Mid-Year Estimated Population	
	n	% of total
Eastern Cape	6 738 223	11.1
Free State	2 913 531	4.8
Gauteng	15 882 396	26.3
KwaZulu-Natal	11 563 357	19.1
Limpopo	6 063 742	10.0
Mpumalanga	4 733 276	7.8
North West	4 158 730	6.9
Northern Cape	1 320 924	2.2
Western Cape	7 092 527	11.7
Total	**60 466 705**	**100.0**

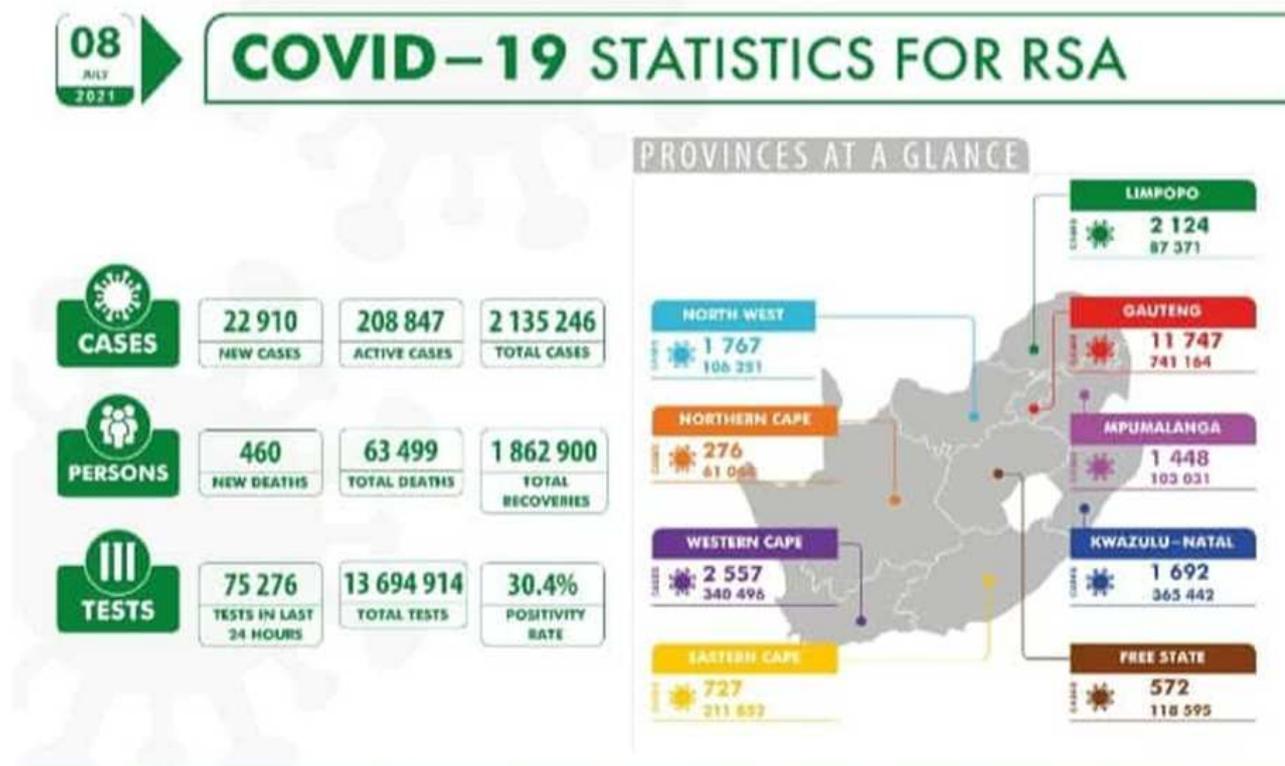
Table 1: Mid-Year Estimate Population (2021). Source: 2021 Mid- Year Estimate Population.


Figure 4. Daily infections and active cases South Africa. Source: https://www.nhls.ac.za/latest-confirmed-cases-of-covid-19-in-south-africa-08-july 2021/#iLightbox[gallery19033]/1

The health plan response also had to address the challenges of health infrastructure to avert the fatalities that the other parts of the world experienced as a result of the increased burden of disease and poor infrastructure maintenance. South Africa had to reprioritize its healthcare system, create hospital wards and beds in facilities to accommodate Covid-19 patients, and repurpose additional identified spaces in certain health facilities. The discussion below illustrates the use of three spheres of government in regulating the Covid 19 pandemic in an effective manner.

6.1 South African governance system

The government is divided into three spheres: national, provincial and local. The legislatures in all three spheres are directly elected every five years by South African citizens of 18 years and older (SA Constitution 1996, S. 46). Only the second house of Parliament, the National Council of Provinces (NCOP) is not directly elected. Its ten (10) members per province are indirectly elected by the provincial legislatures.

The Constitution (S. 55 (2)) also requires that the National Assembly provide mechanisms to ensure that the executive organs of state remain accountable to it. This was the framework of government within which the Covid-19 pandemic had to be managed in line with the Constitution's provisions regarding a state of emergency (S. 37). In order to curb the spread of Covid-19, the country put measures in place such as restrictions on public gatherings; cancellations of events; closures of workplaces, schools and public transport; stay-at-home requirements; public information campaigns; restrictions on internal movements; and international travel controls.

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

6.1.1 National level

South Africa's experience with the Covid-19 pandemic and the manner in which its government coped raised concerns about its impact on the country's democracy. This was because several democratic states' constitutional and political dispensations were directed towards more autocratic tendencies. During the pandemic, predictions were made that this trend could end in permanent regressions in democratic systems.

The current research assesses the South African government architecture, especially in the context of accountability and oversight requirements. In this regard, the relationship between the legislature and the executive is most relevant. The South African government decided on a state of disaster to manage the pandemic in contrast with a state of emergency as the constitutional alternative. Its implementation is analysed, especially the institutional framework underlying it. The role of Parliament during the pandemic is thus used as an important test of the quality of democracy. The summary is that South Africa's democratic principles did not degenerate during the pandemic, as determined by Freedom House (2021), but the pandemic's major impact was on the quality of democracy. The state of disaster's institutions, for example, were not those prescribed by legislation. Moreover, Parliament's involvement in the state of disaster's decision-making was limited. The 2021 local government election, on the other hand, was judged free and fair and its outcomes have been implemented without any public challenges. The main negative outcome is the public's trust deficit in the ruling party's use and abuse of pandemic regulations (Public Health and Democratic Governance, 2022).

6.1.2 Provincial level

The institutional arrangements of South Africa during the pandemic mainly included the Cabinet as led by the President, as well as the national and provincial Coronavirus Command Councils which were responsible for coordinating government's response by all spheres of government and society. The key role-players in these structures were the President of the Republic of South Africa (as the head of the NCCC), the various Ministers who issue regulations, Premiers of Provinces (as heads of Provincial Coronavirus Command Councils) and MECs, as coordinators of implementation (De Visser and Chigwata, 2020). In terms of sub-level governance, the question of who was responsible for the implementation of the directions issued in terms of the Disaster Management Act 57 of 2002 (RSA 2002) arises. This was placed on all premiers, Members of the Executive Councils (MECs) responsible for Local Government in the provinces, the President of the South African Local Government Association (SALGA), all mayors (whether executive or non-executive) and institutions of traditional leadership (De Visser and Chigwata, 2020). The directions issued to deal with the Covid-19 pandemic instructed each province to establish a Provincial Command Council (PCCC) and coordinating structures to support the national institutional arrangements (COGTA, 2020d).

The delivery of major infrastructure projects on time and within quality standards is largely a concern in the South African public sector. This had further implications and challenges when it came to the delivery of functional beds to mitigate the challenges of accommodating the Covid-19 patients. These challenges also included the procurement of capital infrastructure, which was a consequence of poor planning. The national treasury consequently issued instruction number 08 of 2019/2020 to specifically deal with issues of emergency procurement for Covid-19. This was implemented, although infrastructure delivery management system provides a clear process that must be followed in the procurement of infrastructure in practice note number SCM 3 of 2003.

6.1.3 Local government level

At a local government level, the South African Local Government Association (SALGA) directed the Committee on the actions which had been taken to assist local government to implement the Covid-19 disaster management directives. SALGA subsequently highlighted a wide range of challenges faced by municipalities as a result of the pandemic's economic impact. A major concern was the projected reduction in revenue collection by the municipalities owing to job losses, reduced household incomes, and local authorities being unable to rent out their facilities or generate the normal level of revenue from areas such as traffic fines. Simultaneously, the lockdown required people with reduced incomes to stay at home, resulting in higher-than-normal water and electricity usage. Municipalities were heeding SALGA's call not to disconnect residents who were unable to pay their electricity or water bills, but Eskom did not support the

proposal that municipalities be granted a payment holiday because of their revenue collection challenges. Moreover, R20 billion had been set aside by the Treasury to assist municipalities (Role of local government in combating the spread of Covid-19 virus, 2020).

6.2 Global governance structures in China and Covid-19 responses

The results reveal that there are weaknesses in a constitutional democracy with a three-tier system of government and an independent judiciary. This aggravated the severity of Covid-19 which negatively impacted people and put more strain on the healthcare system and the economy. Governance structures' late response to adjust led to losses of lives and the rapid spread of the virus led to strict lockdown measures to contain the virus. On the contrary, the Chinese government's robust global governance structures enhanced its ability to promulgate laws and guidelines which informed rapid changes across all aspects of its functions. This resulted in the swift implementation of initiatives which ensured strict safety protocols to reduce the spread of Covid-19 and generated advanced analytical technological systems to control the virus and create new markets for some new technologies. As a result, of the global phenomenon, South Africa has learnt from China's experiences as the largest developing economy in the world.

7   LESSONS LEARNT AND POLICY IMPLICATIONS

The Covid-19 pandemic was unprecedented in the history of humankind, and South Africa was not an exception in experiencing these uncertainties. Nevertheless, South Africa succeeded in providing infrastructure in the form of functional beds to accommodate Covid-19 patients. This was necessary for the country to adapt to changing needs which required an innovative approach and comprehensive strategy to respond to the health plan. Despite shortfalls in the delivery of capital infrastructure and planning processes, Covid-19 provided an opportunity for the public health system to be strengthened. Through these lessons, the health system responses were tried and tested which could help mitigate the negative impact of future emergencies should they arise. Studies show that a single source of data management, digital technology is critical for monitoring and reporting. This serves as an important lesson to be learned in cases of future healthcare diseases and emergencies since such data plays a very critical role in decision-making. These resources strengthen the centralized data repository for record-keeping, as well as for data analysis.

South Africa has, therefore, learned a valuable lesson through the intervention's measures implemented against great challenges and experiences. This has helped to shape its governance model. These experiences are not limited to the role of all stakeholders from both public and private sectors, academia in the form of researchers and scientists, civil society organizations, and communities in the fight against infectious disease. Effective political and administrative leadership has also played a critical role in the establishment of necessary governance structures and systems needed to coordinate and drive interventions and responses to future pandemics.

8   CONCLUSIONS

The emergence of the Covid-19 pandemic largely impacted the global governance system and led to growing concerns and uncertainties amongst the world's economies. South Africa like other countries, had to ensure that there were prevention strategies in place and functional health facilities to respond to the growing crisis. The World Health Organization 2020 provided the necessary expeditious guidance regarding responsive policies and frameworks which different countries implemented to manage the impact of the pandemic.

From this study, it is evident that Covid-19 pandemic had a negative impact on global governance. Nevertheless, lessons could be drawn from China's response in the application of its governance system, and in reshaping its governance model during the pandemic. South Africa was able to move decisively to construct systematic responses to the threat of the pandemic. However, the pandemic had an impact on the GDP demand and supply economies which led to increasing rates of unemployment, poverty, and hunger, impacting millions of livelihoods of South Africans.

For example, Stats SA in its published Quarterly Labour Force Survey, indicated that the country's unemployment rate had increased by 1.0 percentage points thereby increasing to 30.1% in the first quarter of 2020 (Stats SA Quarterly Labour Survey, March 2020). The Covid-19 pandemic further demonstrated the need for the leadership management to close the existing gap between policy, planning and implementation in the immediate short-term. In this regard, a capable and effective state requires a long-term investment in

its communication systems as well as appropriate use of technology to respond to complex and changing demands in future emergencies. This study concludes by showing that an integrated planning approach is key for the country to achieve its intended outcomes in managing the pandemic and reshaping its governance model and systems.

(Prof. Trynos Gumbo, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, tgumbo@uj.ac.za)

(Ass. Prof. Thulisile Mphambukeli, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, tmphambukeli@uj.ac.za)

1 ABSTRACT

Land is a valuable resource which contributes towards the economic and social well-being of communities, and secure land tenure is therefore a crucial factor towards addressing poverty and inequality. This paper examines the role of secure land tenure policy and practice in relation to the socio-economic development of communities and sustainable human settlement planning in South African cities. It explores the statutory mechanisms in place for the enablement of secure land tenurewhich addresses the negative effects of the fundamental structural challenges left by the apartheid planning regime on the current urban policy context. It draws lessons from the Edendale Unit H and Ambleton Townships, Pietermaritzburg, as well as case studies at Msunduzi Local Municipality in the KwaZulu-Natal province. A qualitative case study design was employed, and primary and secondary data were gathered through open-ended interviews with key stakeholders responsible for land tenure restoration. The findings highlight efforts to formalize ownership and engage communities, but challenges persist. For Ambleton's unauthorized occupants, the upgrading of the Land Tenure Rights Act should be used to formalize ownership. It is recommended that Edendale's boundary disputes can further be addressed through an approach which integrates the Systematic Theory. The Adaptation Theory can ensure that fair community involvement, and eviction procedures should align with the Prevention of Illegal Eviction Act. Regular monitoring and evaluation will enhance its implementation, where integrating legal and theoretical frameworks, adjusted for subsidized housing, can lead to a just and secure tenure system for Ambleton and Edendale Unit H.

Keywords: Land Tenure Policy, Sustainable Human Settlements, Land Tenure Restoration, Spatial Planning, South Africa

2 INTRODUCTION

There are various types of legislation established in South Africa as a backbone for Title Deed Restoration, Land Reform, provision of housing, and Security of Land Tenure Rights. Access to housing and ensuring the security of tenure rights is part of the government's strategy to eradicate poverty and improve the lives of all South Africans through providing socio-economic related opportunities (Hull and Whittal, 2018). A land audit report conducted by the Department of Land Affairs in 2017, showed that a total of 30% of individuals (1 579 543 ha) in KwaZulu Natal own private and secured land compared to the 39 % (37 031 283 ha) in the rest of South Africa. The South African Institute of Race Relations (IRR) also published a report in March 2018 indicating that "114m ha of 122m ha of land in South Africa is registered with the Deeds Office", with urban land constituting of 3,2m ha. Therefore, in KZN, 39,5 % of Africans on urban land and 3.5 % in rural areas are registered individual landowners. There exists slow progress of securing land tenure rights with the main focus being placed on agricultural land but not individual properties. Government is also providing more RDP housing without title deeds, while there is still a huge number of households who have not received title deeds since 1994. The aim of the study is to examine the impact of the South African Urban Policy governing land tenure security and restoration on the economic potential of people in the Edendale and Ambleton areas in Pietermaritzburg. The study also identifies the strategies used by the government to implement this policy and secure land tenure rights in these areas. The objectives of the study are firstly to evaluate, the effects of secure land tenure in the Edendale and Ambleton areaswithin the framework of the South African Urban Policy for land tenure security and restoration. Secondly, it examines the effectiveness of the government strategies used to secure land tenure rights in the Edendale and Ambleton areas and identifies the challenges and opportunities for improvement in the implementation of the policy within Pietermaritzburg. Finally, it provides recommendations for improving the strategies and informs policy development and implementation in other similar contexts for the benefit of the residents.

3 CONCEPTUAL SYNOPSIS

Secure land and property rights play a crucial role in reducing poverty and promoting economic development,while mismanaged land can lead to conflicts and disruptions, causing land degradation and loss of socio-economic opportunities (UN-Habitat, 2014). Therefore, ensuring land tenure security is internationally recognized as a key factor in positioning a country for global competitiveness (UN-Habitat, 2014). Land tenure systems encompass both customary and statutory rights that exist between land, society, and people, and each country develops its own land tenure concept based on historical and current legislation (UN-Habitat, 2014). To understand this concept, it is important to break down the meanings of land tenure and tenure security. Land tenure refers to the rules and institutions governing land use and property rights, and it encompasses the allocation and control of natural resources in society (UN-Habitat, 2008 cited in Kasimbazi, 2017). Tenure security, on the other hand, is challenging to measure as it depends on the landholders' perceptions of security for their property. It generally includes rights that allow property owners to use their property as collateral and which provide legal protection against eviction (Barnes and Enemark, 2020; Aliber and Popoola, 2018). It involves land administration processes that protect land tenure security and allow for dispute resolution and adjustments of rights (Aliber and Popoola, 2018; Pienaar, 2013). Land tenure security also ensures individuals have the legal right and confidence to transfer their properties, leading to social stability and economic opportunities (La Croix, 2002; Pienaar, 2013).Thus, tenure security relates to land ownership and the protection of landholders' rights.South Africa's Constitution commits to rectifying historical land injustices, establishing a foundation for secure land tenure. Key policies like the Land Reform (Labour Tenants) Act 3 of 1996 protect labor tenants, while the Interim Protection of Informal Land Rights Act 31 of 1996 shields communities in resource-rich areas. The 1998 Prevention of Illegal Eviction Act balances property owners' rights with those of occupants, and the Upgrading of Land Tenure Rights Act 112 of 1991 formalizes traditional land ownership. Together, these policies represent South Africa's comprehensive approach to addressing land rights and tenure security.

3.1 Overview of the South African land tenure system

In the context of South Africa, ensuring that people have secure rights to their land is also a crucial goal for reducing poverty, boosting the economy, and maintaining social stability. This is a challenging task due to the country's historical background. Having proper ownership and rights to land is now recognized worldwide as a key factor for any country's competitiveness (UN-HABITAT, 2014). Looking back at how land was lost and regained in the past can give us useful information about how stable land ownership is today (Sunderlin and Holland, 2022). Moreover, to comprehend the current challenges of the land tenure system in South Africa, it's essential to consider the enduring repercussions of apartheid-era policies. For example, the impact of the Natives Land Act of 1913 and the1936 Native Trust and Land Act remains evident in the form of "Trust Land," characterized by insufficient surveys and the restrictive "permission to occupy (PTO)" system (Ntsebeza, 1999). Kloppers and Pienaar (2014) emphasize that these Actsentrenched inequality and denied black individuals ownership rights, shaping the landscape for post-apartheid land reform.

Following 1994, South Africa embarked on ambitious land reform initiatives aimed at addressing historical injustices. This reform seeks to strike a balance between land redistribution, restitution, and tenure security, a complex endeavor with far-reaching implications (Adams, 2000). Nevertheless, despite progress in land reform, obstacles persist such as inadequate funding and limited private sector involvement which hinders effective implementation(Lekaba, 2016). The major challenge is misunderstanding the role of these land reform initiatives in securing land rights. For example, in a study conducted by Makombe (2018) the government aimed to redistribute 30% or 24,5 million ha by 2014. Anseeuw and Mathebula (2008) cited by Makombe (2018) mention that between 1995 to 1999 about 41 restitution claims were made on 112 919 ha, between 1999-2004 about 56679 claims were settled and in 2012 about 32% of the target was met. However, Makombe (2012) mentions that Land reform in South Africa between 1994 and 2010 progressed slowly, with about 3 million hectares redistributed for land reform, and tenure to189,633,000 individuals. Costs exceeded R29 billion, split between redistribution, restitution, and compensation. While redistribution made strides, land tenure security lagged, impacting economic growth. South Africa has been dealing with land challenges since 1990, and they still existing within the democratic developmental state in terms of the need to address disparities in land distribution, tenure security and ownership conflicts.Kingwill et al. (2017)

highlight that land tenure remains problematic in South Africa, particularly for farm workers and their families on privately owned land, as well as individuals residing in areas established under the Group Areas Act. As from observations from working at Human Settlement dealing with tenure related matters, many properties are still registered under deceased great grandparents, complicating the transfer of ownership due to family disputes and document accessibility issues. The sluggish pace of land reform, lack of clear vision, and misalignment with pro-poor initiatives further hinder progress. This indicates that despite efforts, the land tenure situation in South Africa remains complex and inadequately addressed.

3.2 Exploring theoretical frameworks shaping land tenure security

Understanding the different theories guiding land tenure security in South Africa offers insights into how the country manages its land ownership systems. For example, the Conservation Theory supports the idea that customary land ownership provides the most effective tenure security. It emphasizes that land holds social, political, and economic importance, especially in African countries where land plays a pivotal role in socio-economic development. The theory suggests that land titling overlooks the social dynamics within rural communities and proposes that "de facto" tenure security, rooted in land control rather than legal formalities, holds greater significance. Traditional leaders are significant in this context, as they allocate land in rural areas, however, it's worth noting that historical practices show that traditional leaders may not have always prioritized community interests. This theory tends to align well with subsistence agriculture but might face challenges in commercial farming, where economic interests and traditional leadership might conflict (Hull et al., 2018). Secondly, the Adaptation Theory is important for justice and government accountability. It aims to find a balance between South Africa's customary and statutoryland tenure systems. Its goal is to safeguard people from abuse by traditional leaders while protecting the rights of poor rural and urban individuals facing illegal evictions. This theory also addresses the issue of traditional leaders perceiving land as their possession and sometimes benefiting themselves over the community. The study by Buthelezi and Yeni (2016) highlights the need to rectify this perception. There's a distinction between formal rules, which establish legitimate land tenure systems, and informal rules based on community values, and the challenge lies in harmonizing these rules. The theory also emphasizes community involvement in formalizing property rights and tenure security, which is vital for subsidized housing. This approach encourages practical solutions that provide secure housing for those in need (Hull et al., 2018).

Thirdly, the Replacement Theory suggests replacing outdated land management methods with new approaches. It advocates for private property rights supported by clear title deeds and registrations. While this approach seems promising, critics argue that its applicability to South Africa might be limited. There's concern that it could exacerbate existing power imbalances, potentially granting more control to those already in influential positions. Historically linked to apartheid-era practices, the theory hasn't fully resolved land security issues and might not be ideal for attracting investments. Moreover, the failure of land titling can be attributed to government's lack of support for community development and poor alignment with national policies (Muchechetere and Kurwakumire, 2020). Fourthly, the Systematic Theory advocates for an organized and clear land ownership system. It emphasizes replacing customary land ownership with systematic rules to enhance economic opportunities for the poor. However, this approach acknowledges the need for flexibility, as solutions that work in developed countries might not suit developing nations like South Africa. It raises important questions about whether people are willing to use their land as collateral for loans and whether banks are ready to support them. This theory requires consideration of various factors and contexts to find the right approach, much like piecing together a puzzle that fits its unique shape (Weeda and Butt, 2018).

These theories present different avenues to tackle the issue, each with its own advantages and limitations. They help us navigate the complex puzzle of land tenure security in South Africa and more specifically Ambleton and Edendale Unit H, considering historical, political, and economic factors that shape the landscape.

4 RESEARCH METHODOLOGY

This study on land tenure securityemployed a qualitative case study design, and primary and secondary data sources were utilized. Primary data collection involved the use of open-ended interviewsadministered to key stakeholders responsible for land tenure restoration. These interviews were carefully designed to elicit

detailed responses from the participants, enabling the researchers to gain insights into their perspectives and experiences. The open-ended nature of the questions allowed the stakeholders to express their insights freely, providing a nuanced understanding of the complexities surrounding land tenure security. Secondary data sources were also utilized which included relevant literature, reports, and studies that contributed tounderstanding the background of land tenure security.

5 RESULTS AND DISCUSSSIONS

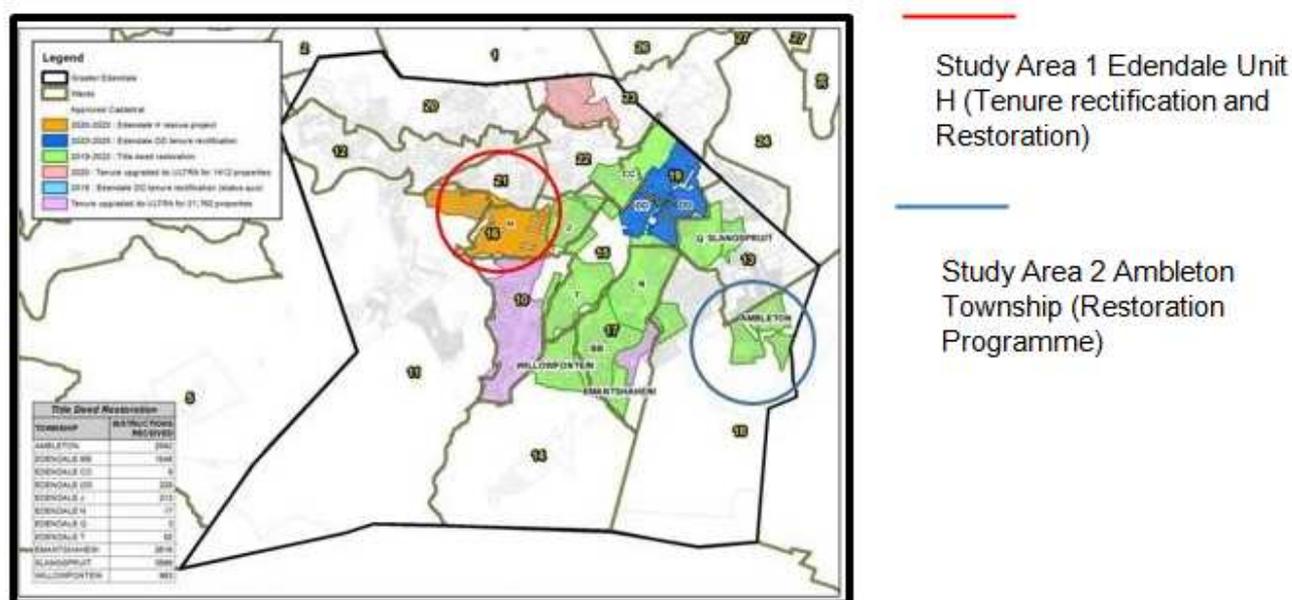
The study areas were theEdendale unit H and Ambleton Townships situated within the Msunduzi Municipality (PMB), the second largest city in the KwaZulu Natal province, located near the N3 freeway. This allows it to be connected to the global economy and to Durban and Gauteng. Msunduzi is within the uMgungundlovu District bounded by Mkhambathini on the east, Mshwathi on the north, Richmond on the south, Impendle and UMngeni on the west (Msunduzi Municipality IDP 2020/2021). The Municipality has implemented a broader scope of human settlements that will require transfers and tenure restoration to be undertaken of properties constructed pre 1994 and Post 1994 which totaled a backlog of approximately 12004 in 2016.


Figure 1 Edendale Unit H and Ambleton Study Area. Source: Author (2021).

Interviews were conducted with Msunduzi Municipal officials on land tenure security and restoration in Pietermaritzburg. During these interviews, they discussed their responsibilities, registration processes, policies and bylaws, stakeholders involved, financing, challenges, and the status of land tenure in Ambleton and Edendale Unit H. Their responses provided valuable insights into the implementation of the South African Urban Policy for land tenure security and restoration in the Edendale and Ambleton areas. These are addressed in the synopsis below:

Objective 1: To evaluate the effects of secure land tenure in the Edendale and Ambleton area within the framework of the South African Urban Policy for land tenure security and restoration.

The interviewee's responses reveal that they play a rolein assisting Edendale Township with its spatial transformation implementation that will promote the objective of tenure security and improve their livelihoods. The common goal of granting title deeds to communities aligns with the policy's emphasis on secure land tenure. This, through effective social facilitation, supported by local political structures, promotes community engagement and cooperation—a vital aspect of achieving tenure security. The capturing of beneficiaries through a GIS database with FICA information and the subsequent passing of titles to beneficiaries further contributes to secure land tenure. Additionally, the interviewee's emphasis on creating camaraderie from the outset through local political structures and introducing project participants to local communities speaks to the goal of ensuring social inclusion and equity. The social compact created to govern the project demonstrates a concerted effort to involve all stakeholders, disseminate information, and achieve meaningful participation, thereby aligning with the policy's objective.

Objective 2: To examine the effectiveness of government strategies used to secure land tenure rights in the Edendale and Ambleton area and identify challenges and opportunities for improvement.

The municipality's adoption of a range of policies, guidelines, and mechanisms reveals their comprehensive approach to secure land tenure rights. For example, the use of Immovable Property Market Valuation Guidelines and the Benchmark Report showcases their adaptability to diverse acquisition scenarios. This also ensures efficiency in resolving land invasion disputes within the study area and it aligns with the policy's focus on effective strategies. Furthermore, the use of the Land Title Adjustment Act and the Rates Exemption on Private Land Initiatives demonstrates the municipality's recognition of complex scenarios, such as deceased estates, and the financial challenges posed by invasions. The engagement of organizations and private firms, appointed through the Municipal Supply Chain process or funders furthermore reflects collaboration, technical support, and alignment with the policy's goal of effective implementation. However, the interviewee's mention of challengessuch as beneficiaries refusing to provide information, non-compliant properties, and conflicts arising from ownershipindicates areas that may require improvement.

In Ambleton, the information reveals that 60% of the area's properties have obtained title deeds, indicating a considerable level of achieved land tenure security. However, a notable 20% of this comprises individuals who did not originally qualify as beneficiaries, having acquired occupation through illegal sales or without the proper beneficiary claims. This aspect highlights the complex nature of tenure security, where legal and rightful ownership is challenged by unauthorized actions. Additionally, 10% of the properties are under regulation through existing policies, suggesting a structured approach to ensuring land tenure security.

In Edendale, specifically in unit H, the land tenure situation appears more challenging. Only 10% of properties have acquired title deeds, indicating a lower level of tenure security compared to Ambleton. One of the prominent challenges is encroachment over property boundaries, implying disputes over land ownership and utilization. This situation requires a comprehensive approach to rectification of illegal tenures, including an expropriation process and dispute resolution mechanisms. The need to amend the existing general plan further emphasizes the complexities of land tenure security in this area.

5.1 Integration of legal framework and theoretical components

The interview data from Edendale and Ambleton highlights the integration of the legal framework and theoretical components for land tenure security, showcasing a proactive approach to address historical land injustices. The municipality has effectively utilized policies, guidelines, and mechanisms such as valuation guidelines, benchmark reports, and the Land Title Adjustment Act of 1993 to secure land tenure. However, challenges persist in policy implementation, evidenced by cases of non-compliant properties and conflicts arising from unauthorized occupations.

Objective	Challenge	Consequence	Implementation Steps
Ambleton: Address Unauthorized Occupancy (20% properties)	Unauthorized occupants on subsidized properties	Insecurity of tenure, potential conflict among rightful beneficiaries	1. Identify properties with unauthorized occupants through GIS database and community engagement. 2. Conduct thorough beneficiary verification. 3. Utilize the Upgrading of Land Tenure Rights Act to formalize ownership for rightful beneficiaries.
Edendale: Define Clear Property Boundaries and Address Encroachment	Boundary disputes and encroachment	Insecurity of tenure, potential conflicts, lack of property value	1. Survey and demarcate property boundaries. 2. Implement a comprehensive expropriation process where necessary. 3. Utilize the Systematic Theory to establish organized land ownership system.
Community Involvement Address Perception of various stakeholders and Ensure Equitable Participation	Potential bias and, lack of community input	Discontent, mistrust, exclusion	1. Engage with community representatives to ensure their unbiased involvement. 2. Conduct awareness campaigns to educate occupants about their rights. 3. Implement community feedback mechanisms. 4. Utilize the Adaptation Theory to ensure justice and community protection.
Eviction Management: Ensure Fairness and Protection during Evictions	Eviction-related conflicts	Human rights violations, legal disputes	1. Implement the Prevention of Illegal Eviction Act for eviction procedures. 2. Establish a transparent process for eviction based on legitimate reasons. 3. Provide legal assistance to occupants during eviction procedures.
Monitoring and Evaluation: Continuous Oversight and Improvement	Implementation challenges, potential gaps	Incomplete outcomes, inefficiencies	1. Establish a monitoring and evaluation framework. 2. Regularly assess progress and challenges. 3. Make necessary adjustments based on evaluation results.

Considering that Ambleton and Edendale are not rural areas, and that the properties are government-subsidized housing, the integration of the legal framework and theoretical frameworks remains relevant but with a focus on urban contexts and subsidized housing challenges. In Ambleton, where 20% of properties have unauthorized occupants, the Upgrading of the Land Tenure Rights Act of 1991could be employed to

formalize ownership and address the issue of illegitimate occupancy. This would involve legal mechanisms to rectify property ownership, ensuring that rightful beneficiaries obtain secure tenure. The Prevention of Illegal Eviction from and Unlawful Occupation of Land Act, 1998 could be used to manage evictions while safeguarding occupants' rights. In Edendale, where boundary encroachment and disputes prevail, the Systematic Theory gains importance. By implementing an organized land ownership system, property boundaries can be clearly defined and legally enforced. The legal framework should incorporate the principles of this theory to enhance tenure security within subsidized housing projects. Additionally, the Adaptation Theory remains significant, emphasizing community involvement and rectifying perceptions of various stakeholders involved. In the context of subsidized housing, community engagement is vital to ensure that the needs and rights of occupants are upheld. Below is table 1 of integrating the legal framework into the Edendale Unit H and Ambleton security of tenure system:

6 CONCLUSION

In the context of South Africa, securing land tenure rights has emerged as a pivotal issue that intertwines historical legacies, current challenges, and aspirations for socio-economic progress. The complexities surrounding land tenure security are particularly evident in areas like Edendale and Ambleton, where a blend of legal measures and theoretical frameworks is being employed to tackle issues rooted in the apartheid era and post-apartheid land reforms.The findings reveal the hurdles faced by Msunduzi Municipality in its pursuit of securing land tenure rights in urban contexts. Despite notable advancements, issues like unauthorized occupancy and property boundary disputes persist, necessitating tailored approaches for resolution. The suggested recommendations for Ambleton and Edendale, such as using the Upgrading of Land Tenure Rights Act to address unauthorized occupants and applying the Systematic Theory for defining property boundaries highlights the importance of customized solutions. Additionally, effective management of evictions, inclusive community engagement, and consistent monitoring play pivotal roles in ensuring successful policy implementation.In conclusion, South Africa's journey towards achieving secure land tenure and facilitating restoration is a dynamic and intricate process. It calls for a careful equilibrium between acknowledging historical injustices, fostering economic growth, and providing legal safeguards. By weaving together legislative frameworks, theoretical insights, and community involvement, South Africa aspires to address the complexities of land tenure, stimulate all-encompassing development, and extend the benefits of secure land tenure to its populace.

The Role of Smart Cities on Smart Healthcare Management

Neda Omidlou, Hans Rüdiger Kaufmann

(MA Student Neda Omidlou, University of Applied Management Studies, Mannheim, DE, neda.omidlou@student.hdwm.org)
(Prof. Dr. Hans Rüdiger Kaufmann, University of Applied Management Studies, Mannheim, DE, hans-ruediger.kaufmann@hdwm.org)

1 ABSTRACT

This qualitative study examines the role of Smart Cities in smart healthcare management. Interviews with eight practitioners in the field were conducted and analyzed using qualitative content analysis. The findings highlight the significant contributions of Smart Cities in healthcare, such as improved data collection, analysis, and communication between providers and patients. Challenges include the integration of healthcare technologies within Smart City infrastructures and addressing privacy and security concerns. The research underscores the importance of robust digital infrastructures and collaborative efforts between public and private sectors to support the implementation of smart healthcare services in Smart Cities. Recommendations include enhancing adaptability to new technologies and improving communication between healthcare providers and patients.

Keywords: practitioners, Smart City, qualitative research, healthcare, management

2 INTRODUCTION

The rapid urban population growth, projected to reach 60% by 2030, presents significant challenges such as waste management, air pollution, and resource shortages (Pierce & Anderson, 2017). The healthcare industry also faces constraints in delivering patient-centered care due to limited resources. Smart healthcare management solutions have emerged as potential remedies, saving costs and improving patient access. Stakeholders recognize the benefits of smart healthcare systems (Sligo et al., 2017; Renukappa et al., 2022). The shift towards proactive health management is driven by an aging population and the rise of chronic illnesses (Touti & Tabish, 2017).

Smart cities rely on advanced technologies to streamline municipal operations, with various components contributing to their concept (Hancke et al., 2012; Khan, Algarni, and Quasim, 2021). The Internet of Things (IoT) enables innovative healthcare applications (Budida et al., 2017).

This research project aims to explore the role of smart cities in healthcare and address obstacles to their implementation (Mbunge et al., 2021). The paper's structure includes sections on relevant research, methodology, analysis, findings, and conclusions. The literature search involved using specific keywords in search engines and databases to gather relevant studies.

3 LITERATURE REVIEW

3.1 Smart City

The present research examines the state of smart cities and smart healthcare management. The literature search involved two stages. Initially, a comprehensive internet search was conducted using public search engines. In the second stage, keywords such as smart city, smart healthcare, digital healthcare, e-healthcare, and technological adaptation were used to search Google Scholar and ScienceDirect. Various AND/OR operators were used to ensure an adequate collection of studies.

Smart cities have gained significant attention due to the increasing global urbanization. This urbanization process brings forth economic, social, and demographic changes. Advances in hardware and software design have led to a revolution in information and communication technology (ICT), offering opportunities to address urbanization-related challenges. A smart city aims to improve the quality of life by utilizing ICT and other means, ensuring effective urban operations and services while considering economic, social, and environmental aspects (Mohanty, Choppali & Kougianos, 2016).

The growing population and rising living standards highlight the need for smart cities. It is predicted that by 2050, 70% of the world's population will live in cities, which currently consume 75% of resources, produce 80% of greenhouse gases, and threaten the ecosystem (Mohanty, Choppali & Kougianos, 2016). Smart cities

offer a natural approach to tackle the challenges associated with rapid urbanization and population expansion (Khan, Algarni & Quasim, 2021).

These cities leverage cutting-edge technologies to enhance living standards while addressing climate change concerns. Smart cities combine democratic governance, efficient resource management, ubiquitous computing, artificial intelligence, and the Internet of Things (IoT) to generate ambient intelligence. They collect and analyze urban big data to support decision-making, leveraging technologies like AI and machine learning (Xu & Geng, 2019). Technology acceptance plays a crucial role in smart city development, with two approaches: technology-driven method (TDM) and human-driven technique (HDM) (An, Kim & Kim, 2020).

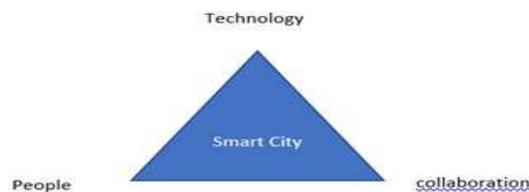
Smart cities exhibit diverse characteristics and consist of nine components: infrastructure, networks, transportation, energy, healthcare, technology, government, education, and citizens. These cities aim to achieve sustainability, quality of life, urbanization, and intelligence, addressing societal, economic, environmental, and governance aspects (Mohanty, Choppali & Kougianos, 2016). Various definitions of smart cities exist, with Holland's definition emphasizing investments in human and social capital, sustainable economic development, and wise resource management through participatory governance (El Hilali& Azougagh, 2021). Common components proposed by Pardo and Nam are widely acknowledged as critical to the success of smart city initiatives (Pardo & Taewoo, 2011 in El Hilali& Azougagh, 2021).


Fig. 1: Smart City Core Dimension. Source: (El Hilali& Azougagh, 2021)

Technology plays a crucial role in smart cities, serving as the foundation for rethinking various aspects. Smart cities leverage technologies such as the Internet of Things (IoT), Internet of Drones (IoD), and Internet of Vehicles (IoV) to develop sustainable urban environments. These technologies generate data that is analyzed to gain insights for enhancing the efficiency and effectiveness of smart societies and cities (Heidari, Navimipour & Unal, 2022).

While technology is important, it alone cannot create a smart city. The involvement of human resources is essential. Smart residents play a significant role in driving the smart city through their data, education, and creativity. Residents are at the core of city issues, and their input is crucial for finding solutions (El Hil, Ali& Azougagh, 2021)

Collaboration is a vital aspect of smart city governance. Smart governance, also known as smart collaboration, involves the interaction of all stakeholders, including the public sector (local government), private sector (industries), university (researchers and experts), and citizens, to design and implement smart city projects (El Hilali& Azougagh, 2021). People-centric smart city development requires governments to consider the perspectives and preferences of the residents when providing smart city services. Unfortunately, in many top-down implementations of smart city programs, the genuine needs of people are often overlooked (Wu, 2020; Ji et al., 2021).

To avoid investing in smart city projects that do not meet citizens' needs and expectations, city administrators must understand the preferences of local citizens for smart city services. This understanding can help inform decision-making on investment priorities and resource allocation for services that citizens genuinely need (Ji et al., 2021). Data warehouse technology is a critical component of smart city services, but issues such as data protection, privacy, and regulations need careful consideration (Lytras, Visvizi & Sarirete, 2019).

3.2 Smart Healthcare

In the context of smart healthcare, digital sensors, nanotechnology, fog computing, cloud computing, and telemedicine are examples of innovations that utilize the Internet of Things to generate and share data among stakeholders. These advancements in information management enable better data collection and create a foundation for "smart" healthcare platforms (Chakraborty et al., 2022). However, security and privacy in

smart healthcare systems must be addressed to prevent unwanted attacks and threats. Information security and privacy are crucial to protect against privacy violations and their potential impacts on individuals' lives (Chakraborty et al., 2022).

The healthcare industry faces various challenges due to rapid population growth, limited resources, and outdated healthcare systems. Traditional healthcare often struggles to meet the needs of the growing population, resulting in overburdened hospitals and occasional errors in treatment. In many rural areas, accessing adequate medical care remains an unattainable goal. To address these challenges, intelligent healthcare, enabled by modern technologies, has emerged as a solution (Mohanty, Choppali & Kougianos, 2016).

Smart healthcare is a system that actively accesses information, connects various stakeholders involved in healthcare, manages the needs of the medical ecosystem, and responds to those needs. It encompasses technologies such as wearables, the Internet of Things (IoT), and mobile internet, facilitating communication among all parties involved, ensuring appropriate care for patients, enabling informed decision-making, and optimizing resource utilization (Tian et al., 2019).

The year 2020, particularly with the COVID-19 pandemic, has accelerated the shift towards virtual healthcare encounters and the adoption of digital health technologies. These include shared electronic health records (EHR), remote visits, telehealth, wearable tech, and digital medicines powered by machine learning and artificial intelligence (Bergier et al., 2021). However, the digitalization of healthcare also presents significant challenges for patients, professionals, and healthcare systems.

Smart or modern technology-enabled healthcare allows people to receive medical assistance and services anytime and anywhere through digital devices such as laptops, tablets, or smartphones. The smart delivery management system enables services like emergency care, diagnostics, and monitoring. However, implementing smart healthcare solutions can be challenging, leading to a discrepancy between anticipated benefits and actual results. Factors such as resistance from healthcare practitioners, practical challenges, data security, and system vulnerabilities pose hurdles to successful adoption (Quasim et al., 2021; Renukappa et al., 2022).

To ensure the effective implementation of smart healthcare initiatives within healthcare provider organizations, it is important to understand and assess potential barriers. This can be done by identifying dilemmas and implementing proactive strategies to address them, thereby increasing the likelihood of successful adoption (Renukappa et al., 2022)

Smart healthcare relies on technologies like biotechnology, IoT, cloud computing, big data, 5G, microelectronics, and AI (Pan, 2019; Tian et al., 2019). These technologies enable disease monitoring, research, diagnosis, treatment, and patient management. Wearable devices, virtual assistants, information platforms, surgical robots, mixed reality, RFID, mobile platforms, big data, and machine learning all contribute to improving healthcare (Pan, 2019; Tian et al., 2019). Smart healthcare has the potential to reduce costs, enhance resource utilization, foster collaboration, accelerate telemedicine, and provide personalized medical services (Farahani, 2018; Tian et al., 2019).

Understanding the effective elements of IoT adoption in healthcare is crucial for maximizing its potential (Al-Rawshdeh et al., 2022). The concept of technology transfer, which examines users' adoption behavior in a connected context, is relevant in smart healthcare (Song et al., 2009; Pan et al., 2019). The Technology Acceptance Model (TAM) is often used to study users' intentions to adopt digital technologies in healthcare. TAM suggests that users' attitudes, influenced by perceived utility and ease of use, drive their intentions to use technology (Davis, 1989; Mangi et al., 2021).Factors such as gender, age, and experience have been found to influence user behavior and can modify the relationships between the components of TAM. For instance, in the healthcare context, research has shown that doctors are less likely than nurses to record incidents using an online information system (Chang and Hsu, 2012; Kingston et al., 2004). Another important factor influencing the acceptability of new technology is convenience, which comprises time and location utilities. Users are more likely to accept and adopt technology if it is easy to use and simplifies their lives (Kim, Mirusmonov & Lee, 2010; Lu et al., 2021).

Digital infrastructure refers to the technological foundation that enables the collection, storage, transmission, and analysis of healthcare data. It encompasses both public and private components, which play distinct roles in supporting the delivery of healthcare services (Buetow and Niederhuber, 2009).

Public digital infrastructure in smart healthcare involves technology and systems established and maintained by government or public entities. Examples include Health Information Exchanges (HIEs) that facilitate secure data exchange among healthcare providers, government-managed health databases for public health monitoring, and national health information networks that support interoperability between different healthcare systems (Sahay, T Sundararaman and Braa, 2017).

Private digital infrastructure in smart healthcare is implemented and managed by private healthcare organizations. Examples include Electronic Health Records (EHRs) that provide comprehensive patient health information within a healthcare organization, telehealth and remote monitoring systems for virtual care and remote patient monitoring, and patient portals/mobile apps for patient engagement and self-management (Ben Ahmed et al., 2021).

Novelty is another key factor in the adoption of smart healthcare devices. High levels of novelty indicate high innovativeness and commercial differentiation. These devices are associated with radical innovations, which can positively impact organizational outcomes and meet consumer demands. From an individual perspective, new smart healthcare devices with new services enhance customer attraction and better address their needs (Amara et al., 2008; Lu et al., 2021).

In the context of smart healthcare adoption, practitioners play a crucial role. However, previous research has indicated that practitioners face challenges in adjusting to new technologies and may not be fully enthusiastic about participating in digitalization efforts. Understanding practitioners' perceptions and uncovering the reasons behind their hesitancy is essential to promote successful adoption of digital technologies in healthcare (Pan et al., 2019).

Research Objective	Research Questions	Interview Questions	Sources
To investigate the smart city role in Smart Healthcare Management	RQ1: How does Smart Healthcare technologies ease the work for Health professionals and practitioners?	Q1-Do you think using innovative Technology in the Medical field such as IOT, AI… is Important? If yes Why and If No why Not? Q2-Why do you Trust on smart Technology or Why NOT? Q3- How do you think novel Technology would increase the patient's satisfaction?	Titan et al., 2019 Mohanty, Choppali and Kougianos, 2016). Al-Rawshdeh et al,2022 Renukappa et al., 2022
	RQ2: How do smart cities influence the perception of practitioners towards smart Health care?	Q1-Do you perceive SHCS as useful for the realization of the human needs of your patients? If yes why? If No why Not? Q2-Do you perceive working with smart Healthcare services to be easy or difficult? Please explain Q3-How do you find the role of smart cities in protecting the data in smart health care services? Q4- what additional success factor could you see for adaption of practitioners to the Technology? Q5- what kind of barriers or challenges do you see in adaption to the new technology?	Mangi et al., 2021 Tian et al, 2019 Ji et al., 2021 Lytras, Visvizi and Sarirete, 2019
	RQ3: How can smart cities motivate practitioners to accept and adopt the SHC technology?	Q1- Which beneficial influences of SHC technologies for practitioners and Healthcare organizations do you see? Q2- Which potentially negative aspects for practitioners do you see? Q3- How smart cities could increase the motivation of practitioners in using SHCS? (Educating? Workshop?)	Lu et al., 2021

Table 1: Research Table.

This study used a qualitative research approach with semi-structured interviews to explore roadblocks in smart healthcare adoption. Purposive and snowball sampling were employed to select participants. Interviews were conducted in English via video chat or phone from February 7th to 20th, 2023, with

durations of 20-35 minutes. Participants were practitioners in smart healthcare with knowledge of smart cities. The study aimed to understand their perceptions and challenges regarding digital technology adoption in healthcare.The collected material was analyzed using qualitative content analysis.(Kuckartz, 2018). This approach allows for rule-based analysis while preserving the originality of the data. A category system was developed, combining deductive and inductive approaches. Main categories were defined deductively, and subcategories were formed inductively based on the content. The coding process involved applying the category system to the entire material, facilitated by the use of MaxQDA analysis software.

Respondent	Job description	Interview Type	Interview length (Per minute)	date
R1	Pediatrician in Melbourne Royal children Hospital	Phone	25 Minuets	7/02/2023
R2	Dental Surgery Practitioner	Video chat	33 Minutes	9/02/2023
R3	Specialist in ophthalmology	Video chat	27 Minutes	9/02/20223
R4	General dentist at smart Dental clinic	phone	20 Minutes	12/02/2023
R5	General practitioner in Women's Mercy hospital	Video chat	30 Minutes	12/02/2023
R6	Medical Doctor and Director of Smart Moves Healthcare	Video chat	33 Minutes	13/02/2023
R7	Decision scientist in public Affair at Meta	Video chat	25 Minutes	19/02/2023
R8	Psychologist, researcher, Mental Health and well-being in modern working world	Video chat	35 Minutes	20/02/2023

Table 2: interview respondents.

4 PRESENTATION OF FINDINGS

This section presents the findings from the interviews, summarizing the extracted categories and providing supporting quotes from the interviewees.

4.1 Novel Technology

This main category explores the integration of smart healthcare with the technology-driven concept of a smart city, addressing the conflict between technology and resource utilization described in the literature review. The subcategories "inevitable role of innovative technology," "reliability," and "satisfaction" were created within this category.

4.1.1 Inevitable Role of Innovative Technology

The respondents unanimously identified the significant role of innovative technologies such as AI, IoT, robotics, precision medicine, 3-D printing, augmented reality/virtual reality, genomics, and telemedicine in healthcare delivery. For example, one respondent (R4) stated, "The entry of technology into the medical field is not only important but also necessary." Another respondent (R6) mentioned, "This kind of technology can help healthcare services recognize diseases with fewer failures compared to humans." Additionally, several respondents (R1, R6, R7, R8) highlighted the benefits of cost savings and efficiency. Furthermore, one respondent (R5) emphasized the critical role of technology in early illness detection, which can be a life-saving factor. The respondents also mentioned the use of technology in education to enhance learning quality and reduce the trial-and-error approach (R8).

4.1.2 Reliability

Based on the eight interviews, there is a low level of trust in innovative technology among treatment professionals. Only one respondent (R3) expressed unconditional trust, while others mentioned trusting smart technology for its efficiency (R7, R3). However, factors like lack of conclusive results, testing, assurance, technological limitations, and subject sensitivity make it difficult for practitioners to fully trust (R1, R2, R4, R5, R6, R7, R8). Respondents emphasized the need for experimental stages, patient safety, and human participation in data analysis (R6, R1, R5). Concerns about safety and security were raised,

contributing to mistrust among treatment personnel (R4, R5, R6, R7). One respondent stressed the importance of privacy in protecting patients' lives (R5).

4.1.3 Satisfaction

Patient satisfaction is crucial for evaluating care quality, and all eight respondents stressed the importance of smart healthcare technology in improving it. Time and cost savings were mentioned as significant benefits, particularly for the elderly and people with disabilities (R1, R7). Respondents also noted how revolutionary technology can enhance the patient experience, reducing discomfort and increasing satisfaction (R4, R6). The use of digital systems for data collection and storage was highlighted for improving efficiency and medical record safety (R7, R6). Furthermore, respondents recognized the impact of practitioners and treatment workers on patient care and satisfaction (R6).

4.2 Treatment staff perception

The perception of treatment staff regarding smart healthcare is influenced by smart cities, as indicated in the literature. This section focuses on the categories "human needs," "easiness and severity," "data protection/information privacy," "success factors and challenging aspects," and "adaptation motivation factors" to explore how smart cities impact the perspective of treatment staff.

4.2.1 Human needs

Patients' needs vary depending on the severity of their condition and their stage in the treatment process. The importance of addressing patients' psychological, physical, and social needs, and their interplay within larger systems such as family and society, is emphasized (R6). Five out of eight respondents agree that smart healthcare systems are effective in meeting patients' human needs (R1, R4, R6, R7, R8). Respondent 2 suggests that practitioners should provide necessary information and explain the benefits and ease of access to improve patients' understanding and positive perception of novel technologies and digitalized services. However, respondents also acknowledge that human contact cannot be replaced by smart technology (R3).

4.2.2 Easiness and severity

This section examines whether smart technology is easy for practitioners to use. All eight respondents agree that dealing with new technology can be initially difficult and challenging. However, with training, learning, and gaining expertise in innovative technology, practitioners can become more confident in using it. R6 mentions that teaching and learning new technology may be challenging at first, but it becomes easier over time. Respondents R5 and R8 highlight that persuading practitioners, especially younger ones, can be difficult due to concerns about privacy and security. Ethical and regulatory issues are also mentioned as factors that may hinder the adoption of innovative technology by practitioners (R8).

The findings indicate that while smart healthcare can meet patients' human needs and improve accessibility, there are challenges related to ease of use, privacy and security concerns, and regulatory and ethical considerations that need to be addressed to ensure the successful adoption and acceptance of smart technology by treatment staff.

4.2.3 Data Protection/Information Privacy:

Respondents emphasized the significance of data security and confidentiality in smart cities. They stressed the need for laws and regulations to protect data and information. The integration of multiple organizations in a smart city was seen as a way to enhance the healthcare system. Smart access controls, transparent regulations, and secure data platforms were identified as essential for preserving data, reducing costs, and engaging patients effectively.

4.2.4 Success Factors and Challenging Aspects:

Thorough training and understanding of new technology were seen as important for practitioners' trust and confidence. Easier communication, remote education, and therapy were mentioned as success factors. Cost, potential risks to practitioners, and the difficulty of learning new technology were identified as challenges.Sustainability was also highlighted as a factor for success

812

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4.3 Adaption Motivation Factors:

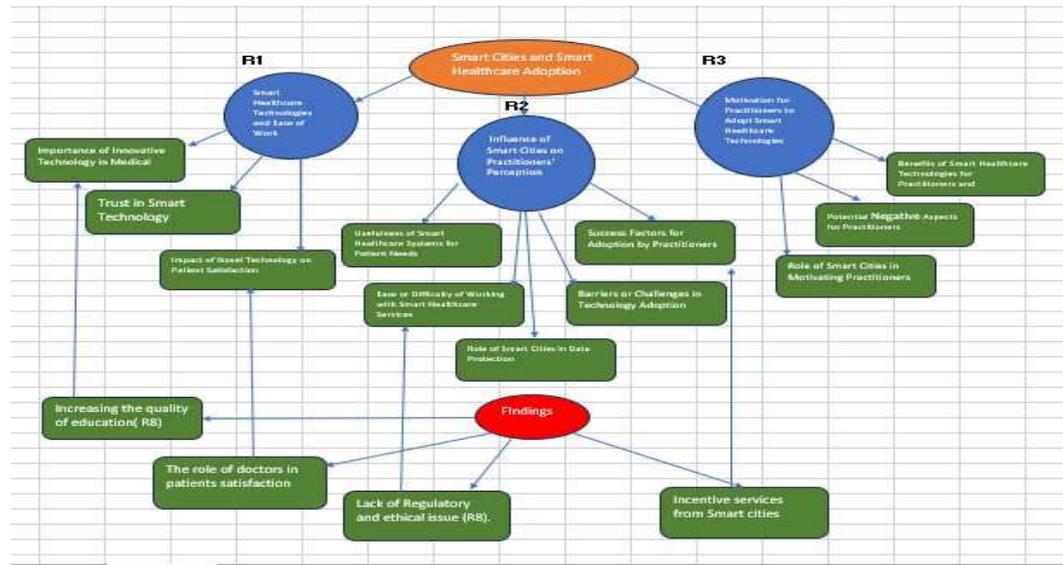
To increase practitioners' motivation to adopt new technologies, smart cities should provide appropriate infrastructure and organize seminars and workshops to enhance knowledge and trust. The positive influences of new technology include reducing the risk of failure, improving access to reliable data, and increasing practitioners' knowledge. Negative aspects include data security concerns and communication breakdown. The following figure 3 depicts the main findings.


Fig. 2: Final conceptualization

5 DISCUSSION AND PRACTICAL IMPLEMENTATION:

The study highlights the significance of practitioners' perception and the role of technology in smart healthcare within smart cities (Heidari, Navimipour & Unal, 2022). While technology offers various benefits to practitioners, reservations exist regarding its limitations and the potential displacement of human roles in healthcare (R1, R2, R4, R5, R6, R7, R8). Balancing technological advancements with the essential role of human intervention is crucial. Patient satisfaction and positive experiences are also important outcomes, with patients benefiting from online services and improved treatment processes (R3). The attitude of users, influenced by anticipated benefits and ease of use, plays a significant role (Fletcher-Brown, 2020). Addressing data protection, information security concerns, and building trust are essential (R6, R8). Successful adoption requires training, improved communication, straightforward acquisition processes, post-sales support, and addressing cost-related challenges (R3, R8). The integration of technology in healthcare practices should consider practitioners' perception, human factors, patient-centric considerations, user attitudes, trust-building measures, data protection, and cost considerations (Heidari, Navimipour & Unal, 2022).

6 LIMITATION AND CONCLUSION

The study focuses on understanding how practitioners perceive smart healthcare technology within the context of smart cities. The findings emphasize the significant role of technology in advancing healthcare practices. It is evident that technology plays a crucial role in reducing human errors, aiding in various medical fields, enabling early disease diagnosis, and enhancing educational understanding. However, the study also reveals that practitioners have certain concerns and limited trust when it comes to adopting new technology. They perceive limitations and question the role of humans in smart healthcare. Factors such as user attitude, professional benefits, and ease of use influence practitioners' acceptance and adaptation to technology. On the other hand, patient experiences with smart healthcare technology are generally positive. The use of online services, diverse applications, and innovative gadgets can save time and money for patients. Patients with special needs also find smart healthcare technology to be satisfying, as it reduces discomfort and improves treatment experiences compared to traditional methods. The study highlights the importance of addressing human needs and providing patients with knowledge about revolutionary technologies to positively influence their expectations. The relationship between practitioners and patients is

considered a crucial aspect in shaping perceptions and acceptance of technology. Factors such as training, data protection, and ethical regulations are identified as key elements in building trust and confidence among practitioners. Pre-introduction training and continuous learning are identified as success factors in technology adoption. Additionally, smart cities need to invest in government regulations and ethical guidelines to ensure practitioners' confidence in data protection and information security. Cost-related challenges are recognized as barriers to technology adoption, especially in the early stages. There is also a fear among practitioners that technology might replace human involvement in healthcare processes. However, the study highlights the positive aspects, such as reduced failure rates among practitioners and improved access to integrated and accurate data, leading to time and cost savings.

In summary, the study emphasizes the central role of technology in advancing smart healthcare within smart cities. While practitioners have concerns and limited trust, patients' experiences with smart healthcare technology are positive. Addressing human needs, providing knowledge, ensuring data protection, and offering training opportunities are essential in bridging the perception gap and facilitating technology adoption in the healthcare industry.private and public infrastructure both play critical roles in the adaptation of practitioners to smart healthcare. Private sector investment drives innovation, provides training and support, and offers advanced technologies, while the public sector establishes policies, provides funding and incentives, develops infrastructure, and promotes research and knowledge dissemination. Together, these efforts create an environment conducive to practitioners' adoption and effective utilization of smart healthcare technologies.

1 ABSTRACT

Urban climatic analyses and planning recommendation maps are becoming increasingly important in the climate-sensitive planning of cities. Urban climatic maps typically include two main components (Ren et al. 2012): an urban climatic analysis map and an urban climatic planning recommendation map. Given the urgent need for action due to climatic changes in urban areas, planning recommendation maps are essential for introducing and locating measures that effectively increase the adaptive capacity of cities, thus increasing the resilience of urban areas and their inhabitants (Baumüller 2015). The first urban climatic maps were produced in Germany in the 1970s and currently they are used worldwide.

The aim of this contribution is to develop a theoretical and methodological framework for the development of urban climatic planning recommendation maps. The main focus is on the review of existing theories and methods that serves as a roadmap for developing these maps. The examples show that these analyses usually consist of four steps or four areas of processing: (i) an urban climatic analysis, (ii) additional in-depth analyses, (iii) the development and location of measures and (iv) the consolidation in a planning information map (Ren et al. 2011).

Within the urban climatic analysis two main approaches are common: pure static GIS (Geographic Information System) derived maps or mainly meteorologically focused maps including the calculation of regional climate simulations (and hybrid forms thereof). Supplementary in-depth analyses are often carried out, such as the intersection with socio-demographic data to identify areas that are particularly vulnerable from a social point of view, or analyses based on specific urban or spatial configurations (Reisinger et al. 2020). In the third step of the process, measures are usually developed at different levels or for different sectors of urban development. As a final step, the results are summarised in planning recommendation maps and the measures are spatially located (Baumüller 2015). Each of these individual steps has been intensively researched in the last few years; the synopsis or bringing together of these numerous research projects and approaches is a gap that this contribution seeks to fill.

The contribution demonstrates available approaches, methods and tools necessary to translate scientific climatic knowledge into urban planning recommendation maps, considering that the analyses for a particular city or municipality are strongly limited in reproducibility to other citys, even in the same country. Based on this, a theoretical and methodological framework for the development of urban climatic planning recommendation maps is elaborated that enables the creation of these.

2 INTRODUCTION

2.1 Changes in climate signals and impacts on urban development

Urban areas are particularly affected by climate change: the ever-progressing urban development in combination with the increased occurrence of extreme weather events has resulted in a growing number of hot days and warm nights that result in increasing heat stress. In addition, more frequent and intense heavy rain events are expected (IPCC 2021).

Urban climatic maps therefore represent an important link for inter- and transdisciplinary communication and collaboration between urban climatologists, urban planners as well as decision makers and administration employees. They are as well becoming an increasingly important platform to inform planning decisions in the realm of legally binding spatial planning. There are many different approaches to cover and analyse hazards, exposure and vulnerability (see figure 1).

2.2 Hazards, exposure and vulnerability

People, ecosystems and cities and their infrastructures are differently affected or vulnerable to the impacts of climate change. Vulnerability is defined by susceptibility or sensitivity as well as response and adaptation capacity. It is a sub-component and determinant of risk together with the exposure and hazard components. Risks in the context of climate change can "only develop through linkages with exposed and vulnerable societies, cities, infrastructures or ecosystems" (Birkmann et al. 2017, 270). Since adaptive capacity is often difficult to determine and sensitivity is considered by many scientists to be the driving component of vulnerability, in practice, instead of vulnerability analyses, affectedness or climate impact analyses are often carried out (Kemper 2016).

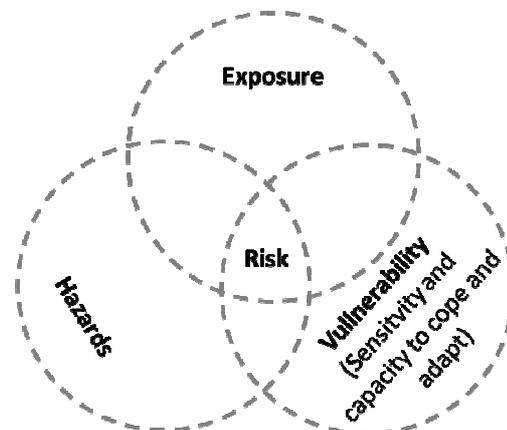
Before the planning recommendation maps are produced, further analyses are often carried out to identify particularly affected areas or vulnerable population groups. In the preparation of planning recommendation maps, various climatic, land use or social data are usually included and combined with local planning or expert knowledge.


Figure 1: Incorporate hazards, exposure and vulnerability to determine risk as a basis for urban climatic analysis (IPCC 2014, Estoque et al. 2023).

2.3 Urban climate analyses and their use in urban planning

Urban climatic maps are becoming increasingly important in the everyday planning of cities. Urban climatic maps are a climatic information and evaluation instrument to inform planners and policymakers about (changing) urban climatic-environmental conditions and to assist them in urban climate adaptation and mitigation planning (Ren et al. 2012). In order to assist planners and policymakers, the urban climatic knowledge must be translated into a planning language that is actionable in regard to climate change policy (Alcoforado 2006; Alcoforado et al. 2009).

German researchers first developed the concept of urban climatic mapping in the 1970s Stuttgart (Matzarakis 2005) to mitigate air pollution during reduced airflow conditions and to apply climatic knowledge to the planning realm (Ren 2015). In the context of air pollution mitigation programs, urban areas have been identified for planning purposes according to their different climatic functions and characteristics. Based on land use information and its climatic characteristics, the different urban climatic conditions were defined as climatopes - the spatial units of the urban climatic maps (Ren 2015, see chapter 4.1.1.). In the 1990s several cities in Germany (e.g. Stuttgart, Berlin) continued to conduct climatic analyses, resulting in a series of climatic atlases that informed urban planning decisions aiming at improving the exchange of air in these urban areas (ibid). In 1993 the "VDI 3787: Part 1" was published to guide the urban climatic analysis practice in Germany (ibid). This national guideline defines symbols and representations used in UC-Map studies and recommended a rather vague method for developing urban climatic maps with the aim to create a

standard for their application (VDI 1997). Since its publication, this guideline has been used as a reference for UC-Mapping and has been adopted and developed by many countries worldwide, with Asian research teams from Japan and China in particular driving the process (Ren 2015; Jégou et al. 2022).

In Austria and Germany, many urban climatic analysis maps are based on this VDI directive, but mostly the maps are tailored to the special needs of a city and thus also differ a lot. Internationally, there are some projects which try to methodically standardise the approach such as the „Urban Climatic Map System" for Dutch spatial planning (Ren et al. 2012) which also mainly follows the German VDI directive or the "Heat Environment Map" from the Tokyo Metropolitan Government (Japan) which indicates 10 types of heat environments (Tokyo Metropolitan Government, 2005).

More and more European cities are commissioning urban climatic analyses or participating in research projects on climate change adaptation in order to generate relevant information to be able to influence their urban development towards more climate resilient structures. However, there is a lack of a strict and applicable methodology for conducting urban climatic maps both for the VDI based and the simulation based climatic analyses as well as for the development of urban climatic planning recommendation maps.

The aim of this contribution is, therefore, to develop a theoretical and methodological framework for the development of urban climatic planning recommendation maps, in order to better guide the conduction of the different steps of urban climate mapping. The main focus is on the review of existing theories and methods that serve as a roadmap for developing these maps that usually consist of four steps or four areas of processing: (i) an urban climatic analysis, (ii) additional in-depth analyses, (iii) the development and location of measures and (iv) the consolidation in a planning recommendation map (Ren et al. 2011).

3 MATERIAL AND METHOD

Since the development of urban climatic analsysis requires a thematic intersection of landscape and urban planning disciplines, meteorology and urban climate modelling and, last but not least, the involvement of planning practice and local decision-makers, an inter- and transdisciplinary approach was chosen.

The contribution is embedded in a "climate proofing framework" (Schindelegger et al. 2022). Climate proofing examines the question of adequate planning responses to climate change-related impacts on planning projects. In addition to the development and implementation of adaptation measures, effective climate change adaptation also requires an analysis and continuous improvement of the (political) decision-making basis, the capacities and competences of planning authorities, and the analysis and planning processes themselves. Following this understanding, "climate proofing" for the (Austrian) spatial planning context comprises three fields of action: (A) the overarching framework conditions and policy objectives, (B) the analysis and strengthening of capacities and competences of planning authorities, and (C) the concrete implementation of climate change adaptation through the integration of relevant steps into planning instruments and planning processes at regional and municipal level (see figure 2).

The contribution focuses on the analysis or improvement of the analysis and planning processes (Part C) by developing a theoretical and methodological concept for the development and implementation of urban climatic analysis aiming at planning recommendation maps as a basis for the adaptation of spatial planning and developments to the challenges of climate change.

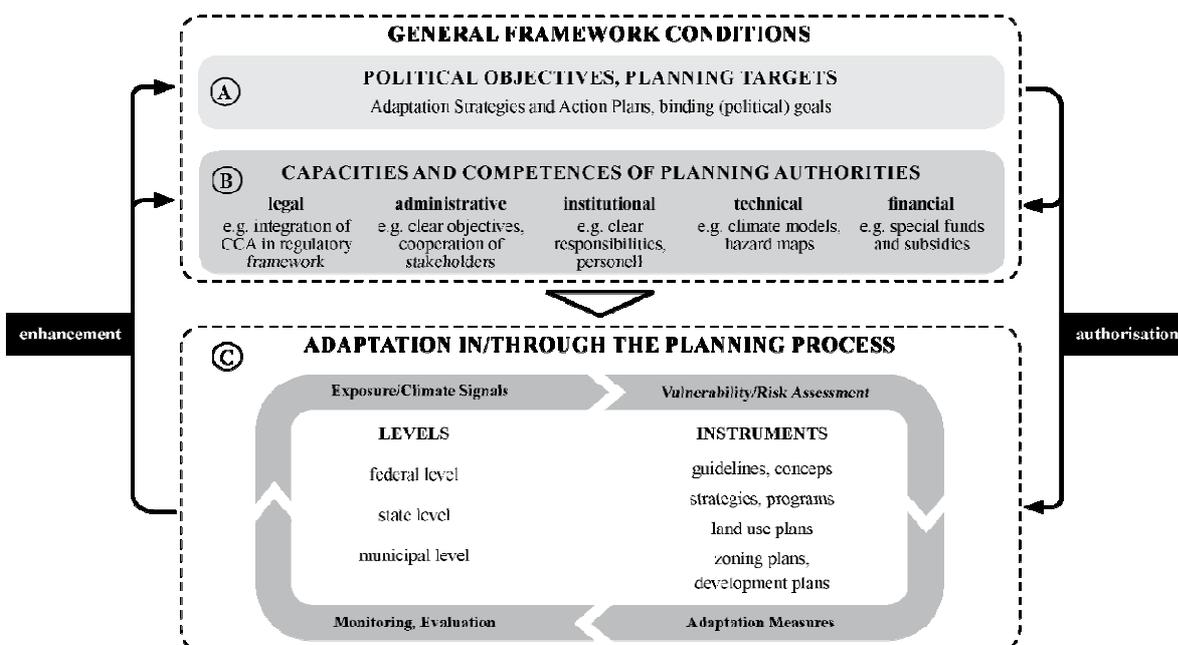
The paper is based on an extensive literature review and analysis of the different methods and approaches to urban climatic analysis as well as the necessary steps described in the literature and the instruments and methods used. In addition, numerous practical examples (mainly from Austria, Germany and Switzerland) were analysed and compared to complement the (partly missing) scientific and theoretical approaches.


Figure 2: Climate proofing framework © Reinwald, F., Schindelegger, A. & Weichselbaumer, R.; published in: Schindelegger et al. 2021, 2022.

4 RESULTS – METHODS AND STEPS TO DEVELOP URBAN CLIMATIC PLANNING RECOMMENDATION MAPS

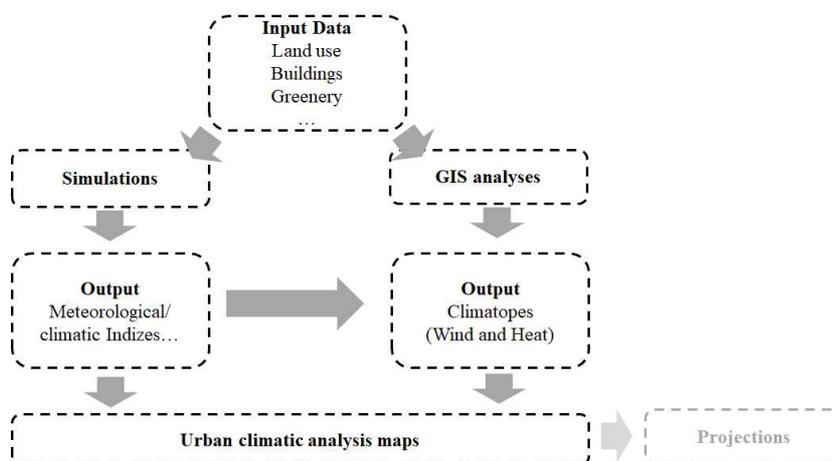
Urban climatic maps usually contain two main components (Ren et al. 2012): an urban climatic analysis map and an urban climatic planning recommendation map. Given the urgent need for action due to climatic changes in urban areas, planning recommendation maps are essential for introducing and locating measures that effectively increase the adaptive capacity of cities and thus increase the resilience of urban areas and their inhabitants (Baumüller, 2015). However, scientific disciplines usually develop approaches for their sectors. For urban climatic mapping, this means that the urban climate analysis maps were mostly produced by climatologists and climate impact researchers. The complementary analyses are mostly carried out by planning experts, while the development of measures is dominated by a collaboration between practitioners and researchers, and the planning recommendation maps combine these findings and also incorporate local knowledge (Ren et al., 2011). Thus, not only an interdisciplinary but also a transdisciplinary approach is needed to combine climate and planning science with the knowledge of practitioners and local administrations.


Figure 3: Climate hazard analysis using either Simulations or GIS analyses

4.1 Climate hazard analysis – urban climatic analysis

The urban climatic analysis maps provide a platform for climatic information and evaluation of cities. There are two main climatic aspects examined in urban climatic analysis maps: i) the thermal environment (UHI

and heat stress, urban bioclimatic variations) and ii) the wind environment (ventilation zones, local air circulation patterns, existing and potential air paths and the barrier effects by buildings or plants). A third aspect, iii) air pollution, is often additionally included in the analysis (Ren et al. 2011).

Within urban climatic analyses two main approaches are common: pure static GIS (Geographic Information System) derived maps or mainly meteorologically focused maps including the calculation of urban climate simulations (and hybrid forms thereof) (see figure 3). This fundamental difference in the approach affects all further steps of the analysis.

4.1.1 GIS-based analysis and Climatopes

Urban climate analysis based on GIS mapping consists of several input layers typically based on information on land use, topography, vegetation and wind (Ren 2015). Especially in the early days of urban climate map studies the types of climatopes were mainly classified by land use (VDI 1997). Climatopes are the main features of GIS-based analysis maps. Climatopes are non-parcel-specific spatial units that represent areas with similar climatic characteristics which are mainly distinguished by daily thermal variations, the surface structure and vertical roughness, the topographic situation or exposure as well as the type of land use and vegetation cover (Baumüller 2015). Their spatial scales commonly range from several tens to hundreds of metres (Ren et al. 2011). According to the VDI 3787-Part 1 there are nine climatope classes that are named after the dominant land-use type (Water body Climatope, Forest Climatope, Open land Climatope, Urban green space Climatope, Garden city Climatope, Suburban Climatope, City Climatope, Inner City Climatope, Commercial/Industry Climatope, etc.) (VDI 1997). However, climatopes are based on expert knowledge of local topography and climatology and specialized to particular urban areas. Consequently, each city exhibits a unique set of Climatopes meaning that intercity comparisons or generalizations are of limited use (Stewart & Oke 2015). In the first step, Climatopes are derived from the respective georeferenced and land-use data and are classified and allocated. The data basis should be latest digital, geo-referenced data:

- land use data
- topography (e.g. digital elevation model and information on slopes),
- data of building layer (including building height, densityand degree of sealing)
- data of vegetation type and structure
- aereal images with high spatial resolution (VDI 1997).

These data feed various GIS layers – e.g. building volume, ventilation paths, green areas, slopes, etc. – where climatopes can be delineated. This classification of climatopes should then be further improved with information on the distribution of basic climatic parameters (e.g. air temperature, humidity, wind speed and direction, radiation), cold air drainage and thermally induced wind systems, as well as information on human-biometeorological conditions (VDI 1997).

4.1.2 Urban climate simulations

Numerical urban climate models have been developed to analyse physical atmospheric processes within the urban boundary layer (e.g. Sievers et al. 2016; Maronga et al. 2020). They simulate radiation balance, energy exchange and wind flow by taking into account land use and land cover information, urban structures, surface characteristics and vegetation. Different meteorological parameters are calculated to analyse urban climatic conditions and urban heat island (UHI) effect. Combining the results with regional climate models, the models can be further used to provide long-term climate projections on urban scale, considering different greenhouse gas emission scenarios (Früh et al., 2011; Oswald et al., 2020).

In recent years, urban climate models have been extensively used to support urban planning decisions and climate adaptation strategies by providing city-specific climatic information. Covering a broad range of spatial and temporal scales, different types of models are applied to address different problems and to respond to local challenges. While urban climate models are usually applied on city scale and thus, on a level of strategic urban planning, micro-scale models have been designed to simulate the effects of (single) buildings and vegetation on their environment on a microscale, thus considering detailed building geometry and type, surface materials and vegetation properties (e.g. Bruse & Fleer 1998; Lindberg et al. 2008). Due to

their higher resolution and enhanced computational requirements, their application is usually limited to district or block level and they are often used within the framework of individual construction projects.

Within the scope of urban climatic analyses, urban climate simulations help to identify regions potentially affected by heat hazards by analysing the spatial distribution of surface or near-surface air temperature or climate indices like the mean annual number of summer days or hot days. As such, they can serve as a basis for generating urban climate analysis maps, covering the thermal component of the analysis. Model results can be further used to derive biometeorological parameters that characterise human thermal comfort like the Perceived Temperature (PT) (Jendritzky 1979), Physiological Equivalent Temperature (PET) (Höppe 1999) or the Universal Thermal Climate Index (UTCI) (Jendritzky 2012). In addition to the thermal component, cold air drainage models are applied to complement the analysis by providing information about important ventilation and cold air pathways (e.g. Sievers, 2005).

4.2 Exposure and vulnerability – in depth social and spatial analysis

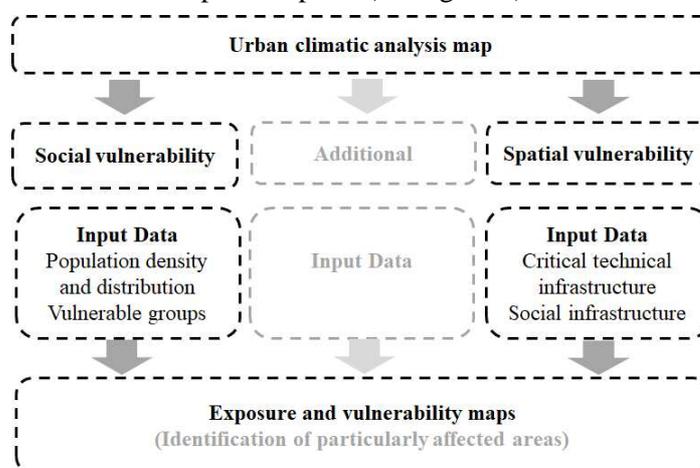
People, ecosystems as well as cities and their infrastructures are affected or vulnerable to the impacts of climate change in different ways. For the analysis of exposure and vulnerability, in-depth analyses are carried out according to both social and spatial aspects (see figure 4).


Figure 4: Exposure and vulnerability – in depth social and spatial analysis.

4.2.1 Social vulnerability

The changing temperatures and other climate signals have a strong influence on the human bioclimate. Factors like heat, cold and air humidity strongly influence people's well-being and health. It is therefore important to identify social vulnerability by analysing for example population density or the differing distribution of the most vulnerable groups. The most common demographic indicator groups are elderly residents over 65 years of age and infants and young children. Other socio-economic aspects – such as pre-existing health conditions, ethnicity, gender and income – are rarely considered, even though they influence ones vulnerability to heat and other climate signals as well (APCC 2018; BMSGPK 2021).

4.2.2 Spatial vulnerabillity

For a spatial vulnerability analysis, sensitive facilities such as hospitals or childcare centres can be presented in combination with climatic indicators such as, for example, the average number of hot days. The sensitive infrastructure facilities include facilities that are particularly relevant for the previously mentioned age groups that are especially affected (children, elderly people) as well as other vulnerable groups such as people with care needs (e.g. due to pre-existing health-conditions).

4.3 Vulnerability and adaptive capacity – measures and effects

There are numerous measures that support urban adaptation to climate change. Climate resilient measures can be implemented in existing structures, driven by factors such as heat hotspots or the need for renovations. They can also be incorporated into the development of new climate-adapted buildings and infrastructure. These measures can be categorized into the following groups (Jiricka-Pürrer et al. 2021):

- Strategic measures, such as preserving ventilation pathways and increasing albedo.

- Green infrastructure, including initiatives like tree plantations.
- Blue infrastructure, encompassing approaches like the sponge city principle for roadside trees.
- Technical measures, such as the use of permeable asphalt and water-bound surfaces.

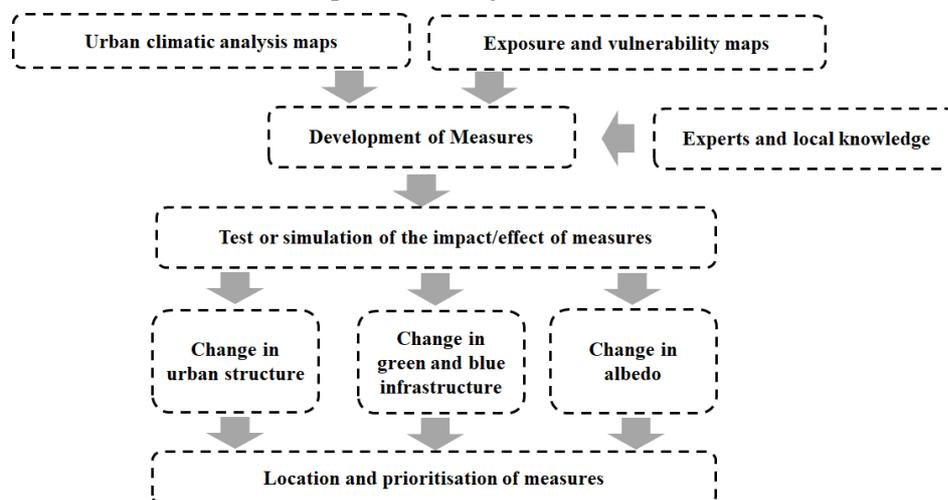
Based on the previous analyses, measures are developed and discussed with local stakeholders. Simulations can then be used to test the impact of the various measures. In this way, their efficiency is assessed and the different locations and their effects are captured (see figure 5).


Figure 5: Vulnerability and adaptive capacity – measures and effects

4.3.1 Development of measures

The overarching goal of these measures is to combat heat islands by promoting shaded and green surfaces, reduce the impact of drought through improved local water management and the sponge city principle for roadside trees, and mitigate the consequences of heavy rainfall events through retention spaces like sponge city structures. Changes of the urban structure can also help, for example, to improve ventilation or to make better use of the shading provided by the buildings (MA 22, 2015).

It is crucial for public administrations and businesses to possess climate competence. This includes acquiring the necessary knowledge and skills to implement climate-responsive measures and to prioritise their implementation based on climate fact-based information – a crucial step for which urban climate maps are an aid.

4.3.2 Sensitivity analyses

Not all adaptation measures can be implemented everywhere in a city. Depending on the location or urban typology, only certain measures are suitable or their effectiveness varies.

Urban climate models have been used to evaluate the cooling efficiency of climate adaptation measures by carrying out sensitivity simulations. The potential of different adaptation measures (e.g. implementation of green and blue infrastructure, unsealing or a change in albedo) to reduce thermal heat load can be assessed by the model and the results can be used to support urban planning and climate adaptation strategies (e.g. Oswald et. al., 2020, Zuvela-Aloise et al., 2017).

Depending on the urban context, type of application and considering the model's resolution and planning level, adaptation measures are evaluated on a city scale, as well as on a district or block scale. The measure's efficiency can be expressed in terms of a reduction in local air temperature or heat-related climate indices in comparison to the current situation. Sensitivity analyses have shown that adaptation measures on urban scale are most effective when applied extensively and that a combination of different measures can lead to strong cooling effects (Zuvela-Aloise et al., 2016).

Moreover, sensitivity analyses using urban climate simulations are performed to evaluate impacts of densification and urban sprawl on urban heat load, based on future urbanization scenarios. Depending on the type of model and planning level, the effects of single buildings or entire new development areas on urban temperature can be assessed (e.g. Reinwald et al., 2021).

4.4 Planning recommendations and planning recommendation maps – guidance to reduce the risk

Deriving planning recommendations from the urban climate analysis map is a crucial step to assist planners, policy-makers and decision-makers towards a stronger consideration of climatic criteria. As such, a map with recommendations for planning should contain an integrated assessment of the materials represented in the urban climatic planning recommendations map (Baumüller 2015).

In the final step of creating the planning recommendation maps, the results of the previous analyses are combined and the measures are explicitly spatially located. These maps are an important basis for both strategic planning and zoning and development planning at municipal and regional level.

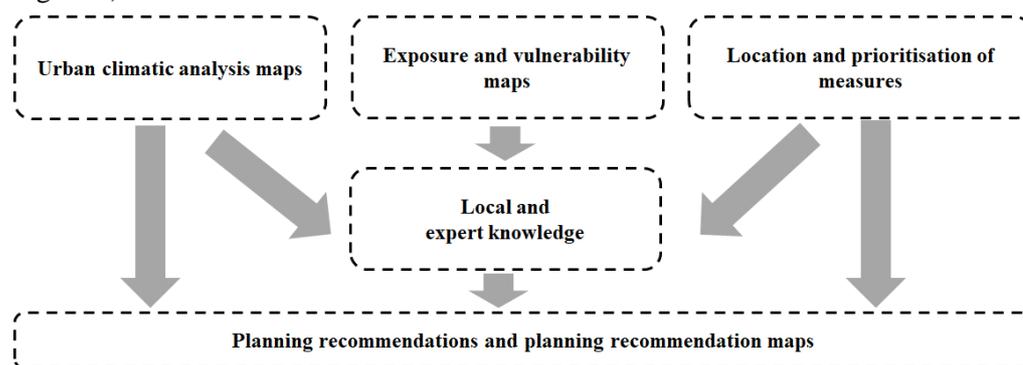
Planning recommendation maps summarise the analyses obtained and usually combine them with local knowledge on the current situation and possible adaptation options for different urban structures to a varying degree (see figure 6).


Figure 6: Planning recommendations and planning recommendation maps – guidance to reduce the risk

4.4.1 Combining analysis and local knowledge

Based on the urban climatic analysis maps, an integrated assessment of current climatic spatial characteristics needs to be carried out in order to identify climate-sensitive urban areas that require strategic attention and development. Therefore, at this stage, urban climatologists, planners and policy makers need to work closely together to combine their different perspectives on local knowledge. Different cities have different urban planning systems and climatic challenges, which means that different aspects need to be emphasised when it comes to deriving planning recommendations (Ren et al 2010).

Furthermore, a decision tree can play a crucial role in assisting administrations by providing important guidance for the selection and evaluation of the effectiveness of measures.

4.4.2 Planning recommendation maps

The urban climatic planning recommendation map is an integrated, planning-action-oriented assessment base that can be applied at the regional, city or neighborhood level (Ren et al. 2011). Planning recommendation maps provide general planning advices for sub-areas of the city in order to improve the urban climate in those areas through urban and landscape planning.

Planning recommendation maps usually contain information on two central topics: adaptation measures depending on the thermal load and the urban structure as well as on securing the production of cold air and cold air conduction. A distinction is usually made between "green" areas or areas that have an urban climatic function (cold air production and conduction) and those in which urban overheating occurs – to varying degrees. Recent urban climatic planning recommendation map examples from Germany usually distinguish between three main spatial assessment units:

- Settlement area
- Green and open spaces
- Public roads, paths and squares (e.g. the urban climatic planning recommendation map from Berlin 2015, or Leipzig 2019).

Often, particularly "sensitive" areas are designated where there is a special need for action due to the presence of vulnerable infrastructure or vulnerable populations.

Planning recommendation maps introduce and locate measures that enable urban areas to strengthen their adaptive capacity, respond to a changing climate and thus increase the resilience of cities to adverse climate impacts (VDI 1997).

5 CONCLUSION – THEORETICAL AND METHODOLOGICAL FRAMEWORK FOR THE DEVELOPMENT OF URBAN CLIMATIC PLANNING RECOMMENDATION MAPS

The analysis and descriptions showed that four steps or four areas of processing to develop a sophisticated urban climatic recommendation map are used and necessary (see figure 7):

Step 1: An urban climate hazard analysis is the first step. Two main approaches are visible: GIS-based analysis which result in climatopes which separate a city into different affected areas and urban climate simulations which deliver different climatic indicators to show the different affectedness of urban areas

Step 2: Additional exposure and vulnerability analysis are carried out to analyse in depth the effects on different population groups and their distribution in a city as well as the analysis of exposure and vulnerability regarding infrastructure.

Step 3: Based on the exposure and vulnerability, measures are developed and in many cases their effects are analysed using simulations to verify the adaptive capacities.

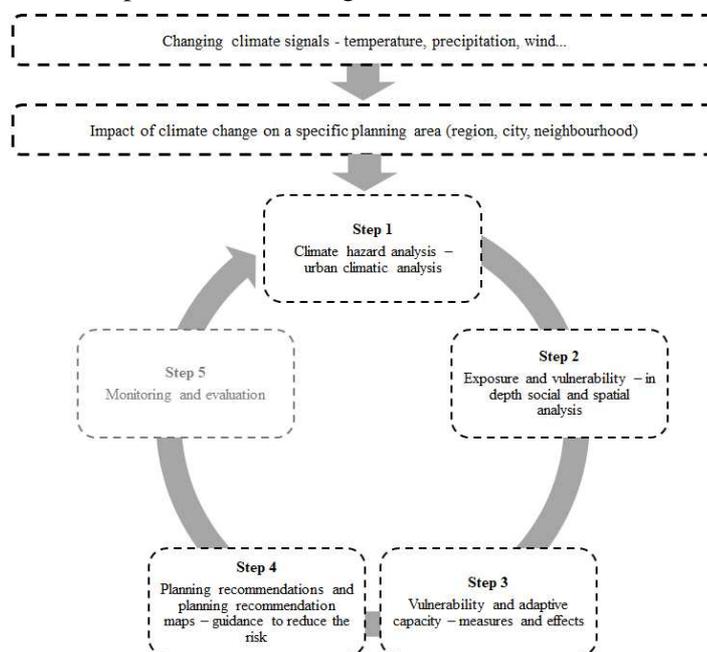
Step 4: As a last step, planning recommendation are explicitly spatially located and planning recommendation maps are developed which build a guidance to reduce the risk.


Figure 7: Theoretical and methodological framework for the development of urban climatic planning recommendation maps

The total spectrum of urban climatic analysis maps ranges from purely static GIS (Geographic Information System) derived maps to mainly meteorological maps including urban climate simulations. A thorough analysis that supports subsequent climate-responsive urban planning processes requires the combination of static data and urban climate simulation results, potentially complemented by microclimate simulation results. Therefore, a synopsis of GIS-based and simulation-based analyses is necessary. Alternative approaches to urban climatic maps include evaluation of individual parameters from various data sources and the derivation of conclusions:

- Surface temperature from earth observation data (e.g., Landsat-8) may provide information about overheated areas in a city.

- Vegetation data offers information about cold air production areas.

- In-situ measurements can provide point data of several parameters of interest for a required time range or selected days. For further verification of urban climate analysis maps, these measurements are often used in a complementary way.

- Calculation of sun hours in a 3D city model allows to draw conclusions about thermal comfort.

While each of the above-mentioned alternatives (and others) provide information on individual aspects, the holistic synopsis of urban climatic maps provides a more complete picture and allows to explain the interrelationship and impacts of various parameters.

An in-depth analysis of exposure and vulnerability is only carried out in a few projects. However, these analyses help to identify particularly affected groups and areas. This can also be used to better target or prioritise measures for adaptation and/or mitigation – both critically needed in urban planning to react to urban climatic changes as well as demographic changes.

The preparation of catalogues of measures is a common step in the preparation of planning recomendation maps. Whereas few examples and projects explicitly test the impact of these measures to demonstrate the adaptive capacity. However, this is a particularly important step, as the measures can have different effects depending on the urban fabric and the mesoclimatic conditions.

In the area of urban climatic planning recommendation maps, the research gap is even larger and the practice is far less extensive than in the area of urban climatic analysis maps. Only a few Austrian cities – the situation is comparable internationally – have their own climatic analysis map. The urban climatic planning recommendation maps currently available in Austria do not differentiate according to urban structure, use or function. For example, an industrial area can fall into the same category of climatic stress as an inner-city area – with the same recommendations for adaptation. In the planning reality, however, there are different administrative responsibilities for different areas, different policy and control instruments are required, and the possible measures for climate change adaptation and their effects vary depending on the urban planning situation.

Further research is needed to standardise the internationally diverging procedures for generating urban climatic maps, including urban climatic recommendation maps. Most analyses consider only urban warming and the wind field, changes in other climate signals or consequences (increase in heavy rainfall events, increase in drought, etc.) are mostly not considered, which is especially important for urban climate adaptation planning. Further research is also needed on standardisation for the inclusion of other important climate signals. But the biggest gap is in monitoring and evaluation. There are few cases to support an assessment of objective achievement.

1 ABSTRACT

This study assesses the coupling features of socio-environmental depriviation for heat adaptation through the case study of urbanised areas within Taipei Basin. Multiple data including weather, green space features and socio-economic attributes are used to understand their interplay across urban neighbourhoods. Using the weather records from 28 weather stations located inside Taipei Basin and its surrounding hills, this study maps spatial variation of wind dynamic and temeprature at daytime and night-time in summer months between 2011 and 2020. Spatial statistical analysis was conducted between this climatological information, green spaces, and socio-economic status of aging, household income, and education levels.

The result shows that summer temperature is unevenly distributed and has diurnal difference. Downwind areas tend to be warmer both during the day and night, even though the development in these areas might be less intensive and have more green and blue spaces. Further analysis with socio-economic status of these areas finds that some downwind communities are also socio-economically more disadvantaged. This spatial pattern suggests an unfair consequance due to past urbanisation, which put vulnerable commnties at higher heat risk. Nature-based interventions should therefore prioritise the reduction of such impacts through a more systematic consideration of land use zoning, wind path, and mechenism for compensation.

Keywords: socio-ecological system, urban planning, spatial inequality, heat risk, nature-based solutions

2 INTRODUCTION

Conserving and reintroducing nature into built enviornments for rehabilitating ecosystem functions and natural process of cities is urged by the latest global agendas on climate chagne for buffering impacts and for adapting to extreme weather. It is increasingly recognised that climate impacts, vulnerability, and resources for responses are unevenly distributed across space in cities, leading to climate injustice. The spatial inequality to climate risk is particularly manifested in heatwave events. Some neighourhoods are subjected to higher heat exposure and less adaptive capacity than the others. This inequality is socio-ecologically bonded, and is often produced by past urban planning and development decisions. Studies based on USA cities often found an association between higher heat risk at socio-economically deprived areas due to its lack of green spaces. Whilst studies in Paris and Taipei demonstrated a different result, suggesting socio-economically disadvantages are are not necessarily to expose to higher temperature in summer (Shih, 2022).

Nevertheless, increasing green and blue spaces for cooling and ventilation is one of the strategies to reduce urban heat. Delivering effective and justice cooling outcomes via this nature-based strategy requires understanding of not only city's natrual ventilation, but also the socio-economic variations across its neighbourhoods. To this end, this study adopted weather infromation of air temperature, wind speed, and wind direction together with geographical features of Taipei basin to understand the specific local climate with socio-economic variation. It is expected to identify areas subjected to higher heat risk in summer.

3 CASE STUDY AREA

This study took the urbanised areas of Taipei Basin as a case study area, including parts of the juristition of Taipei City and New Taipei City (Fig. 1). This includes 991 urban neighbourhoods in the basin area, which is surrounded by hills and forested mountains. The area covers approximately 2,726 km2 and has population estimated to 6.67 million by 2014. The basin sitting in the Northern Taiwan is connected to the sea on the north via the Tamshui river and on the East via the Keelong river. The Da-han River running from the central to the south-west of the basin is another main river corridor of the basin. Due to its specific geographical features that keep heat inside the basin and intensive urbanisation in the past, urban heat island effect has

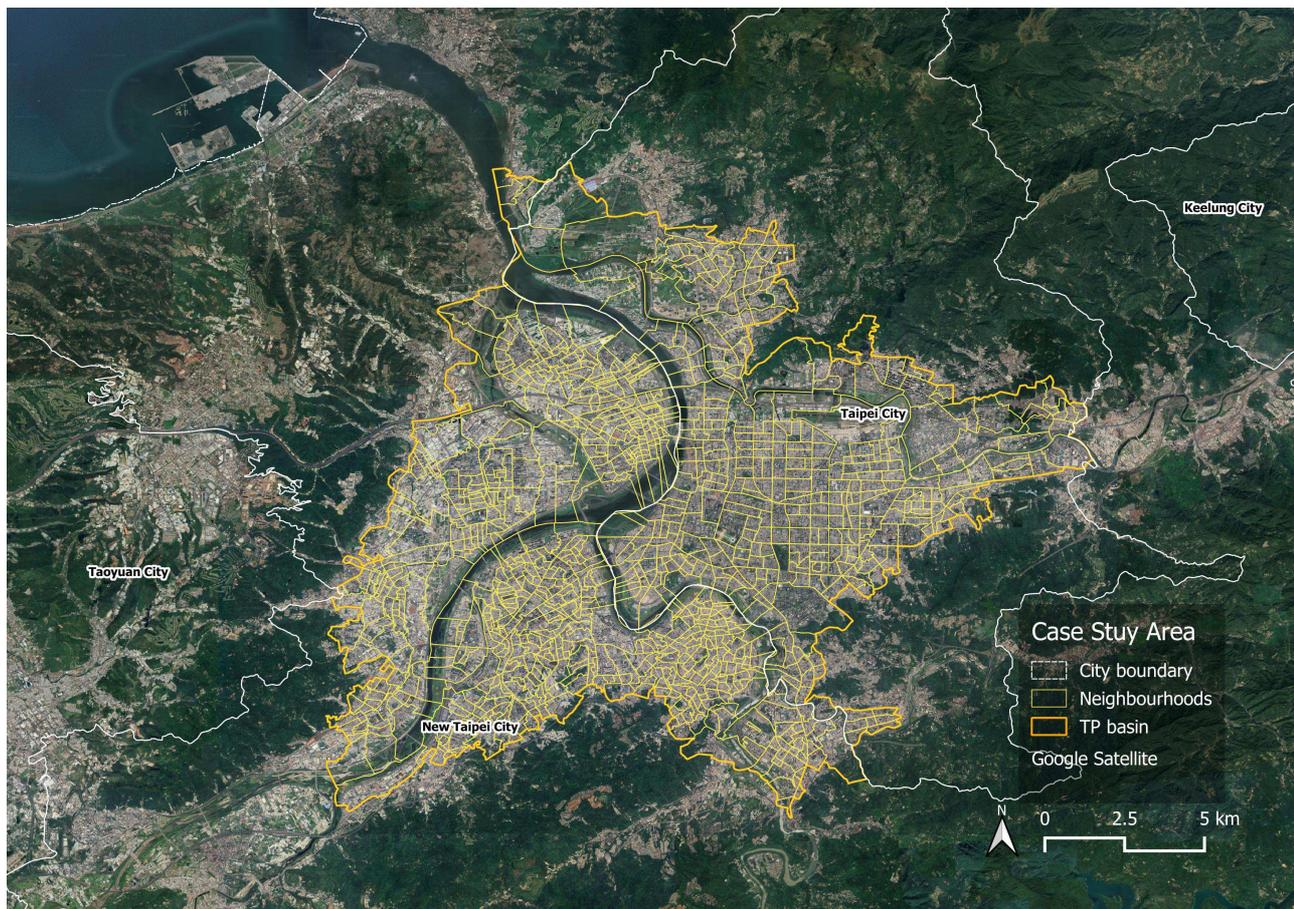
---


Fig. 1: The Location of Case Study Area.

4 DATA AND METHODS

4.1 Weather Data and Compilation

Weather information used for analyses was collected from 28 weather stations located either in the basin or on surrounding hills by the Central Weather Bureau in Taiwan. Daily records during June to September between 2011 and 2020 were retrieved in hourly basis. Twenty-one stations have completed data for ten-years, wereas 7 stations have less information spaning from 2 to 9 years. Data were aggregated to represent daytime (from 07:00 to 18:00) and night-time (from 19:00 to 06:00). Descriptive statistics were computed to produce mean temperature, average wind speed and major wind direction for further analysis and mapping.

4.2 Socio-economic Data

For understanding socio-economic conditions of across urban neighbourhoods, this study adopted aging index, education level and household income in 2020, which were gained from the Socio-Economic GIS platform of Ministry of the Interior in Taiwan Government. Aging index was calculated by the ratio of the elderly population (aged 65 years and over) to the younger population below 14 years old per hundred people. Education level is defined as the percentage of population holding a bacheloar degree and above. Household income was measured by median value of income within a given neioghourhood.

4.3 Green Space Interpretation

This study utilised high resolution satellite imagery from Sentinel 2 to interpretate the distribution of green spaces of the case study areas. The Sentinel imagery was acquired at 7:41am on 12 March 2019 from U.S. Geological Survey. Using the near-infrared and red bands, this study calculated the Normalized Difference Vegetation Index with equition of (NIR-R)/(NIR+ R) to identify the degree of greenness.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4.4 Spatial Statistics Analysis

In order to gain a spatially contineous weather information, spatial interpolation was used to generate mean temperature and average wind speed of unobserved areas between stations. Co-Kriging was applied for interpolation via Quantum GIS software, using the elevation of stations as an additional variable to refine the predition of average wind speed and temperature. Accordingly, both daytime and nighttime wind speed and temperature were visualised and extracted to be combined with the socio-economic attributes of each neighbouhood via the zonal statistic methods. These two sets of data were initially computed by IBM SPSS to assess the weight and the direction of their linear relationship using the Pearson correlation coefficient.

5 RESULT

5.1 Temperature variation of the cities

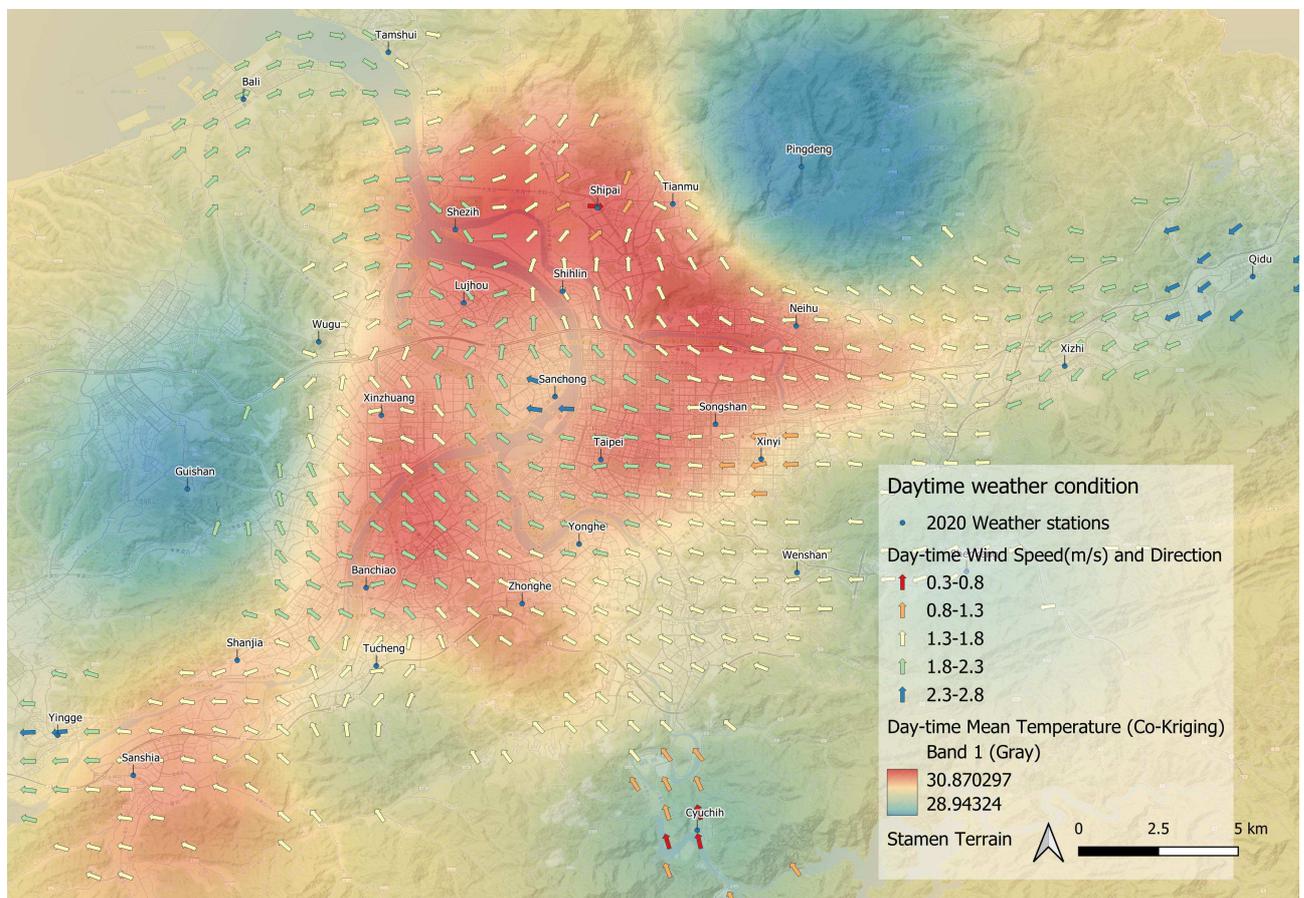
The highest average air temperature was observed around Shipai (30.92°C), followed by Shezih (30.82°C), Lujhou (30.72°C), Taipei (30.63°C), and Shihlin (30.62°C) during the day-time of June to Septemper. At night-time, higher temperature was found in Lujhou (28.48°C), Sanchong (28.20°C), Shipai (28.17°C), Sinzhuang (28.13°C) and Shihlin (28.13°C). Obviously, Shipai, Lujhou, Shihlin, which are located to the north of the basin, was covered by higher air temperature regardless of day- or night- time in summer.


Fig. 2: Average air temperature and wind speed at day-time of Taipei Basin.

5.2 Spatial association between green infrastructure and air temperature

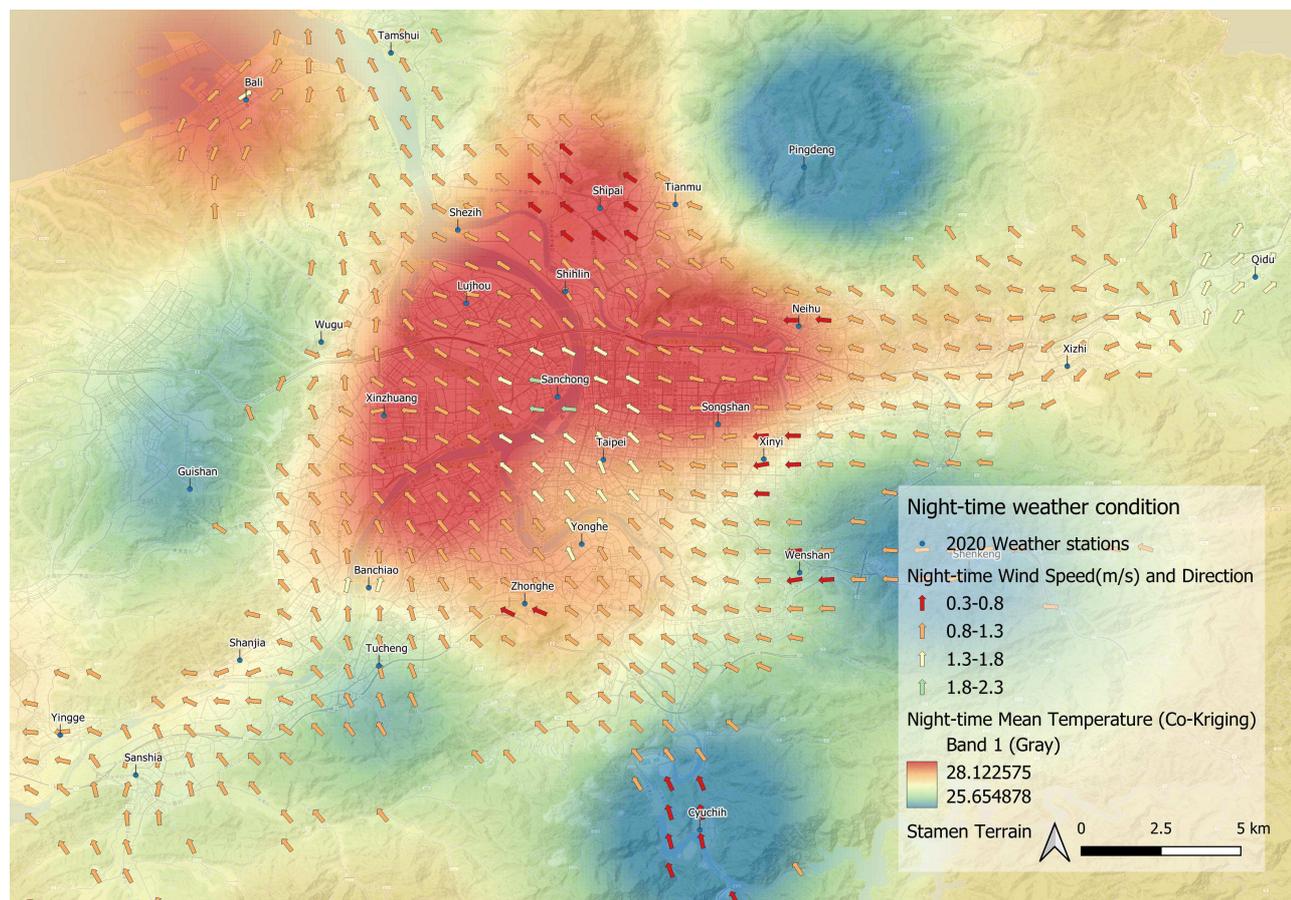
The correlation analysis between daily temperature and NDVI against urban neighbourhoods suggested a weak negative relationship between the degree of greenery and mean air temperature ($r(889)=-.24$, $p<0.001$) at a significant level in summer. However, the visualisation of the distribution of green spaces and mean air temperature showed that some suburban areas are subjected to higher temperature despite of greater green coverage. This is particularly obvious in Shezih, where has measured with the second highest temperature during the day. This phenomenon might be related to downwind heating as described below.


Fig. 3: Average air temperature and wind speed at nighttime of Taipei Basin.

5.3 Wind flows and influences on air temperature

The wind pattern showed a diurnal difference. Due to its closeness to the sea, a sea-land circulation was observed. Sea breeze from the North entred the basin through the Tamshui River and can reach Sanchong. According to the geogrpaphyical features of Taipei Basin and the analysis of prevailing wind in summer, the east side of the basin is strongly influenced by the wind coming from the Keelong River all day, whereas west side of the basin subjected to higher frequency of southeast wind.

The major downwind areas were identified as the Northern region of the basin, including Shihpai, Shezi, Shihlin, and Luzhou areas (Figures 2 and 3). During the day, the incoming sea-breaze from Tamshui River tended to encounter hot air from the city at this region (Fig. 2). This wind dynamic as well as the mountain barriers on the north may cause wind turbulence and stop hot air to be quickly discharged from the river valley. At the nighttime, land breeze from the south of mountains was more prevailing (Fig. 3). Yet the wind speed at night is relatively weak and might not be able to effectively bring hot air out of the basin from Tamshui River either.

Coversely, despite being the main air exit of the South-West side of the basin, areas around Shanjia, Sanshia, and Yingge along the Da-han river valley showed relatively low temperature. The air path displayed in Fig. 2 and 3 suggested that hot air from New Taipei City might turn northward and hence imposed less influence on this region. The fresh and cooler air joined from the southern hills might further cool down the valley. Overall, upwind areas are mostly cooler in summer.

5.4 Socio-economic association with weather conditions

Mean air temperature was negatively correlated with aging index, average household income, and education level at a weak but significant level. Mean wind speed showed a moderate and negative relationship with average household income and education level. This suggests socio-economic more deprived areas tended to live in environments that subjected to poor ventilisation. Some of them could be also hotter.

	Aging Index	Average Household Income	Education level

Mean Air Temperature	Pearson Correlation	-.109**	-.085**	-.179**
	Sig. (2-tailed)	.001	.007	.000
	N	991	991	991
Mean Wind Speed	Pearson Correlation	.064*	-.384**	-.409**
	Sig. (2-tailed)	.045	.000	.000
	N	991	991	991

Table 1: Correlation between weather conditions and socio-economic attributes. (**Correlation is significant at the 0.01 level (2-tailed; *Correlation is significant at the 0.05 level (2-tailed)).

The spatial distribution aging, average household income and education levels of neighghourhoods further showed that the downwind areas of Shezih is subjected to both higher summer temperature and lower socioeconomic status. Yet, although upwind area of Xinyi tended to be weathier, more educated, cooler, but have lower average wind speed. This complicated socio-environmental association might further connected to development characteristics of the areas.

6 CONCLUSION

This study spatially interpolated air temperature, wind speed, and prevailing wind direction to observe weather variation accross spaces of Taipei Basin. One of the findings from this assessment suggests upwind areas tended to be cooler whereas downwind areas of Northern basin were hotter in summer. This temperature distribution is attributeable to the specific topography of the basin which is more difficult to discharge hot air. The wind coming from city centre further brought hot air to the downwind areas and increase their temperature even they might be located in less developed suburban areas. The findings on temperature, greenery, and socio-economic association is to some extent consistent to previous studies suggesting socioeconomic disadvantaged areas are hotter. However, such socio-enviornmental relationship tended to be weak. It is noteworthy that poor ventilisation might be a more prominant factor in summer for socio-economically deprived areas.

1 ABSTRACT

The European feminist planning community (including the authors) has been addressing the challenge of a gender-just transition to climate neutral cities offering high quality living conditions for all users for decades. The planning model of a "City of proximity" – originally postulated by feminist planners– has recently evolved to the model of the "15-Minute-City". It is time to revisit 50 years of European urban time policies underlying this planning model and the theoretical ground for a temporal just city ("zeitgerechte Stadt"). The research project "DraussenDaheim" (=At Home Outside) puts this into practice.

The project aims to develop a methodology and toolbox which not only serves the participatory assessment of urban public spaces and their complex spatio-temporal use patterns, but also the co-creative simulation-based design of different planning scenarios. Taking into account a gender- and group-specific perspective, the focus is particularly on the development of less "gender-blind" participation tools that serve the analysis, assessment and co-planning of public open spaces. The target group-specific application of a digitally supported tool mix is described on the basis of two use cases and its added value for the key elements of a temporal just city, procedural and distributional justice, is shown. By making public spaces and vulnerable user groups a focus for the participatory implementation of temporally and spatially just urban transition, this will help to ensure that the transformation is inclusive, responsive to community needs, environmentally sustainable and socially just.

As the core of this paper, examples from European city-regions on time-planning practices as well as from the use cases of the DraussenDaheim project are presented with the purpose of informing gender-responsive participation and planning tools.

The conclusions highlight both the potentials and pitfalls of time-planning approaches in collaboratively assessing urban public spaces. Moreover, they anticipate a crucial endeavor: enhancing the adaptability and usability of these spaces for care-givers and care dependents. This task is a crucial step towards a more inclusive and gender just urban transformation.

Keywords: spatio-temporal use patterns, digital participation, planning tools, gender, public space

2 INTRODUCTION

The European feminist planning community (including the authors) has been addressing the challenge of a gender-just urban transition to climate neutral cities, offering high quality living conditions for all users for decades. The planning model of a "City of proximity" – originally postulated by feminist planners (Dörhofer/Terlinden 1985) – has recently evolved to the time based model of the "15-Minute-City" (Moreno et al. 2021). The ongoing research project "DraussenDaheim" (=At Home Outside[1]) addresses the urban time policies underlying this planning model and the theoretical ground for a temporal just city (Henckel/Kramer 1999).

DraussenDaheim applies different concepts of spatial justice to support equal access to planning processes and data generation. It aims to raise awareness within a neighbourhood and amongst policy makers of the diversity of daily routines and on different accessibility of public spaces. The goal is to improve fair and equitable access to public spaces with a special focus on care-givers and care dependant people. For these purposes, the project DraussenDaheim is developing a methodology and toolbox which not only serves the participatory assessment of urban public spaces and their possible uses (simultaneous, overlapping, etc.), but also the co-creative simulation-based design of different planning scenarios. Taking into account a gender- and group-specific perspective, the project puts special emphasis on the use and development of digitally

---

supported tools that are less inclined to overlook gender-related factors in the analysis, assessment and co-planning of public open spaces. DraussenDaheim also gives the opportunity to revisit plannning strategies and implementations of European cities with up to 40 years of experience in time planning by transferring selected methods, theories and practices to the challenges of two use cases: an urban square in a dense fin de siecle quarter (Aumannplatz, Vienna), and a newly built housing area in a peri-urban location south of the town of Zell am See (Sonnengarten Limberg, Salzburg). In particular, a mix of analogue and of digitally supported tools is used and adapted to the application context. While in both use cases a special focus is placed on gender-relevant groups (e.g. their needs in relation to the studied focus area, their requirements for handling the tools or their equal inclusion in the workshops), the tools are individually combined and adapted depending on the specific research question and local context (see chapter 4 in corp paper Fessler et al 2023).

This paper reports on the preliminary findings of the applied research as well as its theoretical basis, particularly addressing the subquestion: What can we learn from European time practices? One key lesson learned from the examined time-planning approaches is the understanding of time and space as resource, and as an indicator of inequalities. This understanding brings to light a new set of values for the planning community in finding time-based solutions for gender-just, low carbon and sustainable urban transformation: time and gender justice in goals definition and in the selection of design criteria.

The paper is structured as follows: first, we clarify the background on gender in urban planning, introduce key-concepts for a temporal just city and present methods used to evaluate time-space policies and co-creation processes. Next, in section 4, we discuss urban time-policies with focus on time-space patterns in a brief literature review to investigate how the diversity of tempo-spatial use patterns is theorised and implemented. Furthermore, selected examples from European time-planning practice are presented, which are able to inform the DraussenDaheim use cases with a gendered lens. Section 6 then shows selected transfer applications from two Austrian use cases. Finally, section 7 summarises the findings from European time-space planning practice, proposes some recommendations identified for a just urban transformation and highlights open research questions.

3   BACKGROUND, KEY-CONCEPTS AND METHODS

3.1 Background: Gender in Urban Planning

Various guiding principles fundamental to urban development, such as the United Nations Sustainable Development Goals (SDGs), cite equality and the reduction of inequality and discrimination as the basis for inclusive and resilient urban development and social cohesion. The gender mainstreaming strategy (EC 1999) anchored in the Austrian legal system, which includes elements such as gender budgeting, is also oriented towards these goals, especially SDG 5 "Gender Equality". In accordance with gender-equitable budgeting, the federal government, the provinces and the municipalities commit themselves to strive for the actual equality of women and men in budget management and thus to take the needs of both genders equally into account. This applies, for example, to the construction of public buildings and the design of public parks. Such strategy papers, which aim at the right to participation and equal opportunities, regardless of gender and sexual orientation, always include basic principles of good urban development. It is no longer appropriate to imagine guiding documents for integrated and sustainable urban development policy in Europe, such as the New Leipzig Charter, without addressing gender. There, for example, it is stated that the transformative power of cities must ensure equal opportunities and environmental justice for all, regardless of gender, socio-economic status, age and origin. All social groups should have equal access to open space and services of general interest. This is now widely recognised in the planning community, but has not always been taken for granted. Today's visible remains of (car-centred) spatial planning, almost exclusively from an economic breadwinner perspective, driven by speed and efficiency thinking, are evidence that diversity and needs outside the norm (traditionally assumed to be healthy and full-time working men) have long been disregarded. More than 40 years after the famous envisioning of a feminist city (Hayden 1980), there is still great inequality in our cities, which promotes a rethinking towards traffic calming and improving sustainable accessibility for all. The critical debate driven by representatives of feminist urban development has not only paved the way away from a dualistic view (man vs. woman) towards gender-just urban development (all genders) and a general gender-responsive planning approach, but has also created

836

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

awareness for the complex interplay of different forms of inequalities. These mutually reinforce each other and increase the vulnerability of already disadvantaged groups even more (intersectionality).

In this context, models such as the "15-Minute-City" have great potential insofar as they focus, besides traffic avoidance, on the integration of different needs in terms of sustainable accessibility. The model potentially offers easy and time-saving access to services, as well as attractive mobility options for accessing opportunities that are affordable, usable and non-discriminatory. Finally, gender and other diversity factors have a decisive influence on the quality of life in cities and municipalities and must therefore be considered in urban planning to ensure social and spatial justice (Terazza et al. 2020, Kempin Reuter 2019, De Siqueira et al. 2022). For example, at the neighbourhood level, requirements for lighting, pavement width, furniture and surface materials differ by gender, but also by other social categories such as age (Brüchert et al. 2022; Krishnamurthy, 2019) and physical or cognitive impairments (Kempin Reuter 2019). So, if one wants to know for whom our cities and (transport) systems are designed, one only has to look at how different needs are captured and whose (time) constraints are taken into account. The authors of this paper advocate for climate-friendly urban planning that incorporates diverse needs and is temporally adapted to include, rather than exclude urban residents.

A sexist city is not a sustainable city, because of its social and economic inequalities. Until recently gender equality focussed on the redivision of income and particularly unwaged care (see for example Zibell, 2022). Reconciliation between paid and unpaid care work, productive and reproductive work, child friendly and fair shared cities as planning and design tasks are one answer to the dysfunctionalities of urban spaces. Now we know that reducing CO_2 emissions needs more than a new deal for unpaid care work: it requires a gender-just transformation. This brings the need to rethink time-based planning strategies undelying the 15-Minute-City planning model, i.e. rethink how we reorganise cities, balancing waged and care work through services, mobility and housing.

3.2 Key-concepts for a temporal just city

For defining the key conception of a temporal just city, we follow Henckel & Kramer (2019). In their comprehensive reader they introduce the following key elements for a temporal just city:

(1) procedural justice, the question who has a say and whose voice is heard in planning and design decisions,

(2) distributional justice, who has access to which urban resources.

In order to achieve a temporal just city, procedural justice - i.e. fair participation and equal distribution of power in planning processes and beyond - is a prerequisite.

All forms of tempo-spatial justice suggest that a just urban transition cannot be thought nor realised without gender equality. In planning terms, equitable access to spatial infrastructures and resources as indicated in SDG 11 involves access to adequate housing, basic services (11.1), universal access to green spaces (11.7) and barrier-free access to sustainable transport offers (11.2). Special attention shall be given to include care givers (majority women), care dependants (children), persons with disabilities and older people who are more likely to be 'in vulnerable situations' (11.2). Putting care-work in focus immediately links the distributional and procedural justice to time: Fair/equitable access to spatial resources depends on distance, transport and mobility offers as well as on the autonomy of the users. Especially daily routines depend on the accessibility and availability of infrastructures of everyday life including opening hours and location (Horelli 2006, Wien 2013). Furthermore, the temporal design of participation processes (who can participate at what time and under what conditions?) determines plurivocality and thus the (more or less pronounced) representation of diverse spatio-temporal patterns of use. This is an essential component of procedural justice in urban planning and design.

Inspired by these concepts, the following main-research questions linked to spatio-temporal justice in planning have been identified.

For distributional justice: Which different time-space patterns and daily routines of urban users are addressed and is there a gender bias? Which analytical methods for analysing and mapping inequalities can be found in Euroepan time plannning documents? How equal or unequal is availability of and access to spatial ressources (=everyday life infrastructures including public space) and to temporal ressources (personal time and time poverty).

For procedural justice: How do different time-space patterns inform the design and (barrier-free) access to all steps of a planning process? Which actors are identified and how are these different actors adressed to have a say in the planning cycle (context based analysis, visioning, co-planning etc.).

3.3 Research methods: developing a model of care-profile, evaluating time-space policies and co-creation processes

To overcome stereotyping and 'sex counting', the authors have developed a model of care-profile which characterises residents and other urban users according to their care responsibility (Tummers & Wankiewicz 2021). This model differentiates from the habitual definitions of 'target' or 'user' groups, in that it does not put the personal characteristics on the foreground, but looks at the determining conditions for the use of (semi-)public urban space. Key conditions which influence stongly the temporal and spatial flexibility or rigidity and the autonomy or dependency of persons in accessing urban ressources are care responsibilities (e.g. perceived by parents) and care dependency (e.g. of children). Persons with care responsibility have little flexibility in their daily time-space-trip-chains. For example, the schedule of a part time employed single parent depends on working-hours and the availability, costs and opening hours of child care facilities.

Besides care responsibility and care dependency tempo-spatial autonomy and flexibility is related to a persons' gender, age; physical and cognitive ability (barreer-free accessibility). Last but not least, a person's occupation (employment, education, volunteering) determines their respective time-schedules and autonomy. This knowledge, bundled in care profiles[2], was applied in various online surveys (including questions about care responsibilities or dependencies) and co-creative workshop formats of the two use cases Aumannplatz (Vienna) and Sonnengarten Limberg (Zell am See), which focused in particular on group-specific spatio-temporal patterns of use. One of the main intentions is to contribute not only to equitable participation in participatory processes, but also to the spatio-temporal organisation of open spaces so that they are accessible to vulnerable groups without displacing others.Gender is at the centre of this debate and is reflected in both the use of space and time. From statistics and available data (Trapez 2020, Gender Equality Index 2022)[3], we know that in current European societies the following typical gender roles and care-related responsibilities are not equally divided between women and men. Particularly women in general perform more (unpaid) care-tasks (taking care of children, elderly and impaired persons as well as participating in cooking and housework) while they have less income. Men, by contrast, tend to have more free and leisure time, as time-use studies in Austria and Germany show (Panova et al. 2017, Statistik Austria 2009).

Building on this background knowledge, the authors' task within the research project DraussenDaheim was to select and present key topics, methods and tools for territorial and spatio-temporal analysis and to report back to the project team. For this purpose, the policies of European time planning frontrunner city-regions were analysed, which address different daily routines and rhythms of urban user groups. Further, desktop research and document analysis were carried out to investigate planning documents (time plans, urban strategies) to see to what extent and how tempo-spatial planning strategies and design criteria are reflected in them. Finally, an iterative approach was adopted in dialogue with the research partners to explore how these strategies were implemented in collaborative and co-creative planning processes. Moreover, following and participating in online discussions about the concepts and state of the art of implementing the 15-Minute-City enabled the project team to cross-check its findings. On this basis, the knowledge gathered was incorporated into the use cases of the DraussenDaheim project, in which two participation processes were carried out using digitally supported tools, taking into account the gender and time planning perspective.

4   TIME AND SPACE PATTERNS IN URBAN PLANNING AND GEOGRAPHY

This section gives a brief introduction on the history of temporal just plannning and highlights the links between time planning, sustainable and inclusive human settlements (SDG 11), followed by an overview on how the diversity of tempo-spatial use patterns and daily routines are addressed and mobilised to advance gender equality and inclusion.

---

4.1 Theorising diversification of time-space patterns

Time in planning theory and practice started about 50 years ago with Hägerstrands time geography (1970). The current revival of time-based urban strategies includes the 15-Minute-City and the Superblock model (Paris, Barcelona, Vienna), as well as the 2021 Barcelona Declaration and work programme on Time policy 2.0[4] by the European network of regional and local authorities.

The Swedish Lund school on time geography around Hägerstrand, theorized the concept of space time cube. Using 3D visualisation of time paths (=trajectories) and bundles, the diversity of time-space patterns and the different constraints which influence the choices of people became visible (Hägerstrand 1970).

Feminist researchers and practitioners have criticised the time-geography approach, but also used and further developed it with gender and diversity issues (Rose 1993, Kwan 2000, Ellegard & Karlsson 2009). The US-time geographer Kwan for example looked at the impact of time-space constraints on time-space patterns (1999), visualizing these use patterns in GIS with layers of networks, settlement structure and the daily movement of time-paths from different user /gender+-groups (e.g. Afro-American women in Portland) (

(Kwan: http://meipokwan.org/Gallery/STPaths.htm) based on a great number of time diaries.

Action research like Eurofem (2000) introduced female everyday life use patterns and rhythms and placed the related infrastructures into the centre of planning and design.

For the Dutch planning culture, Tummers (2009) and van Schaick (2011) looked at the implications of this tempo-spatial diversity for planning and design innovation in the network city. Tummers proposes a set of flexible and adaptable planning and design criteria which enable user friendly and high quality urban environments for the variety of users and life situations. Further she proposes collaborative and participatory planning processes addressing the diverse users and their daily routines adequately. Schajck pursues the possibilities of tracking to understand time-space patterns (2011).

Thus, a body of knowledge about complex (female) trip chaining of part-time care-givers vs. simple full-time 9-5' commuting tempo-spatial use patterns has entered traffic and mobility planning. It inspired many projects in gendered infrastructure and open space planning. Horelli (2006, 2013) and Damyanovic et al. (2013) argued that managing time and space as a challenge for residents as well as the accessibility and availability of everyday-infrastructures (including open spaces, care-facilities and meeting points) ought to become a main planning task for sustainable urban living environments.

4.2 Collecting data on time and space patterns

Italian time policy gives the most comprehensive and inspiring answer to meet inequality and reconciliation challenges at local level. It was strongly supported by academic action research from Politecnico di Milano and Torino (Bonfiglioli, Stabilini & Zedda etc.) as well as embedded into a legal framework prescribing and obliging local and regional authorities to develop and implement a local time plan. Cities like Bolzano, Bergamo, Pesaro and Genova experimented with cooperative processes including surveys, with innovative spatio-temporal analysis and co-diagnosis as well as with integrated time and development plans (e.g. Time plan Bergamo 2004, Bolzano 2006). The mapping of urban rhythms, the harmonisation of collective and private time schedules, the mismatch between needs and opening hours of shops and services, the urban night time and the lack of personal free time are in the centre of these time planning processes (Zedda et al, Bolzano 2006). Some cities show a remarkable continuity and long soufflé in time planning: Bolzano started in the mid nineties and is part of the time policy 2.0 movement of 2021, committed with a work programme on 15-Minute-City implementation (Barcelona declaration).

In terms of data gathering, nowadays, we still face the lack of empirical data on gender+[5] differentiated time-use, daily routines and time space patterns. In Austria, the last statistical survey data from 2008 (!) only gives geographical differences at province level. In Germany, since 1992 each 10 years a state-wide survey on time use gives information on gender, age, household and care-responsibilities for children (Zeitverwendung

---

[4] See the "Barcelona Declaration of a European cities network of cities promoting the 2nd generation of time policies. https://www.gemeinde.bozen.it/UploadDocs/31421_DECLARATION_BARCELONA_ON_TIME_POLICIES_EN.pdf 14.01.2023)

[5] Gender+ indicates theory the complex interplay of different forms of inequalities (intersectionality) placing gender at the core.

Deutschland). However, no data evaluation for cities nor regions is possible. In 2017, Panova et al. have published a study based on the 2013 data which gives detailed data on time use and constraints of mothers and fathers in the 'rush-hour of life' (care givers of children younger than 15 years old) and compared it to other age groups. A more detailed picture of gendered time space use patterns concerns the scale of districts and may be generated from regular mobility surveys. In Austria, the most recent data on mobility patterns date from 2013/14 (Österreich unterwegs) with a special evaluation on gender differences of these data (Knoll et al. 2016).

5 LEARNING FROM TIME SPACE PLANNING PRACTICE

From the literature review, we derive four types of time-space approaches in urban planning: time as a resource; time space patterns and public space; analysis based on time-space patterns and co-planning strategies.

5.1 Understanding Time and space as a resource

5.1.1 Bolzano Integrated Time Plan (2005 – today)

The initial aim of the Bolzano Time Plan 2005 was a better distribution of care work to improve access to the labour market for care-givers (mostly women). During more than 10 years of a collaborative co-creation process accompanied by action research and evaluation by Politecnico di Milano, this time plan evolved to a fundamental shift in planning visions, goals, planning tasks and instruments to achieve a time and gender just sustainable urban transformation. Already in 2005, Bolzano has postulated the 10-Minute-City with sustainable and inclusive public transport, a compact city model and a high quality public space for a diversity of users. Time is a key indicator and success factor for justice and wellbeing in the Urban Time Plan of the city of Bolzano (Stadt Bozen 2005, 7). It is one of the most comprehensive time planning documents and results from long-term experience with a very pronounced gender equality priority aiming to alleviate women's everyday life. Defining the increase of personal time as success indicator for the time plan goes beyond and redefines the task of planning and design. By this, Bolzano strives for distributional justice in the access of personal time as a resource. Further, Bolzano has been experimenting with co-creation, pop-up workshops, temporal use change and co-diagnosis to raise awareness of the diversity of time-space-patterns. A few practical examples are: Time diaries, pop-up workshops, street art, temporary closure of public spaces for sport and play, opening of school courts for a broader public as co-creation and discussion places. Collaborative service development for lunch meals, new infrastructures and opening hours of childcare facilities, shops, municipal and health services react to the diversity of daily routines of citizens, clients as well as employees. These planning processes are conceived to achieve more procedural justice. Implementing the vision of the 15-Minute-City in Paris

The City of Paris is a frontrunner in envisioning and implementing „la ville de quart d'heure"/the 15-Minute-City at district level. "15-Minutes-Paris" strives for urban districts suitable for everyday life: neighbourhoods which provide accessible infrastructures for the diversity of tempo-spatial daily routines, with a focus on care givers and care dependants. This includes accessible shops and services, a network of high quality and safe streets and roads, a multifunctional new infrastructure, a citizen kiosk as indoor place to meet, and high quality public spaces as outdoor meeting and activity points. This vision asks for a creative transformation in the use of existing infrastructures (e.g. school yards), the development of new public infrastructures and a revised management of public services. In short, Paris strives for distributional justice in the built environment.

Both Paris and Bolzano provide many inspiring answers to the questions 'how will life be organised in a time just city?' and how a co-creation process towards non sexist, gender equal and low carbon cities could look like.

5.2 Diversity of time space patterns and public space

The next examples propose a shift in norms and values as well. They are facilitating the autonomous mobility of children in urban public space, at the same time alleviating their care givers, giving them more personal time. If young children and older people move autonomously in their city, they do not need another person (care giver) as companion, so the care givers gain personal time.

5.2.1 Network of child-routes - Kindlint (NL/BE):

The main interest of these "Child-routes" is to give children as pedestrians access to urban resources. In a co-creation process, the child routes are selected and visualised with colours and other signs in the streets and squares. The relevance for care givers is high: if children are able to move autonomously in their city, the care givers do not need to walk with them and will have time for other things. This instrument comes from the Netherlands and Belgium. Experiences show that older people also use these routes very much. They are attractive and easy for orientation.

This strategy also reverses the planning approach: adapting the city for children as a safe walkable space all day long instead of protecting and 'fencing' children when walking to school and back.

Fig 1: Network of child route in Middelburg, NL (Online: https://www.pzc.nl/overig/middelburg-heeft-veilig-kindlint~a5194ec0/?referrer=https%3A%2F%2Fwww.google.com%2F) – (access on 18.03.22)

5.2.2 Temporal change of use - Hackney-Play-Streets (UK)

Based on a cooperative implementation of a public health progamme in east of London, a temporal change of use of public and semi-public streets and squares has been established (Hackney Play Association 2015). Public spaces are closed for traffic circulation regularly for an afternoon or a weekend, to give children and their parents temporal access to streets as playground and exercise area. This example also changes the rules of the planning game: instead of monofunctional traffic lanes, public space is used as playground, sports field and meeting place for the local community from time to time. People of all ages, genders and colour are treated as actors, especially giving groups in vulnerable situations access to sport and play facilities. This example also gives answers to our reseach question of how life will be organised and co-planned in a time-just, non-sexist, low-carbon city.

5.3 Contextual (territorial) analysis based on time-space use patterns

Understanding time-space patterns in the local context is crucial for developing strategies. Several methods of analysing, data-harvesting, mapping and visualising diverse patterns of use of time and space have been developed, some of which we present here.

5.3.1 Diversity of tempo-spatial use pattern in Nantes metropole (F)

Based on surveys or time diaries of typical week-days and weekend-days, Nantes has developed an infographic which shows the variety of time-space-patterns and the activities over 24 hours of four members of a family. This easy understandable visualisation of different time-space-patterns within four family members of both sexes is based on qualitative interviews. It can be used to start a collaborative territorial diagnosis andplanning towards more tempo-spatial just and sustainable city regions.

5.3.2 Time-use survey in Germany (2002/2012/2022)

This Germany-wide survey shows the differences in time use of people of all genders, age, occupation and family situation (with and without care-responsibilites). The data give a detailed idea of gender differences in care work and the burden of women with children under 15 years of age (Panova et al 2017). These data are unfortunately not availabe for Austria (last data from 2008).

As a very comprehensive and periodic survey it is an excellent source for comparing time use patterns of male and female inhabitants in different family situation, age or living environment over decades. Comparing local differences (for cities, urban quarters or regions) is not possible though.

5.3.3   Mapping urban rhythms: Chronotopes of shops and services in Lyon (F)

This spatio-temporal mapping method has been developed by a French research team and is called "Chronotope"[6]. For the Gerland-Quarter in Lyon, the location and the opening hours of shops and services are mapped in hourly intervals. A video performance of the different maps shows the quality and accessibility of shops and services within 24 hours. It highlights daily rhythms, local and temporal differences in access to shops and services. By doing so, this mapping method can focus on reconciliation and supply deficits of residents and workers. The topics may be extended to child-care facilities, day care centres for senior citizens etc. to highlight distributional injustice in cities.

5.4 Co-Planning Strategies committed to procedural justice

Female and feminist scholars looked for more gender balanced planning processes and broader representation of female lives and interests. Both digital and analogue tools and methods are needed for this step towards procedural justice. Widely practised is walking to share and exchange everyday life experiences and different trajectories of residents. Walking has been established as a method that is published and incorporated in planning processes.

5.4.1   LENA-the Nordic approach for redefining co-planning in time and space

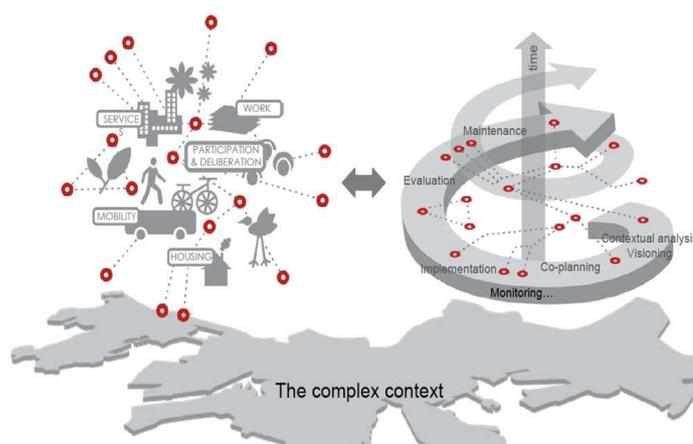
This LEarning-based Network Approach to participatory urban planning and action research has been developed since 2000 by Scandinavian planners who form part of the tradition of feminist critique on mainstream planning. Beyond these infrastructures and the challenge to manage time and space, the digital tools supporting the everyday are also relevant for this paper, as well as the LENA-planning cycle with contextual analysis, visioning, co-planning, implementation, maintenance and evaluation (Horelli 2006, Wallin 2013,15).


Fig 2: The Learning-based network approach to participatory urban planning and action research. (Wallin 2013, 15 – Fig. 1.1 by courtesy of the author) The red ellipses symbolise the use of digital tools

LENA systematically integrates the accessibility and the co-development of infrastructures of everyday lives and the diversity of spatio-temporal use patterns (distributional justice) into a collaborative 'co-planning' arena, with strong focus on digitalisation as well as on deliberative and self-organised processes (procedural justice).

5.4.2   Walking as a method for co-planning – Paris and Barcelona

The City of Paris (Guide Réferentielle 2017) and the Barcelona based private urbanist collective "Collectiu Punt 6" (2017) have elaborated manuals with Gender Walks methods building on the long-term experiences of the bottom-up organised Jane's walks.[7] Paris has professionalised this Gender Walking method from "top-down" to assess and co-develop an urban quarter from the perspective of (mostly) female users (Ville de Paris 2022). For the bottom-up driven and implemented approach of the Catalonian group "Col-lectiu Punt 6" walks are followed by a great variety of co-creation and participatory methods and procedures for a

---

[6] More details in Equipe Chronotopies – Alain Guez – Laboratoire Architecture-Anthropologie Paris (2003bxx): https://www.laa.archi.fr/+-Chronotopies-+ (access on 21.03.22).
[7] Lets get walking (2022): Janes Walks Festval. https://janeswalk.org/ (access on 25.04.2022)

'gendered urbanism' (Col-lectiu Punt 6, 2017). The crucial role of public services, the quality and usability of public space at day and night-time and the visibility of female lives and contributions to local, urban economy is in focus (distributional, procedural justice and representation (Gutiérez-Valdivia 2021)).

Walking as a method is one of the most successful collaboration instruments for bringing into the planning process the experiences and user perspective of the (normally unheard) urban users. This instrument may be applied both for diagnosis and analysing spatial qualities and disfunctionalities, as well as for proposing new spatial and temporal organisation at local level (arrondissement, neighbourhood). In this way, walking empowers women and contributes to more procedural justice.

The following section shows how these findings have informed the DraussenDaheim case-studies.

6 TRANSFER AND TEST IN LOCAL USE CASES

Based on the practical examples of space-time planning in European practice outlined here, recommendations were derived on how insights gained from them could be usefully applied to the DraussenDaheim use cases. Regarding the collection and evaluation of data (e.g. on the daily use of a public space in Vienna or the recreational use of open spaces in and outside a settlement in Zell am See), it was decided that the specific analysis of diverse mobility and use patterns should not only be differentiated according to age, but also to gender and care responsibilities. The differentiated interpretation of the use case results would thus facilitate the setting of group-specific incentives for a time- and emission-saving qualitative stay in open spaces close to home.

In general, the findings from the analysis of European time-planning approaches could contribute to specify requirements for researching gender+ differentiated spatio-temporal patterns of use and daily routines. This includes the precise recording, analysing and visualising of data. Adapting the methodological approach from a user-sensitive perspective and carefully embedding the developed tool chain (as a mix of analogue and digitally supported tools)[8] in participatory formats ensured that gender- and care-relevant information was collected in preliminary surveys and linked to other participation and simulation tools in the further process. In addition, the design of participatory involvement (in data collection and co-creation process) could thus be adapted to specific target groups (e.g., their requirements regarding the toolset and their time availabilities). This ultimately benefits both procedural and distributive justice.

6.1 Use case Aumannplatz in Vienna's 18th district

Due to traffic issues and inadequate design, Vienna's 18th district central square no longer serves its users' diverse needs. In a broad participation process based on a functional and socio-spatial analysis, a redesign of the square is being sought, supported by the DraussenDaheim project. It contributes to the identification of the spatial qualities of the square as well as the current and future possibilities of use for specific target groups, taking into account temporal components (times of use and personal time resources).

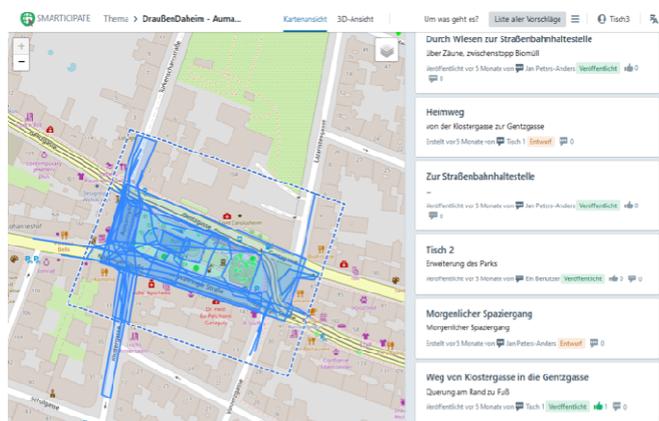

Fig. 3: Overview of all mapped pedestrian pathways (blue lines) including comments on temporal use (e.g. "morning walk") resulting from the tool workshop using "Smarticipate"

---

[8] more about combined (digital) tools and methods used in DraußenDaheim see chapter 3 Fessler et.al (2023)

The initial results from the online survey (n=47) offer insights into the spatio-temporal patterns of use on weekdays and weekends as well as at different times of the day. They also shed light on respondents' socio-demographics and caregiving commitments. Analyzing these complexities from a gender perspective reveals that although nearly 70% of respondents have care-giving responsibilities, they rarely use the space with children or older people. The survey, a vital research element, connected personal attributes (e.g. gender, age or employment) and usage preferences, engaging the local community and encouraging participation in follow-up workshops. To be considerate of the valuable time resources of different groups and to increase the reach of the survey, it was offered via digital devices (smartphones, tablets) as well as for analogue completion. For seniors, visually impaired and people with language difficulties, personal assistance was offered on the spot. This also applied to the actual workshop with the digital participation tool "Smarticipate", where the focus was on the possibilities of crossing the square and using it as a place to stay and play. By jointly mapping footpaths walked at different times in mixed-age and gender groups, complex temporalities and rhythms of different users became visible and negotiable.

In addition to proposing new paths, participants had the chance to make new design proposals for the square. Using the "Simulate" tool, a real-time pedestrian simulation illustrated the impact of these designs on movement throughout the day. This highlighted everyday activities like commuting (to work or school), offering insight into the square dynamics at different times (morning, midday, evening). The outcome showcased scenarios with new design elements, altering spatial boundaries and influencing path-time dynamics.

6.2 Use case Sonnengarten Limberg in Zell am See

Unlike the Aumannplatz use case, the Sonnengarten Limberg research didn't begin within a redesign process. Instead, it offered the chance to monitor gender-specific spatio-temporal patterns of use inside and outside the freshly developed housing estate. Using a diverse method mix, similar to Aumannplatz, enabled wide participation through various channels (e.g. a WhatsApp group for residents). Housing management, played a major role, acting as a bridge to residents and amplifying individual engagement.

While the Aumannplatz workshop was held in a nearby shop bordering the square, the participation in Sonnengarten Limberg was organised directly in the housing management's premises. This communal space served to introduce participants to the "Smarticipate" tool for creating an online open space use diary. Participation requirements included completing an online survey (n=59) on leisure and mobility habits, spread through emails, the WhatsApp group, and personal conversations. Collecting details on social background (including care responsibilities) and housing situation as well as mobility habits provided insight into the participating group, which finally (partly) took part in the workshop with the digital tool (remaining persons were provided with a handout) and the creation of the diary. Both steps of participation were compensated. By analyzing the preliminary survey and categorizing participants by specific mobility behaviour types, diverse focus groups emerged. These groups included people such as a digitally savvy young mother, an environmentally conscious childless couple, and an older lady with limited technical skills. During the workshop, participants reconstructed their typical weekday and weekend routines (open space use and destinations inside and outside the neighbourhood, additional information on time, duration and purpose of use as well as means of transport) and entered these details into the "Smarticipate" tool.

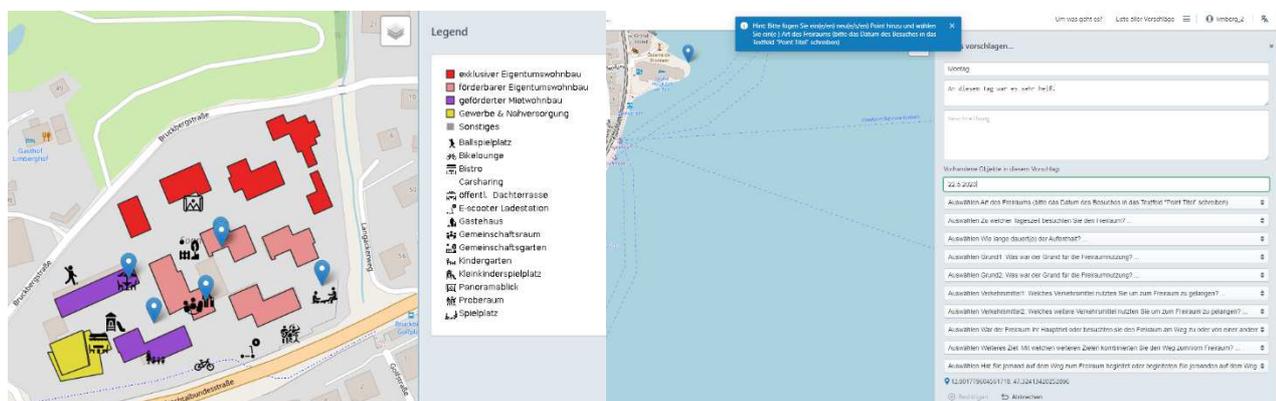

Fig. 4: Mapping of leisure destinations inside and outside the settlement at different times using Smarticipate.

14 of the approximately 60 people who participated in the first survey committed to keeping the space use diary over the period of several weeks and thus sharing personal data on the temporal use of points of interest with the research team. The analysis of the diaries and thus of all collected entries, which can be assigned to group profiles previously collected in the survey, makes different individual and group-specific use patterns and rhythms comprehensible and representable. In addition, possible temporal overlaps of user groups in certain open spaces can be identified. Subsequently, the results can provide far-reaching indications for the (spatial and temporal) optimisation of (semi-)public open spaces in the neighbourhood and thus contribute to an inclusive, gender-just and CO_2-avoiding urban redevelopment.

6.3 Lessons and possible transfers from the goal the DraussenDaheim study

Preliminary results show that collaboration and consultation processes that promote shared decision-making, low-threshold design, participation, and careful selection of digital participation tools to take account of gender- and group-specific needs and ideas are crucial for inclusive and gender-just space-time planning.

Based on practice analysis and findings we have identified the following factors to operationalise time-just urban transformation:

- Put time on top of the planning agenda as core indicator of access to personal leisure and flexible time, and its fair distribution as a core value.

- Strive for distributional justice (equal access to tempo-spatial resources) as well as for procedural justice (who has a say and whom do we reach and how)

We suggest to add representational justice (Gutiérrez-Valdivia 2021) which asks if female lives and their contributions to urban life and economy are appreciated and reflected in public spaces (e.g. name of streets), in planning methods and data generation.

7 TOWARDS TIME-BASED USER-FRIENDLY TOOLS FOR GENDER-JUST URBAN TRANSITION (CONCLUSIONS)

7.1 Findings from European time-space planning practice

One key lesson and inspiration from European time planning practice for our approach was to understanding time and space as resource and indicator to analyse inequalities. This implies a new set of values: goals definition and design criteria. Space-time-policy is a field where values and norms matter. Nevertheless, EU or state-wide representative surveys of time use and activity patterns are rare and there is no or little spatial aggregation of statistics. Cities and regions make their own surveys and are creative in visualising the different daily routines where gender, age, household situation and other sociodemographic categories are widely considered. These qualitative data are used for awareness raising in participatory planning processes. They can be incorporated in the form of innovative presentation methods such as maps and infographics like Chronotopes, spatio-temporal diagrams of the activities of individuals or a population.

Distributional justice is not mentioned explicitly, but on top of the agenda are the following planning tasks: fair/equitable and barrier-free access to high quality public spaces, user-friendly mobility (walkable city), new services and infrastructures (lunch meals for teenagers, citizen kiosk), extension of opening hours and mobility offers.

Most of the practice examples have integrated gender issues in all process-phases, sometimes implicitly by addressing reconciliation challenges or dysfunctionalities and mismatch of opening hours. Specific attention is given to women, families, children and teenagers (not gender differentiated).

Procedural justice is not mentioned explicitly, but is visible as value. A variety of user groups together with schools, public and private service providers and civil society are integrated in all phases and in some cases strongly supported for self-organisation and autonomous implementation. From context based territorial analysis and interpretation to data generation, visioning, planning and design to implementation, a wide range of collaborative methods are applied: co-diagnosis, walking interviews, pop-up workshops, pop-up concerts and discussions as well as time diaries. However, research about the inclusive or exclusive effects of digital tools in collaborative planning process is project-related and cannot be generalised.

Even if the repertoire of methods was not fully exhausted in the context of the DraussenDaheim project, it is clear that in both use cases a wide variety of efforts were made to contribute to procedural justice. Different

communication strategies and a mix of methods were used to involve diverse groups of people of different ages, with and without care responsibilities, as well as people with (mobility) impairments. In this way, new perspectives on their use of time and space could be gained and group-specific requirement for the multifunctional use of time and space could be identified. This made it possible to reflect and represent different life conditions in the development and design of diverse and gender-just public spaces and to incorporate the resulting outcomes into the underlying space-time policy. This approach could in turn benefit the well-informed creation of a time management concept for urban open spaces, such as Aumannplatz, and thus strengthen distributive justice.

7.2 Implementing time-space planning in practice

For distributional justice

- Investigate, analyse and map the diversity of time-space use patterns with special attention to care tasks and care dependencies is an eye-opener for residents, employees and other everyday- life-planning experts.
  - o Putting on the gender+ lenses to assess spatial qualities and dysfunctionalities of urban resources and how accessible they are for different users. Put a special focus on how this accessibility changes at different hours of a day, on weekends, at night, during holidays etc.
  - o This core planning task can only be realised as a horizontal task in cooperation with many other disciplines/departments (social work, labour market regime, opening hours, etc).

For procedural justice

- Co-creation and co-planning start with stakeholder-mapping (who is the most concerned and interested) and the question how these groups can be included into the planning process.
- Digital participation tools can support the collection of gender- and group specific needs, requirements and ideas, as the outlined use cases show. The quality and equity of their results is influenced by the (low-threshold) design, the (inclusive) design of the participation formats
  - o Digital tools combined with face to face workshops and qualitative surveys support the collaborative generation of data (e.g. diversity of time-space use patterns with time diaries).
  - o There is still much to do for improving the usability of the tools and the co-design with residents, which has a great potential for increasing easy accessibility to the planning process.

Further research is needed on the following questions:

How to investigate the diversity of time-space patterns at community and neighbourhood level and the distribution of unwaged work between genders, age groups etc.?

Under which conditions (inclusive process design and cooperative tool selection, usability e.g. smartphone-app, settings etc.) can digital tools enhance or hinder (exclusion of digital illiterates) residents and other user groups from participation in a planning process.

1 ABSTRACT

The Fourth Industrial Revolution is a reality to be reckoned with in cities. Many cities across the world have ventured into various technological innovations to keep up with the demands of the need for free and/or affordable data in the context of data drive smart cities. However, in the African context, there are valid concerns that such interventions are often not sustainable. This paper provides an attempt to contribute a conceptual framework for a sustainable municipal technological innovations in municipalities, using the municipals free Wi-Fi as an example. Currently, there is no framework model, and many municipalities are implementing free Wi-Fi in rather uncoordinated ways, leading to unsustainable outcomes. The paper was based on literature review and empirically gathered views of key local government stakeholders in South Africa.

Keywords: City of Tshwane, Fourth Industrial Revolution, Spatial Planning, Free municipal Wi-Fi, Smart City

2 INTRODUCTION

This paper proposes a conceptual framework model for sustainable free municipal Wi-Fi programmes for consideration by cities in South Africa. This conceptual framework model can be used utilized as a broad framework to design and/or evaluate the sustainability of municipal technological innovations by municipalities in South Africa. The target potential users of this conceptual framework model include city managers, heads of departments responsible for designing free Wi-Fi programmes, local government practitioners, councillors (politicians), scholars and academics, civil society organizations, the private sector, NGOs, and organized local government formations/associations, such as South African Local Government Association (SALGA) and the South African Cities Network (SACN).

3 WHY SHOULDN'T DATA BE SEEN AS A FREE BASIC SERVICE?

The first key element of the framework tackles the question of data as a free basic service to be provided by municipalities. Scholars such as Ramokgopa (2018) support the notion that free Wi-Fi be designated as a basic municipal service in South Africa. However, other scholars such as Nalla (2021) argue that South Africa should first focus on basic needs such as shelter, water, food, etc. This study aligns with the views of Ramokgopa (2018), and other scholars, i.e. that free Wi-Fi be designated as a basic municipal service in South Africa. This study supports the view that data should be designated as a basic municipal service in South Africa, especially where some of the basic services in the 21st century can be provided digitally. In such instances, lack of access to data can become a hindrance.).

4 KEY ELEMENTS OF THE CONCEPTUAL FRAMEWORK MODEL

The key elements of the conceptual framework model for sustainable free Wi-Fi programs in municipalities (cities) are discussed below.

4.1 Data-driven Smart City

The second key element of the framework tackles the question of smart cities embracing the use of data for decision-making (Mazzei and Noble, 2017). Many 'big' metros in South Africa profess to be working toward being smart cities (Das, 2020). The reality is that smart cities employ the Internet of Things (IoT) and big data analytics (Bassoo, et al., 2018); and use sensors to generate data (Gohar et al., 2018). So data management systems are one of the major imperatives for smart cities (Tang et al., 2015). In addition, smart cities are required to have a proper appreciation of the strategic implications of data (Wang et al., 2018). The capability to capture and analyze data to generate value is highly important (George et al., 2014). Digital transformation cannot be achieved in organizations which do not employ a digital-savvy workforce (Warner

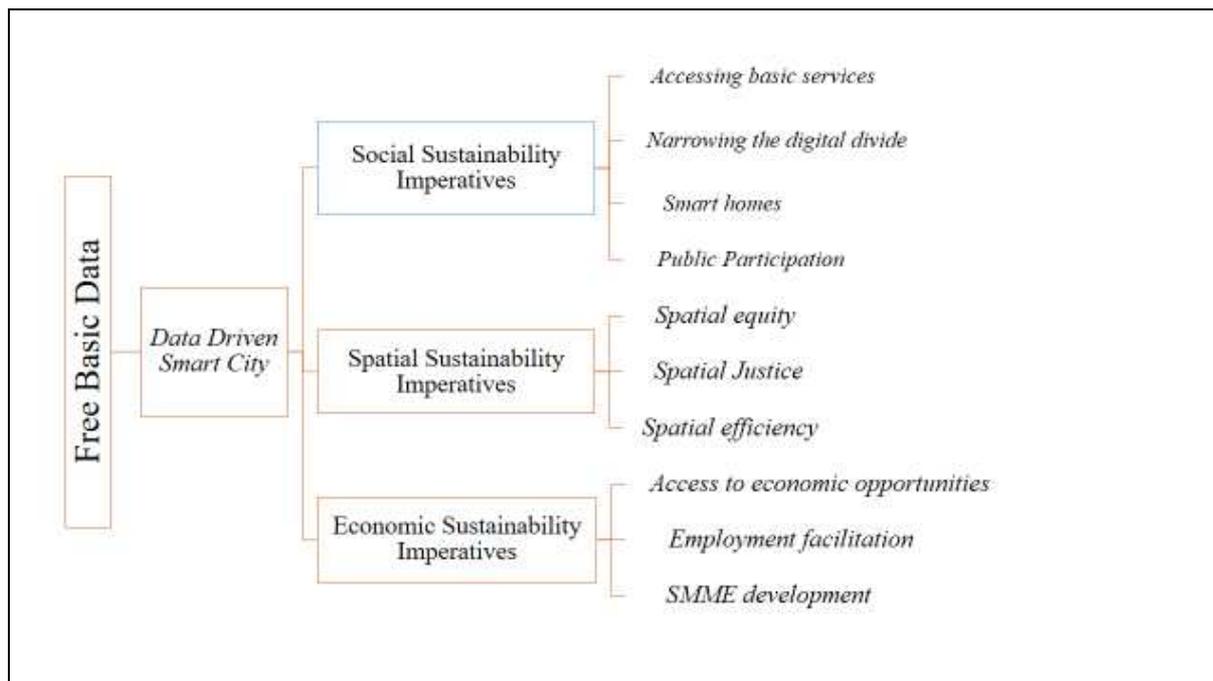
and Wager, 2019) because these workers shape the organizational digital capabilities of an organization (Felin et al., 2012). Some of the key skills needed include data analysts, who handle data flow management and deploy data analytics tools (Mikalef et al., 2018). Meanwhile, data scientists assist organizations to derive insights from data (Ho et al., 2019). The appointment of competent key C-suite functionaries such as the Chief Information Officer (CIO) and Chief Data Officer can assist organizations to build capabilities to use data for decision-making purposes (Vogelsang et al., 2019). A CDO, for instance, can lead digital transformation (Singh et al., 2020), and the development of a "digital" strategy for an organization (Tumbas et al., 2018). The implications of all these for smart cities is that cities should appreciate that communities are using the Internet of Things more than ever before. So, cities need to develop strong capabilities to handle data-savvy communities. Importantly for this study, cities need to find ways of assisting communities, especially the poorest of the poor, to access data, due to cost or data restrictions (Golub, et al., 2019). This matter is discussed further below.


Figure 1: Key elements of the conceptual framework model for sustainable free Wi-Fi programs in municipalities, Source: Author (2023).

4.2 Social sustainability imperatives

Under the social sustainability imperative, the first motivation is that the actual reality is that some of the basic services in the 21st century can be provided digitally. So, access to data as a free service would have multiplier effects for accessing other basic services as well. For instance, Robertson, et al (2019) found that the provision of free Wi-Fi contributes to narrowing the digital divide and assisting residents to view their utility bills online. In addition, many scholars (Vigil-Hayes, et al. (2018); Zarocostas (2020); Hanson, et al. (2020), Kroese et al., (2021); Ullah, et al., (2021); Gibbs, et al., (2022) found that Internet access is one of the means through which communities access health-related services. It has been found that since the advent of the COVID-19 epidemic, the delivery of education services has changed, and embraced digital methods (Joffe, 2021; Vigil-Hayes, et al., 2018). So, internet access is one of the most prominent means to access education services (Cobo et al., 2020; Antoni, 2020; Mondal, 2020). Libraries in most parts of the world utilize free Wi-Fi (Vigil-Hayes, et al., 2018; Mersand, et al., 2019; Lenstra and Campana, 2022).

Scholars such as Castells (2000:442), we are living in the days of an "information society", characterised by "flows of capital, flows of information, flows of technology, flows of organizational interaction, flows of images, sounds, and symbols". This "information society" further creates network societies between the virtual and real worlds; thus creating social capital (Claridge, 2018; Colbjørnsen 2021). So, internet access is no longer a luxury, as it is needed by all communities to share information and content-related data (Vigil-Hayes, et al., 2018). From this perspective, the provision of free data can enhance societal transformation (Crowdy and Horst, 2022). Free data can enhance the application of smart homes (Nettikadan, and Raj,

2018). For many poorer households, this will never become a reality without the assistance of free municipal Wi-Fi. Free municipal Wi-Fi can assist greatly in youth development efforts. Young people spent at least 20% of their daily time on the Internet, for various reasons (Agbawe, 2018; Fab-Ukozor and Ojiakor, 2020: 24); including skills development (Ojeleye, et al., 2018); and wealth creation in the world of self-employment and entrepreneurship (Agbawe, 2018). Free municipal Wi-Fi can assist municipalities to enhance their informational right to the city. The informational right to a city can be seen as a "sub-set" of the concept of the right to a city. On its own, the right to the city is seen as an agenda for social change (Vergara-Perucich, and Arias-Loyola, 2019), especially in the context of smart cities (Van der Graaf, 2020). So, Free Wi-Fi possess the potential to promote informational access for the citizens because today, networks are based on borderless informational networks, powered by the internet (Yang and Saffer, 2019). In South Africa, Section 32 (1) (a) of the Constitution provides that everyone has the right of access to information. Similarly, the Promotion of Access to Information Act (2000) advocates for the informational rights of citizens.

In this study, a majority (68%) of the free Wi-Fi users who participated in the online survey believe that the Tshwane Free Wi-Fi made either lot or modest contribution to the residents exercising their informational rights in the City of Tshwane. It is encouraging that the users express a positive affirmation about the contribution of free Wi-Fi in advancing informational rights in the context of the fourth industrial revolution.

Equally, the majority of stakeholders who participated in the interviews believe that the free Wi-Fi's making a lot of contribution (60% plus) in terms of promoting informational rights to the city. However, one of the independent experts points out that sometimes information asymmetries negatively affect the informational right of the city. These findings seem to align with the findings of other scholars. For example, Robertson, et al. (2019) posit, among others, that the provision of free Wi-Fi can contribute to narrowing the digital divide. Similarly, Vigil-Hayes, et al. (2018) found that where data is 'effectively free', informational right to a city can easily take place (Crowdy and Horst, 2022). The information right to the city can be pertinent to the youth, who use a lot of data for a variety of informational purposes (Umeogu and Ojiakor, 2014). From a policy perspective, if achieved, the South African government's ambitious target of achieving 100% broadband access to everyone by 2030 could lead to better informational rights in the city. International research by the United Nations (2020) found that the deployment of ICTs can facilitate digital interaction and public participation. The informational right to a city can be seen as a "sub-set" of the concept of the right to a city. On its own, the right to the city is seen as an agenda for social change (Vergara-Perucich, and Arias-Loyola, 2019), especially in the context of smart cities (Van der Graaf, 2020). Free Wi-Fi can positively contribute to social networking created through digital technologies. So, they possess the potential to promote informational access for the citizens. Today, networks are based on borderless informational networks, powered by the internet (Yang and Saffer, 2019).

In South Africa, Section 32 (1) (a) of the Constitution provides that everyone has the right of access to information. Similarly, the Promotion of Access to Information Act (2000) advocates for the informational rights of citizens. In this study, the results showed that a majority (68%) of the free Wi-Fi users who participated in the online survey believe that the Tshwane Free Wi-Fi made either lot or modest contribution to the residents exercising their informational rights in the City of Tshwane. It is encouraging that the users express a positive affirmation about the contribution of free Wi-Fi in advancing informational rights in the context of the fourth industrial revolution. Various scholars confirm that in South Africa, prohibitive costs, and access to data remain some of the key challenges (Lorini et al., 2019; Tshishonga, 2020, and Muridzi, et al., 2021). Free data can enhance the application of smart homes (Nettikadan, and Raj, 2018). For many poorer households, this will never become a reality without the assistance of free municipal Wi-Fi. Sixthly, free municipal Wi-Fi can assist greatly in youth development efforts. Young people spent at least 20% of their daily time on the Internet, for various reasons (Agbawe, 2018; Fab-Ukozor and Ojiakor, 2020: 24); including skills development (Ojeleye, et al., 2018); and wealth creation in the world of self-employment and entrepreneurship (Agbawe, 2018).

4.3 Spatial sustainability imperatives

This framework model posits that a sustainable free Wi-Fi programmes should assist municipalities to address issues of spatial injustice in cities. Spatial inequality is one of the strongest predictors of disparities in the digital inequality stack. In countries such as India, just over 20% of people in rural have access to

internet connectivity. Taiwan has managed to address this through the provision of good-quality internet access and computer training in rural areas. The introduction of free Wi-Fi technologies can go a long way to halting the widening of the gap between rural and urban residents. Such efforts should be accompanied by skill-building opportunities, along with investment in infrastructure, and improvement of information services (Robinson, et al., 2020). In South Africa, the municipalities are required by law to consider principles of spatial justice, efficiency, and sustainability (RSA, 2013). This implies that when municipalities consider investment decisions on free Wi-Fi, they must consciously and deliberately ensure that such investments will have the effect of building inclusive cities and communities (spatial justice). In other words, municipalities must not use free Wi-Fi technologies to entrench and reinforce apartheid spatial injustice in South Africa.

In this study, the results showed that a majority (92%) of the free Wi-Fi users who participated in the online survey believe that the Tshwane Free Wi-Fi is making a lot of contributions in terms of enhancing spatial justice. Equally, the majority of stakeholders who participated in the interviews believe that free Wi-Fi's making a lot of contribution in terms of addressing the question of spatial justice. Some of the stakeholders believe that some people wouldn't have to travel if the township economies were strong and vibrant. However, others believe that free Wi-Fi is only beneficial to those living in closer range of the Wi-Fi. However, as a matter of principle, the free Wi-Fi users who participated in the online survey believe that free-Wi-Fi should serve everyone irrespective of their location. A majority of these participants (52%) value the importance of free Wi-Fi to address spatial inequalities. In addition, even though the majority of stakeholders who participated in the interviews believe that free-Wi-Fi should serve everyone irrespective of their location, from a practical point of view, a majority of these respondents either disagree or strongly disagree that the current modus operandi is one where the free Wi-Fi benefits everyone irrespective of their geographic locations. They believe that the free Wi-Fi tends to benefit those that are located in cities and urban areas. They argue that the Wi-Fi's are accessible to, and favours the rich, whereas the poor can't access them due to locational disadvantages. This is a spatial justice matter that cities should give close attention when they design their free Wi-Fi programmes.

There is a need to take an integrative approach in tackling pertinent questions about the use of municipal technologies to address spatiality questions in cities. The views of free Wi-Fi users and stakeholders regarding their perspectives on the extent, and whether or not the free Wi-Fi is advancing goals of spatial justice, access and equity need to be engaged. The use of Geographic Information System (GIS) tools to show the extent to which the spatial allocation of the free Wi-Fi in different regions and/or areas in cities is promoting principles of spatial justice, access and equity is also important. Municipalities need to have transparent and objective tool/criterion for allocating free Wi-Fi sites per region and/or area. For instance, in the case of the City of Tshwane, it is not clear if the city uses data on the population size, digital literacy, community needs, and data usage trends. In the absence of such an objective and transparent data-based process, key decisions about allocating free WiFi infrastructure could be based on political considerations, thus threatening the sustainability of the programme. The spatial planning principles of equity, efficiency, good governance, and spatial justice could be useful in this regard. Another interesting observation is the possibility of cross-border usage by residents between wards and between regions. In addition, cities need to consider strategies to allocate free Wi-Fi infrastructure in rural and/or agricultural areas. These are critical questions worth investigating further.

It should be mentioned that geographic universal provision of WiFi encounters the same problem as supplying other services throughout remote and low density areas (e.g. public transport, health care provision, etc). Other spatial policies would need too be considered simultaneously, as well as fiscal arrangements which would cross subsidise consumption services in remote low density areas. It is also a matter of finding the funding for universal provision of wifi at municipal level. By their nature poorer communities have more restricted budgets to spend on public services. Installing WiFi masts throughout the vast country of South Africa may be beyond municipal budgets. Perhaps experimenting with, and adopting alternative, cheaper, more efficient technologies like light driven 'LiFy' could be an option (see BBC radio 4, The Life Scientific (interview of Harald Haas by Jim Al'Khalili, 230627, 9am on optical wireless communication technology to access the internet, BBS sounds – a simple desk lamp was used to stream a video on 2011).

4.4 Economic sustainability imperatives

This framework model posits that a sustainable free Wi-Fi programmes should assist municipalities to address issues of economic disparities in cities. In South Africa, cities like Cape Town have high levels of economic inequality (Enqvist and Ziervogel, 2019). It means the rich are getting richer and the poor getting poorer. So, municipalities can use free Wi-Fi to address some of the intricate issues about economic injustices. Admittedly, often, there is an overlap between social and economic and/or distributive justice (Moroni, 2020). In this regard, it is argued that cities should find innovative ways to use free Wi-Fi platforms to foster environments where access to opportunities which can better the economic and/or financial position or status of community members can be constructed. So, free Wi-Fi can be deliberately used by cities to serve redistributive intentions of addressing some of the economic dimensions of justice within a city, especially in cities where the rich are getting richer and the poor getting poorer.

As cities go through periods of economic decline, the issue of economic justice becomes even more prominently important (Rodrigues and Franco, 2020). Free Wi-Fi should be used to reverse all forms of marginalisation and exclusion of people, whether based on gender, creed, class, etc can be a norm in cities. When justice is delivered to people, this can have positive economic outcomes on people in cities (Baars, et al., 2021). In the context of the "right to the city", free data should be seen as one of the foundational basis for smart city endeavours. As scholars such as Ragnedda et al. (2020) correctly posit, the economic class does affect the accumulation of digital assets and capital. This means that those who have access to economic opportunities and higher incomes are more likely to acquire digital tools than low-income groups.

So, the free Wi-Fi interventions can be designed from a policy perspective with an inherent agenda to redress such inequalities and imbalances. The reality is that access to the Internet access is one of the potent means through which communities access economic activities/services (Vigil-Hayes et al., 2018); and lack thereof can lead to a state of poor income, or financial instability (Lau, et al., 2022). So, the relationship between access to income and access to data remains (Smith, 2020). In countries such as Indonesia, free Wi-Fi interventions have been used successfully to assist village entrepreneurs to improve online marketing; thus promoting their products to the wider market (Kania, Anggadwita, and Alamanda, 2021). Such efforts of using free Wi-Fi as an economic tool of redress are needed, especially in African cities, where economic inequalities are growing. In this study, the results showed that a majority (79%) of the free Wi-Fi users who participated in the online survey agree that many residents in Tshwane rely on the Tshwane Free Wi-Fi for economic opportunities such as job application and business transactions. Equally, the majority of stakeholders who participated in the interviews believe that the free Wi-Fi's making is making a modest contribution (40%-59%) in terms of enhancing access to economic opportunities.

In South Africa, many municipalities talk about developing the local township economy. So, the free Wi-Fi data can be used to enhance the implementation of this strategy, through focussed attention to local small bsuinesses such as grocery food stores, spaza shops, shisanyama, pubs, hair salons, car wash businesses, internet cafes. The free Wi-Fi data can be used to empower local small businesses for a variety of things, including, to communicate with clients and suppliers, promoting and market local businesses, participating in social media platforms, accessing financial opportunities, doing financial transactions, etc. So, municipalities need to design their free Wi-Fi programmes with the small business operators in mind, with a view to assist them to improve sales; and income/profits. However, for that to happen effectively, municipalities need to overcome challenges such as distance, poor network, poor reliability, and load shedding, etc.

5 CONCLUSION

This paper makes some contribution on the discourse regarding whether free data should be seen as a basic service to be provided by municipalities in South Africa. This contribution is made in the context of data driven smart cities. The study does not endeavour to set a fixed amount of data as minimum free service. A one size fits all approach is not advocated. So, this is left for each individual municipal council to make policy choices in this regard. Inadvertently, some municipalities would afford to make a certain amount of data free; others could afford to offer more. This would depend on various contextual factors, including: budgets, affordability, and the ability of municipalities to embark on crowdfunding and partnerships with other stakeholders, etc. Significantly, the paper presents a conceptual framework model for sustainable municipal technological innovations in municipalities, using the free Wi-Fi in South African municipalities as an example. Currently, there is no framework model, and many municipalities are implementing free Wi-

Fi in rather uncoordinated ways, leading to unsustainable outcomes. This is one of the areas where this study is making some modest original contribution to the academic and practical discourse on sustainable municipal free Wi-Fi. In this regard, the paper presents three imperatives for a sustainable free municipal Wi-Fi programme, to cater for social sustainability imperatives, spatial sustainability imperatives, as well as economic sustainability imperatives. The conceptual framework model is flexible enough to be adapted for a variety of municipal technological innovations in municipalities, not just free Wi-Fi.

1   ABSTRACT

Coastal cities evolve in alignment with people centred development to accommodate their needs. Nevertheless, uncontrolled changes of significant elements of urban morphology such as land uses along the waterfront and respective public activities, lead to alterations in the quality of life provided. The research explores models that study the various configurations and implying the effective role of controlling urban developments guidelines in terms of environmental behavioural, social well being, health and safety.

This paper is divided into two main sections: Firstly, it focuses on Alexandria City's Urban Morphology, prospect of transformation plans and highlights the nature-based integrative solutions on its waterfront for the short and long-term plans through multiple disciplinary contributions. Secondly, the research defines the structured model to assess Quality of Life of Waterfront Settings, «QLWS» in Alexandria City, used for the analysis of selected sites. This model is used as a tool to assess the attractiveness and satisfaction of the existing spatial configurations in regard of professional observation. The discussion derives implications from the analysed data to support tracking relevant morphological mutations of social and physical parameters.

The research provides a guide to evaluate and promote natural based system integration for further transformation of sites incorporated within the city's strategic plan of 2032 to ensure sustainabillity, inclusivity, liveability and resilience.

Keywords: Coastal Cities, Natural Based Solutions, assessment indicators, Waterfront, Quality of Life

2   INTRODUCTION: URBAN DESIGN AND PLANNING DRIVEN BY NATURE-BASED SOLUTIONS

Coastal cities evolve in alignment with people centred development to accommodate their needs. Nevertheless, uncontrolled changes of significant elements of urban morphology such as land uses along the waterfront and respective public activities, lead to alterations in the quality of life provided. The research explores models that study the various configurations and implying the effective role of controlling urban developments guidelines in terms of environmental behavioural, social well being, health and safety. Urban design and planning driven by nature-based solutions play a significant role in transforming urban waterfront areas into sustainable and resilient spaces. It offers a transformative approach to building sustainable and liveable cities and has the ability to mitigate climate change, enhance biodiversity, improve human well-being, and foster economic growth.

Alexandria's waterfront proximity to the coast and recreational areas makes it an important setting for studying the health and well-being of residents and planning aspects that contribute to residents' quality of life (AS+P, 2020). The Alexandrian waterfront has undergone significant urban development and redevelopment projects, The city's waterfront has undergone two phases of development (AFD Report, 2015). The first phase involved widening the road and adding lanes by backfilling a portion of the sea. The second phase concentrated primarily on economic factors (Tawil, Arnouty, & Fadle, 2020).

3   RESEARCH METHODOLOGY

The research is divided into two main sections. Firstly, the study focuses on Alexandria City's Urban Morphology and its prospect of transformation plans, highlighting the nature-based integrative solutions on its waterfront for the short and long-term plans through multiple disciplinary interventions. Secondly, The research introduces the details of the structured model to assess Quality of Life of Waterfront Setting "QLWS" in Alexadria city, used for the analysis of selected sites. This model is used as a tool to assess the attractiveness and satisfaction of the existing spatial configurations in regard of professional observation. Finally, The discussion derives implications from the analysed data to support tracking relevant morphological mutations of social and physical parameters.

3.1 Nature-Based Solutions

The research relies on the opportunities provided by the hybrid (or multi-actor) governance for upscaling urban nature-based solutions (referred to as urban NbS), representing a demand-driven and cost-effective realization of urban enhanced spatial quality of life. The notion of applying nature-based solutions in urban development strategies implies the integration of multiple disciplines for the adapted design amd diversity of settings along the extended waterfront of Alexandria city that sustains the transformative potentials. The policies and procedures needed by urban planners have an open approach to collaborative governance of applying nature-based solutions while learning with and about new appealing designs, perceptions and images of nature from different urban actors (Haase A., 2018).

The most relevant concepts in adopting nature-based infrastructure and engineering with nature are the two common concepts which define NbS as "actions to protect, sustainably manage, and restore natural or modified ecosystems, that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits"; while the second concept states that "NbS are inspired and supported by nature and simultaneously provide environmental, social, cultural and economic benefits" (LIU, etal., 2021). Therefore from the two main approaches of NbS, the process adopted in this research enables a balanced system maintaining nature-based solutions through professional observation and analytical representation of the community and social perceptions to ensure inclusivity, liveability and resilience.

3.2 Quality of Life in the Alexandria Waterfront «QLWS» Assessment Model Indicators Setting

Contemporary lifestyle patterns have changed the meaning and scope of activities in open public spaces, shifting their focus from daytime to nighttime. In these circumstances, the vitality and liveability of these spaces depends on their ability to adapt to and support the flexibility of these changes, despite their physical limitations (Rokanjac, 2022). The principles of improvement and the criteria for assessing the public spaces of a large city, such as multifunctionality, safety, legibility, sustainability, human scale, interactivity and flexibility (Kozlova et al., 2018). Existing open spaces adhere to most of these criteria classified into two categories, physical and socio- cultural (Nayer, 2015). Finally, the urban spaces are evaluated by identification indicators associated with each criterion, and classification of it. The evaluation can determine the value of each indicator and its role in increasing the quality of life in an urban area, and in the present, spontaneously supplemented with objects and structures, expanding their boundaries and following the rhythm of urban development (Mahdzar S, et al., 2014).

To conclude the set of indicators and sub-indicators proposed in this research as a prominent tool for the assessment for the Quality of Life in Alexandria Waterfront "QLWS", they are used to analyse respective zones along the extended coastal line of the City of Alexandria. The structured model refers not only to quantitative but also qualitative dimensions related to the Nbs approaches, where the categories and indicators are derived from the Smart Urban Quality by Chiara G. et. Al., 2018. The set of indicators also supports the observation process by the research team, as the sub-indicators describe the urban context with completeness eliminating subjectivity during the evaluation process. This significant assessment is represented by the information displayed in Table 1.

"QLWS" combines traditional aspects of urban quality with smart and sustainable aspects related to quality of life, health and well-being. The observation enables the researchers to consider the perception levels of visitors of the waterfront regarding: a) Emotional wellbeing, b) Spatial and Environmental Characteristics, c) Social wellbeing, and d) Safety and security. In addition, each of these aspects is defined through the sub-categories identifying the actual status of users' experience in the visited sites presented in the case studies, such as presence of green area, attractiveness of surrounding buildings, quality of street lighting, easy mobility and others.

The overall analysis derived from the structured model indicators set supports the relevant integrated environmental services to maintain quality of life. The study extends to overlook the potential activities and their inclusivety to assure liveability and sustainable public space in terms of economic opportunity and social inclusion. The perspectives summed up by the research team describe each variable and sub-set of indicators in order to actively apply sustainable management and conservation of natural resources to meet major societal challenges. Therefore "QLWS" provides for a balanced analytical scheme carried out using

858

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

this assessment model of quality rating, relative to every need, at the census area of study, while investigating potentials of liveability and sustainability in the studied public spaces along the waterfront.

Main Indicators	Emotional wellbeing	Spatial and Environmental characteristic	Social wellbeing	Safety and security
Sub - Indicators	Presence and quality of green area	Noise control (Urban traffic)	Presence of spaces, services and activities suitable for children	Security and accessibility
	Attractiveness of surrounding buildings	Air pollution Control		Endurance to natural disaster
	Easy mobility	Presence of open spaces, services and activities	Economic opportunity and social cohesion	Design elements (Preventing any crime or injuries)
	Environmental maintenance	Healthcare services	Perception of safety	

Table 1: Indicators for the structured model of Quality of Life of Alexandria Waterfront, "QLWS", by authors.

4 URBAN MORPHOLOGY AND LANDSCAPE

The morphology of Alexandria City is strongly influenced by its coastal setting. The city has a long coastline that extends about 32 km along the coast of the Mediterranean Sea. It plays a significant role in shaping the city's identity and development and offers its residents a combination of natural beauty, recreational activities, cultural experiences, economic opportunities, and community gathering spaces. According to El Tawil et al.(2020), it is one of the major touristic targets, as well as one of the major motorists roads linking the entire city due to the linearity of Alexandria as a city.

Alexandria's waterfront proximity to the coast and recreational areas makes it an important setting for studying the health and well-being of residents and planning aspects that contribute to residents' quality of life. The Alexandrian waterfront has undergone two phases of significant urban development and redevelopment projects. The first phase began in the year 2000 and involved widening the road and adding lanes by backfilling a portion of the sea. The second phase began in the year 2018 and concentrated primarily on economic factors by moving some recreation areas and positioning the Sidi-Gaber bridge, which is elevated over the main street (Tawil, Arnouty, & Fadle, 2020).

The first stage of development improved social cohesion and harmony by making the city more walkable, connecting it longitudinally and providing spaces for cycling, creating an active zone. Providing spaces for walking (leisure and exercising) and cycling played a major role in enhancing the physical activity levels and mental health of residents (Farag, Saadallah, & Ayad, 2021). However it witnessed an increase in air pollution due to increased traffic density. The second stage relied on restaurants, cafeterias, and siting zones, whereby it encountered an increase in water pollution as a result of the presence of new places built directly on the sea without leaving any buffer zones. Furthermore, the construction of new cafes and restaurants and parking areas for them resulted in the loss of some parts of the sea view (Figure 1 a&b), which is a prominent natural view for Alexandria's residents. This led to a rise in despair by the residents (Tawil, Arnouty, & Fadle, 2020).

Figure 1 (a) and (b): Cafes, restaurants and parking areas blocking parts of sea view, by authors.

5 STUDY AREA AND SELECTION CRITERIA

Since improving public spaces, revitalizing the waterfront, and promoting sustainable development practices have been the main goals of modern urban planning initiatives, six open public places are selected for this study in an attempt to assess their attractiveness and satisfaction as a contribution to making the waterfront area a desirable place to live and enjoy the benefits of coastal living. By assessing environmental behaviour and its impact on the quality of life along the Alexandria Egypt waterfront, valuable insights can be gained to inform strategies for enhancing sustainability, fostering a sense of environmental responsibility, and improving the overall well-being of the community. The findings can guide the development of targeted

interventions, policies, and educational initiatives aimed at promoting sustainable behaviours and improving the environmental quality of the waterfront area.

The selected sites for the study are public open spaces and they extend along the shoreline of Alexandria City. The selected open areas for the study are located in the following areas respectively : 1) "Qaitbay" waterfront area, 2) "Ras El Tin" area, 3)" El Selsela" park area, 4)"Cleopatra" area, 5)"Louran" area and 6)"Bir Masoud" area (Figure 2). These six study areas are selected because they are not restricted to a specific group, but rather are welcoming to individuals and families of all ages. They are accessible all year and provide the best possible sea view. Moreover, they encourage interaction and connection between residents and the waterfront. Each of these areas represents a 100 to 500 m walking buffer.

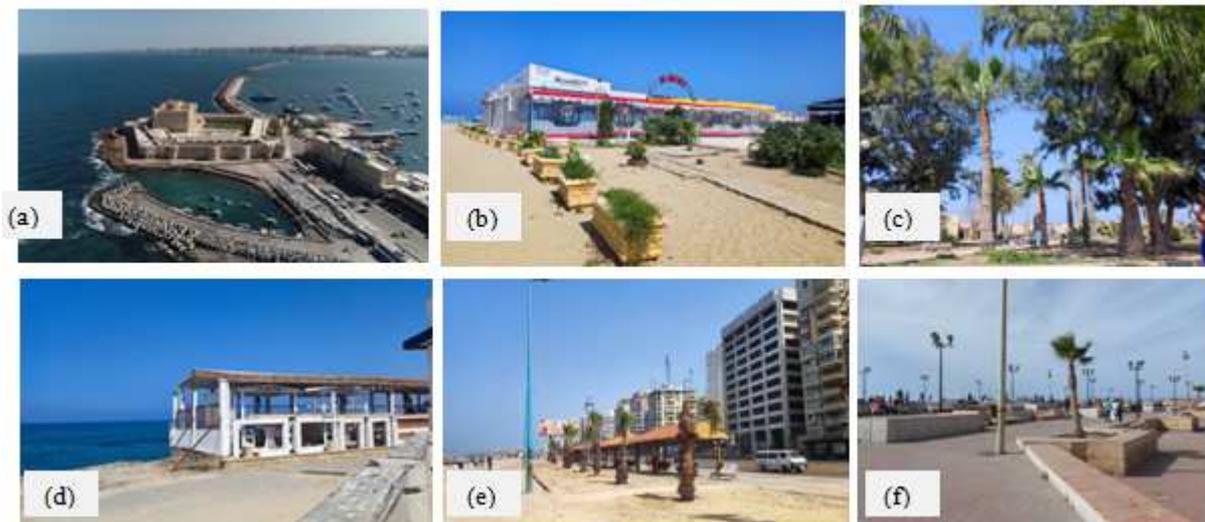
Figure 2: Base map of the Six Selected Study areas along Alexandria extended Waterfront, by authors.


Figure (3): Six study areas (a) "Qaitbay" waterfront area. (b) "Ras El Tin" area, (c) "Selsela" park area (d) "Cleopatra" waterfront area, (e) "Louran" waterfront area and (f) "Bir Masoud" area, by authors.

5.1 "Qaitbay" Waterfront

The Citadel of Qaitbay area is situated in the Eastern Harbour of Alexandria city overlooking the sea (Figure 3a). It is known for its historical significance and is a major asset to the city and attracts citizens for gathering and tourists to enjoy its great view and enhance its monumentality. Qaitbay Citadel is a fortress built in the 15th century by Sultan Qaitbay. It offers panoramic views of the surrounding cityscape and the sea. It features cultural and recreational spaces that add to its appeal. A mix of facilities is provided along the waterfront that would appeal to visitors, and establish a specific local sense of place due to the Citadel of

860

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Qaitbay. There are also shops, cafes, and restaurants that cater for the needs of residents and visitors. The area has a lively atmosphere with a blend of local businesses and tourist-oriented establishments.

5.2 "Ras El Tin" area

Ras El Tin is situated on the eastern edge of Alexandria, along the Mediterranean Sea. Its location provides direct access to the waterfront. The Ras El Tin area features beautiful sandy beaches along the waterfront (Figure 3b). Residents and visitors can enjoy sunbathing, swimming, and beachside activities. The beaches in this area offer a space for people to unwind and enjoy the coastal environment. The Ras El Tin waterfront offers a pleasant promenade where residents and visitors can stroll and enjoy views of the sea.

5.3 "Selsela Park" area

Selsela Park is a public park located in front of the Bibliotheca Alexandrina in Alexandria City. It is a popular recreational space that serves as a gathering place for residents and visitors (Figure 3c). Its location provides convenient access for visitors to enjoy the park, relax and socialise. The park includes paved walking paths that meander through the greenery. It also provides seating areas scattered throughout the park.

5.4 "Cleopatra" waterfront area

The Cleopatra area is a well-known district. It is a bustling and vibrant part of Alexandria city. It is characterized by its wide streets, high-rise buildings, and a mix of residential, commercial, and recreational spaces. There is also a path only for pedestrians where they can walk and exercise freely. The waterfront parts of this area is home to numerous restaurants, cafes, and entertainment venues easily accessible by various means of convenient transportation options such as: public buses, taxis, and private cars. However, the presence of restaurants and cafes along the waterfront affect the sea view for the residents where some of these establishments partially obstruct the view of the sea (Figure 3d) and block parts of the walking paths made for pedestrians.

5.5 "Louran" area

Louran is a residential area in the middle of Alexandria city. The waterfront area in Louran also contains promenades that offer opportunities for leisurely walks, picnics, and gatherings to its residents. The studied area in Louran is a shaded public area constructed for pedestrians to sit and rest in the shade, socialise and enjoy the waterfront atmosphere, with restaurants and cafes beside it to provide food and beverage services. Patches of green areas and palm trees are also present but are currently under development (Figure 3e).

5.6 "Bir Masoud" area

"Bir Masoud" is an open space overlooking the sea located in the Sidi-Beshr residential area. This place has many legends revolving around it and is famous for a being a place that fulfils wishes by throwing coins into the well. The open space provides opportunities for socialising, picnicking, and enjoying the view of the sea. It also serves as valuable public resources where individuals and families can unwind, engage in leisure activities and some where residents can do some fishing. Restaurants are available around the area to provide food and beverage services to the residents (Figure 3f).

6 URBAN REGENERATION OBSERVATION AND ANALYSIS RESULTS

A site visit to the six sites under study was carried out in order to gather data, assess the attractiveness and satisfaction of the current spatial configurations, and record observations. Assessment was done using the survey mentioned above, that evaluates the following attributes: a) Emotional Wellbeing, b) Spatial and Environmental Characteristics, c) Social Wellbeing and d) Security and Safety from Natural Disaster, Crime and Injuries of each site. The following section discusses each of the mentioned indicators in the areas under study.

6.1 Emotional Wellbeing Attribute

Emotional well-being is influenced by various indicators, which are shown in table 2.

EMOTIONAL WELLBEING	INDICATORS	SUBINDICATORS
	i. Presence and Quality of green area	% of green area available
	ii. Attractiveness of surrounding buildings	Relative attractiveness
		Design : form and material
		Finishes
		Maintenance
	iii. Easy mobility	Availability of different transportation modes
	iv. Environmental maintenance	Cleanliness of space
		Condition of space
		Condition of pedestrians' area
		Quality of seating

Table 2: Indicators influencing the Emotional Wellbeing Attributes, by authors.

Figure 4: Surrounding area at (a) Qaitaby waterfront area, (b) El Selsela park area and (c) Cleopatra waterfront area, by authors.

Table 3 illustrates observations of each site under study regarding the emotional wellbeing attributes.

Indicator: (i) Presence of Green Area		
Study area	%	Actual Condition for related settings
Qaitbay waterfront area	0%	No green area
Ras El Tin area	20%	Ras El tin mainly consists of beaches along with restaurants, cafeterias and clubs. The available green space can only be found in the children's playing areas
El Selsela Park area	85%	The entire park comprises green areas with pedestrian paths flowing through them, as well as trees and palm trees to provide shade to people.
Cleopatra waterfront area	0%	No green area
Louran waterfront area	67%	The existing green areas and palm trees are between the seating area and pedestrian route, however these green spaces were still under renovation at the time of the site visit.
Bir Masoud area	0%	No green area
Indicator: (ii) Attractiveness of Surrounding Buildings		
Study area	%	Actual condition of related settings
Qaitbay waterfront area	65%	Some of the buildings there are currently under renovation
Ras El Tin area	42%	Buildings in the Ras El Tin area are not attractive and some need maintenance
El Selsela Park area	83%	The park is located in front of Bibliotheca Alexandrina. Moreover, it contains a white statue of a mermaid which is considered as a landmark of the area
Cleopatra waterfront area	67%	Consists of residential buildings overlooking the sea. Some of them are newly built, others are old and need some renovations.
Louran waterfront area	67%	
Bir Masoud area	67%	
Indicator: (iii) Presence of Easy Mobility Services		
Study area	%	Actual condition for related settings
Qaitbay waterfront area	100%	All areas are reachable and accessible via several means of transportation, including public transportation, taxis, private automobiles, and buses.
Ras El Tin area		
El Selsela Park area		
Cleopatra waterfront area		
Louran waterfront area		
Bir Masoud area		
Indicator: (iv) Environmental Maintenance Indicator		
Study area	%	Actual condition of related settings
Qaitbay waterfront area	55%	Poor condition of space and pedestrian area as a result to the current developments taking place there
Ras El Tin area	67%	Moderate condition of space in which maintenance is required to the seating areas and to the restaurants and cafeterias located there
El Selsela Park area	80%	The overall condition is due to cleanliness and good condition of the pedestrian route
Cleopatra waterfront area	75%	Some of the seating areas there need maintenance
Louran waterfront area	75%	Moderate condition of space and seating area due to the current development taking place there
Bir Masoud area	90%	Good condition of the space, pedestrian area, and seats

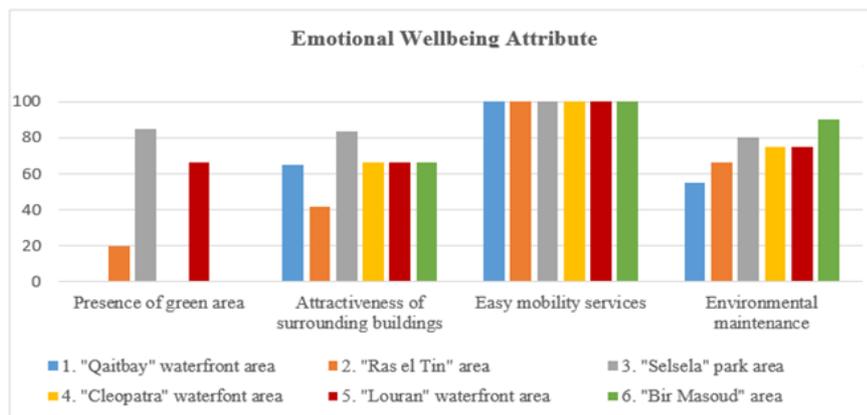
Table 3: Percentage and observation of the Emotional Wellbeing Attributes in each site under study, by authors.


Figure 5: Percentages of Emotional Wellbeing Indicators in the six understudy areas, by authors.

6.2 Spatial and Environmental Characteristics Attribute

The assessment of Entivronmental Characteristics attribute adopted a number of indicators. They are shown in table 4.

	INDICATORS	SUB - INDICATORS
SPATIAL AND ENVIRONMENTAL CHARACTERISTICS	i. Noise control (Urban traffic)	Horns level control
		Distance from traffic, cars
	ii. Air pollution Control	Number of street lanes
		Flow of traffic
		Availability of trees
		Availability of open space
	iii. Presence of open spaces, services and activities	Percentage of open space
		Quality of services
		Presence of urban furniture
		Presence of parking areas
	iv. Healthcare services	Presence of medial office
		Quality of medical office
		Presence of ambulance

Table 4: Indicators adopted for the Environmental Characteristics Attribute, by authors.

Figure 6: Urban furniture and seating areas at (a) El Selsela Park, at (b) Louran area and at (c) Bir Masoud area, by authors.

Table 5 illustrates percentages and observation of each site understudy in Environmental characteristics attribute.

Indicator: (i) Noise Control (Urban traffic)

Study area	%	Actual Condition for related settings
Qaitbay waterfront area	95%	The furthest away from car traffic. People enter the area with their cars only to park. This results in the low levels of car horns in the area.
Ras El Tin area	50%	Beaches are considered far from the traffic, but restaurants and cafeterias there are closer to traffic
El Selsela Park area	33%	Closer to car traffic, resulting in light levels of car horns makeing the place a bit noisy during some times of the day.
Cleopatra waterfront area	33%	
Louran waterfront area	33%	
Bir Masoud area	33%	

Indicator: (ii) Air Pollution Control

Study area	%	Actual Condition for related settings
Qaitbay waterfront area	85%	Air pollution control in the six understudy areas are moderate to high. This is because they all overlook the sea and thus receive fresh air from it. However, they are near the cars traffic with wide street and high traffic flow condition.
Ras El Tin area	67%	
El Selsela Park area	83%	
Cleopatra waterfront area	67%	
Louran waterfront area	75%	
Bir Masoud area	65%	

Indicator: (iii) Presence of Open Spaces, Services and Activities

Study area	%	Actual Condition for related settings
Qaitbay waterfront area	73%	The Qaitbay waterfront has high percentage owing to the availability of vast open spaces and good quality of services available
Ras El Tin area	67%	Availability of vast open spaces but moderate quality of services
El Selsela Park area	55%	Moderate quality of services and urban furniture. Absence of parking areas
Cleopatra waterfront area	55%	Moderate condition of urban furniture where some of the seating needs maintenance as well as moderate quality of available servies
Louran waterfront area	27%	Got the lowest perentage due to the lack of parking spots, in addition to the fact that it is now under development, resulting in inferior service quality.
Bir Masoud area	67%	Lack of parking areas along with moderate services and urban furniture.

Indicator: (iv) Healthcare Services

Study area	%	Actual Condition for related settings
Qaitbay waterfront area	70%	Health care services are available as it is an important touristic attraction area
Ras El Tin area	60%	There is a healthcare medical office available near there but it needs improvements
El Selsela Park area	0%	These areas rely on mobile ambulance services
Cleopatra waterfront area	0%	
Louran waterfront area	0%	
Bir Masoud area	0%	

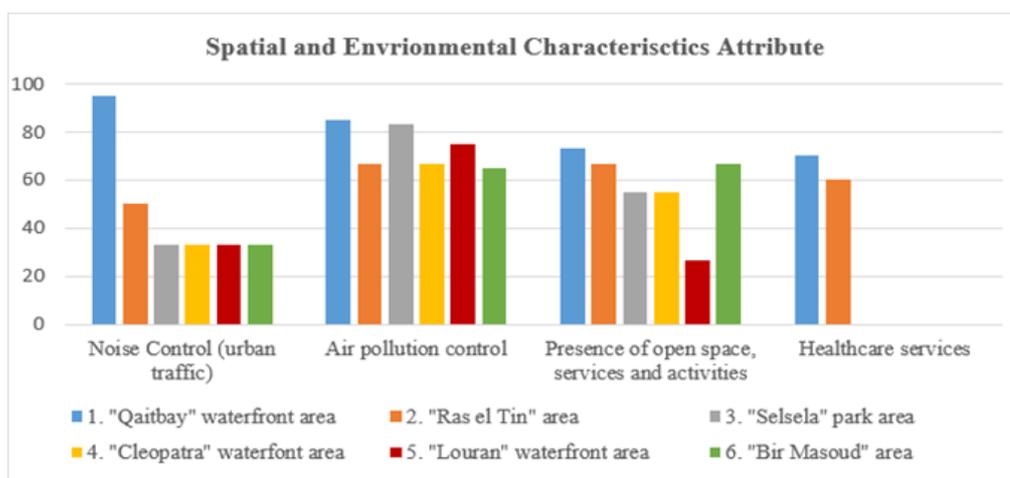
Table 5: Percentage and observation of Environmental Characteristics Attributes in each site under sstudy, by authors.


Figure 7: Percentages of Spatial Environmental Characteristics Indicators in the understudy areas, by authors.

6.3 Social Wellbeing Attribute

Social wellbeing is also assessed by evaluating and observing several indicators, they are demonstrated in table 6.

	INDICATORS	SUB - INDICATORS
SOCIAL WELLBEING	i. Presence of spaces, services and activities suitable for children	Availability of Childcare facility
		Quality of available childcare facility
		Percentage of open childcare space
	ii. Economic opportunity and social cohesion	Socio-economic level
		Social Cohesion
	iii. Perception of safety	Sense of safety
		Availability of threat
		Type of threat (if available)

Table 6: Indicators assessed in the Social Wellbeing Attribute, by authors.

Indicator: (i) Presence of Spaces, Services and Activities Suitable for Children		
Study area	%	Actual condition for related settings
Qaitbay waterfront area	0%	No playing area for children available
Ras El Tin area	60%	There is a playing area for children but of poor condition
El Selsela Park area	15%	No playing area for children available, however they can play in the green areas available
Cleopatra waterfront area	89%	There is a playing area for children alongside the cafés and restaurants situated there
Louran waterfront area	0%	No playing area for children available
Bir Masoud area	0%	No playing area for children available
Indicator: (ii) Economic Opportunity and Social Cohesion		
Study area	%	Actual condition for related settings
Qaitbay waterfront area	89%	The highest percentage, because the majority of visitors are tourists and the location provides excellent opportunities for social cohesion
Ras El Tin area	50%	It allows high social cohesion opportunities among residents, however the people are of moderate socioeconomic and economic status.
El Selsela Park area	67%	They are equal in percentages because they receive residents of similar socio-economic level. Social cohesion is high but less than that at Qaitbay waterfront area.
Cleopatra waterfront area	67%	
Louran waterfront area	67%	
Bir Masoud area	65%	It allows very high social cohesion opportunities among residents, however the people are of moderate socioeconomic and economic status specially visitors from neighbouring rural areas.
Indicator: (iii) Perception of Safety		
Study area	%	Actual condition for related settings
Qaitbay waterfront area	89%	High sense of safety as they are crowded with people during the daytime, especially on weekends. However the presence of beggars results in the slight decrease of security perception
Ras El Tin area	56%	May experience more risks than other areas because of their lower socioeconomic status. However, it is crowded with people during the daytime and at night especially on weekends and in the summer.
El Selsela Park area	56%	Sense of safety at El Selsela park area decreases at night because the street lights are inadequate, thus people avoid going there after it gets dark
Cleopatra waterfront area	89%	High sense of safety as they are crowded with people during the daytime especially on weekends. However the presence of beggars results in the slight decrease of security perception
Louran waterfront area	67%	Even though streetlights in the Louran area are also inadequate at night, but with the presence of nearby cafes, people feel safer there than they do in the El Selsela park area
Bir Masoud area	56%	May experience more risks than other areas because to their lower socioeconomic status. However, its crowded with people during the daytime and at night especially on weekends and in summer.

Table 7: Percentage and observation of Social Wellbeing Attribute in each site understudy, by authors.

Figure 8: Open Spaces at (a) Selsela park area, (b) Ras El Tin area and (c) Louran waterfront area, by authors.

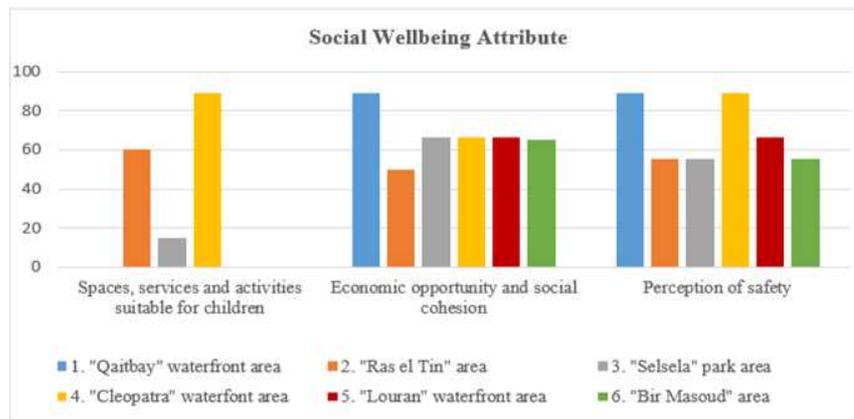
Table 7 illustrates percentages and observation of each site understudy in Social wellbeing attribute.


Figure 9: Percentages of Social Wellbeing indicators in the six areas understudy, by authors.

6.4 Security and Safety from Natural Disaster, Crime and Injuries

Indicators and Sub-indicators that are used to assess security and safety from natural disaster and crime are illustrated in table 8.

	INDICATORS	SUB-INDICATORS
SECURITY AND SAFETY from natural disaster, crime and injuries	i. Security and Accessibility	Surveillance
		Security presence
		Low level of crime
		Sightlines and clear visibility
		Clear access points
		Convenient access points
		Clear boundaries of space
	ii. Endurance to Natural Disaster	Endurance of space from natural disaster
	iii. Design Elements (to prevent any crime or injuries)	Quality of paving materials
		Smooth and safe pedestrian movement (no obstacles)
		Clear pedestrian routes
		Lighting levels of space
		Density of visitors

Table 8: Indicators and Sub-indicators assessed in the Security and Safety Attribute, by authors.

Table 9 illustrates percentages and observation of each site understudy in Security and Safety Attribute

Figure 10: Percentages of Safety and Security indicators in the six areas understudy, by authors.

Indicator: (i) Security and Accessibility		
Study area	%	Actual Condition for related settings
Qaitbay waterfront area	95%	It is found to be the highest/ Due to the importance and significance of the Qaitbay waterfront area as a main attraction site for tourists in Alexandria City, there is constant surveillance and security presence to reduce the level of crime. There are also clear and convenient access points to the area. However, some buildings there are under development that slightly reduces the clear visibility of the whole area.
Ras El Tin area	76%	It is near a military base and has clear accessibility points, however these access points need improvements to be more convenient
El Selsela Park area	81%	It is near a military base and has clear and convenient accessibility points
Cleopatra waterfront area	76%	Has relative high percentage of security in addition to clear and convenient accessibility points
Louran waterfront area	70%	Has moderate percentage of security, however there are clear and convenient accessibility points
Bir Masoud area	70%	
Indicator: (ii) Endurance to Natural Disaster		
Study area	%	Actual condition for related settings
Qaitbay waterfront area	70%	Endurance is high due to water catchments installed around the area
Ras El Tin area	25%	Endurance is low because it is mainly a beach that makes it very susceptibility to any changes of the sea and some of the restaurants and cafeterias are on the beach.
El Selsela Park area	60%	Perentage is moderate because there is a military base there that has catchments installed to prevent any harm
Cleopatra waterfront area	35%	Endurance is low due to the proximity to the sea and susceptibility to its effects.
Louran waterfront area	35%	
Bir Masoud area	67%	Endurance is relatively moderate to high because its level is higher than that of the sea level and the main street as well.
Indicator: (iii) Design Elements		
Study area	%	Actual condition for related settings
Qaitbay waterfront area	75%	Design elements are affected, due to current development taking place there
Ras El Tin area	76%	Area recieves high density of residents. However, smoothness in movemenr and lighting levels of space are moderate in level
El Selsela Park area	80%	Good condition of paving materials. There is smoothness in movement and clear pedestrians paths, however the areas has low lighting levels at night
Cleopatra waterfront area	86%	Good condition of paving materials, smoothness in movement and clear pedestrians paths
Louran waterfront area	62%	Lowest in percentage due to the developments that are currently taking place there.
Bir Masoud area	90%	Good paving materials, high density of visitors, smooth movement in the area and adequate lighting levels

Table 9: Percentage and observation of Security and Safety Attribute in each site understudy, by authors.

6.5 Quality of Life in each of the areas under study

Combining the attributes evaluated above: a) Emotional Wellbeing, b) Spatial and Environmental Characteristics, c) Social Wellbeing, d) Security and Safety from Natural Disaster, e) Crime and Injuries of each site, it is possible to determine the quality of each of the areas under study, illustrated in the Table 10, below. Impact of indicators are calculated with equal weights to assure maximum value of quality of life to all study areas.

Indicators / Area understudy	Emotional wellbeing	Spatial and Environmental characteristic	Social wellbeing	Safety and security	Total score	Total Quality of life
	Out of 400	Out of 400	Out of 300	Out of 300	Out of 1400	%
Qaitbay waterfront area	220	323	178	235	956	68.3%
	The Qaitbay waterfront area has the highest quality of life, as it is one of the primary tourist destinations. Nevertheless, quality of life there is affected by lack of green areas, lack of children facilities and development taking place there. However, the percentage of its quality of life is projected to rise once the developments there are completed.					
Ras El Tin area	229	244	166	177	816	58.3%
	Quality of life in the Ras el Tin area is considered low because of the few green areas with only some trees and palm trees, low maintenance and quality of services, moderate condition of space, and is near traffic causing noise. Moreover, it has low endurance to any natural risks.					
Selsela park area	348	171	138	221	878	63%
	The Selsela Park area has moderate quality of life as it is very close to traffic, has no parking, no kid-friendly amenities, and is dark at night. However, it has a large green area and good endurance to any natural risks.					
Cleopatra waterfront area	242	155	245	197	839	60%
	The Clepatra area contains a path only for pedestrians, where they can walk and exercise freely. However, some of these paths are obstructed by cafes and restaurants. Its percentage can be considered moderate due to several factors such as: lack of green areas, some of public seating needs repair, proximity to traffic which results in loud noise from car horns, especially during the rush hours/ Moreover it has low endurance to any natural risks.					
Louran waterfront area	309	135	134	167	745	53.2%
	The Louran area has the lowest quality of life percentage, which is likely due to the ongoing development there, where green spaces are still being refurbished and finishing touches are still being added. It is also near to traffic and has no children friendly area.					
Bir Masoud area	257	165	121	227	770	55%
	Quality in the Bir Masoud area is considered aas low, due to the absence of green areas and trees and being situated near car traffic. Moreover, there is no nearby medical healthcare facilities and no security presence.					

Table 10: Quality of Life for each area understudy, by Authors.

7   DESIGN GUIDELINES AND RECOMMENDATIONS

The analytical assesment demonstrating the integrative approach is represented according to the impact of the measured aspects collectively as per Figure 11 (below). The results shows that there is always capacity for integrating solutions related to spatial configurations in order to simulate visitors experience in the selected site. However, as the analysis demonstrates, the impact varies between the areas selected due to differences in design capacities and existing infrastructure.

One of the major implications is demonstrating how a longer promenade enhances the visitors' experience such as at "Qaitbay" waterfront area and "Cleopatra" waterfront area, where visitors experience the most social well being aspects due to the variety of activities and the changing views along the waterfront. On the

866

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

otherhand, the more contained sites as the "Selsela park" and the "Ras El Tin" area offer more greenery and zones of activities, however, they do need more pedestrianised continiuity in the pathways. Using the open areas as cultural hub spaces through gathering and open exhibitions areas for public art works can highlight the local identity of the, which improves the social wellness of the area with low social wellbeing attributes. Organizing seasonal festivals, and cultural events can also encourage social interaction and celebrate community diversity.

Regarding the emotional wellbing, the research recommends urban greening by increasing the landscaping features with greenery and trees as noticed on the high impact of integrated values in the "Loran" waterfront and El Selsela areas, and moderate at Ras el Teen, meanwhile sites as Qaitbay and Cleopatra lack the benefits of green covers and provided shades. Moreover, green areas and trees reduce ambient temperatures, improve air quality, and lower energy demands for cooling. Designing the waterfront area with therapeutic landscaping elements such as sensory gardens, aromatic plants, and textures can engage the senses and promote attractiveness of the space. Some retail areas promote the use of artificial plants in the last two sites, this decreses the aesthetic values as well as the environmental considerations.

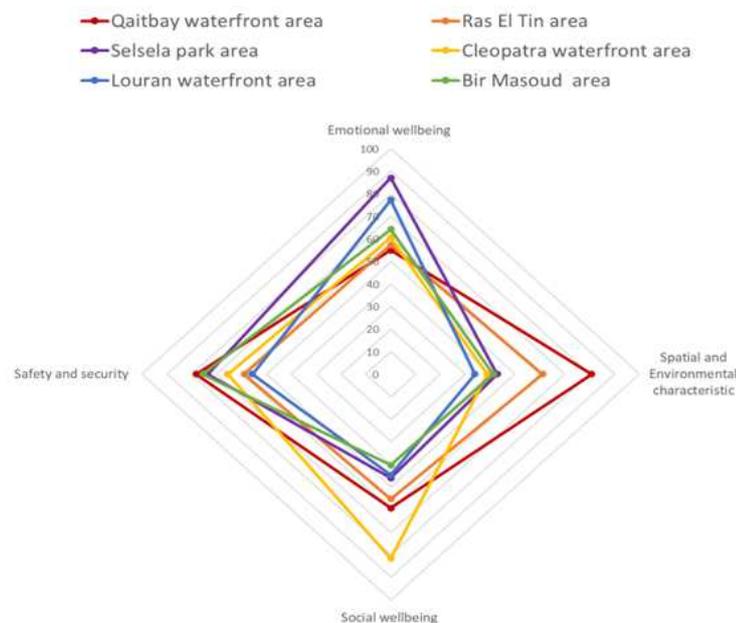
Relatively all the sites require more integration of safety measures by installing well-placed lighting to illuminate pathways, seating areas, and gathering spaces, enhancing the spacial arrangements, furnishings the transitional activities, the quality of sustainable materiality of the furnishings, pavement, and fixtures. Moreover, enhancing the resilience aspects of all waterfront areas to natural disasters is crucial to improve safety and security of areas.


Figure 11: Integrative assesment for selected indicators, by Authors.

8 IMPACT OF URBAN POLICY REGARDING NBS IN SELECTED SITES

The researchers recommendations derived from the model verification of the quality of life in the study areas along the Alexandria waterfront support an integrative urban policy approach. The set of recommendations include socially sustainable and responsible mobility solutions.

The researchers promote the idea of "Green and Blue Infrastructure" as natural infrastructure linking the whole territory of a city by integrating green spaces, parks, and pedestrian-friendly waterfront promenades into the planning tools. Implementing green and blue infrastructure involves creating a network of interconnected natural and semi-natural features in urban waterfronts, which is also stated in the authorities' strategic planning procedures. Community responsiveness towards existing and future interventions should be integrated in the decision making process. For example, Green and Blue Infrastructure contributes to monitoring extentions of retail facilities, which takes into account spatial potentials as well as social, economic and cultural factors.

Green and Blue infrastructure attracts tourism, improves property values, and stimulates economic development, particularly in waterfront urban areas that prioritise sustainable and nature-oriented design.

Another nature-based solution is incorporating green roofs into waterfront buildings. as it can help manage the strain on urban drainage systems during rain, and improve water quality. Green roofs can also contribute to energy efficiency by insulating buildings and reducing the urban heat island effect.

Finally, the recommendations for improvements along the waterfront of Alexandria also concern the sociatal responsiveness to the deterioration of the distributional and procedural effeciency of plans, the need to provide choices, as well as incorporating public contribution into the short and long term processes of decision making.

9 CONCLUSION

The research findings support the integration of citizens' contribution in the decision making process to confirm the consistency of policies and planning processes which will maintain the characteristics of Egyptian cities, bearing in mind the need to control change and inform new development attempts along the extended waterfront.

The green and «blue» spaces in and around the city fulfil an increasingly important role in the welfare of Alexandria's inhabitants and as criteria for businesses to establish themselves in the city. Positioning itself as an international attractive city Alexandria should use its events as an occasion to foster not only the core of the metropolitan area, but also the neighbouring cities.

The findings of the Assessment Model "«QLWS»" highlight how implicit opinion of expertise in combination with bottom-up consultation procedures can impact new policy formulation. They recognise the role of current and future voices in upgrading level of services and quality of life provided on the waterfront. They recognise that accessibility, transport, joint events, communication and marketing will become priority measures to ensure the success of future regeneration of communities and overall potential of Alexandria waterfront.

1 ABSTRACT

Publicly accessible and usable green spaces in cities and smaller settlements are important for promoting physical activity and consequently for maintaining and improving public health. Adequate provision of such spaces is crucial for planning of a quality living environment. Research to date has identified different aspects in linking public health and green spaces. However, the problems of existing approaches and methods include inconsistencies in evaluating different aspects of public spaces for physical activity, lack of inclusion of social and health benefits of green spaces in green space indicators, and lack of integrated approaches towards defining the provision of green spaces to promote physical activity. Accordingly, a solid spatially explicit indicator for assessing the provision of settlements with green spaces for physical activity is non-existent. The purpose of this paper is to present the literature review and methodological framework developed within the Slovenian research project titled Development of indicators for the assessment of the provision of settlements with green spaces for outdoor physical activity that addresses aspects of public green spaces and related indicators for assessing the adequacy of the conditions provided by urban green spaces for different types of physical activity. We have defined three basic types of physical activity, namely: activities that are carried out in one place, activities that cover distance for leisure of recreation, and activities that cover distance to reach a goal (i.e., daily active mobility). Guided by this definition, we conducted a literature review to examine: (1) which spatial aspects of enabling or promoting physical activity are addressed by existing green space indicators, (2) to which spatial scale and to which spatial planning levels are indicators linked and, (3) whether indicators address different types of physical activity. Based on the findings, suggestions are made to develop a more spatially explicit indicator to assess the provision of green spaces in settlements for the three types of physical activity. Such an indicator can strengthen the long-term monitoring of the condition of publicly accessible green spaces for recreational use by the population.

Keywords: physical activity, public health, green space provision, spatial planning, spatial indicators

2 INTRODUCTION

In recent years, attention to adequate physical activity has been raised by leading health organisations and official bodies on different levels. The World Health Organisation (WHO) has been promoting increased levels of physical activity to prevent chronic non-communicable diseases and maintain a healthy lifestyle, most recently with very precise recommendations for physical activity and health, which define the recommended amount of physical activity per week for different age groups (World Health Organization, 2020). Moreover, in Europe has the European Commission (EC), beside acknowledging the importance of raising physical activity of the population, recognised the importance of supporting a cross-sectoral approach to tackle unhealthy lifestyles. The EU Guidelines on Physical Activity (2008) give an important role to spatial planning and, in the guidelines for spatial planning, highlight the importance of creating an environment in which the population can be physically active, in particularly with regard to ensuring safe and comfortable everyday mobility, interlinking of recreational areas when building new neighbourhoods, the protection of the natural environment, and taking into account the needs of different population groups.

In recent years, the importance of spatial planning to support people's physical activity has been recognised also in Slovenia, not only in research but also in policy making. The national Resolution on the National Programme on Nutrition and Physical Activity for Health 2015–2025 (ReNPPTDZ, 2015) is an important document which supports cross-sectoral cooperation to tackle the inactivity of population and, among others, stresses the importance of ensuring a healthy living environment for all population. Furthermore, the Spatial Development Strategy of Slovenia (2004) is the overarching document that defines the objectives of spatial development and is the basic strategic spatial document for the coordination of sectoral policies. The new Draft (MOP, 2020) emphasises the pursuit of a high proportion of green spaces in cities, allowing residents

and visitors to socialise and recreate outdoors. Providing opportunities for healthy lifestyles in cities through the creation of green urban systems is also listed among the priorities for achieving the Strategy's objectives. Since 2017, the Ministry of Health has been funding activities to closely integrate different aspect of physical activity into spatial planning. As a result, the authors prepared a manual and guidelines to support municipalities in planning, evaluation, improvement and monitoring of public green open spaces for the population's physical activity (Šuklje Erjavec et al., 2020b). This study continues these efforts by inspecting indicators for the provision of green spaces to promote physical activity. We suspect that despite the existence of strategic documents such as the Spatial Development Strategy of Slovenia, and legislation in the field of spatial planning (e.g., Spatial Management Act (ZUreP-3)), which emphasise the importance of green spaces for the quality of the environment and the health of the population, methods and tools for evaluating the adequacy of the planned and existing spatial conditions of municipalities for a healthy lifestyle are scarce, and sectoral transfer of knowledge is only just starting to be established. We see the potential in developing an indicator which is adjusted to Slovenian spatial characteristics. The latter relate to small settlements size in comparison to other European countries, the absence of regional planning, the tendency towards an ageing population, giving priority to tourism over the needs of the local population, and land property regulations.

Accordingly, this study aims to critically inspect the literature to set a framework for the development of a spatially explicit indicator for assessing the provision of green spaces to promote physical activity, adjusted for Slovenian circumstances. We set the following research questions:

(1) Do existing green space indicators address spatial aspects of enabling or promoting physical activity?

(2) For which spatial scale and spatial planning levels are indicators of physical activities in green spaces designed?

(3) Do these indicators address different types of activities?

To answer these questions, we performed a non-systematic review of existing aspects of green space and indicators of physical activities in green spaces. Based on the review, we set the framework for the assessment of aspects and indicators to support green space planning and management of Slovenian settlements.

3 NON-SYSTEMATIC REVIEW OF RELEVANT ASPECTS AND INDICATORS

3.1 Aspects of green space provision to promote physical activity in settlements

A growing body of research has examined how different aspects of green space, such as access, size and design features, relate to leisure and physical activities. Most of the literature highlights three aspects of provision: accessibility: proximity or coverage of a settlement based on established distance criteria; green space size and extent, which is mostly linked to population density within specific areas and the green space network; and assessment of quality, which is primarily focused on the presence of natural elements(see, for example, de la Barrera et al., 2016; Grunewald et al., 2017; Hillsdon et al., 2006).

In our review, we focused on aspects which are relevant for spatial planning. With this regard, Kaczynski and Henderson(2007) reviewed fifty quantitative studies and found that proximity to parks and recreational environments (public green spaces) is generally associated with people being more physically active. Qualitative evidence further suggests that safety, aesthetics, convenience, maintenance and proximity to public open spaces are important features that support physical activity(McCormack et al., 2010).In the Slovenian context, Šuklje Erjavec et al. (2020b)identified quality aspects of green space design to promote active lifestyles, highlighted from the perspective of urban and neighbourhood planning and partly through management. Based on these reviews, we further inspected aspects, important for the aims of this study. Each of them is briefly described and assessed in the following sub-sections.

3.1.1 Public access to green spaces

This aspects a basis to achieve equal opportunities for green space use and a key factor for assessing the green space provision of settlements. It is closely linked to the aspect of distribution, connectivity, and continuity of green spaces. Various studies have found that proximity to green spaces is crucial for its use (Cohen et al., 2007; Giles-Corti and Donovan, 2002; Harnik and Simms, n.d.). Most research methods are

based on measuring the distance of dwellings to the nearest green space. Usually they use buffers with a specific radius, most commonly a 300m for walking distance to the nearest green space(see for example Coles and Bussey, 2000; Giles-Corti and Donovan, 2002; Grahn and Stigsdotter, 2003; Nielsen and Hansen, 2007).In these studies, green spaces are often determined on the basis of land use data and their accessibility is measured with the geographic information system (GIS) tools. The problem with such approaches is that many public green spaces that are important for promoting physical activity are not included in the land use databases or are classified as some other land use (such as residential landscapes, hiking trails, urban forests, riverbanks and similar). Besides, distance radiuses quite often do not provide accurate information about accessibility due to different spatial barriers such as high traffic roads, railway lines, steep slopes but also lack of appropriate pedestrian and cycling pathways. Therefore, measurements of accessibility that use a network of existing pathways, e.g. the Network Analyst tool (Oh and Jeong, 2007) are much more accurate but less common mainly due to technical complexity of its use.

Furthermore, physical distance is just a part of the accessibility aspects. In addition to the physical distance, the time component is also important. Older people, parents with young children, or the disabled will take much longer to cover the same distance than a young, physically fit person(Biernacka et al., 2022; Kimpton, 2017). Therefore, an important factor in assessing accessibility is also the aspect of quality: universal design, safety, climatic and ambient pleasantness, attractiveness, etc.(Šuklje Erjavec et al., 2020b).

Accessibility is also strongly linked to perception of space and social inclusion, or a sense of belonging and acceptance. Some studies take into consideration the perceived accessibility of a green space and examine it by tools such as a user survey of subjective views or expert judgements based on various criteria (Sugiyama et al., 2008; Tilt et al., 2007) as well as other qualitative parameters (Giles-Corti et al., 2022).

3.1.2 Location and connectivity of green spaces

The location and connectivity of green spaces are important for the spatial distribution of green spaces in a settlement, also impacting their accessibility. The distribution of different types of green spaces is also particularly important in this context, as they allow for different forms of everyday use. The provision of multifunctional green spaces is therefore particularly important, especially in small settlements.

A balanced distribution of green spaces in settlements is key to ensuring that all residents have equal opportunities to use green spaces in their daily lives(Verma et al., 2020, Šuklje Erjavec et al., 2020). The distribution is important both at a larger scale (inter-urban, municipal) and at the local level(settlements, neighbourhoods).

Location of green spaces is often pre-defined by landscape characteristics of the settlement and its surroundings. Usually just a part of the public urban green space provision is designed and implemented completely anew. Therefore, their interconnectivity, in the form of pedestrian, cycle, and thematic routes as well as green space features, which in themselves provide stimulating settings for certain forms of physical activity, make an essential contribution to this aspect(Sander et al., 2017).

To ensure equal opportunities for all residents, green spaces need to be planned in a comprehensive and systematic way, considering population density and the distribution of existing publicly accessible green spaces. The most appropriate approach for the integrated planning of a balanced distribution and connectivity of green spaces is the design of a green system or green infrastructure. In Slovenia, as part of the comprehensive green system planning, a Green System Plan for Active Lifestyles is foreseen as a thematic concept of the green system of a settlement. It aims to provide appropriately distributed public green and other open spaces for physical activity of inhabitants(Bizjak et al., 2020).

3.1.3 Attractiveness of green spaces as support for their active use

The attractiveness of a place is a key factor in choosing open space for recreational use and the frequency of its use. Lundh (2017) notes that aesthetic experience is a primary consideration when choosing recreational places to visit, while comfort and meeting other people are important factors when spending time in outdoor spaces. The studies on urban environment attractiveness are often based on establishing indicators of the 'greenness' of a particular space, streets, neighbourhoods, cities. Despite the complex aspect of achieving quality, the quantity of natural elements is most often considered as a key parameter for the attractiveness. Attractiveness is most commonly inspected in studies through measuring natural features such as vegetation, water, animals, and the level of biodiversity (Lundh, 2017).

Methods based on satellite data have been implemented in the past to measure the presence of vegetation in specific areas(Sripada et al., 2006; Tucker, 1979), which include the ground plan representation of green areas, and methods from the perspective of the user, e.g. analyses of vegetation along streets using Google Street View, for example the greening view index(Ki and Lee, 2021). In addition to vegetation, other parameters are also used, e.g. for biodiversity including animals. Lundh (2017) used questionnaire-based and site-specific surveys for measurement of bird retention and detection in urban areas as parameter for the provision of ecosystem services. The measures for this aspect include the presence of natural elements, such as vegetation, water bodies, the evaluation of naturalness as well as potential disturbances and negative environmental effects.

Although the contact with nature is a proven factor of the attractiveness of green space for physical activity, there are some other crucial characteristics that should not be neglected when defining indicators. The biophysical characteristics of the environment such as air, water and soil quality are certainly a very important factor, but also the quality of the soundscape, and the absence of negative factors such as odour, dust, over-heating and dazzle (heat island), dereliction, etc.(Koohsari et al., 2015). Furthermore, the quality of the green space itself is also very important, reflected in its functionality for the use and its experiential and ambient quality(Francis et al., 2012; Pazhouhanfar, 2018).

3.1.4 Size of an individual green space and a total green space quantity in a settlement

This aspect is important in relation to the users' activities in green spaces and satisfying capacity. The determination of the quantity or extent of green spaces depends on the individual characteristics of settlements and their spatial affordances. Most used method for determining the quantity of green areas is the sum of all green spaces in relation to the total population (m2/inhabitant) or to the population in a given spatial unit. However, this method does not provide information either on the distribution of green spaces across a city or settlement, nor on their capacity for everyday use of or number of envisaged users (de la Barrera et al., 2016).

The WHO defined a standard of 9-11 m2 of green spaces per capita, without specifying the spatial extent used to make calculations. Gupta et al.(2012)questioned the relevance of the information on urban green space per capita data, as it provides an imprecise and insufficient answer to the question of distribution and quality of green spaces in urban areas. In addition, the decision on where to set the boundary between the urban area and the hinterland can strongly influence the outcome of the calculation and the comparison of settlements. Increasingly popular are methods which rely on extracting the percent of green space from different land use databases, such as CORINE, EnviroAtlas or Urban Land Cover (ULC). The calculations are based on the proportion of green spaces in the area (Oh and Jeong, 2007; Van Herzele and Wiedemann, 2003; Wood et al., 2017), green spaces per one thousand inhabitants and ratio of green spaces to built-up area (so called green space factors).

Findings from a health-oriented study examining epidemiological aspects (Mitchell et al., 2011) showed that larger green spaces may be more important for health benefits than smaller spaces. The results also highlight that physical activity is one of the 'mechanisms' of health and that the quality of open space is difficult to measure, as perceptions are likely to vary according to the type of the user and their preferences. For example, a relatively wild space suitable for deep contact with nature may be rated as high quality by a lone walker, but low quality by a parent wishing to visit nature with young children(Mitchell et al., 2011).

The aspect of size is very relevant for Slovenian circumstances due to the dominance of small settlements. In Slovenia, only two cities have more than 100,000 inhabitants and the majority of urban settlements are very small. A commonly used size criterion of at least 1 ha or even 2 ha of green space may be suitable for very large cities, but is questionable for the use in smaller cities and settlements where small green spaces may be of great importance for the daily needs of the local population. Slovenian studies therefore suggest to use 250m2 as the minimum size of green spaces that are taken into consideration when evaluating or analysing green space provision (Bizjak et al., 2020; Šuklje Erjavec et al., 2020b).

3.1.5 Variety of green spaces to ensure uses - types of green spaces

Akpinar (2016)researched different types of green spaces in terms of their health impacts on people. They found that not all green spaces should be treated equally and stressed the importance of having a variety of types of public green space rather than just a quantity of green spaces.

In general, all green spaces share very specific characteristics, which distinguishes them decisively from other open spaces, i.e., the presence of natural elements and thus their subordination to natural processes. However, they are very different from each other in other respects. That is in terms of their dominant characteristics (location, function, size and accessibility), nature (natural, urban, residential, connective, introverted, mass-visitor, private) and origin (natural, created). In planning practice, they can be classified according to their purpose such as ownership, predominant use (sport, recreation, rest, multifunctionality, etc.), and public accessibility (Šuklje Erjavec et al., 2020b), among others. According to their role, purpose and function, green spaces can be divided into individual green spaces (parks, recreation areas, etc.), green spaces, adjacent to buildings (e.g. schoolyards, kindergarten playgrounds, residential green spaces), green spaces that are part of buildings (green roofs and vertical greening), green spaces within other land uses (e.g. paths between meadows, urban forests), green spaces linked to transportation uses (avenues, car parks, pedestrian and cycle paths), and other open spaces incorporating natural features and green areas of special natural or cultural value (Šuklje Erjavec et al., 2020b).

We examined Slovenian legislation and national documents related to green spatial planning to understand whether an existing typology could support the aim of our study. We concluded that the existing approaches to land use planning are not adequate because they do not include all relevant types of green spaces that contribute to green space provision. For example, the Handbook on the Green System of Towns and Cities(Šuklje Erjavec et al., 2020a), which is part of the national spatial planning rules of the nearly adopted new National Spatial Order("National Spatial Order," 2023), offers a very comprehensive typology of green spaces which should support a variety of purposes and aims regarding green space planning. Based on reviewed aspects and aims of our study, we assessed it as not being fit for the purpose of this study. Accordingly, a specific approach was developed that adequately reflects the spatial requirements for the implementation of the important groups or types of the physical activity for health, while at the same time representing a suitable base for the guidelines to be used by the Ministry of Health as a National Spatial Planning Authority in the role of the monitoring and guiding spatial planning from the point of view of public health. With this objective in mind, we have identified three basic types of green spaces that are examined when defining green space provision. These are(1) Green spaces providing conditions forspatially concentrated physical activities, (2)linear green spaces providing conditions for distancerelated physical activities and (3) open spaces providing conditions for physical activities as a means of travel– active mobility(Šuklje Erjavec et al., 2020a).

3.1.6   Equipment, safety and maintenance for the use of green spaces

The use of public open spaces is influenced by their equipment, safety, and maintenance. Different spaces require different levels of equipment and maintenance, depending on the type of space, the expected use, the intensity of natural processes in the area, etc. The safety aspect is usually achieved through the criteria as defined by the society, but it has also a subjective component related to an individual's perception. Safety aspects relate to safety from injury and accidents, from violence, from negative influences from the environment and traffic safety(Šuklje Erjavec et al., 2020b). For the study and evaluation of all these aspects, qualitative methods that reflect the (dis)satisfaction of users with a particular space are usually needed, but there are also some more objective data available from evidence and records of the utility company or the service that maintains public green areas.

Research on the use of spaces in relation to user characteristics addresses the time component or duration of use of a green space and user characteristics, e.g., age, gender, education, income. Methods are usually based on the use of GPS technologies to detect spatial-temporal mobility patterns of the population. The use of GPS technologies on smartphones can provide information on how often and for how long people use green spaces for active use (Lachowycz et al., 2012; Nieuwenhuijsen et al., 2014). Conversely, surveys are often conducted through questionnaires and field visits. Questionnaires are mainly used to examine certain characteristics of the specific case studies design, and behavioural maps to examine how they are used. Lundh(2017), for example, identifies the key spatial characteristics for seating are a pleasant microclimate, an attractive view, an appropriate layout with a back screen and a sufficiently low noise level to allow conversation.

3.2 Green space indicators and promoting physical activity

Indicators are important tools of evaluation, monitoring and/or planning suitable green space provision of different settlements and other areas. To address the spatial component through the perspective of different types of activities in green space, the development of spatially explicit indicator for assessing the provision of green spaces to promote physical activity requires a review of existing indicators used for green spaces and the determination of physical activities in green spaces. In line with the objective of this study, we divided the review of indicators in three groups:(1) health indicators, which are important to inform the public and decision makers about the state of public health and to define objectives for improvement;(2) spatial quality indicators, which measure suitability of the spatial factors, and (3) environmental indicators measuring the quality of the environment for healthy active use. However, it is important to point out that these groups of indicators are intertwined.

Health indicators have been widely studied from different perspectives, including quality of life, well-being, walkability and physical activity. A review of health indicators by Pineo et al.(2018)emphasizes the importance of local measures and adapting indicators to local needs. With regard to physical activity, they found that it comprises 75.1% of environmental indicators, the most common being transportation, habits, living conditions, safety, land use, food, environment, demography, leisure and culture, and urban design. An important finding of their research is that data measured at the neighbourhood or individual levels are more suitable for identifying health inequalities and environmental characteristics that contribute to poor health. Indicators at this level can be used to inform development policies in these areas and monitor their impact over time (Pineo et al., 2018).The importance of the local level is one of the starting points for the development of the indicator for green spaces to promote physical activity.

From the point of view of spatial planning, including the provision of green spaces in settlements, indicators of spatial quality are of course particularly important. We have focused on the indicators that assess the suitability of spatial factors related to green spaces and health and thus consider aspects such as socio-economic benefits of green spaces, climate change mitigation, and improvements in urban quality of life. Although not so widely used as health and environmental indicators, there are some interesting research studies and cases related to green space indicators. Koohsari et al.(2015)for example identified criteria such as proximity, number, size, and attractiveness of these spaces. The findings of the study indicated also that the size and attractiveness of local public open spaces played a significant role in residents' preferences. Interestingly, the study revealed that having access to a larger and more attractive public open space, even if it required a greater walking distance, was often more important to residents than having access to a smaller public open space in close proximity to their home (Koohsari et al., 2015). This highlights the importance of considering not only proximity but also the size and attractiveness of public open spaces when evaluating their impact on residents' preferences and usage patterns.

To promote equal access of public green spaces, it is common to establish a "minimum standard for parks."Such standards typically outline the minimum amount of green space per person and the maximum distance to the nearest green space. However, Kimpton (2017)suggests that these standards lack precision when it comes to considering factors like frequency of use, diversity of green space types, and proximity to such spaces. To address this, indicators can be defined at different levels, such as plot, parts of settlements, city/town, and municipal levels. For assessing physical activity provision, both municipal and local level indicators are important. Municipal indicators allow for comparisons over time and between different cities or settlements, while local indicators help identify inequalities within cities or settlements that are not evident when using municipal level indicators (de la Barrera et al., 2016).

Indicators that emphasize measuring the quality of the environment have been identified through a review of existing indicators for green spaces. Several cities, including Berlin, Malmö, Seattle, Helsinki, London, Stockholm, North West England, Washington DC, Singapore, Toronto, and Vancouver, have developed indicators that assess the environmental impact and the proportion of green space in new projects, particularly in urban areas. These indicators are based on the adaptation of existing Green Space Factors (GSFs) used in Berlin and Malmö(Kruuse, 2011; Ring et al., 2021).They consider the ratio of green areas to plot size and take into account various types of greenery such as green roofs and walls, permeable pavements, water, trees, and rainwater systems such as rain gardens. They also consider the presence of different ground types regarding the relation to subsoils. The focus of these indicators is on the

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

environmental and ecological aspects of sustainable urban development. They not only assess the presence of natural elements but also serve as a qualitative measure of the attractiveness of outdoor spaces. According to Ring et al.(2021),the urban green space index promotes urban sustainability by addressing ecological and socio-economic benefits.

The urban green spaces indicator holds a significant role supported by research and international commitments. The European Green Deal places strong emphasis on the importance of green spaces and nature in cities, particularly public green spaces. Urban Greening Plans are instrumental in achieving these objectives by creating additional green spaces, improving connections between them, and protecting biodiversity (European Commission. Directorate General for Environment, 2021).The Green Deal recognizes the ecological and social aspect of urban green spaces, which includes also providing green spaces for the population and fostering interconnectedness among these spaces. These social aspects are further elaborated and specified in documents such as the Green System in Slovenia(Šuklje Erjavec et al., 2020a). The Green System in Slovenia outlines detailed guidelines and strategies for ensuring the provision of green spaces and enhancing their connectivity, thereby addressing the dimensions of the Green Deal. To align with the European Green Deal and the EU Biodiversity Strategy, Urban Greening Plans need to incorporate specific indicators, including the proportion of urban green spaces (public and private), tree canopy cover, newly planted trees, and protected natural areas in public spaces. These indicators are crucial for monitoring and guiding the development of green spaces in cities and municipalities. The Urban Greening Plan Guidance provides guidelines for mapping the land use types of municipalities, utilizing the official Corine land cover classification system("Urban Greening Plan Guidance draft," 2022).

To develop a spatially explicit indicator for assessing the role of green spaces in promoting physical activity, the review highlighted the importance of spatial indicators in general public health assessments. It also identified different approaches to defining indicators for green spaces, depending on their intended purpose. However, it is important to emphasize that international documents primarily focus on the provision of green spaces in urban areas also for the benefit and use of the population. These documents provide guidance and frameworks that prioritize the establishment of green spaces as a means to enhance public health and overall well-being.

4 SETTING A FRAMEWORK FOR GREEN SPACE PROVISION ASSESMENT

Section 3 inspected the spatial aspects of indicators to address the provision of green spaces to promote physical activity. The next step is to identify the physical activities that relate to green spaces and their characteristics. Accordingly, we reviewed the literature on how each of the measured aspects of green space provision is addressed and combined in different indicators according to their purpose and specific criteria for each of the included aspects of green space provisioning.

4.1 Linking green spaces with physical activities

Due to the interlinking of spatial factors, local spatial and social characteristics, research generally neither determines the appropriate size of green space to increase physical activity, nor the quantity of amenity provision to encourage the use of public open space. Typically, research examining the links between attributes of public open space and physical activity are tied to individual case studies. Depending on the purpose of the physical activity provision indicators, the criteria can be adapted according to the type of activity, which leads towards considering types of activities.

Koohsari (2015)underlined the influence of green space on a variety of activities that share certain common characteristics in terms of (mainly daily) use of urban space. Public open spaces can influence physical activity in at least three ways: a public open space can be an environment where people engage in physical activity; a public open space can be a destination where people travel to be active or simply to socialise; a public open space can be used as part of a route to get to another destination (e.g., a shop) or as part of a recreational route for walking or jogging. Accordingly, green space can contribute to different types of physical activity. For example, green space as a thoroughfare is associated with active travel, as a destination with active travel or recreational physical activity, and public open space as an environment can be associated with recreational walking or cycling, jogging, dog walking, formal or informal sports or active play for children. Šuklje Erjavec et al. (2020b) made a step forward and set simple criteria of green space provision for active lifestyle. They specified three types of physical activity in terms of a design approach to

addressing physical activity: (1) space-specific or spatially concentrated activities, (2)distance-specific or long-distance activities, and (3) daily mobility activities or physical activities as a means of travel.

An adopted approach defined types of physical activity regarding the use of different spatial types. Certain outdoor activities can be tied to certain types of outdoor space. The types of spaces can be defined according to the generally defined typology of green spaces(Šuklje Erjavec et al., 2020a) and linked to the land use classes in spatial planning categories, as defined in Slovenian Spatial Management Act (ZUreP-3, RS). Figure 1 shows the activities, sorted in three main groups, and their relation to the spatial context, classified in types of green spaces and in land use classes as defined by the ZUreP-3. Linking types of green spaces to land use classes is important since it eases the transfer of knowledge from research to spatial planning practice which needs to work within legal frames of defining the land use classes. Accordingly, it is crucial also in the development of spatial indicators.

Fig. 1: Overview on the aspect "variety of green space types for different active uses"- the types of public open green spaces and their suitability for different activities(Original table translated from Šuklje Erjavec et al.(2020b)

4.2 Combining provision aspects in green space indicators

Next, a literature review and analysis of indicators were conducted to determine whether the level of emphasis on spatial qualities for promoting physical activity. Content analysis on existing indicators reviewed the combination of methods or measurements in their addressing of physical activity. We focused on the following parameters: the provision aspects addressed (aspects of the quality of green spaces to promote physical activity), spatial level considered (small urban area, city level, region or wider areas), parameters to be measured, a way of addressing physical activity, and data sources for the calculation of the indicator. The summary is presented in Table 1.

As can be seen from Table 1, most indicators of green spaces refer to three aspects of green space provision: quantity (amount), accessibility(distance, distribution) and naturalness(vegetation, natural elements, permeability)of green spaces. For developing the indicator of the provision of green areas for physical activity, combined indicators are certainly more comprehensive and a better starting point than an individual one. A doubt remains whether the presented indicators cover all important aspects of green spaces and useful for municipalities in their assessment, planning and monitoring of the provision of settlements for promoting physical activity. It can be seen from Table 1 that most frequently, combined indicators included aspects of quantity and accessibility. Only one of the reviewed indicators combines three aspects and includes a quality aspect. However, this quality aspect takes into consideration the naturalness of a green space as a main factor for the equality. Aspects of accessibility as well as quantity are certainly important for dealing with the provision but based on the review and the aim of our study, they are not sufficient. For an adequately comprehensive indicator of the green space provision for physical activity (or several of them), the quality aspect should also be added. Such an aspect should reflect quantity and diversity of vegetation but also social

functions, usability, values, and perception of place. This means including the typology of green spaces, quality of setting and equipment, management level and similar.

From theTable1 it is also evident that most of the reviewed indicators have been set to be used on a local level. This is an important step forward from the quantity indicators for a municipality or even regional and national level, however none of the indicators has directly addressed a physical activity for health. An exception are spatial indicators of urban design and transport features (Boeing et al., 2022), but they do not explicitly address green spaces.

Addressed/combined aspects in indicator	Level	Measures	A way of addressing physical activity	Selected sources
Quantity Accessibility	city level	distance variable on household level; coverage of green space (500m buffer), and household social characteristics	Through selection of open space type: addressing green urban areas and forests	Green space provision indicator in relation to the equality (Wüstemann and Kalisch, 2016)
Quantity Natural elements	Urban built plot/parcel	modelling the climatic characteristics of open space elements	Not directly; possible inclusion for activities addressed on individual plots	Green and open space factor (Ring et al., 2021)
Permeable soil Natural elements / greenery and water	Urban built plot/parcel or smaller urban unit - neighbourhood	Surface type (permeability), surface construction, soil depth, water infiltration, water surfaces, vegetation type	Not directly; on ecological and climatic environmental quality for sites	Green space factor (Kruuse, 2011); Biotope area factor – ecological value("Der Biotopflächenfaktor - Ihr ökologisches Planungsinstrument," 2021)
Quantity	smaller urban unit - neighbourhood	Combining large scale and small-scale data (existing land use); including all GS (public and private)	Not directly; addressed as wellbeing and health; not focused on public GS	Green space indicator (Mitchell et al., 2011)
Quantity	part of the city; city level	proportion of green spaces (general), built-up area and population density in each part of the city	Not directly; proportions in different the areas on all green spaces, not focused on public GS	Green space indicators in a social-ecological system (Verma et al., 2020)
Quantity (size) Accessibility (distance)	smaller urban unit - neighbourhood	Use of 2 size categories of public open space (smaller and larger than 1,5ha); Distances to points (stations, services, GS etc.) in relation to the existing network	Addresses walkability to all public spaces; not directly on location/planning adoptable results	Spatial indicators of urban design and transport features (Boeing et al., 2022)
Quantity Accessibility / distribution Quality	General and local level	Combining land use, quality of space (high vegetation and soil permeability); accessibility and shapes of GS	Addresses green spaces in general; different aspects and focused on public GS	Indicators for GS in contrasting urban settings (de la Barrera et al., 2016)
Natural elements / vegetation	Adaptable scale	vegetation cover layers by area, water bodies excluded	Not directly; can be used as a complementary measure of spatial quality	Vegetation indicators NDVI (Tucker, 1979); GRVI (Sripada et al., 2006); SAVI (Huete, 1988)
Natural elements	smaller urban unit - neighbourhood	amount of vegetation and its characterization and neighbourhood types also on height of buildings	Study indirectly addresses social aspects	Urban Neighbourhood Green Index (Gupta et al., 2012)

Table 1: An overview of studied indicators for green spaces in relation to the provision aspects addressing green spaces to promote physical activity.

5 DISCUSSION AND CONCLUSION

The performed reviews of selected literature indicate that criteria for determining appropriate and feasible green space provision indicators is inconsistent, which is also reflected in the practical implementation of indicators, as some of the inspected practical examples have shown. Guided by our objective to develop a spatially explicit indicator, useful for the assessment of green space provision for physical activity in Slovenian settlements, we discuss the two most important findings for our forthcoming work. First is the importance of integrating a variety of parameters in an indicator, second is paying attention to the performance of an indicator at different scales. This also relates to appropriateness of an indicator to be implemented at different spatial planning levels.

With regard to integration of different parameters, existing green space indicators are based on both research and international commitments, but the focus is mostly on environmentally and ecologically measurable

parameters of green spaces, with less attention paid to their social and health benefits that are more difficult to measure, as already highlighted in a 2012 study (Gupta et al., 2012). Often, data is derived from remote sensing imagery and has been used in various studies to differentiate between areas with vegetation and areas without vegetation. Such an approach, however, does not provide any information on accessibility, density of built-up areas and other characteristics of green spaces. It is important to take into consideration that only a fraction of green spaces in cities are publicly accessible and available for active use. We contend that it is due to the complexity by which spatial quality is defined and should be considered, that the existing methods of assessing quality of green spaces for diverse forms of physical activity tend to focus on single parameters, lacking integrated approach towards defining the provision of green spaces to promote physical activity. Accordingly, a solid spatially explicit indicator for assessing the provision of settlements with green spaces for physical activity is non-existent.

With regard to scale, the local level is of particular importance for the calculation of the provision of public green spaces to support physical activity. In general, not enough indicators are developed for small-scale areas such as cities and neighbourhoods, in comparison to large areas such as nations or states, which was also highlighted in a review by Rothenberg et al.(2015).However, locally developed tool which takes into account local conditions and local needs may increase its acceptability(E. Innes and Booher, 2000; Rothenberg et al., 2015).We contend that a spatially explicit indicator should address the provision of a sufficiently generalized yet locally applicable level. The development of providing an indicator further emphasizes the importance of spatially explicit conditions for physical activity. However, it is essential to incorporate relevant, reliable, and verifiable data at the local level to address the specific characteristics of each area. With this in mind, we developed the baseline criteria for each aspect of providing and interconnecting different aspects in evaluating public open spaces, as follows:

(1) Public accessibility: The criteria include proximity, with the requirement of having a public green space of over 500 m2 within a walking distance of 300 m or 5 minutes, and an urban park within a walking distance of 900 m or 15 minutes in cities. Design considerations should ensure universal access, while taking into account public accessibility and the impact of topography.

(2) Quantity: The criteria focus on the size of urban parks, which should be a minimum of 1 hectare and located within 900 m of residential areas. The provision should also offer a variety of choices and typologies to cater for diverse user preferences.

(3) Distribution, coherence, and continuity: These criteria consider the spatial arrangement of green spaces in relation to larger and smaller spatial units. The distribution should ensure a coherent and connected network of green spaces, allowing for continuity and seamless access throughout the area.

(4) Attractiveness: The criteria highlight the importance of greenery and canopy cover, aiming to create visually appealing and inviting spaces for the public.

These baseline criteria will serve as a foundation for evaluating and planning the provision of green spaces in the continuation of the project.

We can summarise that the criteria for examining each aspect shall be defined in relation to the desired achievement of the objective of green space provision to promote physical activity of the population and their applicability. The criteria can be qualitative or quantitative. In our study, we took the spatial-planning approach to provision, grouped in three physical activity types according to the way and purpose of space use. As a result, we developed a framework for a green space provision indicator that is spatially explicit and enables the comparison between settlements. This indicator allows for the identification and assessment of green spaces within settlements which comprise three types of physical activities: space-specific activities, distance-specific/long-distance activities, and physical activities as a means of travel.

1 ABSTRACT

Cargo bikes promote urban resilience as they ensure a local supply of goods, can be used flexibly, are reliable and require low energy, and can even be driven by muscle power. Further, they contribute to socially inclusive mobility. Although driving cargo bikes may require some training, they do not require a driving licence and can be available for different income ranges (e.g. in the form of cargo bike sharing). Thus, they also contribute to health-promoting mobility. Cargo bike sharing is a relevant solution to offer households a practical, environmentally friendly and cheaper mode of transport.

According to public welfare-oriented goals, cargo bike sharing is often provided on behalf of, or with (financial) public sector support, in cooperation with residential developers or based on voluntary work in Austria and Germany. However, peer-to-peer cargo bike sharing offers and host-based sharing systems often do not meet all the criteria attributed to shared mobility services. In order to reach the full potential of cargo bike sharing, a better understanding of spatio-temporal usage patterns is needed to foster a shift towards higher quality service provision, especially regarding tailor-made services for different user groups.

The following article investigates the role of availability and type of service provision by evaluating booking data and spatio-temporal data in three case studies. GPS tracking is rarely used to better understand cargo bike usage, but it reveals further knowledge of the characteristics of users and their spatial usage patterns.

Based on three use cases, usage, users and spatial patterns of cargo bike sharing usage are analysed, the respective potentials are shown, and the added value of spatial data collection is discussed.

Keywords: mobility planning, resilience, spatio-temporal data, sharing, cargo bike

2 INTRODUCTION

The chapter discusses the basics of cargo bike use as part of socially inclusive and resilient mobility, provides an outline of cargo bike sharing systems, and highlights the possibilities of evaluating usage patterns.

2.1 Socially inclusive and resilient mobility

2.1.1 Potentials and fields of use

Existing studies show that cargo bikes are gaining importance in larger cities in the forms of (commercial) cargo transport, for CEP services or privately used for transporting goods and children by private ownership or cargo bike sharing. Up to 51% of all motorised trips in urban areas could be replaced by cargo bikes(FGM-AMOR et al. 2014). This is also reflected in the increase of sales of cargo bikes in Austria by more than 80%(VSSÖ 2021) and Europe by 66%(Statista 2022). However, cargo bikes are rarely seen in smaller cities and rural areas and could still be considered novel transport modes.

2.1.2 Cargo bikes contribute to sustainable and resilient mobility

E-cargo bikes are a sustainable transport mode as they produce nearly no emissions compared to fuel transporters (Fontaine et al. 2021) and reduce traffic noise(Shaheen, Cohen, and Martin 2013). By promoting cargo bikes and cargo bike sharing, municipalities can reduce their dependence on fossil fuels and improve air quality. This primarily benefits people who are vulnerable to health problems (associated with air quality). Cargo bikes as an active mobility mode also promote an active lifestyle and contribute positively to users' physical health.(Kammerhofer et al. 2021; Rabenstein 2015; European Cyclists" Federation 2018; Masterson 2017)

Cargo bikes are less vulnerable to fuel shortages or road closures than motorised vehicles. They can also be used in densely populated urban areas where a lack of space and traffic restrictions can be problematic. By that, cargo bikes help build community resilience by providing alternative transport options, especially in times of crisis or emergency, as they are less affected by traffic congestion and fuel shortages and provide a local supply of goods in the sense of "The City of Short Distances". During high traffic periods, natural disasters or other unforeseen events, cargo bikes can help alleviate traffic congestion and maintain the smooth transport of goods and people. (Randelhoff 2013; Thoma 2014; Kammerhofer et al. 2021)

2.1.3   (E-)Cargo Bikes are socially inclusive

Currently, typical cargo bike users only represent a narrow segment of a diverse population. Cargo bikes, especially in the form of shared mobility offers however, have the potential to enable people of different ages, abilities and financial backgrounds to participate in sustainable transport(Grasso, Barnes, and Chavis 2020; Kammerhofer et al. 2021). Unlike motorised vehicles, cargo bikes are easily accessible and do not require any special skills or a driving licence. They offer an environmentally friendly and cost-effective transport option(Shaheen, Cohen, and Martin 2013) for people who cannot afford or do not want to own a car and who do not have a driver's license. However, by now, cargo bikes are rather used by an exclusive group of citizens (Berger et al. 2019). By promoting cargo bike sharing, municipalities can make their transport infrastructure more inclusive and enable all citizens to get around, regardless of income or mobility.

2.2 Cargo bike sharing

2.2.1   Diffusion and operating models of cargo bike sharing

Cargo bike sharing is a relevant solution to offer a practical, environmentally friendly and cheaper mode of transport to households who do not have access to a car (e.g. affordability, driving rights) or do not want to use a car (e.g. due to environmental concerns). Regarding the potential to further replace privately owned cars, cargo bike sharing contributes to a healthier environment (e.g. by fewer exhaust fumes) (Shaheen, Cohen, and Martin 2013)and frees public space from cars, enabling a redistribution of public spaces and a redesign towards climate-smart public spaces.

Cargo bike sharing schemes can be found in many cities worldwide, especially in urban areas with high cycling infrastructure and a strong demand for sustainable transport options. Germany, the Netherlands, Denmark and many other European countries are pioneers in improving cargo bike sharing services. Concerning the early stage of diffusion, the field of actors and operators is currently rather heterogenous (European Cyclists" Federation 2018). The main actors in cargo bike sharing are often (local) public authorities, non-profit organisations, bicycle cooperatives or private companies. However, only a few bike sharing operators engage in the cargo bike sharing market(European Cyclists" Federation 2018). Recent developments show that private companies struggle with successful operation and feasibility (e.g. GLEAM, SIGO) and that public financial participation is necessary to sustain cargo bike sharing services.

While cargo bike sharing is already widely established in German cities, it is still in its infancy in Austria. For example, the city of Regensburg (approx. 150,000 inhabitants) has approximately the same number of shared cargo bikes as are available in the entire Austria (Radkompetenz Österreich 2023).This might be related to the fact, that, in Austria, most cargo bike sharing offers are peer-to-peer or host-based services.

Peer-to-peer sharing depicts sharing between private persons as clients and providers, who can set user fees independently. In comparison, host-based sharing systems have an organisation which provides the vehicles and sets the terms of use. The vehicles are hosted by small enterprises or private persons, and these hosts are responsible for maintaining the bikes and completing loan processing. In return, they can access vehicles more easily and cheaper. (Dorner 2020) Both peer-2-peer and host-based sharing services are often digitally provided by sharing platforms and in the case of "radverteiler.at", are provided through the same platform.

Most cargo bikes (90 of approximately 130 in total) in Austria are available via the platform „radverteiler.at", which enables peer-to-peer sharing of cargo bikes and is used for host-based sharing systems such as in Graz, St. Pölten or Mattersburg (Radkompetenz Österreich 2023). „radverteiler.at" is not the only initiative to foster peer-to-peer and host-based sharing of cargo bikes in Austria. Other initiatives and platforms inlcude „Grätzlrad" for free cargo bike sharing provided by the city of Vienna, „ListNRide" with mainly fee-based offers and „fairvelo" in the region Vorarlberg.

Public authorities can provide incentives and support for setting up and promoting cargo bike sharing schemes, further to what they provide in general infrastructure for active mobility. Non-profit organisations and bicycle cooperatives are often involved in providing the sharing infrastructure and managing the fleet.

Peer-to-peer cargo bike sharing offers and host-based sharing systems in particular, often do not meet all the criteria attributed to shared mobility services, as they often only have limited rental and availability times and cannot usually be booked or rented independently. Seestadtflotte, for example, was the first fully automated cargo bike sharing worldwide in 2015 (VCÖ 2016), using RFID cards to organise the loaning process.

2.3 Cargo Bike Usage Patterns

2.3.1 Usage Purposes

Cargo bikes are used in both the private and commercial sectors. In the commercial sector, the main areas of use are delivery services (e.g. in the CEP sector). However, hardly any data is available on the use in other types of commercial traffic such as service traffic. Commercial transport accounts for around 49% of journeys made by motorised vehicles in European cities. Commercial traffic distinguishes freight transport ("Güterverkehr" – commercial freight transport, factory traffic) and passenger traffic ("Personenwirtschaftsverkehr" – service traffic, business traffic), of which service traffic accounts for about 20% of commercial traffic. Wrighton and Reiter (2016) estimate that about 50% of service trips could be replaced by cargo bikes.

In the private sector, cargo bike usage covers all areas of everyday life - from leisure rides such as shopping and transporting children as well as transporting larger, bulkier objects and waste disposal trips (e.g. green waste, bulky waste)(Becker and Rudolf 2018; Dorner 2020; Berger, Dorner, and Brugger 2019; Kostka 2020). As shared cargo bikes are mainly used for private purposes, the article concentrates on these in the following sections.

2.3.2 Target Group

As mentioned above, regular cargo bike users are still represented by a narrow field of the population – mainly male persons aged 25-40, with higher levels of formal education(Kostka 2020; Berger, Dorner, and Brugger 2019; Becker and Rudolf 2018; Dorner 2020). However, studies show that by reducing target group specific barriers such as safety perception, infrastructural aspects or family role models, there is a high potential for a more diverse and comprehensive user group(Riggs and Schwartz 2018).

Thus, to reach the full potential of cargo bike sharing, knowledge about and consideration of barriers of non-users is needed. On the other hand, a shift towards higher quality cargo bike sharing services is also needed. Therefore, a better understanding of spatio-temporal usage patterns is needed to foster a shift towards higher quality in the service provision, especially regarding tailor-made services for different user groups.

2.3.3 Spatial Patterns of Cargo Bikes and Cargo Bike Sharing

With the availability of detailed GPS tracks of cargo bike usage, it becomes possible to delve deeper into the spatial patterns associated with their use. This information can reveal the preferred pathways taken by cargo bike users, showcasing the most efficient and convenient routes for different purposes. It can also help identify areas with high demand for cargo bike services, indicating potential areas for infrastructure improvements or service expansions (Romanillos et al. 2016).

GPS data can also be used to identify hotspots such as areas with a high concentration of cargo bike activity. These hotspots could include commercial areas with numerous deliveries, residential neighbourhoods with high cargo bike usage for personal transportation, or specific locations where cargo bikes are utilised for business purposes. Identifying hotspots allows for targeted interventions and infrastructure planning, such as providing dedicated cargo bike parking areas or optimising delivery systems(Li et al. 2020).

In addition, combining GPS tracks with temporal information provides insights into how cargo bike usage varies across different times of the day or days of the week. This analysis helps identify peak usage periods and to better understand temporal variations in spatial patterns. For example, the routes and hotspots may differ during morning and evening rush hours compared to off-peak hours. Such information can be valuable for optimising logistics operations, planning infrastructure, and managing resources effectively(Zhou 2015).

GPS tracks can be used to analyse cargo bike trip origin and destination points of cargo bike trips. This analysis provides valuable information about the origins of cargo bike journeys, such as residential areas or commercial centres, and the destinations, such as specific businesses or delivery points. Understanding the origin-destination patterns helps identify areas with high demand for cargo bike services, supporting urban planners and policymakers in making informed decisions regarding infrastructure development and service provision(Levy, Golani, and Ben-Elia 2019).

By leveraging the detailed GPS tracks of cargo bike usage, research and planning can gain a comprehensive understanding of the spatial patterns associated with these vehicles. This knowledge can guide the development of targeted policies, infrastructure improvements, and service expansion to enhance the integration of cargo bikes into urban transportation systems.

There is a large amount of literature on the spatial patterns of bicycle use (including bike sharing) - but there still needs to be a more explicit focus on cargo bikes in the literature. This paper shows user and usage patterns as well as spatial patterns and discusses the potential of spatial analysis in the context of cargo bike usage.

3 CASE STUDIES

3.1 Methodology

As case studies, cargo bike sharing within „Seestadtflotte" in aspernSeestadt (Vienna) and „KlimaEntLaster" in Mattersburg and St. Pölten will be investigated. In aspernSeestadt, an automated cargo bike sharing was implemented and integrated into the bike sharing system Seestadtflotte. Within the research project „KlimaEntLaster", host-based cargo bike sharing was implemented in small and medium-sized cities such as Mattersburg, accompanied by intensive information and test campaigns. The „KlimaEntLaster" services were further developed into an automated sharing service, e.g. in Mattersburg and St. Pölten. The higher availability of the cargo bike sharing service led to an enormous rise in bookings in Mattersburg.

Available data sources	Case Study Mattersburg	Case Study St. Pölten	Case Study AspernSeestadt
GPS-Data	No GPS-data available	GPS-tracking (via Radland Niederöstereich) of 380 trips from August 2022 to June 2023	GPS-tracking of 29 trips in May and June 2020 (Kostka 2020)
Reservation Data	Data of 161valid reservations from September 2019 to October 2021 via radverteiler.at	Data of 148valid reservations from June 2022 to June 2023 via radverteiler.at	Data of 670 valid loans in 2019 via SeestadtFlotte
Survey Data	99 valid responses to an on-going online survey in 2020and 2021 in all KlimaEntLasterpilot locations	18 valid responses to an on-going online survey from June 2022 to February 2023 within eTransport 24/7	48 valid responses to an online user survey in spring 2020 (Kostka 2020)

Table 1: Available data sources per Use Case

The spatial analysis involved several steps, which are as follows. Initially, the raw data consisted of multiple GPX files for each use case. These GPX files were imported and merged in ArcGIS Pro to create a comprehensive dataset. Subsequently, the "Reconstruct Tracks" tool was utilised to identify connected trips within the dataset. A split value of 15 minutes was chosen, meaning that if the dwell time at a location exceeded 15 minutes, the track was split. This process helped ensure an accurate representation of individual trips. The resulting trip IDs were then appended to the raw point data through a spatio-temporal join. To enhance the analysis, a map-matching algorithm was employed to snap the GPS data to a street graph (GIP). This step allowed for inferences regarding the utilised infrastructure and road network load. Finally, the "Calculate Motion Statistics" tool was utilised to derive additional information such as speed, duration, and other relevant trip attributes.

3.2 Seestadtflotte

3.2.1 Project Background

"Seestadtflotte" is the station-based bike sharing system in Vienna's urban development area "aspernSeestadt". It is part of the mobility concept in aspernSeestadt that focuses on encouraging public transport, active mobility and reducing private motorised traffic. The bike sharing system is open to everyone having a "Seestadtcard" but has a focus on the local population and is not connected to the other Vienna-wide bike sharing-system such as "WienMobil-Rad" and the Vienna-wide host-based cargo bike sharing

"Grätzlrad". Seestadtflotte currently offers 56 bicycles and e-bikes at eight stations and four e-cargo bikes at one station. Further expansion of the offer is planned in conjunction with the on-going development of aspernSeestadt and according to its own statements, it is the first automatically operated station-based bike sharing that offers e-cargo bikes(Wien 3420 aspern Development AG 2023b). Seestadtflotte was evaluated in the context of a master thesis(Kostka 2020).

3.2.2   Spatial Context

AspernSeestadt is an urban development project located in the 22nd district in the northeast of Vienna, the capital city of Austria. With about 10.000 current residents, the aim is to reach about 25.000 residents and 20.000 employees in aspernSeestadt by the 2030s, making it one of Europe's largest urban development projects (Wien 3420 aspern Development AG 2023a). Even though there is a subway connection to the city centre, aspernSeestadt is almost its own city in the city of Vienna due to its remote location in the Viennese outskirts. AspernSeestadt was designed as a multifunctional city quarter and is part of Vienna's smart-city concept, where it is highlighted as a test space for innovative ideas.

3.2.3   Operating Model

Seestadtflotte is operated and maintained by Wien Work, a publicly funded non-profit company that provides jobs for people disadvantaged in the labour market (Knapp 2021). Wien Work has a workshop on site where they can maintain the bikes. Seestadtflotte is financed by the Seestadt mobility fund, fed from charges levied for collective garage operation and construction in exchange for less parking space requirements (Wien 3420 aspern Development AG 2023c). The original idea was that users can ride the bikes 30 minutes for free and have to pay a small amount for longer rentals. However, this is not in place yet, so rentals are still free for at maximum 12 hours.

3.3 Mattersburg

3.3.1   Project Background

In September 2019, three shared cargo bikes were established in Mattersburg, Austria. Cargo bike sharing in Mattersburg was implemented within the research project „KlimaEntLaster (KEL)" using a sharing platform developed within the research project LARA-Share. KEL aimed to implement cargo bike sharing in small and medium-sized Austrian cities, while developing cooperative, feasible concepts for cargo bike sharing. Thus, the central aspect was to identify barriers to implementation as well as barriers to usage. The KEL project was led by Energy Changes in cooperation with Die Radvokaten, Quadratic, Factum and the TU Wien.

3.3.2   Spatial Context

As a small-sized city of approximately 7.500 inhabitants(Statistik Austria 2022b), Mattersburg is considered a regional centre in Burgenland according to the urban-rural typology(Statistik Austria 2022a). Further, Mattersburg has very good public transport accessibility (Statistik Austria 2023).; with a third of Mattersburg's inhabitants being commuters, primarily working in the metropolitan area of Vienna(Statistik Austria 2020), which is easily accessible by public transport.

The cargo bikes were located according to their hosts; the location of the cargo bikes was changed several times within the runtime of the project „KlimaEntLaster". Today, only one cargo bike is available in the centre of Mattersburg, 800m walking distance from the central train station. The other two cargo bikes are use in other municipalities in Burgenland.

3.3.3   Operating Model

Within KlimaEntLaster, a host-based sharing system was chosen. This means the municipality and the mobility centre of the county Burgenland financed the cargo bikes, which were then available for free loan at volunteering local businesses or private persons (the hosts). The hosts specify opening hours when other users can book and use the bike. Apart from these opening hours, the cargo bike is fully available to the hosts. The hosts are responsible for checking the cargo bike regularly for safety reasons. Local workshops act as partners for repairs.

In 2020, project partner QUADRATIC developed a solution to provide shared cargo bikes around the clock, independently based on the availability of the hosts. After successfully booking the cargo bike, the user receives a code to unlock the „SmarteVerleihbox" wall box via SMS. The key for the cargo bike and the charged battery is stored in the box. This wall box was installed for one of the cargo bikes in Mattersburg in May 2020.

The project team set up the sharing service, including legal and technical issues, the search for and training of the hosts, and the allocation of the bikes.

3.4 St. Pölten

3.4.1 Project Background

Since June 2022, a shared cargo bike is offered by Radland Niederösterreich in St. Pölten. The cargo bike was implemented within the project „eTransport 24/7" together with a smart wall box for 24/7 cargo bike sharing in the city centre of St. Pölten. „eTransport 24/7" is a follow-up project of „KlimaEntLaster" aiming to roll out and further test cargo bike sharing based on smart wall boxes for sharing around the clock in small and medium-sized towns and municipalities. QUADRATIC led the project with Die Radvokaten, Energy Changes, Factum and the TU Wien.

3.4.2 Spatial Context

St. Pölten, the capital of Lower Austria, is an urban centre (Statistik Austria 2022a)within close proximity to Vienna and with approximately 56.000 inhabitants(Statistik Austria 2022b). On average, St. Pölten has good public transport access (Statistik Austria 2023) and a high rate of in-commuters (commuting to St. Pölten for work or education) and relatively few out-commuters, most of whom commute to Vienna's metropolitan area for work or education (Statistik Austria 2020).

The offered cargo bike is located in the historic city centre, within a traffic-calmed area within 400m walking distance of the central train station.

3.4.3 Operating Model

Radland Niederösterreich is hosting the cargo bike. Thus, they are responsible for regular check-ups and customer support. Besides that, the cargo bike can be booked via the platform radverteiler.at and is accessible for free via the „Smarte Verleihbox".

4 DISCUSSION

4.1 User Patterns – Who uses cargo bikes?

Having a closer look at the question of who the users of the analysed cargo bike sharings are (Figure 1), it becomes clear that in all cases, male users dominate. In Seestadtflotte, the gender ratio appears to be a little more balanced, however, users may share one SeestadtCard or one account on radverteiler.at, so this data maybe inaccurate. Qualitative interviews within KlimaEntLaster showed that male members tend to carry out the booking process in some households, although male and female members both use the cargo bikes. In most cases users are between 25 and 54 years old, whereby the ones in aspernSeestadt and St. Pölten tend to be younger than the ones in Mattersburg. In Mattersburg, compared to the local population, the age group 35-54 is strongly overrepresented amongst users, while persons under 25, are strongly underrepresented. Furthermore, there are only a few users in Mattersburg (28), who use cargo bikes frequently. Finally, it should be noted that the data for Seestadtflotte is based on the online user survey, whereas the data for the KlimaEntLaster projects is based on user and reservation statistics.

Additionally, the number of loans per user is relatively constant between the three cargo bike systems. About 40 % used the cargo bikes only once in the period under review, while another 40% used them two to five times. Very few users loaned cargo bikes more than ten times, and there were hardly any heavy users. Mattersburg's number of loans per user was slightly higher than in the other systems. The intentions for using the cargo bikes also showed similarities in aspernSeestadt, St. Pölten and Mattersburg. The highest ranked motives for usage were the following: fun for children (as a passenger) and riders (parents); testing a cargo bike; environmental-friendly transport possibility; simple and practical as well as being inexpensive.

## Age and Gender of users

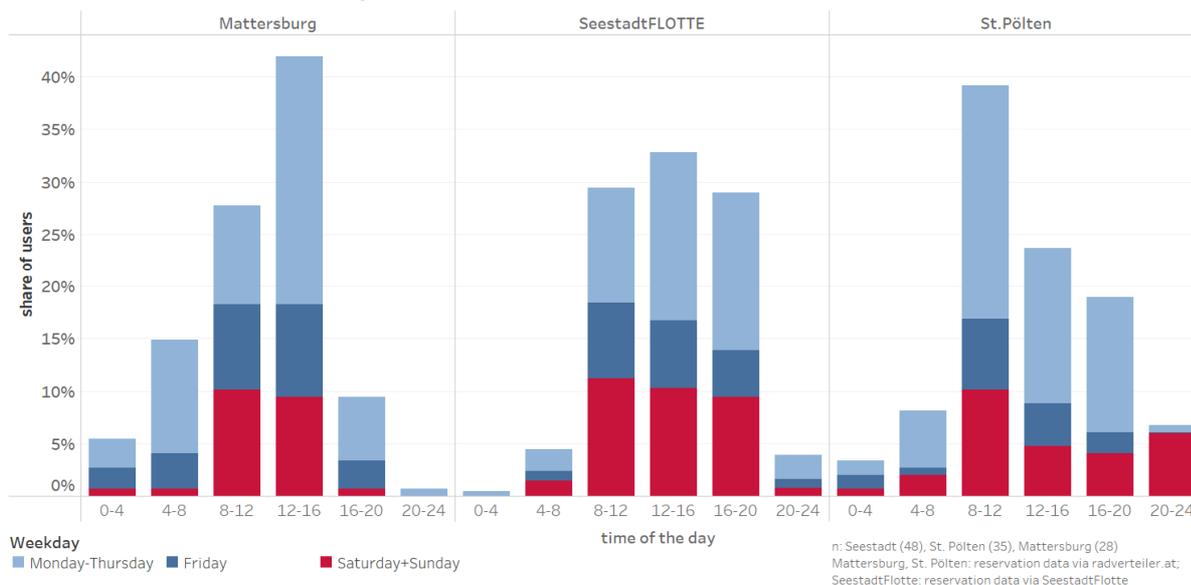
Figure 1: Age and gender of users

4.2 Usage Patterns– How and When are cargo bikes used?

Coming to the usage-related data, we see that most of the bike loan periods begin between 8 am and 8 pm, which is a time span when also host-based services could offer their services. This time span is also related to the purpose of the cargo bike use (see below), where transport of purchases is one of the main issues. Looking at the loans over the course of the day and week in detail, further similarities and differences between the three analysed systems can be revealed. For analysing loans within the course of the week, Fridays were analysed separately from the other working days and weekends, as Friday can be seen neither as a typical working day nor as Weekend. In aspernSeestadt, loans on Fridays and weekends tend to occur earlier than from Monday to Thursday, likely related to users working times. A similar observation can be made in St. Pölten, where users also tend to loan bikes on Fridays earlier than on other days.

On the contrary, some users in St. Pölten reserve bikes also for late Sunday evenings, probably so that they can more easily begin their Monday morning travel from home. Users in Mattersburg behave differently, and the trend to later loans on Fridays/weekends was not observed. While users in Mattersburg took bikes more likely after work too, they also made some loans on working days very early, which was less the case in St. Pölten and rarely so in aspernSeestadt(Figure 2).

Having a look at the loan duration during the course of the week also revealed some interesting aspects. Firstly, loan durations differ significantly between the systems. While users of Seestadtflotte largely loaned the cargo bikes for a very short duration, this was not the case in St. Pölten and Mattersburg.

Even having in mind that the maximum loan duration in Seestadtflotte is only 12h, there are some loans lasting longer. In the other two systems, longer loans are allowed with even whole weekends being possible. It is possible that the very central location of the cargo bikes in aspernSeestadt is a reason for the comparatively short loans because users can easily take a cargo bike again if they need it more times per day. Also, a different purpose of use could be a factor here such as small purchases in the local area and fun rides around the lake for example. While the loan duration in aspernSeestadt is quite constant through the course of the week, this is not the case in St. Pölten, where loans starting on Friday tend to be of longer duration (over the weekend). In Mattersburg, another issue can be observed: While loans on the Weekends last mostly for several hours, loans during the week were either much shorter or longer (more than one day) compared to the other days, whereby longer rentals were rather the case from Monday to Thursday (Figure 3). Reasons for the described usage patterns in Mattersburg and St. Pölten may lie in the bigger spatial expansion of the municipalities compared to aspernSeestadt as an urban neighbourhood of short distances. Further, qualitative and quantitative surveys, as well as GPS-data analysis, reveal longer leisure trips by cargo bike as one of the main usage purposes in Mattersburg and St. Pölten.


Loans in course of the day and week

Figure 2: Loans in course of the day and week

## Loan duration in course of the week

Figure 3: Loan duration in course of the week

In addition to the information presented in the figures, the loan and reservation data analysis revealed that the loans are relatively constant during the week, and there is hardly a difference between the three systems. On Fridays there is a peak in loans in Seestadtflotte and Mattersburg, representing between 15 and 25% of all loans, whereas it is 10-15% on other days. Similarities can also be found regarding transported goods and persons. Cargo bike sharing users primarily transported children, purchases of different kinds, heavy, bulky goods, and equipment for leisure trips to surrounding recreational areas.

4.3 Spatial Patterns – Where are cargo bikes used?

Heat maps are powerful visual representations that provide valuable insights into spatial patterns and distributions based on quantitative data. They are particularly useful in analysing and interpreting the spatial characteristics of various phenomena, including the usage patterns of cargo bikes. Heat maps employ a colour gradient to depict the intensity or density of a particular variable across a geographic area. By visually displaying the concentration and distribution of trips, heat maps enable a first insight into cargo bike usage's spatial dynamics and identify possible key areas for intervention and infrastructure development.

Most trips in St. Pölten are concentrated around the city centre, as the cargo bike station is located at the town hall. This concentration is expected as many trips naturally start and end in this central area. Additionally, the heat map reveals a preference for utilising the dedicated cycling infrastructure along the Traisen River, indicating the importance of well-developed cycling paths in promoting cargo bike usage. Furthermore, the heat map shows that many trips extend beyond the city limits, indicating the potential for cargo bike utilisation in the surrounding, more rural areas, probably for longer leisure trips.

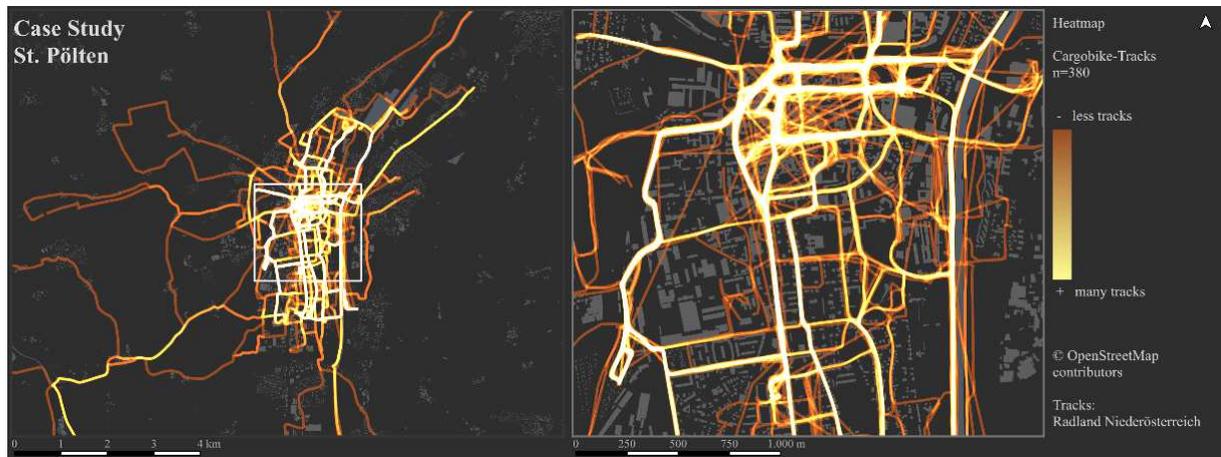


Figure 4: Heat map Case Study St. Pölten.

The heat map of aspernSeestadt illustrates a different spatial pattern characterised by a relatively homogeneous distribution of cargo bike trips. This uniformity can be attributed to the Cargo bike-friendly infrastructure provided throughout aspernSeestadt. The availability of dedicated cycling paths, safe routes, and ample cargo bike parking spaces contributes to a widespread usage pattern. Moreover, the heat map reveals that a significant portion of trips within aspernSeestadt is relatively short, emphasising the suitability of cargo bikes for local trips and the accessibility of amenities within the community, as aspernSeestadt is planned as an urban neighbourhood of short distances. However, it seems that users in aspernSeestadt have not yet recognised the cargo bike for longer leisure trips (e.g., to the surrounding recreational areas).

Figure 5: Heat map Case Study aspern Seestadt

The analysis of speed indicators based on track-level data, considering at least a 15-minute break between each track (see chapter methodology), revealed the following results for the St. Pölten and aspernSeestadt use cases.

These findings indicate notable differences in the average speeds of cargo bike trips between the two locations. In St. Pölten, where the mean and median speeds are higher, suggests a tendency for faster and potentially more direct or longer routes. Conversely, aspernSeestadt, where the mean and median speeds are lower, suggests a preference for slower and possibly more leisurely trips within the neighbourhood.

Speed indicator	St. Pölten	AspernSeestadt
Mean	17,5 km/h	10,1 km/h
Median	18,0 km/h	10,7 km/h

Table 2: Speed indicators.

The track length indicators provide insights into the variability of trip lengths. St. Pölten's longer mean and median track lengths indicate a tendency for relatively more extensive journeys. This may indicate cargo bikes being employed for purposes such as deliveries, transporting goods to farther destinations, or longer (leisure) commutes. Conversely, aspernSeestadt's shorter mean and median track lengths imply a preference for shorter trips within the neighbourhood or immediate vicinity. This pattern suggests that cargo bikes are primarily used for local mobility needs, such as short-distance errands, commuting within the community, or accessing nearby amenities.

Length indicator	St. Pölten	AspernSeestadt
Mean	3164 m	2127 m
Median	4693 m	3766 m

Table 3: Length indicators.

A map-matching technique was employed to align GPS data of cargo bike trips with the GIP graph edges, a comprehensive dataset capturing detailed information about the road network in Austria. This approach enabled insights into the specific infrastructure utilised by cargo bikes, contingent upon the quality and accuracy of the GIP data. By integrating GPS traces with the GIP-edges, it is possible to identify the routes taken by cargo bikes and to analyse the characteristics of the road segments, intersections, and other relevant features along their paths. This map-matching process can provide a deeper understanding of the spatial patterns in terms of used infrastructure and is a basis for finding bottlenecks.

For the evaluation, the number of map matched cargo bike trips per GIP edge was weighted with the length of the GIP edge – the features of longer edges thus have more weight in the result than those of shorter used edges.

Cars on street allowed/not allowed	St. Pölten	aspernSeestadt
No cars allowed	30,9 %	46,1 %
Cars allowed in one direction (one-way restriction)	7,4 %	6,9 %
Cars allowed	61,7 %	47,0 %

Table 4: Map-matched cargo bike trips and used infrastructure types (cars allowed / not allowed)

In St. Pölten, approximately 30% of the cargo bike trips were recorded on streets where cars were not allowed, 7% of the cargo bike trips occurred on streets with one-way restrictions, and the majority of cargo bike trips, accounting for around 60%, took place on streets where cars were allowed in both directions.

In aspernSeestadt, a higher percentage of cargo bike trips, approximately 46%, were recorded on streets where cars were not allowed. About 47% of the cargo bike trips took place on streets where cars were allowed in both directions. These findings suggest that cargo bike users in both St. Pölten and the aspernSeestadt prefer car-free routes, indicating a potential alignment with infrastructure that prioritizes non-motorised modes of transport. The higher proportion of cargo bike trips on car-free streets in aspernSeestadt results from the fact that planning of car-free zones has already been considered in the development plans.

Biking allowed	St. Pölten	aspernSeestadt
No	3,8%	19,4 %
Yes	96,2 %	80,6 %

Table 5: Map-matched cargo bike trips and used infrastructure types (biking allowed / not allowed)

In St. Pölten only a minimal share of the recorded cargo bike trips occurred on streets where biking was not allowed due to biking restrictions. Most cargo bike trips took place on streets where biking was allowed.

In aspernSeestadt, a higher percentage of cargo bike trips occurred on streets where biking was not allowed. These findings highlight both legal and illegal routes taken by cargo bike users, particularly in the

890

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

aspernSeestadt. This concerns many trips in the parks and green spaces around the lake, where cycling is officially prohibited, but residents still like to use it as a shortcut.

The GIP also includes special information for pedestrian and bicycle traffic, which can subsequently be used for bicycle routing. This information - if complete and correctly recorded - could also be used to assess infrastructure readiness for cargo bikes better.

5 CONCLUSION

This article shows in a rough attempt the relevance of reservation and GPS data analysis for implementing and improving cargo bike sharing systems in order to offer accessible, sustainable and resilient mobility alternatives. However, even further potential lies in the deeper analysis and interconnection of different data as well as in the use of further data such as qualitative and quantitative surveys of users and non-users.

The availability and suitability of cycling infrastructure for cargo bikes remain understudied and further research is needed to understand the specific infrastructure requirements and design considerations that cater to the unique needs of cargo bikes. The „cargo-bikeability" of urban areas is a crucial aspect to consider when promoting sustainable urban mobility and to that end, different forms of use of cargo bikes tailored to the different needs of various target groups should be considered. This emphasizes the need for further research on infrastructure and the suitability for different cargo bike usage patterns (see e.g. ENTLASTA project).Different user demands should also be considered when designing the operating model. The case studies illustrate that automated lending facilitates access for regular users and for shorter loans, however, an additional contact person could be particularly supportive for first-time users. To exploit the socially inclusive potential of cargo bike sharing, it is necessary to expand outside urban areas and to reach further groups of people. Thus, further research is needed (see e.g. HAUSRAD project).

Spatial data, particularly GPS data analysis, can play a vital role in identifying bottlenecks and challenges faced by cargo bike users. The integration of GPS data provides added value to understanding cargo bike usage patterns, but it is important to consider the complementarity of additional data sources. Supplementing GPS data with other relevant data, such as demographic information, land use data, and transportation demand data, would provide a more comprehensive understanding of the factors influencing cargo bike mobility.

Understanding the Significance of Urban Lingering Factor of Built Environments in the Socio-Climatic Decision-Making Process for Urban Open Spaces: Field Survey Alexandria University Campus

Sagda Gamaleldin, Zeyad El-Sayad, Mohamed Ibrahim

(Ass. Lect. Sagda W. Gamaleldin, Alexandria University, Alexandria, Egypt; sagda.wael@alexu.edu.eg)
(Ass Prof. Zeyad M. El-Sayad, Alexandria University, Alexandria, Egypt; zelsayad1@alexu.edu.eg)
(Prof. Em. Mohamed A. Ibrahim, Alexandria University, Alexandria, Egypt; abdelallmai@alexu.edu.eg)

1 ABSTRACT

Urban lingering is the practice of spending time in public spaces for leisure, socializing, or simply being outdoors. It is a critical urban factor that is influenced by various factors related to the built environment and climate. Urban open spaces, such as University campuses, plazas, and streetscapes, play a bilateral role with the lingering factor in promoting social and environmental sustainability. However, it is highlighted that the urban space's lingering factor understanding process is essentially affected by the aspects of the built environment especially the climatic considerations, to ensure their resilience and future adaptability.

This paper provides a literature review on urban lingering factor with the built environment and their role behind the climatic-based decision-making of urban spaces. The review is structured around several key themes that provide a comprehensive overview of urban lingering, illustrating its causes, effects, and potential solutions. It emphasizes the importance of understanding the complex and multifaceted phenomenon of urban lingering, which is shaped by a range of social, environmental, and economic factors. The research also discusses the implications of urban lingering for urban design, public policy, and community development, and identifies key areas for future research.

Overall, this review emphasizes the importance of considering the lingering factor and built environment on the climatic design and management of urban open spaces, and how this approach of design can support urban lingering behavior and promote social and environmental sustainability. The findings have implications for urban policy and well-being in urban open spaces especially on university campuses as been the focus of the research. Overall, this research review paper provides comprehensive insights into urban lingering factor and the built environment's potential impact on climatic-based decision-making. then, offers essential recommendations for addressing this crucial issue. The review research is aided by a preliminary comparative field survey that supports the research hypothesis.

Keywords: Climate-Informed Decision-making in Urban Open Spaces, Urban Personality, Urban Built Environment, Urban Lingering Factor, Urban Personality

2 URBAN LINGERING FACTOR

2.1 Lingering Factor Definitions: General Overview

Urban public spaces play a critical role in the social, economic, and cultural life of a city. However, not all public spaces are created equal, and some spaces attract more people and activities than others. The concept of the "urban lingering factor" refers to the qualities and typologies of urban public spaces that encourage people to linger and engage in activities. Understanding this factor is crucial for architects and urban planners to design public spaces that are attractive and inclusive(Wang, Liao, Brandhorst, & Clark, 2022).

Lingering is a complex phenomenon that has been studied in a variety of contexts, including urban open spaces, retail environments, and public transportation. Lingering can be defined as the act of staying in a particular location for an extended period of time, often for social or recreational purposes(UN-Habitat, 2020). Lingering can be influenced by a variety of factors, including the physical design of the space, the social and cultural context of the community, and the perceived safety and comfort of the space. Understanding the factors that influence lingering is important for designers and planners who seek to create urban spaces that are vibrant, dynamic, and well-utilized. This part provides a general overview of the lingering factor definitions that have been identified in the literature and discusses their implications for urban design and planning.

2.1.1 Definitions of Urban Lingering

Urban Lingering is a complex concept that has been defined and studied in various ways by different scholars. In this section, we will review some of the key definitions and understandings of Urban Lingering that have been put forth in the literature.The term "Urban Lingering" was first coined by the sociologist Sharon Zukin's book in 1996 "The Cultures of Cities." In this work, Zukin defines Urban Lingering as the practice of occupying in public spaces for pleasure, entertainment, or social interaction(Zukin, 1996). According to Zukin, Urban Lingering is an important aspect of urban life, as it allows individuals to engage with their surroundings and with each other in meaningful ways.

Since Zukin's initial definition, scholars have expanded the concept of Urban Lingering to include a variety of different practices and activities. For example, some researchers have focused on the importance of Urban Lingering for mental health and well-being, arguing that spending time in public spaces can help to reduce stress and increase feelings of happiness and connection (Pretty , Peacock, Sellens, & Griffin, 2005). Others have emphasized the political and social dimensions of Urban Lingering, highlighting how public spaces can be sites of resistance and contestation, particularly for marginalized groups (e.g., McFarlane, 2010).

The term "urban lingering factor" refers to the tendency of individuals to spend time in public spaces without a specific purpose or activity. The concept of urban lingering is closely related to the idea of "loitering," but generally has a more positive connotation, as it is often associated with social interaction, leisure, and community building.

On the other hand, it may refer to the impact of past decisions on the current state of the urban environment. It recognizes that the built environment of cities is a product of past decisions and that these decisions can have extended effects on the sustainability and resilience of urban areas. The urban lingering factor highlights the need forextensivecomprehensive decisions in urban planning and design (Abd Elrahman & Asaad, 2021).

Broadly, it is argued that there are several definitions of the urban lingering factor, depending on the context and perspective of the researcher. Some definitions focus on the physical presence of individuals in public spaces, while others emphasize the social and cultural dimensions of urban lingering. Here, the following table (1) summarizes several definitions of urban lingering:

Definitions	Reference
The occupying practice in public spaces for pleasure, entertainment, or social interaction	(Zukin, 1996)
It refers to the act of spending time in public spaces without a specific purpose or activity and is often associated with social interaction and community building.	(UN-Habitat, 2020)
The urban lingering factor refers to the degree to which public spaces are conducive to social interaction and leisure activities and can impact the quality of life and sense of community in urban environments.	(Wang, Liao, Brandhorst, & Clark, 2022)
Urban lingering is a form of informal social activity that occurs in public spaces and can contribute to social cohesion, community building, and cultural exchange.	(Aelbrecht & Stevens, 2019)
To describe how past choices have affected the state of the current urban environment. It acknowledges that decisions made in the past have an impact on the built environment of cities and can have a long-term impact on their sustainability and resilience.	(Asadpour, Razmara, Heidari, & Taghipour, 2022)

Table 1: Definitions of Urban Lingering. Source: authors.

Overall, the definition of the urban lingering factor depends on the specific context and research question but generally involves the concept of spending time in public spaces without a specific purpose or activity, and the potential impact of this behavior on social interaction, community building, and urban development.

2.2 Parameters of Urban Lingering

The observation of people's presence is the standard way to visualize urban lingering in existing urban open spaces. This could be considered a basic method to measure the current state of the urban linger factor for an urban space. However, this concept may not be beneficial for analyzing futuristic scenarios of urban open spaces. Urban lingering factors refer to the factors that influence people's tendency to spend time in public spaces, such as streets, parks, and squares. Therefore, measuring the urban lingering factor involves measuring the parameters of the desirable urban built environment that stimulate people to stay in urban open spaces, as well as highlighting the parameters that could affect people's eagerness to stay outside.

It is important to highlight that this research argues that the urban lingering factor should be considered both as an effective urban parameter and as a nominal numeric factor of numerator and denominator.

894

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

The urban lingering factor is a complex and multifaceted concept that is influenced by various factors. Here are some parameters that could be used to measure the urban lingering factor:

- Historical and cultural significance of urban spaces (Shinbira, 2012).
- Accessibility and connectivity of urban spaces (Gehl, 2010).
- Diversity of uses and activities in urban spaces (Elshater & Abusaada, 2022).
- Sense of place and identity associated with urban spaces(Relph, 2022).
- Perception of safety and security in urban spaces (Fleming, Manning, & Ambrey, 2016).
- Environmental and sustainable qualities of urban open spaces (Beatley, 2011).

It is important to note that the parameters for measuring the urban lingering factor may vary depending on the context and location of the urban area being studied. Additionally, the selection of parameters should be based on a comprehensive understanding of the interplay between social, economic, and environmental factors in shaping the urban environment.

The table below (Table 2) provides a projection of the previously mentioned parameters on real examples of university campuses. The examples in the table illustrate the uniqueness of each campus, as well as the subsequent effect of each parameter.

Historical and cultural significance	Accessibility and connectivity of urban spaces
An evaluation has been done of the historical and cultural significance of the University of Virginia's urban open spaces. This evaluation assisted in locating campus areas that required preservation or restoration, which are more likely for people to linger in and integrated with.(Neuman, 2007)(Baldwin, 2020).	Analyzing pedestrian and bicycle traffic patterns allowed researchers at the University of California, Los Angeles (UCLA) to evaluate the connection and accessibility of urban open areas. Which was used to identify places that required upgrading accessibility and promoting amenities. (Critique Access, 2022).
Diversity of uses and activities in urban spaces	Sense of place & identity related to urban spaces
The multi-functionality of the University of Massachusetts Amherst's urban spaces was assessed by users'surveys to classify their favorite outdoor spaces and their engaged activities. The results were used to inform decision-makers in the campus's renovation process. (Sleegers, 2010) (Toom , 2022).	The sense of place and identity At the University of British Columbia was evaluated amongurban open spaces by a series of workshops with users to determinetheir unique characteristics and qualities. Comprehensive development steps have occurred to enhance this parameter (Covin, 2009).
Perception of safety and security in urban spaces	Urban Environmental and sustainable qualities
A study at the University of Melbourne conducts to investigate the perception of safety and security in various campus open spaces. The study found that spaces tended to be perceived as safer are more likely to be used for lingering and socializing.(Piroozfar,et al, 2019).	At the Arizona State University campus, the ecological function of various urban spaces was evaluated and analyzed, which helps to identify areas that require restoration. and guide developers to a comprehensive plan for sustainable campus development. (ASU, 2023)

Table 2: Examples of Urban Lingering Factor Parameters. Source: authors.

2.2.1   The Challenges & Limitations of the Urban Lingering Factor Parameters

- Subjectivity:subjective parameters, which are based on people's perceptions and experiences rather than objective data. For instance, the sense of place is extremely subjective and based on the background, experiences, and culture of the individual.

- Context-dependency:parameters are highly contextual dependent and locational for the studied urban area. As an example, the urban space'scultural significance may be differentiated between old and new cities.

- Data availability: Due to a lack of data, some parameters are more challenging to be measured than others. For instance, they may entail advanced equipment or expertise that might not be available in all contexts.

- Interdependence:they are intertwined and cannot be isolated considered. Such as the urban space's multifunctionalitycould be influenced by its historical and cultural significance, its accessibility and connectivity, and the users' perception of safety and security.

- Resource limitations:the measurement process could be time-consuming and expensive and may require interdisciplinary expertise.

Finally, it is believed to consider the challenges and limitations which are synchronized with these parameters, while interpreting the urban lingering factor results. This process can provide valuable insights intothe social, economic, and environmental factors that shape urban open spaces.

3   URBAN BUILT ENVIRONMENT

The urban built environment has a significant role in the overall aspects of areas. Urban activity, social interaction, and access to resources all could be influenced by the design and layout of the urban context. Additionally, it can associate and reinforce social and economic disparities, affecting health and opportunities for residents. A growing need for examining the relationship between the built environment and urban outcomes has appeared. Such research can support planning and designing decisions, assisting to produce more viable, equitable, and sustainable urban environments(Paudel & States, 2023). Researchers have examined the design and management of open and green spaces, as well as the health, psychological, economic, and social outcomes (Nguyen, Astell-Burt, & Rahimi-Ar, 2021).

Generally, the study of the urban built environment is crucial for understanding how the physical environment affects urban spaces, both tangily and intangibly. By examining the relationship between the built environment and urban outcomes, researchers can inform planning and design decisions that promote the desired outcomes.

3.1 The Definitions of Urban Built Environment

Several definitions could be associated with the urban built environment.However, it generally involves the tangible assets of urban areas, including buildings, transportation systems, public spaces, streets,…etc. Urban open spaces users' health and well-being are significantly impacted by the design and management of the urban built environment, which is influenced by various social, economic, and cultural elements. Table (3) is illustrating the specific definition of both built and urban built environments.

Terms	Definition	Citation
Built Environment	The human-made physical context in which people live, work and play	(Habash, 2022)
Urban Built Environment	The physical environment of cities and towns, including buildings, streets, public spaces, and transportation systems	(Roe, et al., 2020)

Table 3: Definitions of Built Environment and Urban Built Environment. Source: authors.

The interaction between the urban built environment and the climatic and natural elements is a crucial aspect. Urban spaces, such as parks and plazas, are distinctly endangered by environmental threats, including extreme temperatures, air pollution, …etc. These threats can affect the viability and vitality of urban open spaces and may negatively impact the health and well-being of their users.Urban designers and planners hold the responsibility to address these challenges and increasingly incorporate green infrastructure, such as trees, green roofs,rain gardens,etc.through their designs, as well as help relievetheir effects (Habash, 2022).

The World Health Organization (WHO) highlights the importanceof urban built environment integration with natural elements, to enhance the urban quality. WHO emphasizes through their "Urban Green Spaces and Health" report that the human association with green spaces, such as parks and gardens, can promote physical activity, reduce stress, and improve mental health(WHO Regional Office for Europe, 2022).Overall, it is considered that the urban built environment is a complex system. It is shaped by various interconnected factors. It has an essential relationship with the climate and natural elements, (Roe, et al., 2020).

3.1.1 Urban Built Environment and Urban Lingering Factor

Urban built environment has received significant concern, through research, is the role of urban open spaces, such as parks and plazas. These spaces provide important opportunities for relief and social, economic, and cultural interaction. They can also play a role in promoting their usersboth physical and psychological health. Moreover, the design of urban open spaces can have a significant impact on how they are used and perceived by users, which are generally described as urban lingering factors(WHO Regional Office for Europe, 2022).

It is believed that the overall layout of the urban built environment has an impact on its urban outcomes. For instance, high walkability neighborhoods, connectivity, and mixed land uses have been associated with high physical activity and low obesity rates(Gehl, 2010). Similarly, access to public transportation also can improve mobility for users and reduce reliance on individual vehicles(Berg & Ihlström, 2019).

In other words, exposure to air pollution, noise pollution, and other environmental hazards can create negative effects on users' mental and physical health (WHO Regional Office for Europe, 2022). Additionally, social and economic factors, such as destitution and segregation, have reflections onthe built environment, creating disparities in accessibility, security & safety, well-being...etc (Aelbrecht & Stevens, 2019).

Abdelaal (2019) proposes that the urban built environment plays a crucial role in the urban spaces users' existence and well-being, both tangibly and intangibly, directly and indirectly. Byincorporating aspects of the built environments, and climatic and sustainable parameters, urban designers and planners can create more livable, equitable, and resilient urban open spaces(Abdelaal, 2019) (Abd Elrahman & Asaad, 2021).

Thus, it is believed that the urban lingering factor is significantly impacted by the urban built environment of space. University campuses are distinctive urban settings that provide a various range of open spaces, such as courtyards, plazas, and green areas. The way that people utilize and two-way interaction with these spaces, as well as their general satisfaction and well-being, could be influenced by their design (Abdelaal, 2019).

3.2 Parameters of Built Environment in Desirable University Campuses' Urban Open Spaces

Desirable university campuses' urban open spaces are significant campuses' outdoor areas that are used as gathering locations for visitors, staff, and students (Hanan, 2013). These spaces are designed to provide a comfortable and attractive environment for relaxation, socialization, and physical activity. The success of these spaces relies on their design, which should incorporate various characteristics, that could be considered as the conceptual shape of a space's built environment parameters, including multifunctionality, accessibility, sustainability, aesthetics, and safety and security. These characteristics are essential for developing a setting that encourages well-being, stresslessness, and fosters a sense of community. Universities build open-space environments in order to improve the student experience and feeling of communityby considering these parameters (Abdelaal, 2019).

The Characteristics of Desirable University Campuses' Urban Open Spaces				
Chars.	**Multi-functionality**	**Accessibility**	**Sustainability**	**Aesthetics**	**Safety and security**
Description	Spaces which serve multiple purposes, such as providing socialization, studying, and physical activities.	Accessible spaces to all users, including people with disabilities.	Spaces which are designed or functioned with sustainable features such as green roofs, rain gardens, ...etc.	Open spaces should be visually appealing and designed in a way that reflects the campus culture and values.	These spaces should be well-lit and designed to minimize the risk of accidents and crime.
Ref.	(Hanan, 2013)	(Qurratul, Henny, & A, 2019)	(Abdelaal, 2019)	(Yu Lau, Gou, & Liu , 2014)	(Piroozfar,et al, 2019)
Examples	The University of Sydney	University of British Columbia, Canada	UCLA, Los Angeles' Sculpture Garden	The UC Berkeley Strawberry Creek Plaza	The University of Melbourne's South Lawn

Figure 1: A brief about the characteristics of desirable university campuses urban open spaces. Source: authors.

Fig. 1 illustrates a brief about the characteristics of desirable university campuses urban open spaces. The table categorizes the characteristics, supported with relevant examples of university campuses' urban open spaces.

The urban spaces characteristics of desirably university campuses are deeply related to the urban built environment parameters. Various factors should be taken into consideration through designing and planning such as shape and layout, management and system, ...etc. For instance, sustainable features such as solar lighting, green roofs, and greenery, are considered as ingredients of a built entity and can enhance spaces' sustainability and vitality. Similarly, accessibility features such as ramps, sidewalks, and seating areas can be considered through the built environment as accessibility insurance for the space. Additionally, the visually appealing welcoming environment of the space could be achieved byincorporating aesthetically pleasing design elements. By considering these factors in the design of the urban built environment, universities can create desirable urban open spaces that have positive urban impacts (ASU, 2023). Table (4)illustrates the parameters of desirable urban built environments through university campus urban spaces.

Parameter		Description	References
Form	Size	Review space size and proportions, relatedto function and surroundings	(ÇakmakMehmet & Topcu, 2018)
	Configuration& Aesthetics	Thespace'soptimal shape and layout, based on the intended use and the surrounding environment	
LandSacpe	Materials	The space-appropriate materials, considering the function and surrounding.	(Hendel, 2020)
	Vegetation	The necessary greenery ratioin the space.	(ASU, 2023)
	Lighting	Space lighting considerations, of timing, load, and intensity.	(Gokhale, 2013)
	Furniture	Considering the space's furniture availability, suitability, and sustainability.	(Allahdadi, 2017)
System Management &	Maintenance	The space maintenance schedule& degree, based on the intended function.	(UN-Habitat, 2020)
	Long-term viability / Permanence	It is the ability of urban assets, buildings, ..etc. to remain functional, safe, and aesthetically appealing over time. Resilient and sustainable design and management policies are essential to achieving long-term viability.	

Table 4: Built Environment Parameters in Desirable University Campus Urban Open Spaces . Source: authors.

It is believed that the urban built environment of open spaces plays a crucial role in shaping the university campus experience. By considering the built environment aspects and parameters of desirable urban open spaces, there is the ability to create spaces with a wide range of supported activities, enhance well-being, and the overall campus experience.Figure (2) illustrates the interrelationships between the urban built environment and the role of the characteristics of desirable urban open spaces in the formulation of the desirable built environment.

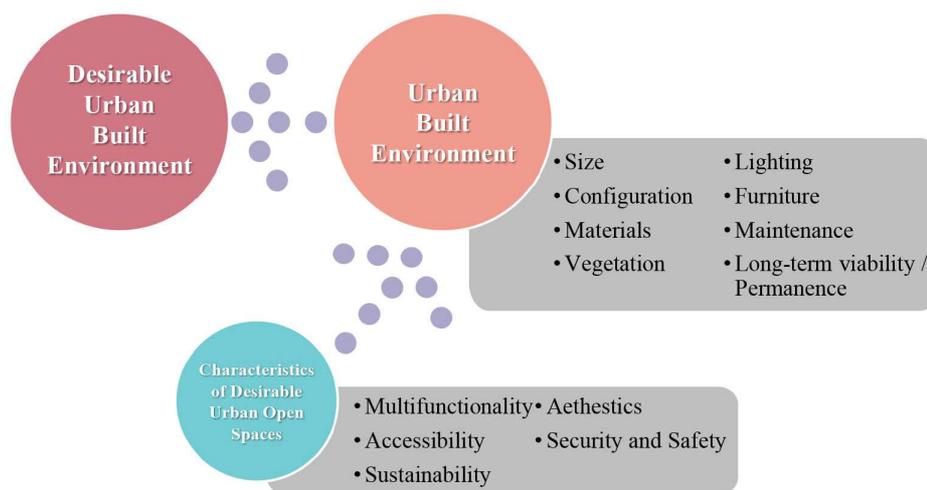

Figure 2: The Hinge Between the Urban Built Environment and the Characteristics of Desirable Urban Open Space. Source: authors.

In conclusion, the intent of desirable university campuses' urban open spaces is to promote well-being, stresslessness, and increaseusers'sense of community. Developing parameters such as multifunctionality, accessibility, sustainability, aesthetics, and safety can enhance these spaces built environmental conditions. It is thought that these parameters can also enhance the urban lingering factor of users through the urban space, and have multifaceted effects, affecting their performance, decision-making process, and overall experience

898

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

of the space for both users and designers. Thus, it is proposed that the designing, controlling, or upgrading processes of these urban open spaces in a way that engages these characteristics, can significantly impact the user experience and the overall success of the space. It is believed that this process could be achieved, through the concept of a socio-climatic informed decision-making process.

4   SOCIO-CLIMATEINFORMED DECISION-MAKING PROCESS OF URBAN OPEN SPACES

Urban open spaces serve as places for recreation, social interaction, and cultural events, while also important ecological functions are provided such as air and water purification, carbon sequestration,…etc. However, with the increasing impacts of climate change, open spaces are facing new challenges that threaten their ability to provide these benefits (WHO Regional Office for Europe, 2022).Socio-climatic factors canaffect the use and accessibility of urban spaces, as well as the presence, health,and well-being of their users. To ensure that urban open spaces continue providing their intended benefits in the face of environmental changes, especially climatic changes, it is necessary to incorporate socio-climatic considerations intothe decision-making process formanaging, designing,and utilizing these spaces(Berkman, Vylegzhanin, & Young, 2023).

This part explores the socio-climate-informed decision-making process for urban open spaces. The socio-climatic factor, effects and integrated with the design and management of urban open spaces, will be investigated, through their users and decision-makers, and how this can lead to more resilient and equitable urban environments. This part will also explore the comprehensive complementary role of these elements through a bilateral bias.Overall, this part seeks to achieve a better understanding of how socio-climatic considerations can integrate with the decision-making process of urban open spaces, and how this can lead to more positive lingering urban factorsin the universities'urban environments.

4.1 Socio-Climate Informed Decision-making - General Definition

It is a theory that acknowledges the interdependence of social, economic, and environmental systems as well as how each of these systems is impacted by climate change. Support climate change-related decision-making, it entails merging scientific data and societal data. As it enables decision-makers to recognize and address the social and economic implications of climate change, this approach is particularly pertinent to public policy, sustainable development, urban planning, and business strategy.

The development of climate change adaptation plans in the agricultural sector is one practical example of the utilization of socio-climate-informed decision-making. The effects of climate change, such as altered precipitation patterns, a rise in the frequency and severity of extreme weather events, and changes to the growing season, are especially harmful to agriculture(Waldman, et al., 2020). Agricultural decision-makers can create strategies that not only address the environmental effects of climate change but also take into account the social and economic repercussions on farmers and rural communities by adopting a Socio-Climate informed decision-making strategy. For instance, to assist farmers in adapting to changing climate circumstances, decision-makers may take into account making investments in crops that are resistant to drought, creating water storage systems, and putting in place training programs for farmers. Figure (3) presents the conceptual framework for the factors affecting decisions made by American farmers in response to climate change (Chatrchyan, et al., 2017).

On the other hand,the development of climate change adaptation strategies for the transport sector is another utilization of socio-climate informed decision-making. The greenhouse gas emissions caused by transportation are an important factor in climate change. Transportation decision-makers can build plans that not only lower emissions but also consider the social and economic implications on communities by adopting a Socio-Climate informed decision-making strategy.

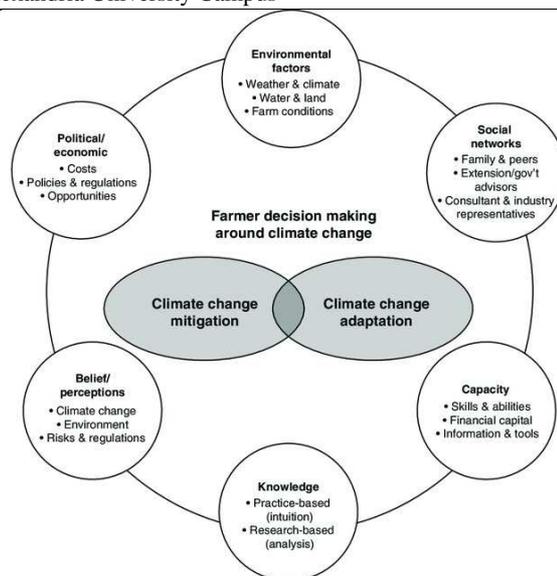
In general, it is proposed that the integration of social, economic, and environmental systems, as well as the climate change effects on each system is recognized as socio-climate informed decision-making theory(Manteaw, Amoah, Ayit, & Enu, 2022). It is believed that this strategy refers to the process of making decisions in an urban built environment with considering both social, environmental,and climatic factors. It is a holistic approach that allows the interplay between these factors and the need for aninclusive understanding of the urban system (Mendoza, et al., 2018).


Figure 3: Conceptual framework for the elements influencing how American farmers execute climate change-related decisions. Source: Chatrchyan, et al., 2017.

Decision makers can create plans that address the social, economic, and environmental effects of climate change by adopting the socio-climate informed decision-making strategy. These actual instances show how crucial it is to consider both the environmental and social effects of climate change, as well as the necessity for a multidisciplinary approach todecision-making (Gargiulo & Zucaro, 2023).

4.2 Interdisciplinary Definitions and Viewpoints

Socio-climate informed decision-making is a complex strategy, that involves incorporating social, environmental, and climate change issues into decision-making processes. Across a range of fields, including environmental research and studies, politics, public health, community development, and engineering, the main definition of socio-climate informed decision-making is comparatively similar. Ensuring that decisions are sustainable, equitable, and resilient to the effects of climate change, is the central idea behind socio-climate informed decision-making(Orlove, Shwom, Markowitz, & Cheong, 2020). This approach is crucial for dealing with the complex issues brought on by climate change and promoting sustainable development. The procedure entails taking into account how climate change may affect social and environmental variables and using this knowledge to guide decision-making in creating policies, designing infrastructure, planning healthcare, and involving the community. Overall, making decisions based on socio-climate information is essential for reducing and adjusting the effects of climate change and promoting sustainable development(Santamouris, 2013). Table (5), summarizes the different perspectives and definitions of the Socio-Climate informed decision-making strategy. The table highlights the approached definition of each perspective that shows the fixed essence of the main concept behind this strategy.

Perspective	Definition	Ref.
Environmental Science	Process of making climate change informed decisions and its social impact.	(Koh , Loc, & Park, 2022)
Sustainable Development	The process that integrates social, economic, and environmental factors to produce sustainable decisions.	
Public Policy	Using scientific evidence and social data to, related to climate change, inform public policy decisions.	(Mendoza, et al., 2018)
General Policy Making	Process of integrating climate change considerations into policy development, implementation, and assessment to ensure policies climate change impacts resilience and support sustainable development.	(Orlove, Shwom, Markowitz, & Cheong, 2020)
Urban Planning	Considering the social and economic impacts of climate change on urban areas planning and design.	(Manteaw et al., 2022)
Business Strategy	Making business decisions that take into account the social and environmental impacts of climate change.	(Waldman, et al., 2020)
Community Development	is a participatory process that involves engaging communities in decision-making processes related to climate change adaptation and mitigation to ensure that decisions reflect the needs and priorities of the community.	(Aelbrecht,2022)
Engineering Perspective	Incorporating climate change impacts and vulnerabilities into engineering design and decision-making processes to ensure that infrastructure and buildings are resilient to climate change impacts.	(Berkman et al. 2023)

Table 5: Socio-climate informed decision-making from Different Perspectives. Source: authors.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

4.3 The Implementation of Socio-Climatic Informed Decision-Making Process Through the Urban Open Spaces

The concept of socio-climate informed decision-making process (SCIDM) of urban open spaces refers to the frameworkthat considers the socio-climatic factors that impact these spaces through the designing, managing, and using processes. Socio-climatic factors involve both the environmental and social aspects of a given location. To create a SCIDM process for urban open spaces, a various range of stakeholders is necessary to be engaged, including urban planners, designers, community groups, and policymakers. These stakeholders must work together to recognize the most relevant socio-climatic factors to the specific urban open space, and to develop approaches for addressing these factors.One substantial aspect of the SCIDM process is the climate data and projections incorporation into the design and management of urban open spaces(Waldman, et al., 2020). A climate model can be included to predict, for example, future temperature and precipitation patterns, and design urban open spaces that can adapt to these changes(Koh , Loc, & Park, 2022). Another key aspect of the SCIDM process is social equity and community engagement involvement. It is important to ensure that the responsiveness of design and management of urban open spaces to the needs and affinities of local communities, and the equitable distribution of these spaces benefits across different socio-economic groups. This includes the community groups'engagement in the design and management process andthe incorporation of their feedback through decision-making(Aelbrecht, 2022).

4.4 The Study Three Aspects -The Triangulated Relationship

Through this paper, it is believed that a comprehensive understanding of these factors is essential for creating sustainable, vital, and viable urban built environments.Urban open spaces are complex mechanisms that are moulded by intertwined factors, including the built environment, social & economic conditions, and climatic conditions.The interplay between these factors is critical to the vitality and viability of these urban open spaces. This parthighlights the interrelationship between the urban built environment, the SCIDMprocess, and the urban lingering factor. It is believed that the interrelationship between these three factors is simple, logical, tangled,and multifaceted. The built environment is influenced by past decisions and current and future socio-climatic projections. The SCIDMprocess recognizes the interplay between these factors and seeks to make decisions that are based on a comprehensive understanding of the urban system. The urban lingering factor is reflecting the urbanaffections of the other factors, which are represented through the innate presence of users in the urban spaces while consideringthe past decisions'impact on the sustainability and vitality of urban areas.Ideally, Urban spaces' users urban lingering critically depended on the interplay between these three variables. It is crucial to have a comprehensive understanding of them. Cities may have the ability to create built environments that suit the demands of the present and future generations while minimizing the effects of previous actions by adopting a holistic approach to urban planning and design decisions that consider the interaction between social and environmental elements, as well as, controlling the urban lingering factor of each urban open space as it is proposed by its designers through controlling the other factors.

Figure 4: The Study Three Interrelationship Aspects. Source: authors.

Overall, the interrelationship between the Urban Built Environment, Socio-Climatic Decision informed making process, and the urban lingering factor is believed to be significant. Both the urban built environment

and the socio-climatic informeddecision-making process play important roles in shaping the current and future conditions of urban open spaces. On the other hand, the urban lingering factor plays a role as a representative key value in the urban open spaces. Fig. 4 presents the interrelationship between these three factors, as well as the role of each factor as either a stimulus or an indicator.

5 FIELD SURVEY –URBAN OPEN SPACES OF THE UNIVERSITY CAMPUS, FACULTY OF ENGINEERING, ALEXANDRIA UNIVERSITY

5.1 Introduction

University campuses are often considered as microcosms of urban areas, with unique characteristics and challenges that play a crucial role in shaping the overall campus experience. The urban open spaces on these campuses have great potential for development through an updated decision-making process based on various aspects that guarantee the achievement of specific goals.

This field survey reviews the literature on the built environment of university campuses and the urban lingering factor, with a focus on urban open spaces. The survey provides an initial sensory evaluation to test the research hypothesis, which proposes a positive relationship between the implementation of built environment parameters and students' urban lingering factor. It also highlights the importance of a decision-making process that considers social and climatic factors (SCIDM).

The field survey identifies the parameters of both the built environment and the urban lingering factor while emphasizing the need for a socio-climatic informed decision-making process for existing, future, or proposed steps that would achieve a positive urban lingering factor for urban open spaces. Finally, the study summarizes the findings through a table with figures and recommendations.

5.2 Methodology

The surveys consist of, firstly, creating a social and climatic comprehensive background regarding the study-selected locations. This has involved conducting surveys or focus groups to determine how people use outdoor spaces in different day times, and weather conditions, and what their most valuable features are in these spaces.Once this data has been collected, it could be possible of creating comprehensive viewpoints of each space's urban environment, both current anddesigned ones. Next, it is important to monitor uses and effectiveness over time. This has occurred through tracking the number of users, observing how people use the space, and collecting feedback from the community about their experience.The researcher used a basic field observation method in this study. The observation process took place for three continuous days, with ninety minutes of observation each day, on the Faculty of Engineering campus at Alexandria University. Figure (5) shows the observation zone that the researcher covered on the campus. As well as, illustrates the construction locations on the campus. It is important to note that approximately 80% of the students were on summer break during the first and second days of observation, while 100% were present on the third day.

Figure 5: Campus Zones Illustration (right), Construction Location (Middle) & Green Area (left). Source: authors.

5.3 Experimental Phase

Below are the results of the field survey for six different zones. Each zone is illustrated with its urban built environment rate based on the parameters of a desirable urban environment. Additionally, the survey includes the urban lingering factor (ULF) for both the observed factor and the expected factor, taking into account the design intentions of the urban area.

Zone 01

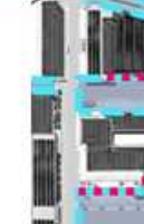
Built Environment: 70% | Existing ULF: 60% / Expected ULF: 90%

Notes: ULF is affected by the continuity of cars among the seating areas

Zone 02

Built Environment: 10% | Existing ULF: 0% / Expected ULF: 80%

Notes: When desirable urban built environment parameters are lacking, users are discouraged from lingering.

Zone 03


Built Environment: 80% | Existing ULF: 45% / Expected ULF: 90%

Notes: The lack of a green built environment and informed socio-climatic decisions have negatively impact the ULF

Zone 04

Built Environment: 10% | Existing ULF: 0% / Expected ULF: 20%

Notes: Despite the suitability of climatic conditions, the lack of built environment parameters has a negative impact on the ULF

Zone 05

Built Environment: 70% | Existing ULF: 55% / Expected ULF: 95%

Notes: the ULF is affected by the density of cars and the location of construction sites.

Zone 06

Built Environment: 5% | Existing ULF: 0% / Expected ULF: 80%

Notes: the absence of the characteristics of built environments have affected directly users' ULF.

5.4 Findings and Recommendations

- Provide and emphasize the reasons for users to stay in the urban open space to increase their engagement and enhance their experience.

- Acknowledge that the campus is considered as a gathering hub by some users during vacations and use this to promote lingering among the campus's urban areas.

- Prioritize greenery and climate-controlled urban areas in the development decision-making process, considering social aspects through the SCIDM process.

- Improve the condition of the urban built environment to positively impact the urban lingering factor.

- Adjust the design of the space to better meet the needs of the community in different weather conditions, such as adding sheltered areas or warming stations to encourage more use during the winter months.

- Students and users concentrate on specific areas for lingering during the construction circumstances and hard climatic conditions.

- It is believed that, by implementing these recommendations, the FOE AU can create a more desirable urban environment that promotes user engagement and enhances the overall campus experience.

- This field survey needs to be more expanded by using more advanced observation techniques in order to produce more accurate results and outcomes.

- It is important to take into consideration the aspects of social cohesion.

- The case study should highlight renowned contributions to "campus design on an international/global scale." By examining prominent examples from around the world, the study aims to identify influential approaches and principles that have shaped campus designs on a global level.

- It is important to note that the impact of the studied examples may not directly relate to the specific case used in the empirical study. The empirical study focuses on a particular campus, and it is crucial to consider similar contextual and environmental aspects when drawing conclusions and making recommendations based on the precedence study. By acknowledging these contextual differences, the research aims to provide a comprehensive understanding of campus design while tailoring the findings to the specific case under investigation.

- It is recommended to create an in-depth verification of built environment definitions through a deeper literature review.

6 CONCLUSION

In conclusion, the interrelationship between the urban lingering factor, the urban built environment, and the SCIDM process is a complex and multifaceted issue that requires a holistic approach to address. Through the field survey conducted on the FOE AU campus, it is clear that the lack of desirable urban built environment parameters can negatively impact the urban lingering factor, despite the suitability of climatic conditions. The field survey also revealed that students are more likely to linger in greenery-covered and climatic-controlled urban areas, which should be considered through the development decision-making process, in consideration of social aspects using the SCIDM process.

Overall, the socio-climatic informed decision-making process through urban open spaces involves gathering data, using that data to inform the design of the space, monitoring its use and effectiveness over time, and making adjustments as needed to better meet the needs of the community in different weather conditions. The FOE AU is recently under reconstruction or renovation, and the concepts and recommendations made through this field survey can be presented to decision-makers to inform the design of the space, in a way that guaranteesa positive impact on the users' urban lingering factor. However, it is essential to recognize that the ULF of the same place may differ from one time to another, and there is a necessity to reconsider and analyze the ULF parameters to produce more accurate ones. Future field surveys should expand the scope of the study and utilize new technologies for observation and visualization of outcomes for more accurate results.

Urban Morphology vs. Social Cohesion: a Study of Two Neighbourhoods in New Borg Al-Arab City, Egypt

Doaa Morsy, Khalid Al-Hagla, Mohamed Fikry

(Doaa Morsy, University of Alexandria, Department of Architecture, Egypt, do3a2_med7at@hotmail.com)
(Prof. Khalid Al-Hagla, University of Alexandria, Department of Architecture, Egypt, khagla@hotmail.com)
(Prof. Mohamed Fikry, University of Alexandria, Department of Architecture, Egypt, mfikry2004@yahoo.com)

1 ABSTRACT

Physically and socially, cities are tied together through neighbourhoods that make up their urban fabric. This research hypothesizes that the levels of Social Cohesion in a specific neighbourhood will differ based on the Neighbourhood's Physical Characteristics. This aspect is crucial for politicians responsible for new urban communities in Egypt. The main contribution of this research is to propose and test a model for comparing the levels of Social cohesion in various neighbourhoods. This is done through mixed research methods ranging from a qualitative stage including the literature review of the main neighbourhood design characteristics and social cohesion domains to a quantitative stage including statistical analysis for two neighbourhoods in New Borg Al-Arab City that differ from each other in their Morphological pattern. The data collected from the questionnaire were analyzed using the statistical package for social sciences (SPSS V26). Regarding the investigation of the main variables, this research concluded that there are significant differences in neighbourhood morphology between the two neighbourhoods, while there were no significant differences in social cohesion between the two neighbourhoods. And this result differs when investigating the subdimensions of the model, where there are significant differences in the levels of some of the subdimensions of Social Cohesion between the two neighbourhoods.

Keywords: Street system, Block system, Design Constraints, Social Cohesion, Neighbourhood Morphology

2 BACKGROUND

The term "neighbourhood" is commonly used to refer to a geographically constrained community of individuals who all make use of the same local amenities and have some degree of social cohesion with one another. The word "place" stands out among the three words "people", "location", and "cohesion" that define the neighbourhood. And in order to analyze such a place the branch of "Urban Morphology" is needed.

The study and design of "Urban Morphology" take into account the physical and spatial components of the urban structure of plots, blocks, streets, buildings, and open spaces, all of which are part of the evolutionary process of development in the specific area of the city being studied. Fundamental concepts of morphology include recognizing the evolution of urban landscapes across long time periods and being cognizant of the diverse cultural, social, economic, and political impacts of various time periods (Oliveira, 2016).

"Social Cohesion" can be affected by urban spaces since they attract large numbers of individuals. Streets, squares, parks, sidewalks, bike routes, and urban furniture tare all easily navigable and spacious and encourage people to engage with their surroundings, generate a productive use of space, and boost the vibrancy of a city. It is not enough to just think about dense metropolitan cores; the outskirts must be taken into account as well, with those living there assured of access to high-quality urban places.

The success of New Urban Communities is primarily dependent on social ties. According to our hypothesis, a connection can be drawn between Urban Morphology and Social Cohesion. In order to determine who is accountable for the development of the new urban communities in Egypt, it is essential to take into account the fact that the level of social cohesion of a neighbourhood can differ according to the physical characteristics of the neighbourhood.

3 LITERATURE REVIEW

The dilemma of Urban Morphology vs. Social Cohesion has been investigated through a limited number of research. The most prominent research in this field belongs to Wanas et al. (2014), Hossam Eldin Moustafa (2018), Aelbrecht et al. (2018), and Mouratidis and Poortinga (2020).

Wanas et al. (2014) provide new insight into how Cairo's urban design could play a part in fostering social cohesion among the city's diverse communities. It provides a comprehensive assessment and critical analysis

of the pertinent worldwide and local literature on the subject, allowing readers to gain insight into the state of our current understanding of the field and the gaps that still need to be filled.

Hossam Eldin Moustafa (2018) presents "Sense of community" as the primary strategy for achieving social sustainability on a local level, so his study aims to evaluate its constituent parts from an urban planning perspective in order to get insight into how locals feel about their neighbourhood. This is done through a literature review of the main domains of "Sense of community". By analyzing the layout design features, the researcher was able to learn about the urban characteristics of four distinct neighbourhoods in the "New Maadi" zone to the south of Cairo. Residents' perspectives on the sense of community aspects were surveyed through in-depth interviews guided by a questionnaire. Then, using SPSS, the researcher measured the correlation between these aspects and neighbourhood characteristics.

Aelbrecht et al. (2019) aim to integrate scholarly research on public space design and social cohesion in both the Global North and Global South. It aggregates research from renowned and rising researchers and practitioners from the Global North and Global South to share their knowledge and experience on these challenges. It compares case studies in different cultural and social situations with varied planning and design principles to understand their similarities and differences and to discover new theories and methods that can expand our knowledge of the topic.

Mouratidis and Poortinga (2020) are using survey and GIS data from the Greater Oslo Area. Their study proposes and tests a model in which urban vitality mediates the relationship between built environment features and neighbourhood social cohesion.

This research aims to provide a comprehensive overview of the necessary regulations, rules, priorities, and design constraints in Urban Morphology that promote greater social cohesion in local communities. The sim is to further elucidate which structural compositions lead to more effective social interaction. Furthermore, it presents a model that assesses the levels of social cohesion based on the different morphologies of neighbourhoods.

3.1 Neighbourhood Morphology

Urban morphology is characterized by factors such as the way buildings and streets are configured, as well as building properties. As the structure of cities is composed of Blocks and the Paths between them; forms of the urban fabrics could be investigated from these two aspects which are known as major components of cities (Arsiya and Mazloomi 2015). With respect to the structure of this research, the researchers present the street system and block system as the main dimensions of Neighbourhood Morphology.

3.1.1 The Street System

The main subdimensions of the Street System range from the Street Network to Street Layout, Street Type, Pedestrian Network, and Access Points.

What is meant by a "Street Network" is the way in which streets are laid out and connected in a given location. A development can benefit from having a well-thought-out structure and an efficient street network. Streets play a crucial role in the planning and layout of both structures and residential areas. It is important to establish links between various street networks (Larco 2014, Auckland Transport 2020). One definition of "street connectivity" is "the number and quality of linkages in the street network." Networks that are connected or permeable make it easier to get around on foot or bike. Similarly to considering how connectivity is concerned with outside connections, permeability looks at how people can move around and interact within a site. The permeability predetermines how easily people can travel between different areas (Bentley 1985, Partnerships 2000, Donnelley 2010, Steiner 2012, Larco 2014, Department of Human Settlements 2019,). Moreover, according to Lynch 1960, "If residents of a connected city can't get the layout of the place and what goes on there, the community will not work as intended. A readable arrangement is one in which mental representations of the content may be reliably formed. Keep in mind that the user, not the designer, forms the image; the designer is responsible only for the overall physical arrangement."

Although there is a wide range of possible "Street Layouts", the two most common network typologies are gridded and dendritic. Local streets only connect to collectors, and collectors only connect to arterials, under a Dendritic or Suburban Hierarchy. This method often encourages high speeds all the way through and concentrates traffic on the already crowded arterial system, and should be avoided. Successful urban street

network designs encourage several street types and a dense system of streets and crossings, allowing for more effective land utilization (Lahart et al. 2013, Auckland Transport 2020). Three different layouts of networks that can be tailored to specific locations are shown in Figure 1. There is a direct correlation between the permeability and legibility of a street network and how orthogonal the streets are.

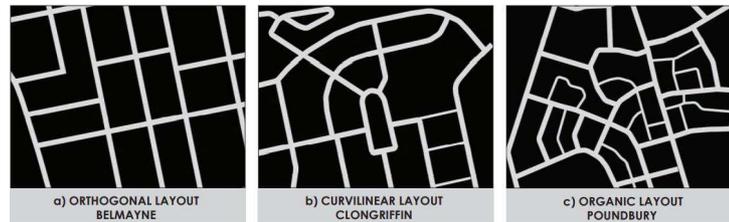
Considering "Street Type", Any given street will often have what is referred to as "many personalities," which may be associated with a variety of functions or features. Each attribute of a street, such as its width, frontage type, or traffic kind, hints at a concept that may be used to categorize and rank it in relation to other kinds of streets. Table 1 presents a sampling of the subjects that were discussed (Marshall 2004).


Fig. 1: Gridded Street Networks Layouts. Source: Auckland Transport (2020)

Set of road types	Classification theme	Type of theme
Square, circus, crescent, cross	Shape of space	Form
Dual 3-lane, dual 2-lane, single carriageway	Carriageway standard	
Limited access road, distributor, access road	Access control	
Street, terrace, mews, court	Built form/frontages	
Narrow street, wide street	Width	
Civic, commercial, residential, industrial	Urban building type	
Shopping street, living street, etc.	Urban uses and users	Use
High volume road, low volume road	Traffic volume	
Long distance traffic road, local traffic road	Trip length (origin and destination)	
Road type used by any mode	Transport modes	
High speed road, low speed road, etc.	Traffic speed (observed)	
Route used by tourist traffic, works traffic, etc.	Road users	
Spine road, connector street, cul-de-sac	Structural role	Relation
Strategic route, link road, local route, etc.	Strategic role	
National road, regional road, municipal road	Ownership/management	Designation
Special road, principal road, A road	Statutory designation	
70 mph, 60 mph, . . ., 20 mph road	Speed limit (designated)	
Bus only; pedestrian only, etc.	Vehicle or user permission	
'Avenue', 'Street', 'Lane', 'Mansions', etc.	Nominal	
Designated route for tourists, works traffic, etc.	Designated route	

Table 1: A taxonomy of road types, classification themes, and theme types. Source: Marshall, S. (2004)

Access to lots and connections to off-street, pedestrian-only and shared routes are all made possible by the network of footpaths and crossings that serves as the backbone of the "Pedestrian Network". When built according to the best rules, they provide easy access for all pedestrians. Figures 2 and 3 depict some suggested layout principles for them (Larco 2014).

Fig.2: Building sidewalks connecting every destination. Source: Larco et al. (2014), Fig. 3: Street crossings should be marked by painted crosswalks on internal streets. Source: Larco et al. (2014).

Promoting resident contact with the surrounding community and facilitating resident mobility to neighbouring residential or commercial areas on foot or bicycle requires an adequate number and distribution of "Access Points". Figure 4 shows how increasing the number of Access Points in a development may reduce travel times for residents by making it easier for them to walk or bike to nearby services. As a corollary, the uneven distribution of access points has consequences for site circulation as shown in Figure 5 (Larco 2014).

3.1.2 The Block System

The main subdimensions of the Block System range from the Block Type,to Density, and Mixed-land Use.

Multiple interpretations may be attributed to the land development that took place inside the block's confines. Next is a taxonomy of the most fundamental shapes that an urban block plan may take, based on the many physical configurations that could be used. "Block Types" have been broken down into the following five categories of building blocks: The Perimeter Block, The Row Block, The Point Block, The Ribbon Block, The Courtyard Block, and Other variants of the urban form (Tarbatt and Tarbatt 2020).

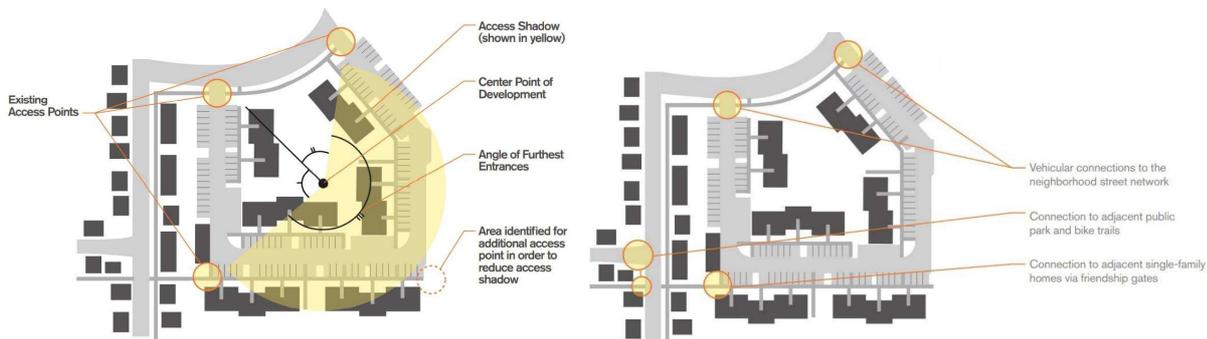

Fig. 4: Implications of Maximizing the number of Access Points.Source: Larco et al. (2014), Fig. 5: Access shadow diagram. Source: Larco et al. (2014)

Rather than viewing "Density" as the result of architectural considerations like accessibility, permeability, assembly, and proximity, it is more common to view density as a "goal". The fact that density can be tackled from a variety of angles is crucially essential. The difference between Physical and Perceived density is a key concept (Pont and Haupt 2007, Berghauser et al. 2009, Ewing and Cervero 2010, Dave 2011, Dempsey et al. 2012). For the purposes of this research, the "Perceived Density" approach is adopted in the model proposed.

The term "Mixed-land Use" is used to refer to the variation in land-related activities that can be found in specific regions. Following is a synopsis of the most important factors to think about while planning a mixed-use development: the Scale of mixed-use, Mixed-use Development Type, Location and visibility of mixed uses [Fig. 6], the critical mass of the supporting population, and the Clustering of uses at nodal points (Partnerships 2000, Barton 2003, Croucher et al. 2012).

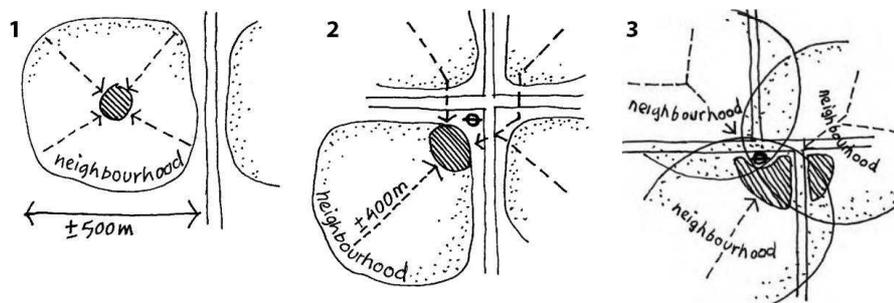

Fig. 6: Location of Mixed Use Areas and Neighbourhood Form. Source: Barton el al. (2003)

3.2 Social Cohesion

Learning what motivates a group to function as a cohesive unit is a central question at the heart of the study of social cohesion. The cooperative relationships between a group's members have their roots in early human evolution. Humans developed the ability to have healthy offspring by learning to work together. Over the

course of human history, this capacity for cooperative social conduct has been applied to situations ranging from clans to tribes to peoples to states to supranational bodies (Dragolov et al. 2016).

Surprisingly, the capacity to forge strong social relationships of cooperation is also a driving factor in the breakdown of groups. There is a natural tendency for the relationships between a subgroup and the members of the broader group to diminish or be overlooked when cooperative social bonds strengthen inside the subgroup. This strengthens or destroys the group's cohesiveness as a whole, while simultaneously creating and fostering cohesion inside the group itself (Dragolov et al. 2016).

Given that social cohesion is abstract and still being worked out in terms of operationalization, it is also multidimensional and interrelated. Its definition, measurement, and operational use are all up to debate. A singular focus on one discipline risks obscuring the importance of other factors—weak or strong—in fostering societal cohesion (Megahed 2017).

The Participation/Solidarity dimension, the Safety/Trust dimension, and the Attachment dimension are only a few examples of how academics have attempted to employ these concepts in empirical studies (Megahed 2017, Bottoni 2018, Liu et al. 2020).

4 METHODS

We have chosen two neighbourhoods for comparison; named neighbourhood two and neighbourhood three; in district one in New Borg Al-arab City, in Egypt, which differ from each other in their morphological pattern, as shown in Figure 7 and Figure 8. Then we examined the inhabitants' perception of both neighbourhood morphology and social cohesion. A random sample consisting of 193 participants was chosen for in-depth interviews using a structured questionnaire. The structured questionnaire can be divided into two main variables; Neighbourhood Morphology and Social Cohesion.

Fig. 7: Neighbourhood Two. Source: Google Earth, Fig. 8: Neighbourhood Three. Source: Google Earth.

The main variable Neighbourhood Morphology is branched out into two dimensions; Street System and Block System. The subdimensions of the street system that have been investigated in the questionnaire are Street Network (Q1:Q6), Street Type (Q7:Q10), Pedestrian Network (Q11:Q12), and Access Points (Q13:Q14). Then the main subdimensions of the Block System are Perceived Density (Q15:Q16) and Mixed-land Use (Q17:Q18).

The main Variable Social Cohesion is branched out into three dimensions: Participation/Solidarity, Safety/Trust, and Neighbourhood Attachment. The main subdimensions of Participation/Trust are Community (Q19:Q20), Political (Q21:Q22), and Solidarity (Q23:Q24). Following are the subdimensions of Safety/Trust: General Trust (Q25:Q26), and Institutional Trust (Q27:Q28). Then the subdimensions of Neighbourhood Attachment are; Identity (Q29:Q30), Ownership and Memory (Q31:Q32), and Belonging (Q33:Q34).

A five-level Likert scale with "Strongly Disagree" until "Strongly Agree", comprises the measurement level of the questionnaire. The data collected were analyzed using SPSS version 26. The Skewness and kurtosis tests were conducted to evaluate the normal distribution to choose between parametric and nonparametric tests. In comparing the two neighbourhoods, we performed the selected test on the three levels of the Questionnaire; The main Variables, the main Dimensions, and The main Subdimensions.

5 RESULTS

In terms of measuring normality, Skewness values between -2 and +2 and kurtosis values between -7 and +7 are considered acceptable in demonstrating normal distribution (Hair et al. 2014). Table 2 displays the results of the normality test, which show that the values of Skewness and kurtosis for the model's constructs fell within the acceptable range. Thus, The parametric test is the appropriate test. Since we are interested in comparing the two neighbourhoods, the appropriate parametric test is independent-samples t-test.

Construct	Notation	N	Skewness	Kurtosis
Street Network	SN	193	-0.463	1.907
Street Type	ST	193	0.354	-1.178

5.1 Comparing The Main Variables

Table 3 provides some descriptive statistics that illustrate the difference between the neighbourhoods in terms of the main variables; neighbourhood morphology and social cohesiveness. Based on the data presented in the table and the graph in figure 9, it is clear that the second neighbourhood is distinctive from the third in terms of its morphology. Despite the fact that there appeared to be no visual discrepancies between the two neighbourhoods in terms of social cohesion. The results of an independent t-test are shown in table 4 to determine whether or not the observed differences are statistically significant.

Variable	Neighbourhood	N	Mean	SD
Neighbourhood Morphology	2	95	3.6794	.32241
	3	98	2.9288	.31232
Social Cohesion	2	95	2.9936	.45698
	3	98	2.9342	.46530

Table 3: Descriptive statistics of the main variables regarding the neighbourhoods. Source: Researchers.

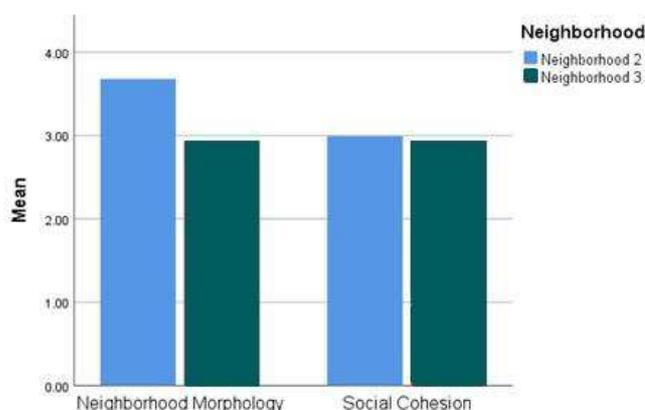

Fig. 9: Bar chart for the difference between the neighbourhoods regarding the main variables. Source: Researchers.

Variable	Levene's Test for Equality of Variances			t-test for Equality of Means		
		F	P-value	t	df	P-value
Neighbourhood Morphology	Equal variances assumed	0.348	0.556	16.429	191	0
	Equal variances not assumed			16.421	190.24	0
Social Cohesion	Equal variances assumed	0.139	0.709	0.893	191	0.373
	Equal variances not assumed			0.894	190.97	0.373

Table 4: Independent Samples t-test for the Main Variables. Source: Researchers.

According to the results of the independent-samples t-test, the morphological differences between the two neighbourhoods are statistically significant (t=16.429, p<0.01). P-value > 0.05 indicates that there is NO statistically significant difference in Social Cohesion between the two neighbourhoods. (t=0.893, p>0.05).

5.2 Comparing The Dimensions of The Main Variables

The difference between the neighbourhoods in terms of the dimensions of the main variables; Street System, Block System, Participation, Trust, and Neighbourhood Attachment; are illustrated in table 5 through some descriptive statistics. Based on the data presented in table 5, the graph in figure 10, and table 6 of the results of Independent Samples t-test, there are a statistically significant differences in the Street system, block system, and Neighbourhood attachment levels between the neighbourhoods, while there are no statistically significant differences in the levels of participation and trust.

Dimension	Neighbourhood	N	Mean	SD
Street System	2	95	3.8088	0.35971
	3	98	3.0514	0.45775
Block System	2	95	3.5500	0.52415
	3	98	2.8061	0.49939
Participation	2	95	2.4842	0.48808
	3	98	2.5782	0.51618
Trust	2	95	2.8158	0.67950
	3	98	2.7653	0.64996
Neighbourhood Attachment	2	95	3.6807	0.57100
	3	98	3.4592	0.69364

5.3 Comparing The Subdimensions of The Main Dimensions

5.3.1 Comparing The Subdimensions of Neighbourhood Morphology

According to the data presented in the table 7, figure 11, and the results of the independent t-test in table 8; there are a statistically significant differences in the following subdimensions of Neighbourhood Mophology: Street Type, Pedestrian Networks, Access Points and Mixed-land Use levels between the two neighbourhoods, while there are no statistically significant differences in the levels of subdimensions Street Network and Perceived Density.

Subdimension	Neighbourhood	N	Mean	SD
Street Network	2	95	3.9053	0.47655
	3	98	3.9388	0.56233
Street Type	2	95	4.0456	0.52953

6 DISCUSSION AND CONCLUSION

This research was keen on comparing the levels of Social coehsion based on different morphologies of Neighbourhoods. In doing so, the research started by tackling some design constraints regarding the neighbourhood that leads to better social cohesion. Then the research presented a model that investigates social cohesion at a micro level by conducting a structured questionnaire on a random sample of the residents of two neighbourhoods in New Borg Al-arab City in Egypt that differ from each other in the morphological pattern. This model is based on comparing the two neighbourhoods and is divided into three levels.

The first level compares the main variables which are Neighbourhood Morphology and social cohesion. What turned out after conducting the statistical test using SPSS that there are differences in the neighbourhood morphology between the neighbourhoods, while there is no statistical significance difference between Social cohesion in the two neighbourhoods.

The second level of the model investigates the dimensions of the main variables, which turned out that there are differences in the street system, block system, and neighbourhood attachment.

The third level of the model is much deeper and investigates the main subdimensions of the main variables. Regarding the subdimensions of Neighbourhood Morphology, there are differences in Street type, pedestrian network, access points, and mixed land use, while there are no differences in street network and perceived density. Considering the subdimensions of social cohesion, there were differences in political identity, ownership and memory subdimensions.

Through this model, much more understanding of the main differences between social cohesion at a micro level is gained. But in general, regarding the main hypothesis, there were no differences considering social cohesion. This may be due to the following reasons that were known during the questionnaire, Neighbourhood Two is considered adjacent to Neighbourhood Three, and also although the residents of Neighbourhood Two are tenants and are not owners like the residents of Neighbourhood Three, the residents of the two neighborhoods have the same social background, and also Neighbourhood Two does not contain amenities like social cafés, which makes its residents resort to the adjacent neighbourhoods for entertainment.

1 ABSTRACT

The built environment is the main habitat for human beings, this makes it act as a driver for climate and biodiversity changes, with multiple potential opportunities for alteration and transition. Therefore, it may be essential for the built environment to go beyond ordinary actions not only to limit the negative impacts, but instead aim for benificial outcomes. Analysing and desigining the urban built environment from the perspective of ecosystems functions and services could help in creating cities where positive restoration of and integration with local ecosystems could be recognised. Urban regeneration could be useful in this regard as it is defined as a comprehensive integration of vision and action aimed at resolving the multi-faceted problems of urban areas in order to improve their quality of life. However, the rapid urbanisation - especially with the exploding urbanism of some cities - controlled sustainable development and carefully considered urban regeneration have not always been achieved. It is also argued that one of the strategies for successful urban regeneration is "High-Quality Architectural Design and Public Space as a Catalyst for a Better City". At a more local perspective, new urban expansions in Egypt lack one of the relevant quality-of-life pillars. Public spaces are currently losing their role in the new communities located in the urban fringe of Cairo. In such context, new urban nucleii are expanding disregarding the necessity of collective public spaces (a continuum of public realm) due to the privatization, disconnection, and introversion. Thus, the aim of this research is to introduce the Urban Nexus, a new approach merging the contemporary trends and emerging theories to design sustainable urban development solutions. The nexus approach seeks to understand risks, engage decision-makers, and enable action with the aim of attaining knowledge integration, efficiency, synergy and 'win-win' solutions. This could be achieved through bridging/ integratng Ecosystem services preserved through Nature Based Solutions (NBS), Human Centred Design (HCD) and the Star Approach, in order to reform public spaces acting as a catalyst for the urban regeneration. Ultimately the study would contribute in improving the built environment and in providing a better quality of life in new urban expansions.

2 INTRODUCTION

2.1 Background

Urbanization is an inevitable phenomenon expanding worldwide, predominantly changing the land use on a large scale and encompasses essential land cover change, even if it is carefully planned (Wang et al., 2021). Around 68% of the world's population will be living in urban regions by 2030 (Blanco, Pedersen Zari, Raskin, & Clergeau, 2021). The African urban population is undergoing the highest rate of urban growth in the world, at 3.3%, and most likely will double by 2050 (Julia & Andrey, 2013). The rapid or unplanned urbanization results in the risk of extreme social instability, risks to crucial infrastructure, potential water crises and the possibility for spread of diseases. If not well managed, rapid urbanisation could be a huge environmental and human health risk and a threat to sustainable cities by 2030 (Nhamo et al., 2021).

2.2 Problem Definition

Growing cities generate conflicts that need to be carefully negotiated and managed (Lehmann, 2019). In the past three decades, the Egyptian capital, Cairo, has experienced a significant boom in the urban expansions including building gated communities and new fringe cities, such as 6th of October and Sheikh zayed,

located in the west. Such trends have grown rapidly since 2010,which have made a lot of Egyptians eager to own a property in one of those well planned new cities and luxurious gated communities (Aboubakr et al., 2020). Recently, several studies discussed that those new expansions lack some of the main urban features that the old, dense and kind of informal fabrics have. Public spaces are considered one of any built environment pillars. It is the main context for social and economic activities that might happen in any community, leading to enhancing the sense of belonging. From Agora of the polis, and open marketplaces of Medieval cities to today's shopping malls, corporate plazas, atria and festival places, public spaces have been a prominent element affecting the design of cities for centuries (Naguib, Abdel-Salam, & Saadallah, 2020). However, cities are undergoing a rapid transformation of public spaces as a result of economic and cultural globalization, demographic transformations, marketing strategies, urban planning, design approaches, privatization and others (Haas & Olsson, 2014). This led to misunderstanding the concept of public spaces within the new urban expansions and communities especially in Egypt.

Figure 1: Examples for the privatized urban spaces located in Sheikh Zayed city, Cairo, Egypt (Researcher)

2.3 Public Spaces

Urban open spaces are one of the fundamental elements shaping cities, they play an important role in urban sustainability and human health (Kefale, Fetene, & Desta, 2023). Several planning researchers and pioneers like George Perkins Marsh, JohnWesley Powell, Patrick Guedes, Sir Ebenezer Howard, and Frederick Law Olmsted, have integrated urban spaces, ecosystems and their services in the process of urban design and planning since the 19th century (Blanco et al., 2021). According to (Lehmann, 2019), attractive public spaces that provide distinctive life experiences result in increasing the liveability of cities. Therefore, it could be debated that the improvement of public spaces is one of the major drivers for urban regeneration, leading to the promotion of social inclusion and creating more interesting and diverse cities (Jacobs, 1961). Urban regeneration is mainly concerned with the rejuvenation of deteriorated urban areas, through interventions such as rehabilitation of old districts, enhancement of living conditions in residential areas, revitalization of public spaces, and renovation of urban infrastructure (Abdo, Abdel-Salam, Ayad, & Taha, 2019). Consequently, the revitalization of public spaces is considered one of the main catalysts for creating regenerative urban environments according to Lehmann (2019) when he stated the ten main strategies of successful urban regeneration.

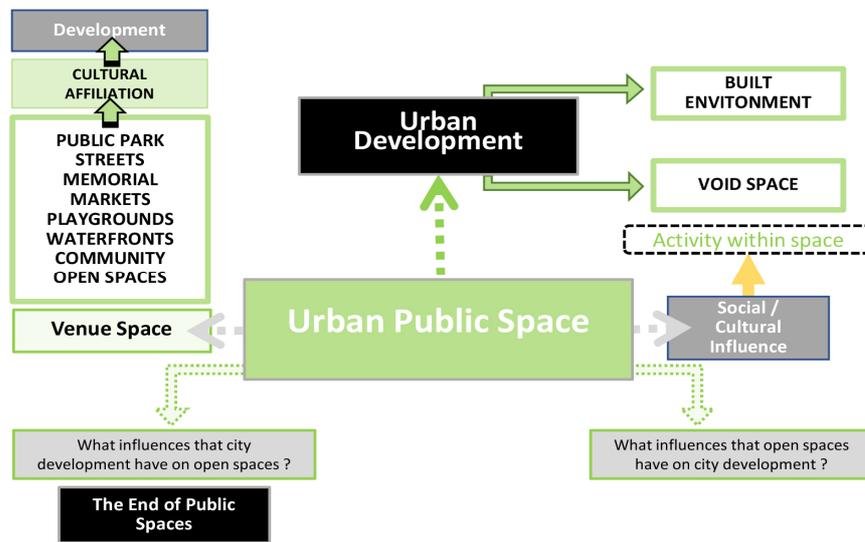
Figure 2: The 10 strategies for successful urban regeneration recommended by Lehmann (2019)


Figure 3: The relationship between urban public spaces and city's development, Adapted from (Ramlee, Omar, Yunus, & Samadi, 2015)

2.4 Urban Ecosystems

Urban ecosystems are cities, their surroundings, and social and ecological systems where citizens inhabit (Maes et al., 2016). They are the main container, including all other ecosystem types (forests, water bodies and agricultural areas) which are influenced by human activities. Urban ecosystems guarantee the provision of essential services for city dwellers (Ahern, Cilliers, & Niemelä, 2014). Those services could be objects, features and processes carried by ecosystems that secure the people's health and wellbeing (Pan, Page, Cong, Barthel, & Kalantari, 2021). It is highly debated that ecosystem services should integrate with urban planning (Ahern et al., 2014). Urban open spaces are fundamental providers of a wide range of ecosystem services in cities, consequently they are one of the main supporters of urban resilience and sustainability (Ibes, 2016). Therefore, Professionals, planners and designers need to take into consideration the preservation of those services through adopting innovative solutions and planning frameworks.

Figure 4:The services provided by the ecosystems classified to 3 main categories (https://www.euskadi.eus/)

2.5 The Urban Nexus Approach: A New Dimension

Although the new communities located in the Egyptian urban fringe are well designed aesthetically, they lack the presence of collective non-privatized open spaces that all people could use freely. The privatisation of public space is growing rapidly, the investment in the public domain is relying more on the private sector, which increases the challenges that cities face. Most of the - so called- public spaces are located within shopping malls like mall of Egypt and mall of Arabia, or business parks like Arkan Plaza and capital business park. Moreover, the lack of any sort of seating or shading elements forces the users to enter the restaurants and cafes. The only possible form of open green spaces could be found inside the luxurious gated communities. Therefore, it is time to benefit from the various urban design tools to achieve the best and most optimum solutions. Architects, urbanists, and urban design pioneers have been calling for the adoption of more integrated approaches, proclaiming that planning and design tools must be amplified as they are

considered the fundamental tools for effectively creating regenerative urban environments. Architects and urban designers play a crucial role in augmenting creative alternatives to the ordinary known forms of urban regeneration (Lehmann, 2019).

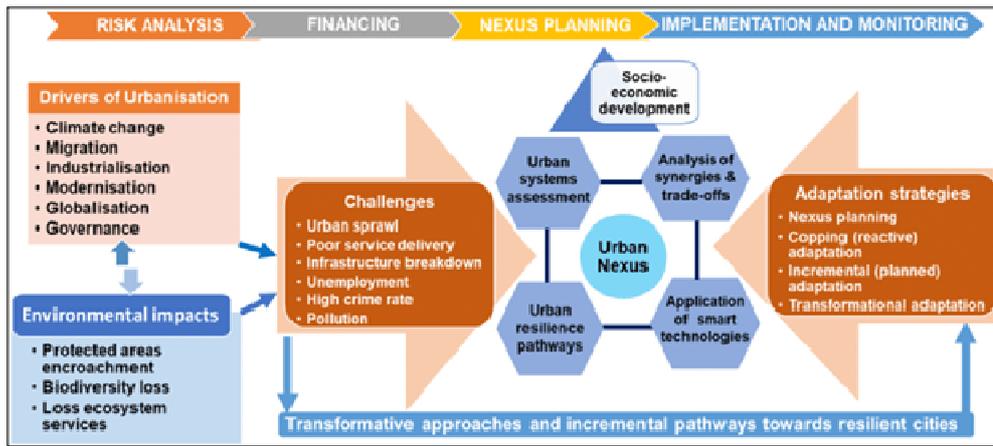
 Attempting to find solutions in a certain field can cause a problem in another. This may be due to lack of proper analysis leading to negative impacts on policies and technological choices. Therefore, the nexus approach tends to understand risks, engage decision-makers, and enable action. It investigates the different pathways that lead to sustainable development and green growth (UN(ESCAP), 2016). A dominant interpretation of the nexus approach is that it stresses knowledge integration, efficiency, synergy and 'win-win' solutions (Nhamo & Ndlela, 2021).The key of the urban nexus is designing sustainable urban development solutions, in order to guide stakeholders with the aim of creating collaborations between different sectors, authorities, and technical domains. This is with an attempt to increase the performance of institutions and optimize resource management quality (Lehmann, 2018).


Figure 5 Key elements of urban nexus design, Lehmann (2018)

3   METHODOLOGY: INTEGRATING URBAN DESIGN TOOLS AND APPROACHES

In order to create regenerative environments, addressing the main isssues that cities undergo is more important than technological solution, while thinking of a comprehensive framework and adopting a reconstructive governance to guide the process, with appropriate indicators to monitor the progress and implementation (Lehmann, 2019).

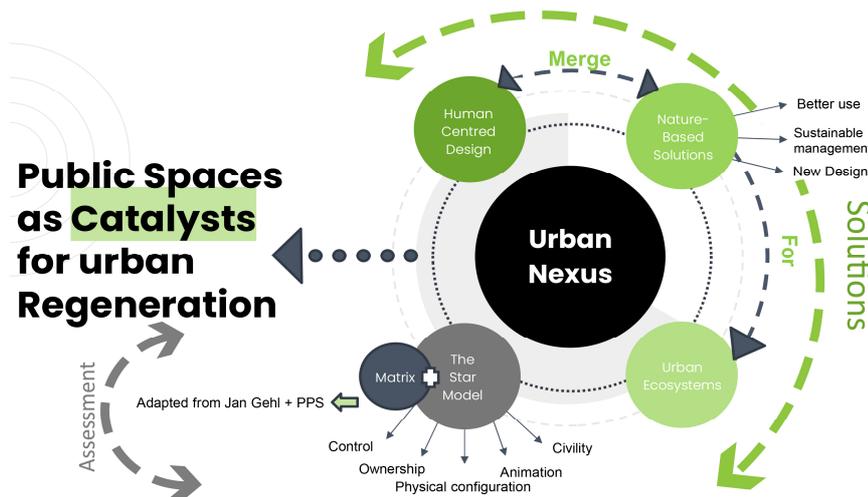

Figure 6: The proposed research hypothesis (researcher)

3.1 The Star Model

George Varna created a diagnostic model that uses simple and measurable tools to evaluate the liveability of public open spaces. It could easily be used by professionals either planners or academians as well as regular people with no experience in urban design. The model emphasizes the attributes related to the publicness of urban open spaces concerning their liveability. Five main dimensions form the star model (Meta-themes):

ownership, control, physical configuration, animation and civility. Those five themes incubate 19 indicators as shown in Table (1). Each indicator is evaluated on a measuring scale of, where 1 is the lowest and 5 is the highest.

The Star model quantifies the quality of open spaces on 3 main levels as described by Aboubakr et al. (2020) as follow:

(1) For comparative purposes: measures the degree of liveability of public places compared to each other; (2) For producing analytic and normative/perceptual stars: a more objective measure of liveability to be compared to the sense of liveability held by specific social groups and individuals; (3) For further expectations: serves as a point for future assessments of certain spaces.

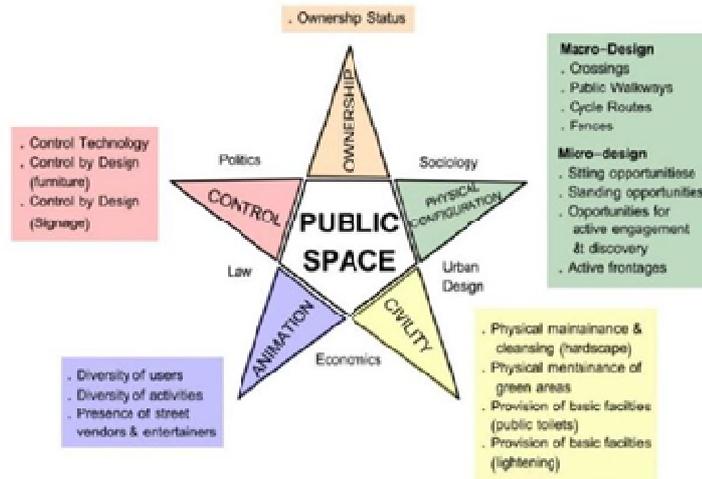
Although the star model offers definite indicators, the model should be used with a certain degree of common sense, as some of the indicators should be evaluated by the researchers.


Figure 7: The Star Model (Aboubakr, Nasreldin, & Abdelfattah, 2020)

Table 1: Calculating te 19 indicators of the star model (Aboubakr et al., 2020)

3.2 The Public Space Qualities

Since it was mentioned in the previous section 3.1 that the star model has some weaknesses whereby it neglects the fact that each public place has its own identity, consequently the model should be used with a fraction of common sense. A primary matrix was created based on the studies of Jan Gehl concerning the studying of public life, Mathew Carmona's listing of public spaces qualities, the place diagram developed by

the Project for Public Spaces (PPS) and the 19 indicators measured by the star model, to act as an aiding tool for assessing the quality of public spaces.

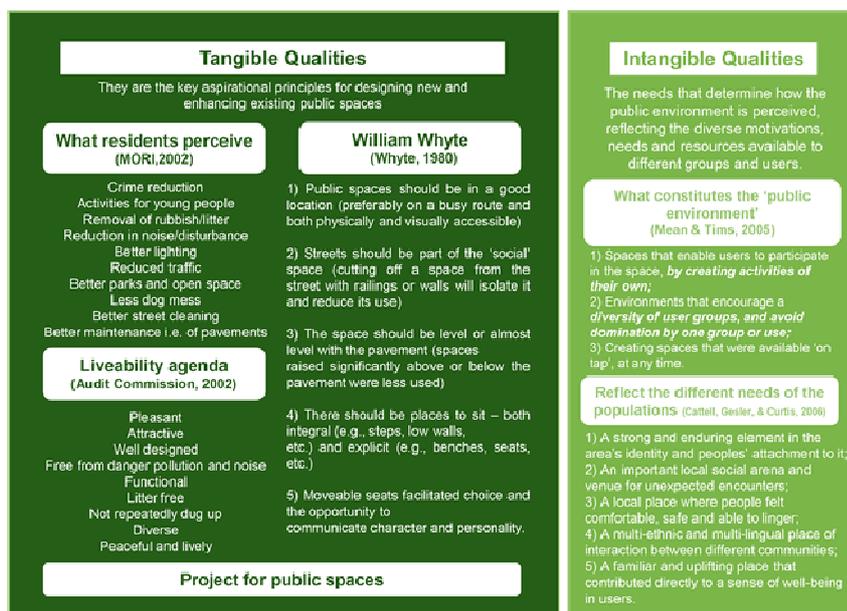
Table 2: The 12 quality criteria for good public space by Jan Gehl, adapted from (Dietrich & Kengyel, 2016)


Table 3: The Tangible and Intangible qualities of public spaces reviewed by Matthew Carmona (Audit Commission, 2002; Carmona, De Magalhaes, & Hammond, 2008; Cattell, Gesler, & Curtis, 2006; Mean & Tims, 2005; Mori, 2002; Whyte, 1980)
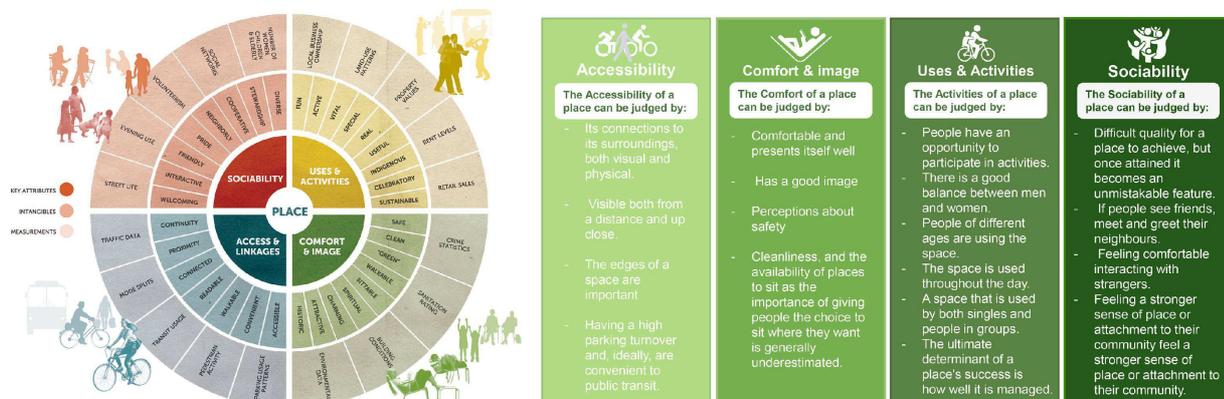

Figure 8 : What makes places succeed, adapted from (PPS, 2000)

The unstable climate variations in the 21st century put pressure on the place diagram as it does not contain a clear perception or solutions for the climatic conditions in terms of comfort. Several authors such as Marcus & Francis (1997) and Whyte (1980) stated the importance of sunlight and temperature and considering reduction strategies in case of overexposure. Also, the airflow was highlighted in studies by Jan Gehl and

924

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

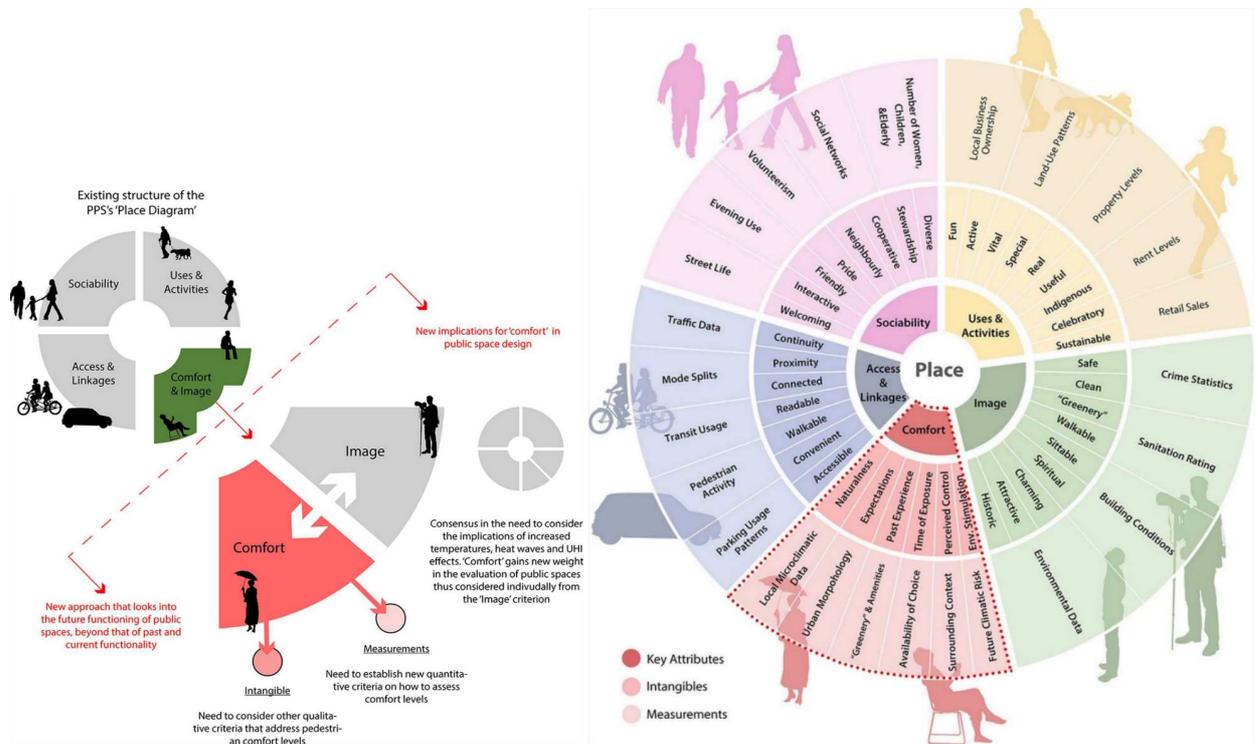
William Whyte due to its role in decreasing the distressing climatic conditions (Gehl, 2011; Whyte, 1980). Consequently, when evaluating the "Place Diagram," based on the currently existing public spaces as examples, several questions arise concerning the delay in the improvement of adaptation efforts in terms of urban design and climatology (Santos Nouri & Costa, 2017). The following Figure (9) illustrates the necessity for including the expected climate change consequences. Therefore, the place diagram by Santos, Nouri and Costa was enriched with new qualitative and quantitative features shown in Figure (10) in order to question the pedestrian comfort. This is achieved by examining several theories aiming to integrate the measurable data and intangible elements of the outdoor thermal environments with the design of the public open spaces to make it climatically responsive.


Figure 9 (left): Extending the "Place Diagram" to consider new implications on pedestrian comfort in the light of climate change (Santos Nouri & Costa, 2017). Figure 10 (right): Restructured Place Diagram by Santos Nouri & Costa (2017), the original adapted from (PPS, 2000)
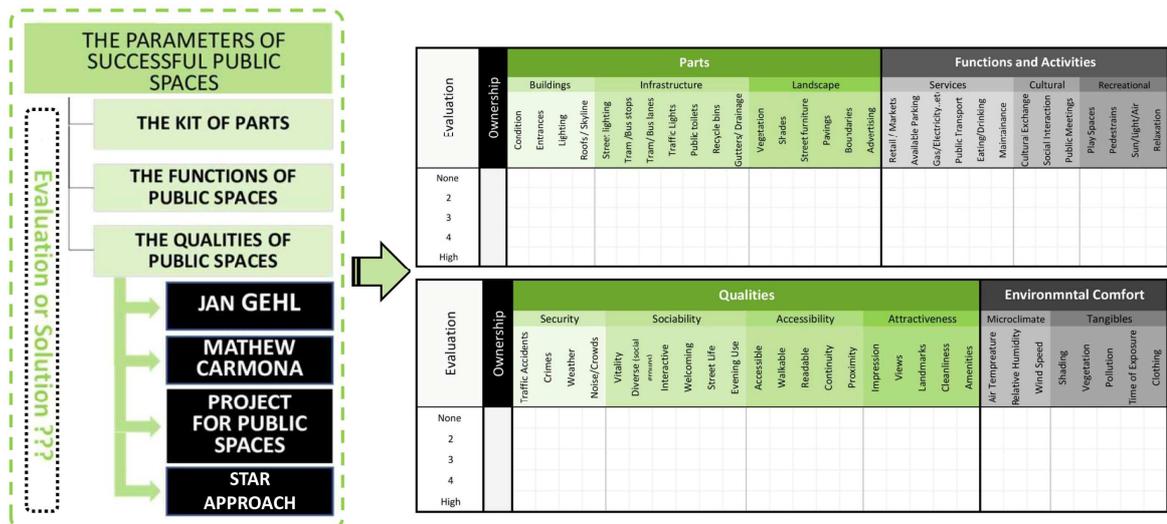

Figure 11: The initial proposed matrix for public spaces qualities (Researcher)

3.3 The Proposed Matrix for Public Spaces Assessment

The following matrix shown in figure (11) gathered the common qualities between the previously mentioned pioneers' theories and approaches shown in Tables (1), (2) ,(3) and figures (7) and (8). The matrix gathered

the common qualities between Jan Gehl, Mathew Carmona and the Project for public spaces. Also from the restructured place diagram illustrated in Figure (4 - 6) which focused on the comfort parameter. The Matrix can be used as a generic tool in assessing the quality of public space design in further studies.

The matrix was tested on two urban spaces located in the western expansion of Cairo. Americana Plaza is a public space located in district two in Sheikh Zayed city. This space accommodates several economic and social uses including shops, restaurants, cafes, cinema, and an indoor kids playing area. It represents a magnet for a wide range of social groups of Sheikh Zayed residents, along with users from all over Cairo (Aboubakr et al., 2020). The second space is the Capital business park located on the 26th of July corridor and owned by the Al-Durra group. This park allows people to escape the crowds of the capital cities (Atwa, Ibrahim, Saleh, & Murata, 2019). It provides employees with safe workspaces in the form of designed green areas surrounding the buildings in the morning, while, besides the morning it is open to the public at night. It accomodates several uses including shops, cafes, restaurants, seasonal kiosks, kids area and a medical centre.

Figure 12: The selected two open spaces in Sheikh Zayed city for evaluation (Researcher)

3.3.1 Capital Business Park

The assessment and real life observations showed more information and differences in the characteristics of the two spaces. For example, being privately owned lowered the results of Capital Business Park in many dimensions. The user of space has to pass several gates and check points at the entrance. Also, it lacked any public furnishing and shadings, which forces the pedestrians to enter the restaurants and cafes. This is a huge reason to downgrade the space's assessment, in addition to the poor vegetation and shading, although the place is well designed and maintained.

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Figure 13: Capital Business Park (Source: Researcher)

3.3.2 Americana Plaza

Americana Plaza received higher results due to the presence of clean, free access, and easy to find toilets. However, the physical configuration was less pleasant than Capital Business park and that is why it received slightly lower results. At Americana Plaza the other restriction is not present as it is not located in a privately owned entity, and users pass through the entrance check point easily and find several public amenities with no obligations.

4 POSSIBLE SOULUTIONS AND INTERVENTIONS

4.1 Nature-Based Solutions

Nature-based solutions (NBS) is a concept that emerged attempting to integrate ecosystem-based approaches in order to achieve sustainable development goals. They are also considered as the optimum solution for preserving the ecosystems and its services (Balzan, Zulian, Maes, & Borg, 2021). Since 2010, the strong relation between NBS and mitigating the environmental challenges has been a crucial dimension in the urban regeneration mechanisms. It is preferable to apply NBS in urban design to secure the engagement in sustainable urban development. Therefore, urban planners and decision makers became more interested in exploring the evidence of the NBS potentials to cope with these challenges. In NBS, ecosystem services play vital roles in addressing urban challenges and with the potential of designing sustainable urban environments (Pan et al., 2021).

Figure 15: Steps for NBS implementation to achieve resilient urban environments (World Bank Global NBS team)

According to the UN environment programme, NBS require an important change of approach in the decision-making process at the institutional and planning level, which is summarized in three main aspects shown in figure (16). The third aspect emphasizes the importance of citizens participation which is one of the Human-Centred design approach main characteristics.

Figure 16: The aspects of change in NBS' approach in decision making (UNEP,2001)

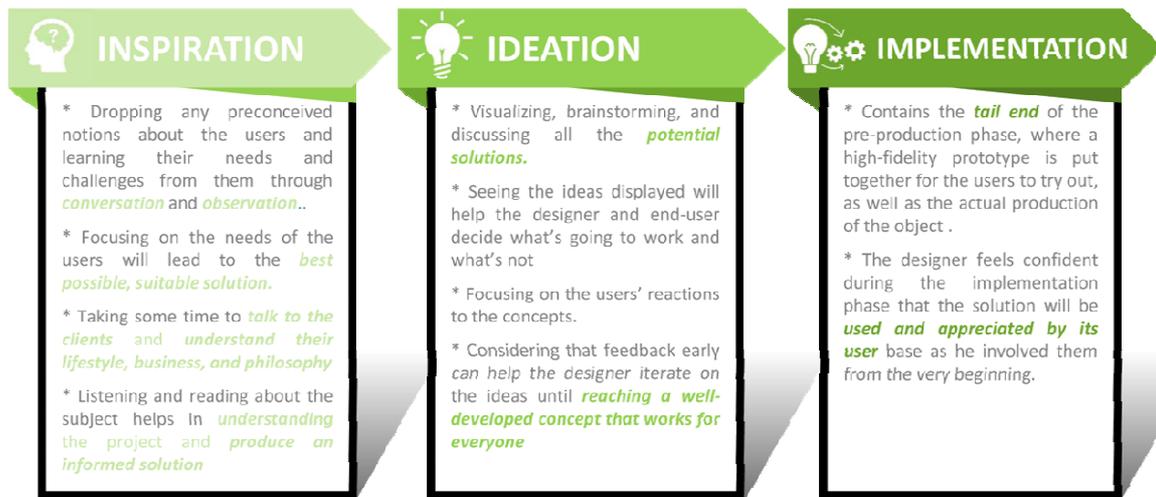
4.1.1 Human-Centred Design (HCD)

According to the previous figure (16), HCD is one of the NBS pillars. Creating effective and sustainable products or services in developing communities, urges designers to understand the social factors, cultural context, and needs of their intended users (Donaldson, 2009). However, understanding user needs can be challenging when designers come from different cultural and socio-economic backgrounds than their targeted users. Design Thinking or Human-Centred Design (HCD) methods provide a wide range of tools that guarantee the participation of the potential users in the design process while taking into consideration their needs and generating solutions (Brown, 2008; Magidsohn, 2019). Human-centred design is an approach that begins with the end-user of a product. It has a different methodology from the commonly used ones, where the products were made first then tested by the users after being created. What is unique about this modern design process is that it analyses the experience of the end-use, assuming that understanding the

928

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

roots of the problem enables the designers to come up with the most suitable user-friendly solutions (Magidsohn, 2019).



INSPIRATION

* Dropping any preconceived notions about the users and learning their needs and challenges from them through *conversation* and *observation*..

* Focusing on the needs of the users will lead to the *best possible, suitable solution.*

* Taking some time to *talk to the clients* and *understand their lifestyle, business, and philosophy*

* Listening and reading about the subject helps in *understanding the project* and *produce an informed solution*

IDEATION

* Visualizing, brainstorming, and discussing all the *potential solutions.*

* Seeing the ideas displayed will help the designer and end-user decide what's going to work and what's not

* Focusing on the users' reactions to the concepts.

* Considering that feedback early *can help the designer iterate on the ideas until reaching a well-developed concept that works for everyone*

IMPLEMENTATION

* Contains the *tail end* of the pre-production phase, where a high-fidelity prototype is put together for the users to try out, as well as the actual production of the object .

* The designer feels confident during the implementation phase that the solution will be *used and appreciated by its user* base as he involved them from the very beginning.

Figure 17: The simplified process of HCD (Keating, 2017)

5 CONCLUSION

A wide spectrum of underused, or misused spaces with different scales are distributed through the urban fabric of cities. They require a communal perception to coinjointy understand their diverse locations and practices. Several criteria and evaluations could be carried out to enable further amplification and deep analysis of the characteristics of these spaces, such as the background of their formation, their scale and shape, the surrounding context, the influence of urban planning on them, and their ownership.

Therefore, based on the study carried-out it could be argued that it has directed the attention to the complexity of parameters affecting the design of public spaces. The physical parameters have been considered through a quantitative integrated approach. An evaluation matrix was designed to assess the missing qualities and physical elements in each space. Also, the matrix could be used in further experiments studying other spaces. In addition, some transformative approaches like the preservation of ecosystems services through Nature-based solutions and the Human-centred design approach were discussed. They are all linked through nexus planning, providing solutions to transform urban areas into resilient and sustainable cities of the future. The majority of future urban developments and their imminent potential would depend on reusing the existing land and urban voids to create regenerative urban environments. This paper presents some of the accumulated key studies on urban spaces that could contribute to the provision of an integrated and comprehensive understanding for professionals and decision makers. It also proposes possible solutions that can be implemented by planners, designers, and urban policy makers in order to create regenerative urban environments leading to ecologically sustainable, economic and social development. Moreover, it visualises alternative urban scenarios, forecasts future demand and simulates the benefits of various density types to better inform policies and decision makers, by reconsidering new urban communities in terms of overall quality of urban life.

The introduction of the urban nexus approach in terms of urban design and planning could positively aid the urban regeneration process as it understands risks, engages decision-makers, and enables action. It also asks what are the different pathways that lead to resource security, sustainable development, and green growth.

6 RECOMMENDATIONS

It is highly recommended that the ownership of – the so called – public spaces in new urban expansions should be reviewed carefully, as they lack the main feature characterizing them which is "publicness " itself. Serving a specific social group does not properly aid the development process as such a community has to be homogeous. Also, urban spaces should not only be judged according to the fancy designs and facilities, but also taking into account the quality of services it provides is a must. For that reason the study adopted several asessment tools and approaches to cover all the possible aspects and details shaping the open public spaces.

Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Urban Regeneration: Identifying Causes and Impacts of Urban Decay within the Pietermaritzburg Central Business District: South Africa

Kwethemba Khumalo, Trynos Gumbo, Jackson Sebola-Samanyanga

(Kwethemba Khumalo, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, khumalo.kwethemba7@gmail.com)

(Prof Trynos Gumbo, University of Johannesburg, Department of Urban and Regional Planning, Johannesburg, South Africa, tgumbo@uj.ac.za)

(Dr. Jackson Sebola-Samanyanga, University of Pretoria, Department of Town and Regional Planning, Pretoria, South Africa, jackson.sebola@up.ac.za)

1 ABSTRACT

Urban decay affects cities worldwide, and South African cities have not been immune to this quagmire. It is regarded as a development that negatively contributes to physical degeneration and high spatial inequality. Most integrated development plans highlight the challenges of South African cities facing environmental decay and inadequate infrastructure maintenance. Consequently, greater regeneration plans for inner cities have been the strategic focus of urban planning. The study aims to investigate the main factors influencing urban decay within the Pietermaritzburg Central Business District (CBD). It is known that urban decay in Pietermaritzburg CBD is associated with economic decline and negatively impacts the city. However, it is unknown what specific strategies or plans the Municipality of Msunduzi is pursuing to combat urban decay, the level of funding available for urban regeneration initiatives, and the role of the private sector in urban regeneration efforts. The work adopted a case study research design and applied a qualitative approach to understanding factors contributing to urban decay in the Pietermaritzburg CBD. An in-depth examination and comparison of the causes and effects of urban decay using interviews with residents and relevant stakeholders, as well as observations of buildings conducted between 1 October 2022 and 30 October 2022, mention that the causes of urban decay in Msunduzi include Urban Planning and Governance: lack of measures to encourage city growth and inconsistent service delivery. The closure of public facilities, inadequate services, and the neglect of properties by absentee landlords worsen urban decay. The research findings emphasise the significance of private investments and changing residents' negative perceptions in achieving successful urban regeneration. A comprehensive approach to urban regeneration should encompass psychological, economic, social, physical, and civic aspects, thereby fostering economic development through collaboration between the public and private sectors. Most Pietermaritzburg participants attribute urban decay to socioeconomic shifts, such as the departure of middle-class residents, the presence of absentee landlords, and the absence of necessary amenities. Proposed solutions to combat urban decay involve implementing a regeneration programs program that prioritises city cleanliness, holds landlords accountable, enforces eviction measures, and offers incentives for businesses to relocate. Effectively implementing these measures necessitates collaboration among the municipality, private sector, community, organisations, and residents to stimulate economic growth, enhance infrastructure, and promote urban regeneration. The paper's overall contribution lies in developing an urban renewal strategy that addresses the factors leading to urban decay and supports efforts toward urban regeneration.

Keywords: Urban Planning, Spatial Inequality, Urban Regeneration, Urban Decay, Governance

2 INTRODUCTION

The built environment is always changing, both physically and functionally. Urban decay is examined from the viewpoints of physical, social, and economic origins, which have detrimental effects on urban planning. Urban decay presents itself in various ways, specifically in the physical deterioration of buildings and declining quality of the environment (Lea, 1972:43). Urban decay happens everywhere in the world in particular places or geographical areas in cities. However, the UN-Habitat (2017) notes that most of the world's population is relocating to cities and is predicted to increase in the next decade. However, urban decay mostly affects cities in developing countries. Urban decay is a global issue affecting developed and developing countries, resulting in the most aggravated effects if not addressed promptly. The cause of urban decay differs in each city. However, the impacts are slightly similar (Smith, 2018). According to Amirtahmasebi, Orloff, Wahba, & Altman (2016), every city either has an underutilised, overused, or distraught parcel of land, which gradually degenerates the city's appearance, liability and production and negatively affects the overall development and economy of the city. According to Andersen (2003:23), urban

decay is the most significant process which negatively contributes to generating high spatial inequality. It should be noted that urban decay is regarded as a global phenomenon affecting both developed and developing countries. Hence, the ARCA conference (2016:382) mentions that the impact of urban decay has stimulated global cities to formulate and implement urban regeneration strategies to address this issue. This research aims to investigate the main contributing factors influencing urban decay within the Pietermaritzburg Central Business District (CBD) and develop an urban renewal plan that addresses the threats contributing to urban decline while promoting urban regeneration. By analysing international case studies, the research will examine the reasons and factors behind the decline of the Msunduzi CBD, evaluate the socioeconomic and physical effects of urban decay in the area, and assess past, current, and future interventions aimed at combating urban decay. Through this comprehensive analysis, the research aims to provide valuable insights and recommendations for sustainable urban development and revitalisation in the Msunduzi CBD.

3   SIGNPOSTING

This paper explores various case studies that offer valuable insights into urban renewal and revitalisation efforts. Specifically, examining the cases of Santiago, Chile; Washington DC; Seoul; Singapore; and Johannesburg, providing a comprehensive understanding of their respective approaches. These case studies demonstrate the importance of comprehensive planning, public-private partnerships, restoring natural and cultural assets, addressing socio-spatial segregation, and having a long-term vision adaptable to changing circumstances. The significance of effective policy frameworks and governance structures in driving successful urban renewal initiatives is also highlighted. Moving on to the study area of Pietermaritzburg, South Africa, the paper delves into the perceptions of urban decay and its impacts through interviews with municipal officials and business owners. They shed light on the causes of urban decay, including middle-class residents leaving the city, absentee landlords neglecting properties, and a lack of services. Furthermore, the paper examined the resulting impacts, such as abandoned buildings, rising criminal activity, and declining property prices. Despite these challenges, there is a sense of optimism regarding the municipality's ability to regenerate the city. Participants propose potential solutions, including implementing a rehabilitation program, holding landlords accountable, conducting eviction processes for overcrowded properties, and providing business incentives. The findings emphasise the significance of private investment, transforming negative perceptions, preserving historical and cultural heritage, creating green spaces, improving transportation infrastructure, and investing in affordable housing and job opportunities as crucial factors for effective urban renewal.

4   RESEARCH METHODOLOGY

The research approach is in line with the study's goals and objectives. Since the study's main goal is to understand other people's opinions and behaviours surrounding urban decay in the Msunduzi CBD, the interpretative paradigm is used (Rahi, 2017). Qualitative research allows for the deep observation, examination, and disclosure of human experiences and behaviour (Alzheimer Europe, 2009). An in-depth examination and comparison of the causes and effects of urban decay are provided using a case study approach, the research design employed in this work. This aligns with thoroughly comprehending how urban decay affects the Msunduzi CBD. The sampling design chosen for the study is convenience sampling, which McCombes (2019) believes involves selecting individuals who are easily accessible and located near the study area. The target population for the study includes business owners located along Upper Boom, Pietermaritz and Church Street and government officials. Data collection instruments include primary data such as interviews with residents and relevant stakeholders and observations of buildings. Interviews took place between 1 October 2022 and 30 October 2022, where participants were asked to demonstrate their understanding of contributing factors and people responsible for urban decay within Msunduzi Municipality. Participants were also encouraged to provide personal views regarding how urban decay has affected them as individuals in their daily personal experiences and provided suggestions for an effective regeneration plan. This aligns to assess the scale of impacts regarding established interventions in Msunduzi CBD. Additionally, as Kabir (2016) indicated, secondary data collection methods are used to gather existing data from peer-reviewed journals and government publications.

5 CASE STUDIES

In the case study of Santiago, Chile, Santiago followed the laws of the Indies for planning but faced socio-spatial segregation and obsolescence in buildings and public spaces. The city lost half its population in the 1940s and implemented the Repopulation Program in 1990 to attract residents and promote urban renewal. The measures included attracting private investors, rehabilitating the physical environment, and changing negative perceptions of the city (Greene et al., 2011; World Bank, 2015). The Washington, DC, case study highlighted the city's strong model of urban revitalisation through the Anacostia Waterfront Initiative (AWI). The initiative aimed to bridge the psychological, economic, social, physical, and civic divide by restoring the river, improving transportation infrastructure, creating public open spaces, and developing cultural attractions and residential areas (Amirtahmasebi et al., 2016; Government of the District of Columbia, 2003). Seoul's case study focused on restoring the Cheonggyecheon stream in the downtown area, which sparked the regeneration of the city's inner districts. Revitalisation involved tearing down an elevated expressway, restoring the stream, and collaborating with the private sector for further development (Amirtahmasebi et al., 2016; World Bank, 2015). Singapore, a highly populated metropolis, faced physical decline and overcrowding in its core section. The city implemented urban rejuvenation strategies through legislative and development action plans, including the Master Plan of 1958. Projects such as the restoration of the Singapore River and the development of the Marina Bay waterfront played a significant role in the urban renewal process (Amirtahmasebi et al., 2016; World Bank, 2015; Guo, 2016). In Johannesburg, the decline of the inner city was influenced by apartheid policies and subsequent political transitions. Urban regeneration initiatives were implemented through area-based initiatives, improved public spaces, and urban development zones, focusing on rehabilitating neighbourhoods and revitalising the inner city (Amirtahmasebi et al., 2016; Nzimande & Fabula, 2020).

6 LESSONS LEARNT

The case studies of Santiago, Washington DC, Seoul, Singapore, and Johannesburg provide valuable lessons for urban renewal and revitalisation efforts. Here are the key lessons learned from these cases:

Comprehensive planning: Effective urban renewal requires a comprehensive planning approach considering various factors such as physical infrastructure, social dynamics, economic considerations, and environmental sustainability. By addressing multiple aspects of urban development, cities can create a holistic and integrated strategy for revitalisation. Public-private partnerships: Collaborating with the private sector is crucial in urban renewal initiatives. Engaging private investors, developers, and businesses can bring expertise, funding, and innovation to support the revitalisation process expertise, funding, and innovation. Public-private partnerships can help leverage resources and ensure the sustainability of urban renewal projects. Restoring natural and cultural assets: Rehabilitating natural and cultural assets within cities, such as rivers, streams, historic sites, and public spaces, can catalyse urban renewal. These assets can attract residents, tourists, and businesses, contributing to the economic and social vitality of the city. Addressing socio-spatial segregation: Urban renewal efforts should address socio-spatial segregation and inequality within cities. Cities can promote inclusivity and social cohesion by providing equal access to quality housing, transportation, public amenities, and economic opportunities. Long-term vision and adaptability: Successful urban renewal requires a long-term vision and adaptability to changing circumstances. Cities should develop flexible plans to evolve and accommodate new challenges and opportunities. Policy and governance: Effective policy frameworks and governance structures are essential for driving urban renewal initiatives. Cities need supportive legislation, regulations, and institutional mechanisms that enable coordinated planning, implementation, and monitoring of urban renewal projects.

7 STUDY AREA

The study area is in South Africa, within the second largest city of the KwaZulu-Natal province, known as the Pietermaritzburg city. The Pietermaritzburg city was originally established in 1838 after the defeat of Dingane at the Battle of Blood River. It was named after the two Voortrekker leaders, Piet Retief and Gert (Gerrit) Maritz. Pietermaritzburg is also known as uMgungundlovu and the capital city of KwaZulu-Natal, as it falls within the uMgungundlovu district and is governed by the Msunduzi Local Municipality (see figure 1). The current Pietermaritzburg population is estimated to be over 600,000 residents (including neighbouring townships). It is deemed to have one of the largest Indian South Africans in this country

(Siyabona Africa (Pty) Ltd, 2021). Pietermaritzburg is popularly known for its history and heritage essence, as it has numerous museums, art galleries and monument sites, historical buildings, and a railway station (Siyabona Africa (Pty) Ltd, 2021). The study area covers the Pietermaritzburg Central Business District, particularly the upper Pieter Maritz Street and upper Church Street (see figures 2 and 3).

8 RESULTS AND DISCUSSIONS

The results and discussions of the study emanate from the perceptions of municipal officials and business owners situated along Upper Boom, Pietermaritz and Church Street. The results and discussions are categorised into themes as per interview questions.

8.1 Conceptualising urban decay

Factors	Percentage
Despair	13.33%
Decline of Economy	40.00%
Decline of Status	20.00%
Unhygienic Habits	13.33%
Social Ills	13.33%

Table 1 Defining Urban Decay

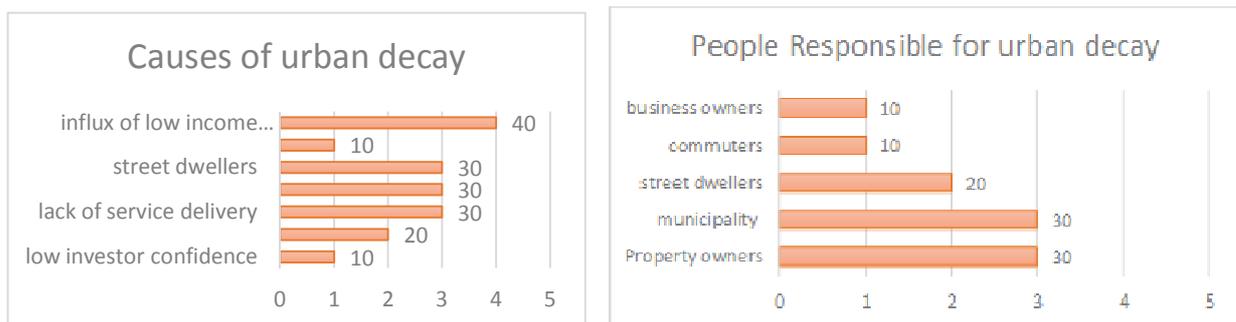
Inquiring about the definition of urban decay allowed researchers to assess how well participants understood it and how it related to their own experiences. Because there are many different ways to define this term depending on the environment, it was suggested that participants think about what they observe in the city of Msunduzi. According to the diagram, most PMB participants associate urban decay with economic decline. According to the participants, urban degradation is the process by which a community gradually deteriorates through time as a result of a change in the socioeconomic circumstances of a community. Cuthbert (2017) states that the cause of urban decay varies, even though the underlying philosophy is comparable and is gradually and permanently deteriorating the city's cities-built form feature. Urban decay is a global issue that mostly affects an area's overall built environment; as such, most root causes require joint intervention from different spheres of government. Urban decay has many undesirable impacts, including a decline in a city's market economy, intensified crime and employment rates, and health effects. According to Shin and Shaban-Nejad (2018:9), various aspects of urban decay have the possibility of causing permanent health issues, especially respiratory-associated illnesses.


Figure 3: Causes of Urban Decay.

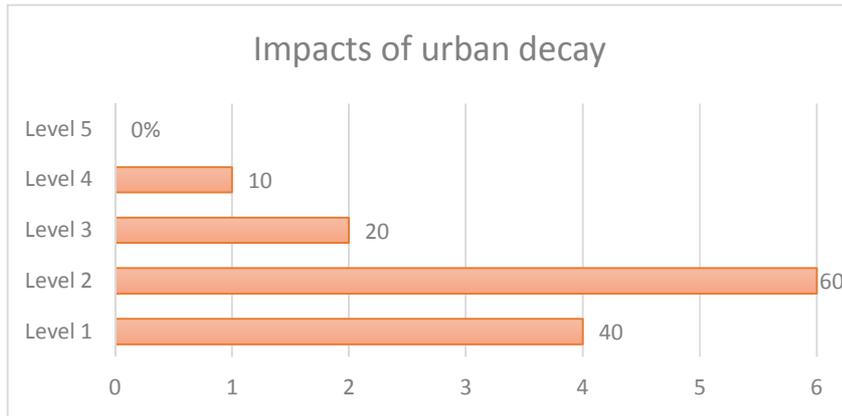
The participants contend that the primary causes of Pietermaritzburg's urban decline are middle-class citizens leaving the city for the suburbs, resulting in a commensurate inflow of lower-class or temporary residents. This is made worse by absentee landlords who do not check on the number of occupants or the condition of their buildings and are unable or unwilling to maintain their properties. The most underrated factor is a lack of services, namely the closure of public facilities, which forces commuters and homeless people to use open spaces like streets as restrooms when public restrooms are unavailable.

The participants continue to argue that the Municipality and property owners bear the primary blame for accelerating urban decline. The lack of consistent service delivery throughout the city with areas not being prioritised, the municipality's non-implementation of measures to encourage growth in the city and developing a favourable environment for economic and social sustainability. Most property owners neglect their homes and are not penalised, which causes the city's attractiveness to deteriorate.


8.2 Impacts of the Urban Decay in PMB

Figure 4: Impacts of urban decay.

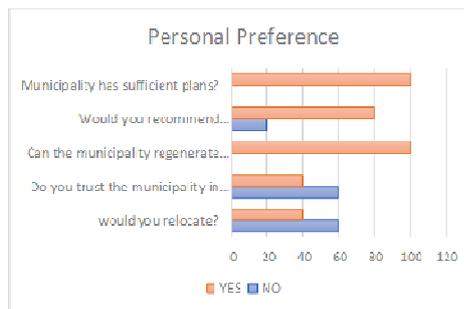
Participants' opinions and observations on the effects of urban decline in the Msunduzi Municipality were requested. They were asked to rank the impact level from 1 to 5 as another criterion. The objective of this study on urban decline was to determine the most urgent issue and encourage community involvement in the process. Participants said Msunduzi Municipality is in the middle of levels 1 and 2. Urban decay's Level 2 impacts, which are more obvious, include unoccupied or abandoned buildings, shattered windows, and a rise in criminal activity. These problems have decreased property prices, deterring regional growth and investment. Level 1 refers to minor issues such as peeling paint on buildings and occasional vandalism.


Figure 5: Personal preference.

Participants were questioned about whether they needed to leave the study's area, whether they trusted the municipality's approach to effective urban regeneration, and whether they would suggest investors in the study area based on the consequences. The findings suggest that there may be a lack of confidence in the municipality's leadership and capacity to take decisive action because 60% of participants do not believe the municipality would work relentlessly to fix the problem. However, the data also reveals that some inhabitants are hopeful and upbeat. There is a view that the problem of urban decline can be solved, as evidenced by all respondents to the question "Can the municipality regenerate the city?" agreed that the municipality can do so. Furthermore, 100% of participants who responded positively to the question "Does the municipality have sufficient plans?" agree that the municipality has adequate plans in place to address the problem of urban decay and that 80% of participants would advise the city to invest both show that residents are willing to support efforts to make the city better.

8.3 Possible solutions to urban decay in PMB

The participants engaged in discussions to suggest potential solutions for addressing urban decay in PMB. Among the participants, 40% advocated for a comprehensive rehabilitation program that adopts a multifaceted approach. This program encompasses various strategies, including initiating a cleanup campaign to reclaim public spaces from vagrants and criminal elements. Holding landlords accountable for their properties emerged as a critical step, emphasising the need for property owners to undertake reasonable maintenance. Additionally, participants highlighted the importance of enforcing eviction processes in cases of overcrowded dwellings. The municipality's role was acknowledged, with suggestions that it should play a part by condemning and demolishing abandoned structures. A proactive approach to law enforcement was

936

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

emphasised to curb criminal activities, and the revival of incentives for businesses was deemed essential to rejuvenate the city's economic landscape. In response to the reviewer's comments, a comprehensive examination of these proposed measures reveals the following recommendations:

Figure 6: Possible solutions.

(1) Establish Rehabilitation Programmes: Develop and implement structured rehabilitation programs that restore deteriorating areas. These programs should involve community engagement, partnerships with local organisations, and targeted interventions to address specific challenges within each locality.

(2) Demolish Old Buildings: Identify derelict and dilapidated structures that contribute to urban decay and pose safety risks. Develop a systematic plan for demolishing and removing these buildings, ensuring proper waste disposal and adhering to environmental regulations. Old buildings listed under AMAFA (Amafa aKwaZulu-Natali) should be comprehensively preserved. This involves detailed documentation, a conservation plan that respects historical value, and adherence to heritage regulations. Stakeholder engagement and sensitivity to original design during restoration are crucial. Periodic maintenance, public access, and heritage tourism can further promote their significance.

(3) Enforce Strict By-Laws for Residents and Property Owners: Strengthen and enforce municipal by-laws that require property owners to maintain their premises in a reasonable condition. Introduce penalties for non-compliance to encourage property owners to invest in upkeep.

(4) Formalize Businesses: Facilitate formalising informal businesses operating in the affected areas. Provide support and resources to help these businesses become legal entities, contributing to the formal economy while promoting safety and regulatory compliance.

(5) Community Clean-Up Initiatives: Mobilize community members to participate in regular clean-up campaigns. Encourage ownership and responsibility for the local environment, fostering community pride and cleanliness.

(6) Business Retention and Incentives Strategy: Develop a comprehensive strategy to attract businesses back to the area and retain existing ones. This could involve offering tax incentives, streamlined licensing procedures, and support for business development.

(7) Address Parking Issues: Implement effective parking management strategies to alleviate congestion and ensure orderly parking. Consider introducing parking regulations, designated zones, and alternative transportation options.

The research focuses on an area outside the city's CBD regeneration strategy, posing challenges in sourcing funds for regenerative efforts in this location. A potential solution involves advocating for policy amendments to encompass these overlooked streets within the regeneration initiatives. A closer examination reveals that the chosen study area is primarily occupied by homeless individuals, leading to investor reluctance due to heightened nocturnal criminal activities. Addressing their inclusion in policy-making requires innovative strategies. To address this, the City of Msunduzi could develop a comprehensive mandate as part of its regeneration policy, collaborating with rehabilitation centres to relocate and support homeless individuals. This collaboration would offer them essential activities, skill development programs, and drug rehabilitation services. The study area also comprises tenants from various African countries

renting properties owned by South African landlords who don't reside there. The city could consider purchasing these properties, enhancing them through rehabilitation, and reselling them under stricter maintenance regulations. Alternatively, exploring expropriation is an option, subject to conditions that allow property owners to provide tenants with sufficient time to relocate, with the city's assistance if needed. Collaboration is key, such as utilising already-built housing programs to benefit these residents, ensuring a joint effort to prevent potential gentrification. Furthermore, part of the regeneration process should involve integrating informal street traders. This could entail reserving ground-level spaces within buildings for economic activities and providing stalls and furniture to support a regenerative economy.

9 CONCLUSION

According to the interviews, it can be inferred that most PMB participants saw urban decay as a process where an area deteriorates because of a shift in socioeconomic conditions. They also think that the outflow of middle-class residents from urban areas, absentee landlords, and a lack of amenities are major factors in urban decline. Urban deterioration is rated as having a level 1 to level 2 impact by participants in PMB, with more obvious problems such as broken windows, abandoned buildings, and increasing criminal activity. Participants don't have complete faith in the municipality to successfully combat urban deterioration, but they think it can revitalise the city. Participants suggest possible solutions, including creating a rehabilitation program that cleans up the city, holding landlords responsible for their homes, evicting extra people, and offering incentives for companies to relocate back to the city. Overall, the findings indicate that urban decline is a serious problem in PMB, but citizens are hopeful and eager to fix it. We can infer from the case study that the key components of effective urban regeneration initiatives include luring private investment and altering negative perceptions of the city, collaboration between the public and private sectors, giving top priority to historical and cultural significance, creating green spaces, putting transportation planning into practice, regenerating natural resources like rivers, and investing in affordable housing and job opportunities.

1 ABSTRACT

Spatial, socio-economic and demographic characteristics of individual areas of the European Union define numerous specific settlements and regions, among which the peripheral areas and small settlements, are particularly interesting and challenging for both researchers and planners, thus they represent the main research problem. It is particularly important to create revitalisation strategies for such areas at the regional and local level, based on the specific characteristics of the place and set within the framework of national and European development criteria. The importance of this research for readers is to highlight the necessity of comprehensive planning and the use of the scenario method, the foundations of which can be mastered in education at the Spatial Planning Workshop, and later applied in urban and spatial planning practice. The aim of this paper is presentation of thematic workshops as education method for future spatial planners, urban planners and architects based on European sustainable development documents, which enables research, analysis and planning at the regional level through application of the scenario method, as *par excellence* tool for definition of future development. The possibility for students to choose both the subject area and the specific topic during the workshop represents an opportunity for further education and development of a visionary approach not just at the regional but also at the local level with the possibility of planning revitalisation strategy for small settlements in the following semester. The case study of Baranja region in eastern Croatia was chosen for the purpose of this research, because of its geographical isolation and depopulation, a lack of micro-regional centres, neglected industry and a relatively old population. On the other hand, its diverse natural and cultural heritage, historical agricultural significance, and the regional specificities of individual settlements, especially Kneževo, represent spatial potential which should be activated in order to stimulate its regional, and consequently, local development. On the basis of the detailed analysis, and the application of scenario method, the result of the work is definition of six possible scenarios for the Baranja region development, determined by dominant activities (smart villages, agriculture, tourism, energy, industry and livestock) which are further broken down into two basic models of space activation approach. The proposed scenarios are based on global sustainable development goals and specific possibilities of spatial revitalisation, which enables definition of an integral scenario (as a result of the valorisation of individual scenarios), further elaborated as a vision of development and revitalisation of the Baranja region with macro and micro projects acting as space activators. The special emphasis is placed on Kneževo, a small settlement with historically significant urban and industrial features which experienced a significant economic and demographic decline due to the dynamics of business and deindustrialization trends in the late 20th century. The introduction of the new function is seen as a potential activator of Kneževo settlement revitalisation, where the construction of a film studio is proposed as the most suitable scenario. It would contribute to the development of culture and media at the national level, while the development of supporting functions and an increase in the number of temporary and permanent residents would enhance the revitalisation of the settlement and the surrounding area.

Keywords: space activation, sustainable development goals, scenario method, spatial planning, revitalisation strategy

2 INTRODUCTION

Spatial, socio-economic and demographic characteristics of individual areas of the European Union define numerous specific settlements and regions, among which the peripheral areas are particularly interesting and challenging for both researchers and planners.

The term "periphery" has numerous interpretations from spatial to socio-developmental perspectives. Pénzes and Demeter (2021) stress that considerations of peripheral areas and their delimitations themselves can be

based on different approaches, and specific indicators should be considered in order to determine their level of development. The ESPON applied research PROFECY (2017) point out the inner peripherality is the result of multiple combinations of processes, features and evolutionary dynamics affecting all kinds of territories across Europe. The combined action of different processes and features on a specific territory can cause significant limitations in its development potential. Peripherality is not only determined by geography but also by non-spatial proceses and factors. Some delineations of peripheral areas are: higer travel time to regional centres, lower economic potential, poor access to services of general interest and depletion. Considered in the territorial context, the most peripheral areas in geographical terms frequently appear as inner peripheries and border regions. Regarding the future development of such areas, development policies on the regional and local level should be based on specific characteristics of peripheral areas and the characteristics of their settlements, defined by national and European criteria. Smaller settlements represent a particular challenge because dynamic processes on higher levels leave greater effects on the local level, thus more attention should be paid to direction of their development.

The main research problem are peripheral areas and small settlements, for which it is necessary to create long-term revitalisation strategies. The importance of the research to the reader is to emphasize the need for comprehensive planning and the use of scenario method in planning both at the regional and the local level, the foundations of which can be mastered in education at the Spatial Planning Workshop.

The aim of this paper is to present thematic workshops as education method for future spatial planners, urban planners and architects, which enables research, analysis and planning on the regional level through application of the scenario method as par excellence tool for definition of future development based on European sustainable development documents. The possibility for students to choose both the subject area and the specific topic during the workshop represents an opportunity for further education and development of a visionary approach on the regional and local level with the possibility of planning revitalisation strategy for small settlements, in this case Kneževo settlement in the Baranja region in eastern Croatia.

The paper will show how students at the Faculty of Architecture in Zagreb in the Spatial Planning workshop on the Master's course in Architecture and Urbanism are directed to think strategically about space through comprehensive planning, using the planning scenario tool.

As a part of Workshop 3: Spatial planning at the Faculty of Architecture of the University of Zagreb, under the mentorship of Professor Lea Petrović Krajnik, head of the workshop, student Petra Banić, created a vision for the development of the Baranja Region named "Re: Baranja: Development and Revitalisaion Scenarios" (Banić, 2023a). Afterwards, she further developed specific location and theme on the scale of urban planning project as the graduation thesis "The Revitalisation of Kneževo", under the mentorship of Professor Damir Krajnik (Banić, 2023b).

3 SPATIAL PLANNERS' EDUCATION AND SPATIAL PLANNING WORKSHOPS

Stategic visions can be considerd as the basis for creating high quality places and delivering a more sustainable future for communities as well as to achieve their long-term needs. The comprehensive planning has to be pointed out as the effective tool for enabling communities to formulate strategic visions of their future development goals. The integrative approach in spatial planning allows an evaluation of the strengths and challenges of the specific area, the definition of opportunities and scenarios, and selection of optimal vision and spatial policies for the future development. Spatial planning operates at all scales, from European, transnational, national, regional to local plans, so spatial planners must have the abilities to cope with different scales and different levels of territorial planning.

According to the Charter of European Planning (ECTP-CEU, 2013) spatial planners play the key role for changes that are needed to manage existing and create new cities and regions. They need to be leaders of change, political advisors, designers, urban managers, and scientists. This would make achievement of the Vision and application of the Charter of European Planning Principles easier.

ECTP-CEU (2017) points out that spatial planning is a distinct profession with its own areas of expertise in territorial development processes. The planners' core commitments, embodied in the Charter of European Planning, include research and analysis, advocacy and mediation, the ability to envision, evaluate and promote potential future options for urban, spatial, and territorial development. Planners need to combine scientific and creative conceptual thinking with practical approaches in order to harmonize society and

environment at various territorial levels. ECTP-CEU explains the framework of guidance based on three needs and the related eight core competences of spatial planners:

- Critical thinking and understanding of the rationale of planning and its theoretical and legal basis (The Rationale od Planing)

- An understanding of the spatial systems (Socio-economic systems, The Built Environment, Environmental systems)

- Technical and creative competence needed to engage in planning practice (Planning Techniques, Planning Instruments, Planning "Products" and Independent Research).

In the spatial planners' education, during the Undergraduate and Graduate Studies in Architecture and Urbanism at the Faculty of Architecture of the University of Zagreb, students encounter various tasks in the field of urbanism and spatial planning: from planning low-density residential areas, high-density residential areas, planning a new part of the city, designing public space, the urban-architectural project of the transformation of a specific city area, and the integral vision of development of cities and municipalities.

On the third semester of the Master Study in Architecture and Urbanism students have the opportunity to choose between fourteen workshops led by professors from the Faculty of Architecture. Workshop 3 - Spatial planning is one of three workshops led by professors of the Department of Urban Planning, Spatial Planning and Landscape Architecture. The main goal of the course is to propose a vision of the spatial development of chosen area (region or city) based on the principles of sustainability and the proposed topic depending on the academic year. The work on the course is adapted to the student, or group of students, and takes place in stages in accordance with the timetable, depending on the chosen subject coverage. The first stage of students′ work includes a consideration of theoretical starting points and a detailed analysis of the existing situation and spatial planning documentation, which ends with a SWOT analysis as a basis for the second stage.

Students are guided to perceive spatial strenghts, weaknesses, opportunities, and threats from different perspectives, that is, to immerse themselves in the different roles played by various actors in the space, in order to be able to determine possible development scenarios. In addition, in the initial stages of planning, they are encouraged to use surveys to determine the key issues and needs of residents and users of the subject area. In the second stage, students independently or in group research and conceive different scenarios for the future development of the chosen area, taking into account complex systems and numerous processes taking place in them. Based on the set criteria, students choose the most appropriate development scenario and propose a development vision and a concept for the subject area (graphics, model). In the third stage, a more detailed elaboration of the program for the selected location and the proposal of strategic and development projects are made.

The scenario method is used as a par excellence tool for determination of the future development possibilities of a certain area. Scenario methods are research subject of many authors, considering the use of scenarios, which has a special significance for spatial planning, and which encourages strategic thinking and helps to overcome thinking limitations. There are numerous definitions of scenarios depending on the authors and areas of application.

Kahn and Wiener (1967), the founders of future studies and scenario planning, define scenario as "a set of hypothetical events set in the future constructed to clarify a possible chain of causal events as well as their decision points". Godet and Roubelat (1996) perceive a scenario as a description of the future state and the sequence of events leading to the future state. Shearer (2005) points out that the scenario is not a "variant of the future" but a mean to achieve the desired state.

The use of the scenario method expanded after WWII, when it was linked to military planning at the RAND Corporation. In addition, the methodology was used during the 1960s for the purposes of social forecasting, public policy analysis and decision making. In the 1970s, scenario planning gained a new dimension in the private sector thanks to the unconventional French oil director Pierre Wack. During the last decades, the use of scenario method has particularly increased, not only in the business sector but also in the field of spatial planning. (Bradfield et al., 2005)

Rothman (2008) emphasizes that scenarios can be presented in textual and graphic form (pictures, graphs, maps, etc.), which enables better perception and understanding of the future. In comparison to other future-

oriented approaches, Ljubenović et al. (2014) stress that scenario planning usually provides a more qualitative description of how the present will evolve in the future, rather than quantitative numerical accuracy which is typical for simulations. They point out that in the scenarios the range of possible outcomes resulting from uncertainty is explored, while creating a vision builds a picture of desired future together with strategies for achieving goals. Friedmann et al. (2004) believe that it is a way of questioning the future for optimal decisions in the present, which have to be based locally. He points out that a detailed investigation of strategic issues is necessary in the context of different assumptions or scenarios in order to enable the assessment of the outcomes and effects on different aspects of sustainability. Kok et al. (2006a, 2006b) point out that scenarios created for lower levels are based on scenarios from higher levels. Higher-level scenarios are usually developed by scientists and stakeholders on the regional and national levels, while local scenarios are developed by local stakeholders.

Radeljak Kaufman (2016) points out the existence of different types of scenarios such as scenarios of exploratory / normative, qualitative / quantitative, expert / participative and basic / managerial character, which indicates the significance of the selected typology in research and spatial planning. She emphasizes that the scenario method is useful in spatial planning because of the creation process during which knowledge about development trends and spatial elements is expanded, but also because of the final results that are important for management strategies and measures.

During studies in spatial planning workshops, students are directed to strategic thinking and the use of the scenario method, which presents an efficient tool to articulate concepts of an uncertain and complex future. Scenario planning serves as a basis for defining an integrated vision of development of cities and regions. The intention to stimulate students′ intuition and creativity is achieved by applying scenario planning based on Intuitive logics school which does not use any mathematical algorithms. The methodology proposed by Stanford Research Institute International (SRI) is one of the most popular and frequently used. The advantage of the SRI approach is the development of flexible, internally consistent scenarios from an intuition and logical perspective (Huss and Honton, 1987). Students are taught the importance of flexibility in the process of creation of a spatial development vision, as well as the need to create four scenarios which enable an open discussion and the combination of different interests of stakeholders in the process of defining the preferred model and creating a common development vision (Vogelij, 2010).

Urban revitalisation represents a special issue in urban and spatial planning. It′s definition according to the CEMAT Spatial development glossary (2007) is: „urban regeneration and revitalisation which aims at transforming the obsolete socio-economic base of certain urban areas into a more sustainable socio-economic base through the attraction of new activities and companies, modernisation of the urban fabric, improvement of the urban environment and diversification of the social structure.“ Urban revitalisation is a complex and long-term process that brings back to life spatial structures encompassing different dimensions such as urbanistic, architectural, technical, cultural, aesthetic, social and natural. Strezelecka (2011) points out that it is understood as a process involving spatial, social and economic transformations of towns. Urban revitalisation should be carried out systematically, in the context of environmental improvement and political and institutional development, in order to enable implementation of adopted strategies in legal frameworks and organizational conditions.

The process is associated with the concept of sustainable development since it is a comprehensive approach which considers three main aspects of urban life, the ecological, social and economic, and puts emphasis on quality of life of town residents. In the process of revitalisation, particular attention has to be paid to social, infrastructural and spatial development (preserving cultural heritage through renovation, modernization and conservation of historical monuments, buildings and public spaces and improvement of the natural environment). Zagroba and Gawryluk (2017) dealt with a revitalisation as a method of planning sustainable development of historic towns. They point out that simultaneous protection of cultural heritage and restoration and improvement of usable functions and strengthening social integration is particularly challenging in the process of revitalisation of a historic town centre.

There are various initiatives and programs for revitalisation of small settlements in Europe. The European Council for the Village and Small Town (ECOVAST) was set up in Germany in 1984 in order to further the well-being of rural communities, and safeguarding of the rural heritage throughout Europe. Its main aim is to foster the economic, social and cultural vitality and the administrative identity of rural communities in

944

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Europe, to safeguard and promote the sensitive and imaginative renewal of their built and natural environments. Nowadays ECOVAST has more than 500 members in 20 countries in East and West Europe, and it can be seen as a bridge between decision-makers and those who are active at local level, between experts and practitioners (ECOVAST, 2023). The Cittàslow movement emerged in Italy in 1999 and has spread to 33 countries during the years, connecting over 287 towns not in Europe and around the world. Bernat and Flaga (2022) stress that membership in the International Cittàslow Network can constitute an alternative development path for the revitalisation of small towns in peripheral areas. Honoré (2005) points out that the idea of slow town is a part of the so-called "slow movement", conceived as a response to the progressing globalisation and in the context of the sustainable development paradigm.

At national level specific policies and tools for small and medium-size towns have been recently developed across Europe (Gros-Balthazard & Talandier, 2020; Rauhut & da Costa, 2021). A series of initiatives have been implemented in some European countries, in order to address the challenges faced by territories defined as internal, peripheral, or lagging-behind places. For example, in France "The national policy Petites villes de demain - Territoires de cohésion au coeur de la relance" was established in 2020, "Kleinstadt Akademie (The German Small Town Academy)" in 2021 in Germany, "Piano Nazionale di Ripresa e Resilienza - Bando Borghi (Call for Villages)" in 2020 in Italy, "Estratégia Portugal 2030. Documento de Enquadramento Estratégico" in 2020in Portugal, and "Plan de Recuperación. 130 Medidas Frente al Reto Demográfico (2021-2023)" in 2020 in Spain. (ESPON, 2022)

4 CASE STUDY: BARANJA REGION AND KNEŽEVO

The Baranja region and the settlement of Kneževo were chosen because of their specific location and characteristics, i.e. as the peripheral area with special challenges of depopulation and deindustrialization, but also a great potential of natural and cultural heritage and historical industrial significance for the entire area of northeastern Slavonia and Croatia.

4.1 Specifitites of the Baranja Region

Geographically, the Baranja region covers parts of the territory of Croatia and Hungary, of which the Croatian part is 20.5% of the total region area. The Croatian part of Baranja occupies the northeastern part of the Osijek-Baranja County, territorially defined by the Drava River on the south and the Danube on the east, while the northwestern border with Hungary is defined administratively. The Croatian part of Baranja has 30,782 inhabitants, which represents 12% of the population of Osijek-Baranja County. Compared to the previous population census from 2011, Baranja recorded a loss of 8,000 inhabitants, which represents a total of 20%. (Croatian Bureau of Statistics, 2023; Banić, 2023a)

Fig. 1: Administrative Division of Croatian Part of the Baranja Region. Source: Banić, 2023a.

The A5 highway, which is an integral part of the pan-European Vc corridor (Ploče - Sarajevo - Osijek - Budapest) and the European route E73 passes through the Baranja region. The completion of he highway route to the state border with Hungary (from 5 km north of Beli Manastir to the state border) is planned in 2024. The Pan-European Corridor Vc railway route is also planned, which should become an important transport route, especially for freight traffic. The area is well connected by local road infrastructure which

connects settlements and enables daily migrations to larger regional centers, while the public transport network is insufficiently developed.

The Baranja Greenways bike path passes through the area, a multipurpose path that supports: walking, horseback riding, cycling and other forms of movement without a motor (Mecseka - Osijek). In its southern part, it passes through the municipalities of Bilje and Kopački rit, passing through Zlatna Greda, Tikveš and Kopačevo. The Pannonian Road, the bicycle path (Osijek - Sombor) passes towards Bilje to the gate of Kopačko rit - Kopačevo, passes through the wastelands of Podunavlje, Kozjak, Sokolovac and Mirkovac, continues via Suza and Zmajevac to Batina. The Danube bicycle route (EV6) has a total length of 4,450 km and passes through 10 European countries, connecting 11 UNESCO World Heritage sites and 6 European rivers. In a length of 150 km, it passes through the eastern part of Croatia through two counties (Osječko-Baranjska and Vukovarsko-Srijemska county), following the course of the Drava and Danube rivers.

The area has a rich natural heritage. A significant part of the Baranja is protected by the NATURA 2000 ecological network, the area along the Drava and the Danube (special reserve Gornje Podunavlje and nature park Kopački rit). The area has a developed network of public facilities: cultural (five museums and one library), educational (five kindergartens, 31 primary schools, one high school and three vocational high schools) and health (three health centers and seven clinics). (Banić, 2023a)

The region is also rich in cultural heritage: manors, sacral buildings and complexes, rural and industrial settlements, archaeological zones and sites. A rich industrial history is evident in numerous complexes called "pustare", which were established in the 19th century, and in the first half of the 20th century. Today, "pustare" are mostly abandoned or have maintained an exclusively productive function, while their spatial potential remains unused. (Ministry of Culture and Media, 2023; Matišić et al., 2017)

In the Croatian part of the Baranja, the main economic branches are agriculture and tourism. The main tourist zones are the Kopački rit nature park and the settlements in the zone of Bansko brdo with tourist offer based on sports and recreation.

Based on the analysis of the existing situation and spatial planning documentation, a SWOT analysis was made pointing out strengths (natural and cultural diversity, agricultural importance, rich tourist offer and numerous specific settlements), weaknesses (geographical isolation, neglected industry, older population and lack of micro-regional centers), advantages (international connection, modernization of industry, activation and attraction of population and formation of regional centers) and threats (exclusively tourism based economy, excessive industrialization, abandonment of agriculture and loss of the historical character of settlements).

4.2 Development and Revitalisation Scenarios of the Baranja Region

Based on the conducted analyses, possible development and revitalisation of the Baranja region is considered through six basic scenarios determined depending on the dominant economic activity in the area, which are further broken down into two basic models of space activation approach. In the process of creating basic scenarios, an attempt is made to investigate the current activities and their impact on the economy and population of Baranja in order to define steps for possible improvement. The proposed scenarios are based on global sustainable development goals and specific possibilities of spatial revitalisation. Evaluation of individual scenarios is carried out in order to determine an integral scenario which is later elaborated as a vision of development and revitalisation of the Baranja region with macro and micro projects as space development activators.

4.2.1   Smart villages

According to the European network for rural development (2003) smart villages are the concept of communities in rural areas that use innovative solutions to improve their resilience. In order to improve their economic, social and/or environmental conditions, they rely on a participatory approach in development and implementation of development strategies and solutions offered by digital technologies. Additional benefit can arise from the cooperation with other communities and actors in rural and urban areas. The basic prerequisite for the development of smart villages is internet networking and internet literacy. Although Croatia is largely covered by a Wi-Fi network, not all areas have broadband Internet (HAKOM, 2023). As a part of the concept of smart villages development, it would be necessary to improve the internet infrastructure and implement the digitization of health, administrative and commercial services (Pavić-

Rogošić, 2019). Since almost all settlements in Baranja, with the exception of Beli Manastir, have a rural character, their survival and development can be achieved through transformation into smart villages.

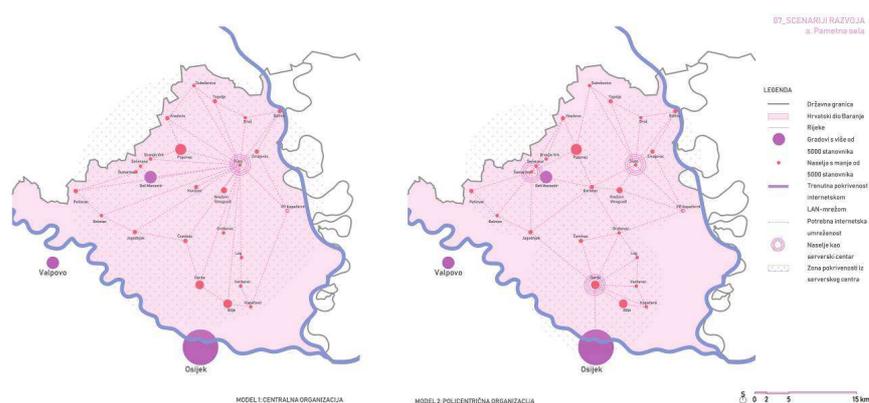

Fig. 2: Development Scenario: Smart Villages - Central Organisation Model (left) and Policentric Organisation Model (right). Source: Banić, 2023a.

The central organization model envisages concentration of digital server and administrative functions in one place, which would thus become the digital center of the Baranja region. The Suza settlement is chosen as the center, due to its undergoing revitalisation and several settlements in the vicinity with high economic potential.

The polycentric village organization model assumes division of the Baranja region into three sub- areas with centers in Darda, Suza and Šumarina, which were chosen due to their location in gravity zones of larger cities. The activation of centers is perceived through new function which ensures creation of new work places, thus improving living standard of inhabitants.

4.2.2 Agriculture

The most important economic branch of Baranja is agriculture, with production of corn, wheat, sugar beet, fodder and industrial plants. The current challenge of agriculture in Baranja is the lack of irrigated areas and the absence of processing facilities. Agricultural production is not on the technological level which would ensure production results in accordance with the quality of the soil. As a solution for improvement of agricultural production, construction of a processing plant which would ensure the export of finished products, resulting in higher revenues (Croatian Chamber of Commerce, 2023; Glas Slavonije, 2023). Two models of the organization of processing centers are proposed.

The central organization model envisages the establishment of one processing center, which is planned in the Čeminac settlement due to the good traffic connection with Osijek as a macro-regional centre. It is located along the railway corridor and is well connected to other settlements in Baranja. Farms and biogas plants are located next to it, which would ensure its supply. The construction of the processing centre would create numerous working places for the residents of Čeminac and its surroundings.

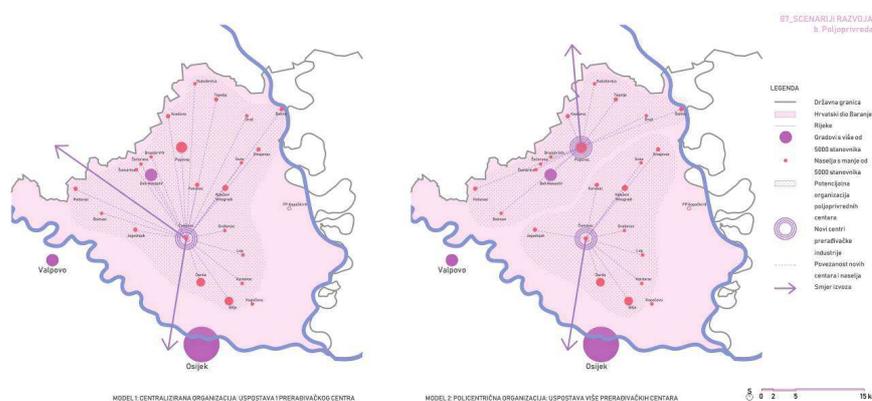

Fig. 3: Development Scenario: Agriculture - Central Organisation Model (left) and Policentric Organisation Model (right). Source: Banić, 2023a.

The polycentric organization model proposes establishment of two processing centers, one in Čeminac and the other in Popovac settlement. The processing center in Popovac would be focused primarily on the export of goods to the European Union via Hungary, and would cover the agricultural production of the settlements north of Bansko brdo. It was chosen because of its central location in northern Baranja and proximity to Beli Manastir as a regional centre. In this way, the northern settlements of Baranja region would also be activated and new working places created.

4.2.3 Tourism

The existing tourism offer in Baranja is concentrated in two zones: the nature park Kopački rit and the southern slopes of Bansko brdo. Kopački rit is the center of active tourism in nature, while the area of Bansko brdo is the center of rural tourism focused on the production of local products, mainly wine. Kopački rit is easily accessible from Osijek, and Kopačevo is the starting point for organized tourist route to the presentation and education center in newly renovated Tikveš manor in the north. The activation of new tourist zones and the integration of the tourist offer is proposed. (Baranja Tourist Board, 2023)

The model of integration of the existing tourist facilities is based on the connection of two main existing tourism assets, with minor expansions west of Beli Manastir.

The model of activation of new tourist centers is focused on the restoration and preservation of existing cultural assets and the formation of new tourist hotspots. These are cultural centers with classicist and historicist manors and parks in Bilje, Darda and Kneževo, while Topolje is a center of traditional rural architecture. Existing centers with already recognized cultural heritage, such as Zmajevac, are not included in this model.

The integration of both models and the overlap of the tourist offer is proposed.

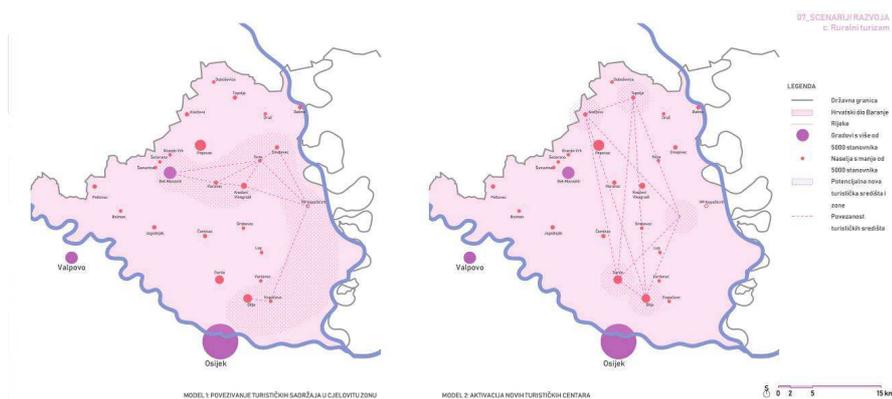

Fig. 4: Development Scenario: Tourism – Model of Connecting Tourist Facilities into a Complete Zone (left) and Model of Activation of New Tourist Facilities (right). Source: Banić, 2023a.

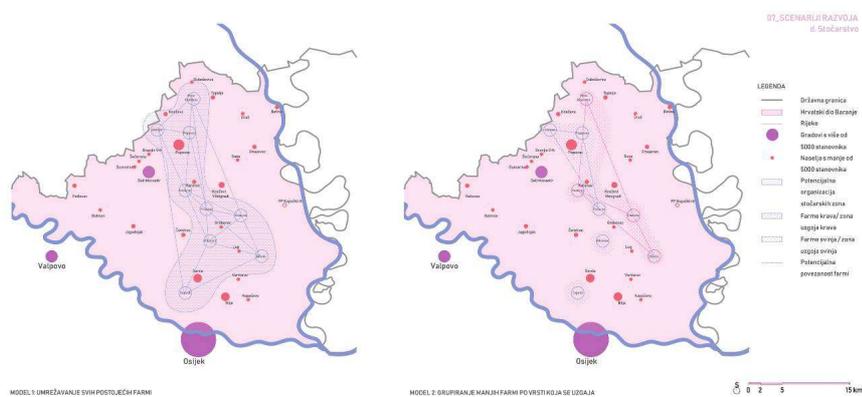

Fig. 5: Development Scenario: Livestock – Networking Model of all Existing Farms (left) and Model of Connecting Smaller Farms Depending on the Type of Livestock (right). Source: Banić, 2023a.

4.2.4 Livestock

Cattle breeding is the second most important branch of agricultural production in Baranja. It is divided into two types: small family farms and large-scale breeding on farms of the Belje industry. Cattle raised on family farms are mainly used for processing into dried meat products and for local use, while the production on Belje farms is organized according to the highest technical standards and it is quantitatively and economically dominant. Additional technological improvement and improvement of production standards on family farms are proposed. (Agroklub, 2008; Kult plave kamenice, 2016)

The model of existing farms networking assumes their digitalization and integration. Digitalization would facilitate communication and migration of experts and the exchange of knowledge, while the centralization would facilitate acess to the market and control of prices and quality. It can be assumed that this model has been partially implemented since most of the farms are managed by Belje, but there is certainly a need for additional improvement.

The model predicts the connection of small farms depending on the type of livestock. Optimization of cultivation is foreseen by connecting small farms in a network thus enabling the competition with larger farms.

4.2.5 Energy

In the Baranja region there are five larger power plants, the goal of which is self-supply of the farms they are built next to. The biogas power plants next to the Topolnik and Mitrovac farms use biomass, which is a byproduct of the farm′s production, while the solar power plant in Zmajevac is for irrigation of vineyards. As a part of the rural development project, the municipalities of Baranja plan to install solar collector panels on roofs of county and municipal buildings, which is a step towards energy self-sustainability, but larger projects are also necessary in order to achieve the best possible results. The goal of this scenario is to create an energetically self-sustainable Baranja region using the existing spatial potential - the construction of biogas power plants next to farms and the installation of solar power plants. (Lider, 2022; Savez energetičara Slavonije i Baranje, 2023)

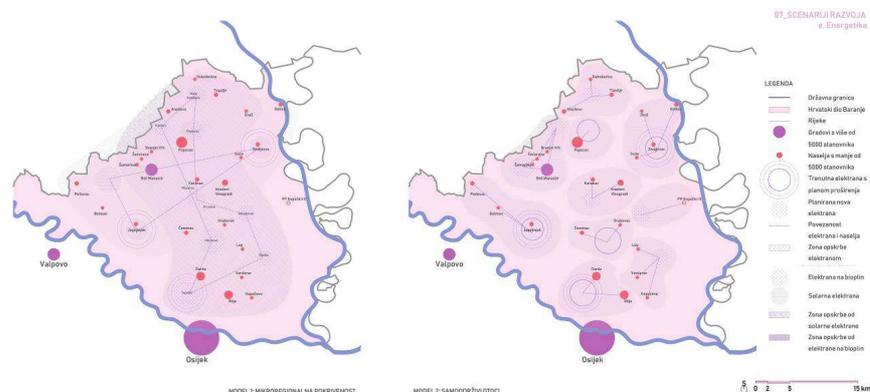

Fig. 6: Development Scenario: Energy – Microregional Coverage Model (left) and Model Self-Sustainable Islands (right). Source: Banić, 2023a.

The microregional coverage model proposes the creation of a microregional energy network that would equally supply the entire Baranja area. This model does not assume power plants next to every farm. It is based on total production which has to be equal or greater than the total energy consumption of each microregion. Two overlapped networks are shown - the network of solar power plants and the network of biomass power plants.

The self-sustainable islands model envisages the construction of power plants next to group of settlements in order to provide the source of energy for each "energy island". In this way, an even development and energy independence of all settlements would be achieved, while power plants in terms of energy production are assumed to be the same as in the previous model.

4.2.6   Industry

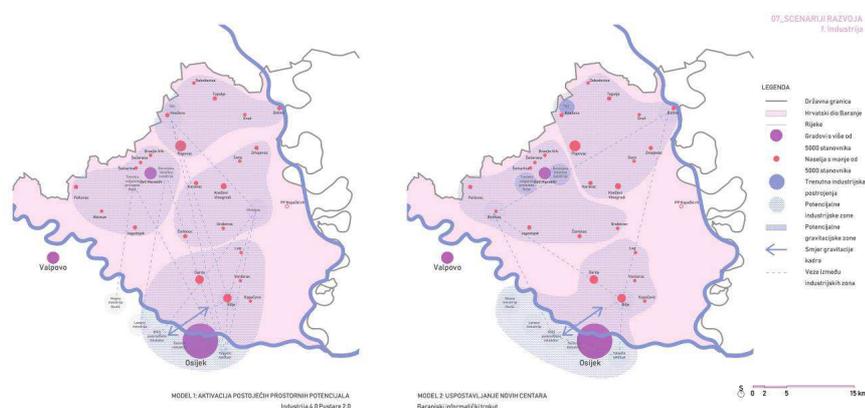
The Baranja region has a rich industrial history. For centuries it has been the center of the Belje agricultural estate, with seasonal migrations of workers from various regions. The process of deindustrialization led to the fact that the former industrial plants are now mostly abandoned, with the exception of a few smaller factories. Former factory workers today mostly daily migrate towards the city of Osijek. The scenario envisages the transformation of existing industrial facilities for the needs of new technologies, in accordance with global trends, which would lead to changes in migration process. (Bug, 2018)


Fig. 7: Development Scenario: Spatial Potential Activation Model (left) and New Centers Model (right). Source: Banić, 2023a.

The model of activation of existing spatial potentials proposes the conversion of former "pustara" settlements and other brownfield areas for the needs of information technology. The establishment of an IT campus in one of the "pustara" settlements (e.g. Mirkovac or Kneževo) would enable a strong relationship between professional staff and students with Osijek.

The model for the establishment of new centers foresees the activation of hitherto inactive industrial areas and suggests Batina, Bolman and Bilje settlements as centers. Their peripheral location encourages activities related to international cooperation with neighboring countries. The scenario is based on smaller business incubators and the idea that IT companies are not necessarily tied to a specific location.

4.3 Vision of Development and Revitalisation of Barnja Region - Re: Baranja

The comparative analysis of six scenarios and the valorization of elements of different models according to the set criteria resulted in a combination of scenarios providing that the integral scenario has an impact on the further development of the Baranja region as positive as possible. The integral scenario represents the basis for development vision and revitalisation of the Baranja region. The proposed vision particularly activates the settlements of Suza, Šumarin, Darda, Čeminac, Bilje, Kneževo, Jagodnjak and Mirkovac, as well as farms and agricultural fields.

In order to realize the vision, macro and micro projects have been proposed, with a defined period necessary for the realization of each project.

Macro projects include various infrastructural, marketing, educational and digitization projects. Planned infrastructural projects include extending the LAN/optical network through all settlements as a prerequisite for digitalization (seven years), increasing the capacity of existing power plants as a prerequisite for the energy transition (ten years), connecting existing producers as a step in the digital transition (two years), maintenance and management of IT systems as an accompanying process to digitization projects (continuous process). Marketing projects include integration of the tourist offer and promoting new destinations as a step in the activation of tourist destinations (three years) and connecting renovated manors into a regional or international network as a step in the activation of tourist destinations (five years). Digitalization projects include digitalization of services as a prerequisite for the realization of smart villages (five years). Education projects include digital education of the population as a step in the revitalisation of the village (two years + continuous), education of farmers as a step in the improvement of agriculture (two years + continuous) and cooperation with Osijek faculties as a result of digital and industrial improvements (continuous).

950

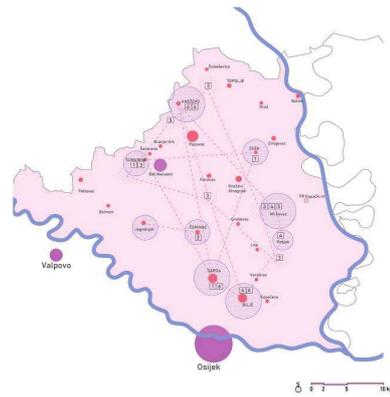
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Fig. 8: Development and Revitalisation Vision of the Baranja Region. Source: Banić, 2023a.

Micro projects at specific locations were also proposed (Figure 8): 1) establishment of IT incubators with server centers, 2) establishment and construction of a processing and distribution center, 3) construction of new power plants (biogas power plants in addition to existing farms and solar power plants); 4) conversion of abandoned brownfield sites for new industry, 5) construction of the IT campus and 6) revitalisation and conversion of manors.

4.4 Kneževo

The special emphasis is on Kneževo, a small settlement with historically significant urban and industrial features (one of the main centers of the Baranja region after the WW2), which experienced a significant economic and demographic decline due to deindustrialization trends in the late 20th century.

4.4.1 "Pustare" in Croatian part of Baranja

Kneževo represents one of the seventy "pustara" settlements in Croatian part of Baranja. The basic meaning of "pustara" comes from the Hungarian word "puszta", which originally refers to a spacious plot of land intended for open-air cattle breeding. In Croatia, "pustare" represent planned industrial settlements with residential areas and public and social facilities (educational, cultural, administrative, etc.). They are located in rural areas and have a rural-urban character. Their history is connected with the manor estate, and later with the industry of Belje. In 1697, Archduke Eugene of Savoy acquired a property on the southern border of Baranja, in today's Bilje, where he builds a manor from which he manages the entire property and economy of Baranja region. In 1825, the center of Belje moved to Kneževo, when intensive industrialization and the construction of most "pustara" settlements began. After WW1 they have been adapted to new industrial conditions and additional facilities were constructed, which resulted in improved quality of life. Although located in completely rural environment, settlements gained urban characteristics which makes them unique construction complexes. (Živković and Horvat, 1986)

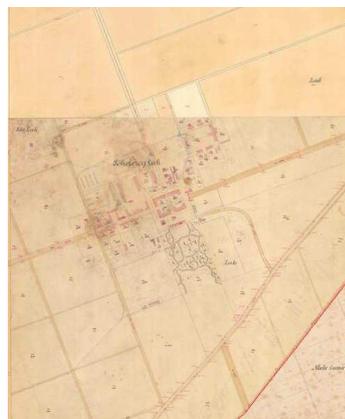

Fig.9: Kneževo on the 19th Cenutry Habsburg Empire Cadastral Map. Source: Arcanum (2023).

Settlements usually have an orthogonal urban scheme, simple rectangular buildings and a central administrative building with a landscaped park. They are characterized by division into three zones; production/agricultural, residential and administrative/social zone. Originally, they did not have the cemetery

or the church. They are low density settlements, mainly with collective one-story buildings with several apartments (6-12 housing units) and shared auxiliary buildings in the garden. The apartments of managers, administrators and doctors were located in separate buildings of a higher standard in the administrative zone. The agricultural or production zone depended on the economic branch and contained stables and warehouses, and later industrial halls and industrial facilities. (Ravas and Stober, 2017)

4.4.2 Specificities of Kneževo

The village of Kneževo is located in the very north of the Croatian part of Baranja, in Osijek-Baranja County, in the municipality of Popovac. The municipality of Popovac, which includes the settlements of Popovac, Branjina and Kneževo, is on the border with the town of Beli Manastir to the east and the municipality of Draž to the west. According to the 2021 census, the municipality of Popovac has a total of 1,446 inhabitants, and the settlement of Kneževo has 485 inhabitants.

The development of the Kneževo settlement dates back to 1818, when the construction of the manor of the Archduke Friedrich Habsburg began by the order of the Habsburg Emperor Karl Ludwig. Various commercial and administrative buildings had been built next to the manor, gradually forming the settlement. Since the end of the first third of the 19th century, Kneževo has been the seat of administration of the Belje estate. Intensive development followed the industrial revolution and construction of the railway in the 1890′s. Until 1914, the settlement was connected by a narrow-gauge railway to Beli Manastir, and from there to other pustara settlements and the river wharf on the Danube. After the collapse of the Austro-Hungarian monarchy, the property became the state property of the Kingdom of Yugoslavia. The period between two World wars was marked by production stagnation and economic decline. During the WW2, the settlement was devastated, and production stopped. With the establishment of Yugoslavia, Belje experienced a transformation into the Belje agricultural-industrial complex as a federal agricultural asset, the intensive reconstruction of settlements and production began, and in the 1950s and 1960s Kneževo had a population of around 1,600. In the 1980s, new plants were built as part of the food industry, but due to the war in 1991, production stopped on the entire Belje estate. After the war it has been only partially restored. (Kukulić, 2021)

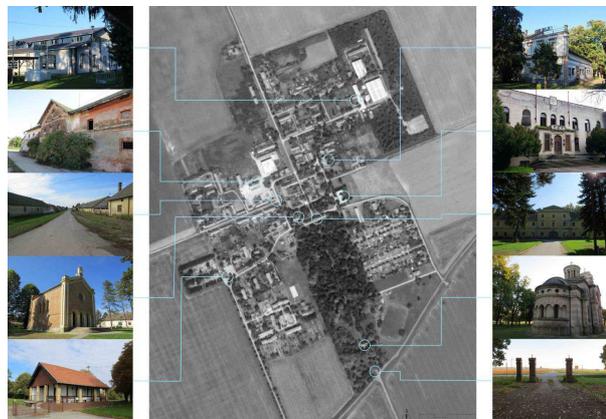

Fig. 10: Characteristic Buildings in Kneževo. Source: Banić, 2023b.

The central element of the settlement is a classicist manor with a 11 hectares park, which represents a valuable example of classicist residential architecture. It is a protected cultural heritage, enlisted in the National register of cultural assets. The transverse (NW-SE) axis of the manor forms the orthogonal axis of the entire settlement. Next to it, the oldest part of the settlement with administrative and commercial buildings that make up the block northwest of the manor and continue into the two main streets is situated. The buildings on that stretch are mostly single-story residential blocks with 4 to 10 residential units, each with separate entrances and auxiliary buildings in the garden. The apartments of clerks and coachmen were originally located in that block. In the southeastern zone, along Graničarska Street, production facilities and apartments for workers were situated, while southeast of the manor there were public facilities: school, kindergarten, teacher's apartment, clerk's apartments and a church. Northeast of the manor in the same axis there were the doctor's and dentist's apartments and the infirmary. A cemetery was built outside the rectangular base of the settlement along its western edge, and the existing railway station was converted into a morgue. The northern zone of Kneževo was a production area, with industrial production (mechanical

952

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

workshop for locomotives and machines, a steam mill and a brickyard) in the eastern part, and agricultural warehouses and stables in the western part. The architecture in the settlement is unusually representative, the brick buildings have numerous design details, profiled wooden beams and decorated brick fences and portals Numerous public facilities and the architecture quality of buildings clearly indicate that the conditions and quality of life in "pustara" were above the standards of the time. (See Figure 10)

The new zone of the settlement consists of two parts, with apartment buildings to the west of the park and family housing area east of the park. In the late 1980s, five multi-apartment two-story buildings were built, housing a clinic, a shop and a cafe, while a new primary school was built next to the park. Most of the residents live in the area with family houses that have been built since 1980s.

Public and social buildings and service facilities are located in the southern part of the settlement. In the old part, north of the manor, there is a local post office and the area of the local board. Most of the facilities (local general practice clinic, dentist's office, pharmacy, cafe and small shop) are located in the zone with multi-residential buildings west of the manor park. To the east of the park, there is a new community center and a soccer field. There are two churches in the settlement - the Catholic Church of St. Hildegarde northwest of the manor and the Orthodox Church of St. Gregory in the southern part of manor park. Along the eastern edge of the settlement, there is a local cemetery with a morgue.

In the northern zone of the settlement, there are remnants of the former industry and the Equipment and Machinery Factory plant, which today operates on a reduced scale. The settlement used to have a cinema, a restaurant, a hospital and a kindergarten.

Fig. 11 (left): Spatial Plan of Popovac Municipality – Land Use. Source: Banić, 2023b. Fig. 12 (right): Proposal for the Conceptual Zones of Kneževo. Source: Banić, 2023b.

The area around the settlement is surrounded by particularly valuable arable land and commercial forest. Northeast of the settlement, next to the planned business zone, there is an agricultural airport with a grass runway. In the area of Kneževo, there are three protected archaeological areas: Brickworks along the southeastern edge of the settlement (from the Roman period, dating from 1st to 3rd century BC), Buziklica - Malo Kneževo (from 5300 BC to 1400 AD) and Ćrna bara-Buziklica (from 800 CE to 1400 AD) northeast of the settlement, along the border with Hungary. The manor of Frederick II. Habsburg is a protected protected cultural heritage, enlisted in the National register of cultural assets, while the manor park is a monument of park architecture.

4.4.3 New Purpose as a Revitalisation Activator of the Settlement

Based on the proposed vision of the development and revitalisation of the Baranja region and detailed analysis of Kneževo settlement, the introduction of a new function is seen as a potential activator of its revitalisation. Based on the research and consideration of the most suitable scenario for Kneževo, the construction of a film studio is proposed, given that movies have already been filmed in the historic part of the settlement and that many of existing buildings have the potential to be transformed to be suitable for the needs of film production. The introduction of a new function would contribute to the development of culture and media at the national level, while the development of supporting functions and an increase in the number of temporary and permanent residents would contribute to the revitalisation of the settlement.

The National Development Strategy of the Republic of Croatia until 2030 (2021) states the development of culture and media as one of five priority areas of public policies, in order to achieve strategic goal 1. "Competitive and innovative economy". The strategy emphasizes that Croatia has been recently profiled as an attractive and cost-competitive location for filming series and movies of foreign production companies, thus attracting considerable foreign capital. This is supported by one of the most profitable state aid programs with a direct economic impact on the audiovisual industry, the international promotion of Croatia, but also the profitability of all related economic branches, primarily tourism. Feasibility studies for the project of a new studio complex in the Republic of Croatia sees Croatia as a possible location for international productions (Olsberg SPI, 2020). The availability of a film studio in the Republic of Croatia would generally enable a longer stay in the country and the realization of larger investments, which would have a positive economic and cultural effect not only at the local level but also at the regional and national level.

From a comparison of the European film studios Cinecitta in Rome and Studio Leavesden in London and the recommended parameters for planning, it is evident that, in terms of necessary area and existing structures, the historical part of the settlement is suitable for a film studio for international production.

4.4.4   Film studio in Kneževo

The existing organization of the settlement is based on two orthogonal axes. The concept proposes densification of the orthogonal street network in order to provide access to existing and planned buildings. The existing settlement is characterized by three zones in which specific interventions are proposed.

In the southern zone, on the area of the existing residential area, minimal interventions of new pedestrian paths are planned in order to connect residential areas east and west of the manor park. The northern zone, where remnants of former industrial complex are located, is planned for functional and structural transformation for the needs of an international film studio. The central zone is designed as a transition zone between the film studio and the residential zone. New public, social and tourist facilities are planned (facilities for film production participants, restaurant, auditorium, part of the film studio intended for educational and local needs, etc.). In the central part of the zone, preservation of the original architecture and its functional transformation according to the needs of new functions for both groups of users is planned.

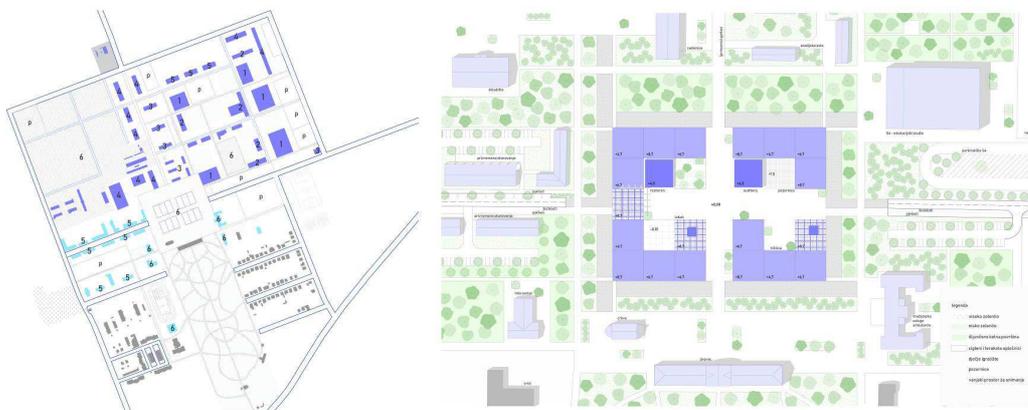

Fig. 13 (left): Planned Structure in Kneževo. Source: Banić, 2023b. Fig. 14 (right): New Central Square of Kneževo. Source: Banić, 2023b.

The system of planned public spaces together with the road network serves to connect and integrate the existing settlement and the planned film studio. The existing public spaces of the settlement (the manor park and the lawn north of the manor) are planned to be supplemented with a new, central square planned as a central public space for all users, while new squares and parks in the northern zone would have a semi-private character. The central square area is designed as a modern architectural interpretation of historical urban block, with public and commercial facilities (auditorium, market, catering facilities, etc.).

5   DISCUSSION

The spatial planning workshop is a platform where students are taught expertise in the processes of spatial / territorial development. In the last workshop before the graduation, students "practice" the application of knowledge acquired during their studies and acquire new knowledge about research and analysis, the field of

954

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

advocacy and mediation, the ability to imagine, evaluate and promote potential options for urban, spatial and territorial development. Students are encouraged to think critically and understand the logic of planning and its theoretical and legal basis, learn to understand spatial systems that, in addition to the built and natural environment, include socio-economic systems, and improve the technical and creative skills necessary for their inclusion in the planning practice.

The use of the scenario method in the education process, not only as a theoretical basis but also as practical application in workshops, is particularly significant because it encourages strategic thinking, the development of intuition and helps to overcome thinking limitations. In order to enable a comprehensive overview of the needs and possibilities as well as aspirations of various stakeholders, the development of several possible scenarios is particularly important, above all for an open discussion and flexibility in the later process of creating a spatial development vision.

The result of this case study is the definition of six possible scenarios for the Baranja region development which are further broken down into two basic models of space activation approach. Various scenarios give a better overview of the spatial possibilities and create a basis for evaluation and decision-making on the direction of further development. Conceiving scenarios based on the global sustainability goals indicates an awareness of the importance of development based on global principles, which through planning and interventions at lower levels contribute to the achievement of global goals.

The possibility to choose an area or location as a task of the spatial planning workshop according to the detailed selection criteria, opens up the possibility to do planning tasks in a familiar area or an area students want to perceive better. In addition, there is the possibility of connecting the task at the spatial planning workshop and the graduation thesis, which enables a more detailed elaboration of the chosen location, and a critical reflection of planning decisions with an offset of one or two semesters.

This paper shows how the work which was focused on the regional development and revitalisation scenarios for Baranja region is in the next step focused on Kneževo, a small settlement with historically significant urban and industrial features which, due to the dynamics of business and deindustrialization trends in the late 20th century experienced a significant economic and demographic decline. The development and revitalisation vision of Baranja region set a wider framework for development planning of the Kneževo settlement, i.e., the settlement was singled out as one of the primary regional centers. On the basis of the knowledge about the specific location and consideration of the national needs defined by the National Development Strategy of the Republic of Croatia until 2030, a new urban function of the film studio was chosen as the optimal activator of the settlement′s revitalisation. The implementation of "unusual" facility in the area represents a challenge in the process of planning and design of the necessary infrastructure, while meeting the needs of film studio users and permanent residents, in terms of achieving the best possible quality of life. By introducing a new cultural and media industry in Kneževo, in addition to contributing to the revitalisation of the settlement at the local level and in the regional context, the former industrial character of the area would be preserved, and at the national level it would contribute to the realisation of one of the strategic national development goals - the establishment of a "Competitive and innovative economy".

6 CONCLUSION

In addition to the theoretical knowledge in spatial planning at the local and regional level acquired during the studies, practical application is essential in order to prepare the future planner for the roles that await him in professional practice. Spatial planning workshop is one of the platforms where strategic thinking is encouraged, research, analysis, synthesis, critical reflection and understanding of spatial systems are practiced, as well as forecasting and planning on different spatial levels. The possibility to choose a workshop according to personal affinity, respectively the possibility to choose both the subject area and specific the topic during the workshop represents an opportunity for further education and development of a visionary approach on the regional and the local level.

The scenario planning methodology is used in spatial planners' education in order to enable future planners to deal with complexity and predict the future development of cities and regions and to conceive consequences regarding specific interventions. Over and above, the scenario planning tool encourages

creativity and intuition and provides a possibility to think "outside the box" and at least one step futher in the future.

In addition to European documents on sustainable development, national, regional and local strategies and plans relevant to territorial development and existing spatial planning documentation are taken as starting points. Students are encouraged to take a comprehensive overview of the area and development process and to determine the scenarios evaluation criteria as a basis for development vision concept. Critical thinking of planning decisions, and consideration of causes and consequences through specific development projects is the basis for creation of new spatial planning documents. Flexibility in planning is a characteristic that stands out as particularly important for achieving harmonization of dynamic circumstances in space and time with the set goals of the long-term development and the legislative framework, in order to accomplish a better quality of life, i.e. sustainable development of the selected area.

1 ABSTRACT

Active mobility is a key factor in the mobility revolution and is thus elementary in combating the climate crisis. At the same time, however, much research is still needed to improve the situation of active mobility, especially regarding inhibiting factors in the choice of active modes of transport. Essential here is road users' positive and negative emotional experiences in different infrastructure settings.

Due to high volumes and speeds of motorised traffic, high noise and pollution levels and a lack of greenery urban space, today is often associated with increased stress and an excess of stress-related diseases such as cardiovascular diseases, depression, or schizophrenia (Adli, 2017). Providing data and objectifying much-discussed issues such as perceived safety in transport infrastructure is essential for decision-making at the community level (Sørensen, 2009). Such data can provide evidence to refine traffic planning guidelines and improve public space for pedestrians and cyclists. It is therefore necessary to get a differentiated picture of social and ecological considerations in the mobility sector.

The BMDV project "Emotion Sensing for (E-)Bicycle Safety and Mobility Comfort ESSEM" investigates the subjective perception of cyclists' safety in urban traffic. With the help of iterative environmental and body-related data collection, stress points in the municipal cycling network are identified and analysed in the two model cities of Ludwigsburg and Osnabrück .

The framework given in this study applies a triangulating approach that allows statements on individual "stress" utilising biological markers (skin conductivity, skin temperature) via a sensor wristband and through standardised questionnaires. In this way, vulnerable groups can be identified, which can be better taken into account in project development and planning. This study focuses on three "stress hotspots" in Osnabrück, considering different forms of bicycle infrastructure.

Keywords: Transportation Planning, Streetscapes, Bicycle Infrastructure, Well-being, Urban Stress

2 INTRODUCTION

To plan ecologically, spatially and socially sustainable and equitable cities of the future, one starting point is to move human perception to the centre. Especially in the field of active mobility, such as cycling, people are directly exposed to their environment. Projects such as the "Emotion Sensing for (E-)Bicycle Safety and Mobility Comfort ESSEM", funded by the German Ministry of Digital Affairs and Transport, focus on researching stress in cycling. On the one hand, body-related data are collected that can indicate a stress reaction in the body. These are geo-referenced and subjective data can thus be made objectively comprehensible in the form of heat maps in QGIS. The results represent an indicator of the subjective perception of safety. Spatial specifics, such as guidance forms and street intersections, have a significant role to play here. On the other hand, different people have different perceptions due to their different characteristics, which also shape the perception of stress. These can be collected through e.g. standardised questionnaires. The ESSEM project takes place in the model cities of Osnabrück and Ludwigsburg. The present study focuses on the results of the research in Osnabrück. The following research questions are guiding:

(1) Where do cyclists in Osnabrück feel stressed?

(2) To what extent do personal dispositions, such as gender, age or personality play a role in this?

(3) To what extent can statements be made about the connection between different designs of bicycle infrastructure and stress?

3 STATE OF RESEARCH

The state of research focuses on the perception of safety, measuring stress and influencing factors.

3.1 Perception of safety

One pillar of the mobility transition in Germany is to increase the share of cycling (BMDV, 2022). Obstacles to changing the mode of transport are manifold. An essential part of this is the perception of safety. On the one hand, there is objective safety. This can be quantified in the form of police accident statistics. At the same time, subjective safety must be taken into account (Johannsen, 2013). This is of great importance when choosing a means of transport. This subjective perception is determined by various factors. On the one hand, there are "exogenous" factors, i.e. external structural factors. These can lead to critical situations, near-accidents, a feeling of being squeezed or a noise-induced stress reaction. The resulting stress in cycling can therefore negatively influence the choice in favour of cycling and is, therefore, an important starting point for research (Graf, 2016). Various personal dispositions "endogenous factors" diversify the picture. For example, there are differences in people who generally use bicycles little, in gender, the purpose of travel, age and the psychological constitution of people when assessing stressors (Schmidt-Hamburger, 2022). When researching stress phenomena and their harmful effects on the human body, it is above all relevant how strongly the respective person evaluates and thus also feels the experienced stress. This subjective stress evaluation can be further specified by adding information about the mobility profile, socio-demographic and socio-psychological assumptions. The endogenous influencing factors refer to individual demographic, socio-economic and sociocultural attributes of individuals and their social environment, which significantly influence perception (Wermuth, 2005). Examples of relevant factors are gender, age, physical constitution, local knowledge or familiarity with the means of transport. Furthermore, from a biopsychological point of view, there are indications that genetic or psychological predispositions can strengthen or mitigate stress reactions. In this context, personality, control beliefs and risk tolerance are particularly important (Schandry, 2016; Kovaleva, 2012). These data are collected utilizing standardized questionnaires before the sensor measurements and included in the evaluation. It is hoped that this will identify particularly vulnerable groups in terms of stress to gain knowledge about barriers to equality for cyclists. Further insights can be gained from the increase in cycling behaviour. According to Geller (2009), cyclists can be divided into four groups: "the strong and fearless", "the enthusiastic and confident", "the interested but concerned" and "no chance, no matter what" (Geller, 2009). An overview of the characteristics is given in Table 1. The transitions between the groups should be viewed dynamically.

Group	Fearless cyclists	The enthusiastic and confident (Everyday cyclists)	The interested but concerned (Interested cyclists)	No chance, no matter what
Characteristics	• cycles always • safely, confident	• Drives daily routes, • confident, medium safety needs	• No everyday cycling • Safety concerns • open-minded towards bicycles	• No cycling in general
Riding skills	Excellent control of the bicycle	Confident, partly defensive because of security	Less sovereign	Poor control of the bicycle, lack of riding experience
Stress tolerance	high	medium	low	very low

Table 1: Types of cyclists (Geller 2009), own presentation.

In terms of cycling promotion, it is interesting in projects such as ESSEM to focus especially on the stress-ful experience of the "interested but concerned".

3.2 The construct of stress

Stress theories differ in terms of adaptability and operationalizability. Stress always arises when, depending on the theoretical underpinning, the physique (stress-as-a-reaction) or psyche (stress-as-a-stimulus or stress-as-a-transaction) has to muster resources to process environmental stimuli. The most prominent is the transactional stress model according to Lazarus (1999), but at the same time, it is also the most com-plex, since stress always arises situationally in the interaction of people and the environment. On the other hand,

there are stress-as-a-reaction models (Selye, 1956; Cannon, 1932), which examine the physical reac-tions to an external stimulus (Bercht, 2013). Critical here is the assumption that a stimulus "stresses" all people equally (Lyon, 2005). The third group of theories, which understands stress as a stimulus, focuses on the psychological effects. Here, it is assumed that there are "critical life events" (Holmes, Rahe, 1967) that are objectively trigger stress to some extent. Due to developments in emotion research in this field, the stress-theoretical basis of this paper is more in line with models from the stress-as-a-reaction perspec-tive. However, subjective components are included in the data collection and analysis.

3.3 Influence of street space on the subjective perception

Safe infrastructure can be named as one key contributor to the promotion of bike traffic in cities (Reyn-olds, 2009; Di Gioia, 2017). Here different design solutions are discussed controversially in the light of conflicts in the use of street space, and space restrictions but also about safe and qualitative bike infra-structure (Hull, 2014; Autelitano, 2021; Van Petegem, 2021). Traffic engineering, therefore, was mostly focused on objective traffic safety, focusing solution finding for certain street designs on the analysis of accident statistics and fluidity of motorized traffic. A more comprehensive evaluation of safe mobility in-frastructure and in particular bike infrastructure today discusses the aspect of subjective safety in addition to quantifiable objective traffic data (Götschi, 2018). Subjective safety among other aspects takes a look at how street users feel in certain contexts, or if they are overwhelmed by other road users, like cars. Multiple studies show the extent of research and debate on the topic (Von Stülpnagel, 2022; Aldred, 2018; Beck, 2021; Nilsen, 2004). All in all the subject takes into account the sense of security and besides positive per-ceptions like comfort, or well-being, the feeling of aforementioned stress.

Today the aspect of subjective safety, or rather safe and comfortable design solutions finds recognition in more and more design manuals of bike infrastructure like the Dutch "Crow Manual", especially consider-ing more vulnerable groups of cyclists like children or elderly people (De Groot, 2016). In Germany, the FGSV (Forschungsgesellschaft für Strassen- und Verkehrswege) addresses the topic of subjective safety, though it can be argued that it's still not implemented in the design solutions of its manual for bike infra-structure the ERA (Empfehlung für Radverkehrsanlagen) or it's manual for city streets, the RAST (in German: Richtlinien für die Anlage von Stadtstraßen/ "Guidelines for the construction of urban roads"). This shows that data and an extensive analysis of the stress experienced on certain cycleways, or rather certain street design solutions are still missing. This data and the aspect of subjective safety have to be evenly balanced with other data like accident statistics, or the capacity of street design and intersections for all street users, e.g. Here the concerns of pedestrians and other social uses of urban streets besides mo-bility have to be highlighted (Gehl, 2015).

4 DETAILS ON ESSEM

The "Emotion Sensing for (E-)Bicycle Safety and Mobility Comfort, ESSEM" project, the subjective safety perception of cyclists in urban traffic. The project aims to increase the comfort and safety of cyclists and thus contribute to sustainable and climate-neutral mobility. In a triangulation process consisting of iterative and sensor-based surveys of environmental and bio-physiological data and standardized questionnaires, stress points in the local bicycle infrastructure are being identified, analyzed and evaluated. The two model cities are Ludwigsburg and Osnabrück, in each around 350 test persons participate during the three-year project period (2022-2025).

The project data collected will be used to develop mechanisms for measuring safety, the perception of safety and mobility comfort in cycling, based on the underlying infrastructure, environmental influences, the cycling equipment used as well as the cycling accessories. The insights gained will help to identify optimization needs for (e-)bicycle infrastructures and components. This will promote modern, user-centred and data-based cycling planning and further advance environmentally sensitive traffic management (UVM) in Osnabrück. In the long term, the project aims to develop an innovative, and above all, practical tool that can be used to review and optimize urban cycling infrastructures.

5 METHODOLOGY

A triangulating procedure between methods (Flick, 2008) is used to research the stress experience of cyclists. With this method, the disadvantages of one method can be compensated for by the addition of another during

data collection, analysis and interpretation. The subjectivity and complexity of the research object require a methodological procedure that reflects these circumstances (cf. Chapter 3.2).

The following Figure 1 provides an overview of the methodological approach. Triangulation was used in the study for data collection (standardized as well as open, sensor data), analysis (spatial and statistical) and interpretation.

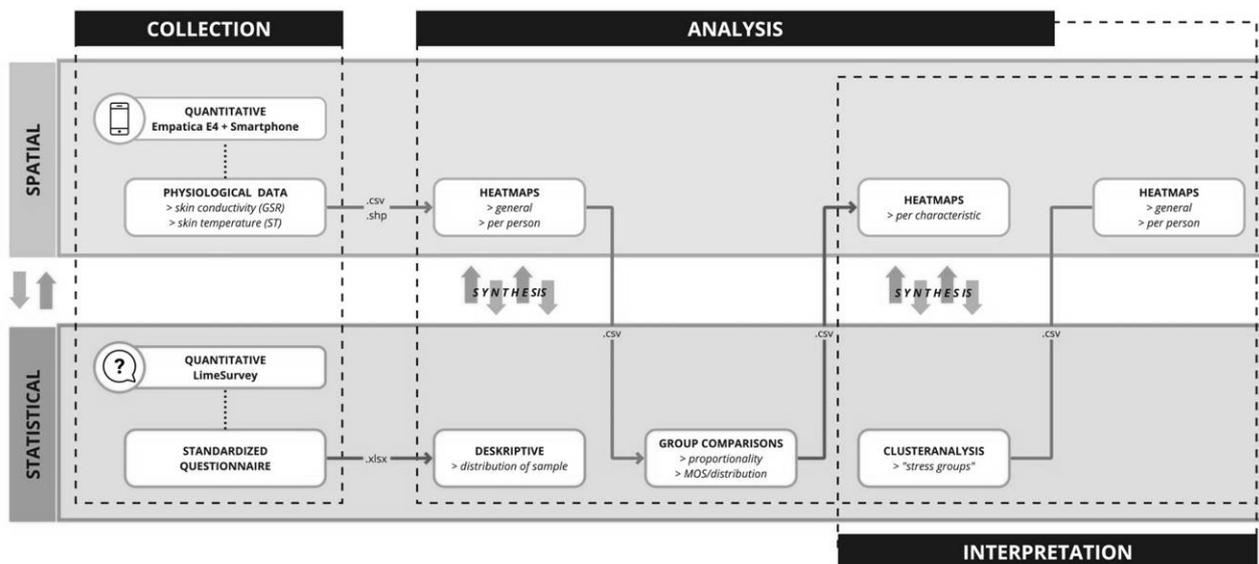

Figure 1: Scheme triangulating process, own presentation

5.1 EmoCycling

Measuring stress in terms of response is feasible, although theoretical limitations must be accepted. Biological indicators are used to identify moments of stress (MOS). When confronted with a stressor, the human organism regulates endogenous stress responses to establish homeostasis. These responses are detectable through a variety of body-related parameters and are recognized as a proven method for measuring stress from external stressors. These include an increase in electrodermal activity (EDA) and a decrease in skin temperature (Kyriakou, 2019; Schandry, 2016). Based on the functioning of these biosignals, Kyria-kou et al. (2019) developed an algorithm that can detect people's MOS using wearable biosensors. The biosensor wristband "E4" from the company Empatica was used to measure the biosignals. The data is collected in an app (e-diary) on a smartphone. The result is a database in which one line corresponds to one sec-ond of the measurement period and provides information about a MOS (yes/no) and its geographic coordi-nates, which can thus be read and visualized in a geographic information system (GIS).

The procedure of recording biostatistical data in a georeferenced manner and following the visualization in maps goes back to Christian Nold (2009). The "emotional cartography" (Nold, 2009) allowed humans and their physiological responses to serve as a kind of sensor for the first time, recording the state of stress or arousal in an urban context. Different developments in the technology itself (e.g. storing of measured EDA and ST in smartphone application) and the methodology (e.g. including ego-perspective cameras) hap-pened since then accumulate under the term "EmoCycling" (Zeile, 2016).

5.2 Standardized questionnaire

Additionally, "EmoCycling" a standardized questionnaire based on validated scales of mobility in Germany (2019) from the BMDV (Nobis, Kuhnimhof, 2018), Leibniz Institute for Social Sciences (GESIS) and Geller's (2009) types of cyclists was developed to record endogenous factors. The questionnaire was used to collect information about the person and his or her sociodemographic background as well as psychological characteristics in addition to traffic behaviours. The personality of individuals is traditionally determined based on the so-called Big Five, which consists of the characteristics of extraversion, neuroticism, openness, conscientiousness and agreeableness. The Big Five are considered to have good predictive power for certain aspects of life. The level of control beliefs describes a person's belief that he or she has control over various situations and that these are the result of his or her actions (internal) or that fate, coincidences, or powerful

962

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

others are responsible for the occurrence of certain events (external) (Rammstedt, 2012; Ko-valeva, 2012; Beierlein, 2014). The degree of control belief is a relevant factor in the evaluation of a stress reaction (Brosschot, 1994).

5.3 Implementation and analysis

The data collection of ESSEM is divided into different phases in each city. This paper presents results from the first period in Osnabrück which took place in September 2022. 30 Participants were to fill in the standardized questionnaire and then were equipped with the sensor wristband and the smartphone which collected the measured EDA and ST. In the following, they collected their data on bike rides in their day-to-day life within two weeks. More detailed information on the former phases of the project can be found in Zeile et al. (2023).

For the data analysis, so-called heat maps were created based on the MOS and endogenous factors. This makes it possible to gain insight into the locations where a large number of MOSs of different individuals occurred. Further analyses focusing on the endogenous factors of the participants were performed by appropriate statistical analyses. In the first step, an overview of the distribution of the expressions was obtained. For this purpose, the distributions of the expressions and the MOS were examined (cf. Table 1).

In this paper cycleways on major streets in cities with a higher amount of motorized traffic are examined and correlations between stress levels and certain design solutions like advisory bike lanes, or "sharrows", separated and protected bike lanes are further examined. To further examine the underlying hypothesis that protected bike lanes and distance to other road users (e.g. cars and pedestrians), different designs of bike infrastructure in Osnabrück are superimposed with the data of the stress levels through the EmoCycling-methodology. Major urban roads are selected because here design solutions differ the most. On minor side streets designs mostly call for mixed traffic and generally speaking can only differ in ordinances like the Bicycle Streets, or more precisely the German "Fahrradstraße ". Major arteries in cities on the other hand are characterized by high traffic volumes, and high speeds and are oftentimes the most direct connection from A to B. Therefore, the analysis of subjective safety concerns concerning design solutions for this kind of infrastructure is of great interest. The analysis focuses on the areas in Osnabrück (cf. Figure 2). Those areas show different streetscapes which made it suitable for our analysis.

(1) Berliner Platz is located at the eastern end of the inner-city ring road "Am Wall". It is characterised by an extremely high vehicle load (evening peak with 3.633 vehicles/h and 345 bicycles/h). The bike lanes mostly show widths below standard, partly < 1.5m. In addition, bus lanes and high pedestrian volumes exacerbate the use of space (Heinke, 2022).

(2) Katharinenstraße is one of Osnabrück's "Bicycle Streets" with mixed traffic. It originates in the west outside the inner-city ring and ends at the inner-city ring. To reach the city center waiting at traffic lights is necessary. Katharinenstraße is highly frequented, but narrow for cycling volumes (pulks), overtaking is not possible. Left turners have no striping/space around to avoid possible oncoming traffic (Heinke, 2022).

(3) Lotterstraße/Am Wall: This intersection is located in the northwest of the city center. Very high traffic volume and the lack of objective safety already resulted in a temporary reconstruction (From the north). The bike lane was moved to the edge of the roadway and is now protected. Currently still under construction, which narrows the space. From the other directions the cyclists either ride on the bike lane in the middle of the road (from the west) or on the bus lane (from the south) (Heinke, 2022).

6   RESULTS, PRESENTATION AND DISCUSSION

30 persons were registered for the data collection. Three were prevented from attending at short notice and one person had not completed the questionnaire. In this context, a pseudonym to anonymously match the MOS and the information from the questionnaire was created. Table 1 provides an overview of the composition of the sample.

In the selection of participants, care was taken to ensure gender parity. This is reflected in the sample. The average age was 45 years. Of the participants, 42% had a university degree, and the educational level can be classified as fairly balanced. In terms of cycling types, there is a preponderance of everyday cyclists (70%), followed by interested cyclists. Most bicycles are powered by muscle power (60%). Overall, transportation infrastructure is rated as poor (46% find this at least poor). On average, participants were more likely to be

extraverted, neurotic, and open-minded. The characteristics of conscientiousness and agreeableness were rather low. The level of internal locus of control was more pronounced than the external locus of control. People tended to be viewed as more likely to believe that they are causally responsible for their actions rather than external forces. In addition, people are more likely to be risk averse (62%).

The 26 participants had a total of 11,996 MOS after adjustment. Average 461 MOS. The median is 443. The range is from 108 to 1205.

Variable	Description	$N_{participants}$=26 (in %)	N_{MOS}= 11996 (in %)
F1a	Age (>45)	54	61
F1b	Gender (female)	46	46
F1c	Education, high	42	
Cyclist	Cycling types

Table 2: Descriptive Analysis of the sample, own calculations

Figure 2 shows the heatmap of the MOS in downtown Osnabrück. After evaluating the interconnections of the volume and the bicycle infrastructure at the hotspots, no significant difference could be found. The underlying hypothesis that protected bike lanes have a positive impact on cyclist exposure could not be confirmed in this case. Here further research is needed as analysis of a short strip of around 150 meters at Heger-Tor-Wall did not show any MOS. Another crucial finding is the occurrence of hotspots especially at intersections, where different vehicles cross, noise is generated, and the situation is confusing. Situations like this a further examined in the following.

In further examination, the situation and potential stressors at those spots have to be observed with camera systems. Surely factors such as time of day and quantity of vehicles must be considered to obtain are more differentiated picture, especially on the effect of streetscapes, especially the design of bicycle infrastructure. Therefore, a comparison of morning or evening peaks at different cycling infrastructures would be favourable.

The analysis of the three study areas showed the following results, underlying some early findings of the research conducted concentrating on two major intersections and Katharinenstrasse a main bicycle route converted to a "Fahrradstraße" in 2011 (Martens, 2011).

964

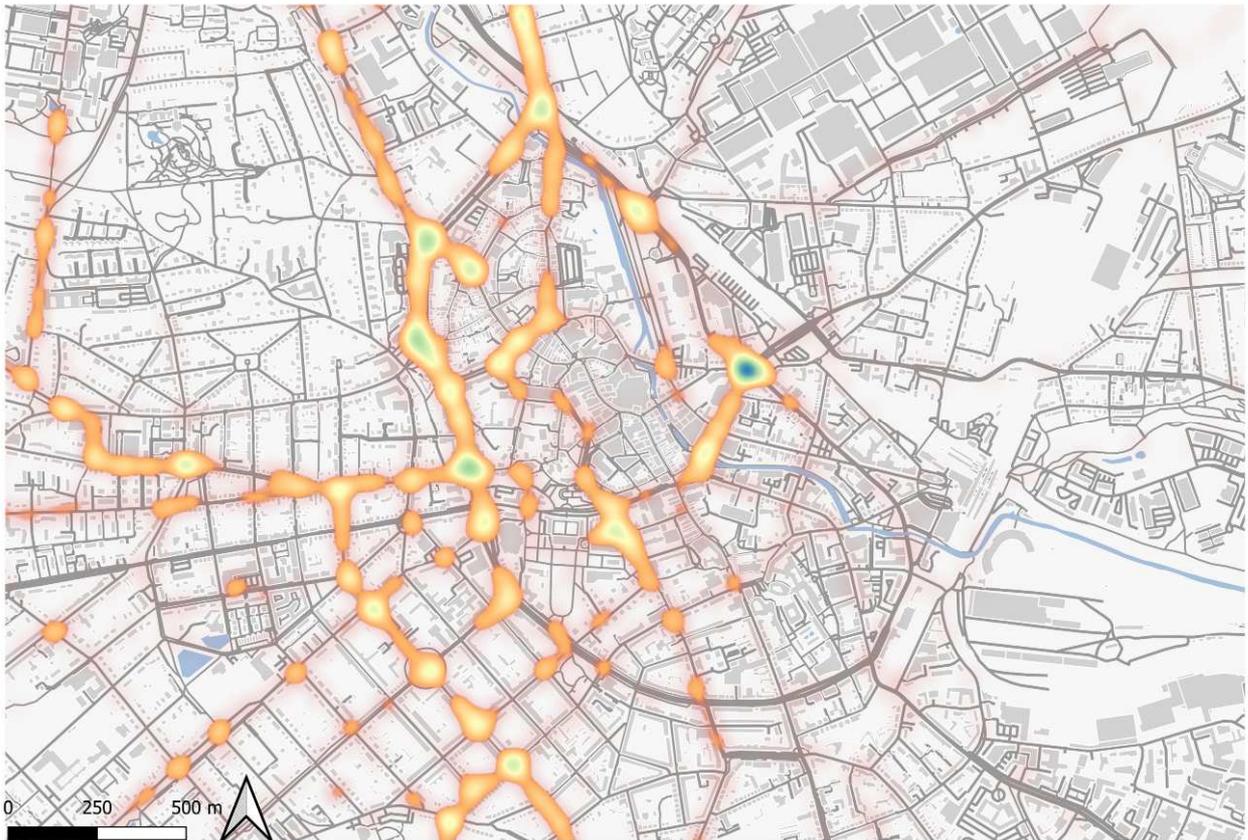
REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Figure 2: Heatmap of the MOS in Osnabrück with focus areas (1:20,000). Own figure based on OSM contributors. 21.06.2023

As Figure 2 shows, the Berliner Platz (1) shows the highest accumulations of MOS in the research area. This main intersection is characterized by high amounts of motorized traffic connecting the ring around the city center with one main artery leading out of the city to the east, the Wittekindstraße. Including the main bus routes the intersection also handles high amounts of bike traffic, as the data shows. Besides dedicated bus lanes, the distribution of street space is mostly dominated by 4-6 lanes, including turning lanes, for motorized individual traffic. The bike infrastructure here is characterized by painted bike lanes and no separation in construction by bollards, curbs or other measures. At the same time turning lanes for car traffic are crossing the bike lanes and cyclist turning left are expected to wait in the middle of the intersection waiting for their signal.

"Berliner Platz" (cf. Figure 3) can be named as a standard example for the design of many major intersections in German cities, including design choices standardized by main guidelines like the RAST, that are discussed in the section above (FGSV, 2006). The amount of MOS in this area shows the need to rethink design choices in the light of subjective safety and the general quality of bike traffic especially in intersections. Further analysis aims to prove the hypothesis mentioned above, questioning intersection designs mainly focused on red paint with no real protective measures, besides aspects like traffic speed and street width.

Another main intersection in Osnabrück that show similar characteristics as Berliner Platz in its spatial relationships within the city, the inner-city ring and outgoing main streets, here the Lotter Strasse. The intersection Lotter Strasse, Natruper-Tor-Wall (2) (s. figure 4) was redesigned converting one turning lane into a designated and protected lane for bike traffic.

On the other hand, the number of turning lanes and the general design of the intersection is very comparable with the situation at Berliner Platz. The research does not provide data before the redesign, but the MOS analysis shows some evidence towards improving stress levels in comparison to "Berliner Platz", which can be related to the redesign of the northern leg of the intersection. To confirm those findings further analysis is needed evaluating the questionnaires and other data comparing the findings at both intersections.

Figure 3: Photos of Berliner Platz (Maximilian Heinke)

Figure 4: Photos of Lotter Strasse – Natruper-Tor-Wall (left) and Bicycle Road Katharinenstraße (right) (Maximilian Heinke)

All in all, the data shows high amounts of stress levels or rather high accumulations of MOS. Relating problems in the design of those major intersections like this are discussed in literature and mobility panels under the aspect of subjective safety. Here protected intersections and roundabouts standardized in Dutch traffic guidelines (Rik de Groot, 2016) can be named as a possible design solution, that needs to be further examined using the methodology detailed in Chapter 5, adding quantifiable data to the discussion of road distribution objective and subjective safety of different street users, especially considering the needs of pedestrians.

Katharinenstraße (3) shows rather interesting findings. The street was redesigned as a bike street still allowing motorized traffic, but giving cyclist priority. The data shows high amounts of trips using Katharinenstrasse on different routes leading from east to west. At the same time, MOS data shows rather high amounts of stress. A closer examination of the street shows a high number of cars parking at a 45-degree angle with the street switching sides from north to south in between parking cars. In general, the street isn't characterized by high amounts of motorized traffic, so other possible stressors need to be further examined through questionnaires and further data analysis. At the same time the legal set-up of the "Bicycle Street" can be questioned concerning qualitative bike infrastructure not accompanied by real design changes including the reduction of street-side parking.

7 CONCLUSION

Contributing information to inhibiting factors of cycling was the main aim of this study. Embedded in the project "ESSEM", funded by BMDV 26 cyclists were equipped with sensor wristbands which measured their stress level whilst cycling in Osnabrück. In general, almost 12.000 so-called moments of stress (MOS) could be identified, geolocalized and visualized. The further analysis emphasized three "stress hotspots" where the

966

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

cycling infrastructure differs. In doing so no mentionable results concerning the streetscape could be pointed out. Meaning MOS showed up on protected bike lines, in mixed traffic and so on. Most of the hotspots are located at intersections, where different modes of transport meet and the situation is unclear.

8 OUTLOOK ESSEM

Data analysis at this point in the project shows several limitations to significance. The study design required participants to ride bicycles in everyday life to rule out MOS associated with study participation ("study effects"). The marked variation in routes and travel times severely limits the comparability of participants' MOS patterns. Further research should focus on comparing street patterns at peak times to provide more detailed information and opportunities to restructure intersections, e.g., to make traffic signal timing more bicycle friendly. Further, after analyzing the routes taken, it seems obvious that some streets or even areas were avoided completely because participants knew in advance that it was not convenient to ride a bicycle there. An important example is "Am Wall". This assumption was substantiated by responses from participants at a workshop in July 2023. Additionally, patterns of MOS by various personal dispositions such as gender, age or bicyclist type could not be considered for the time being. In addition to the small number of participants, the ratio of MOS to the number of bicycle trips made by bicyclists must also be integrated into the evaluation in order to conduct a meaningful statistical analysis. It is worth mentioning that this study and the other studies conducted by ESSEM focus mainly on the cycling domain at this point. In future studies, it is important to consider the entire transportation system when considering emotional responses.

These limitations will now be addressed in the upcoming project phases starting in September 2023. First, more test rides will be conducted, increasing the number of participants from 26 to about 120. In addition, a study design with pedestrians is being considered. To account for the non-comparability of the results provided and to allow studies to examine the role of personal dispositions, an additional study will be designed for spring 2024 to provide reference values. This study will be conducted during rush hour, will follow a pre-designed route that includes bypassed streets such as the inner ring road, and will be representative of all participants who participated in the prior studies. In a complementary way to spatial analysis, the data analysis is carried out by means of statistical group comparisons and cluster analysis (Schmidt-Hamburger, 2022). The aim here is to conduct an in-depth analysis focusing on the quality of the perception of negative emotions as inhibiting factors for cycling in Osnabrück.

1 ABSTRACT

Der Megatrend Urbanisierung stellt Stadtplanerinnen und Architekten vor die Herausforderung, auch in Zukunft die räumliche und strukturelle Gesamtentwicklung einer Stadt anhand den drei Säulen der Nachhaltigkeit auszurichten. Immer mehr Menschen zieht es in dicht besiedelte Gebiete, die Attraktivität der Großstädte wirkt auf die jungen Generationen gar wie ein Magnet. Aus der steigenden Nachfrage einer zentralen Unterkunft im Ballungsraum resultiert jedoch ein Ungleichgewicht aus sozialer, ökologischer und ökonomischer Betrachtungsweise. Ist der Zugang teurer Innenstadtwohnungen vermehrt der oberen Einkommensschicht vorenthalten, müssen sich einkommensschwächere Haushalte mit den frisch versiegelten Wohnflächen im Agglomerationsgürtel zufriedenstellen.

Der bezahlbare Wohnraum, eine ausgewogene Bevölkerungsdichte sowie der Erhalt von Grünflächen – all diese Faktoren bedarf es folglich unter dem Deckmantel der nachhaltigen Städtebauentwicklung zu vereinen. Ein bauliches Mittel zur Reduzierung der anhaltenden Problematik bildet das vertikale Wachstum. Die Aufstockung eines bestehenden Gebäudes mindert zum einen die Flächenversiegelung in der Breite; weiterhin wird neuer Wohnraum dort geschaffen, wo er die größte Beliebtheit erfährt. Die theoretischen Voraussetzungen dieser Erweiterungsmaßnahme im Bestandsbau lassen sich über drei Instrumente charakterisieren: tragfähige Gebäudestatik, rechtliche Zulässigkeit, lokaler Wohnraumbedarf vorhanden. Zeigen Fallstudien und abgeschlossene Beispiele ein hohes Wohnraumpotenzial durch vertikales Wachstum auf, bremsen rechtliche Herausforderungen eine großflächige Praxisanwendung. Um im Interesse der nachhaltigen Städtebaupolitik jene Baumaßnahme eines flächenschonenden Wohnraums häufiger zu realisieren, bedingt es zunächst einer selbstbewussten Auseinandersetzung mit den Bestandsobjekten. In der Folge helfen vereinfachte Genehmigungsprozesse (vgl. Wien[1]), eine stärkere Aufklärung sowie finanzielle Anreize, potentielle Investorinnen und Investoren für das Bauen im Bestand zu gewinnen. Abschließend können industrielle Vorfertigungen Baukosten, Produktionszeit und das Baumaterial nachhaltig beeinflussen.

Keywords: Urbanisierung, Stadtplanung, Architektur, Wachstum, Nachhaltigkeit

2 WAS BEDEUTET VERTIKALES WACHSTUM?

Vertikales Wachstum steht im bauplanerischen Kontext für eine räumliche Erweiterung von Bestandsgebäuden und -flächen ohne zusätzliche Bodenversiegelung. Auf europäischer Ebene wird die Baumaßnahme der Gebäudeaufstockung als Nachverdichtung angesehen. Im nationalen Sprachgebrauch hingegen bezeichnet man das Äquivalent im Fachjargon als Innenentwicklung, obgleich beide Wortbedeutungen dasselbe Ziel anvisieren: auf dem bereits vorhandenen Kostenfaktor Boden weiteren Wohnraum erschaffen, sodass potenzielle Flächen im Siedlungsbestand aktiviert und im Außenbereich geschützt werden.[2] Tragfähige Bestandsgebäude, brachliegende Flächen, Baulücken sowie Flächen in minderstrukturierten Quartieren – all diese Orte weisen durch eine mögliche Verdichtung- bzw. Innenentwicklungsmaßnahme ihr Potenzial auf, neuen Wohnraum zu erzeugen.

In diesem Paper erfolgt die Betrachtung jener Maßnahmen anhand des vertikalen Wachstums auf Bestandsgebäuden. Die folgende Erläuterung des gesamten Planungs- und Bauprozesses mit den resultierenden Nutzen richtet sich in erster Linie an Architekturbüros, die mit dem Auftrag einer Bestandserweiterung vertraut werden. Mithilfe des rechtlichen Betrachtungswinkels auf Ebene der Stadtplanerinnen und Stadtplaner erfolgt am Ende die Gegenüberstellung zwischen Potenzial und Hemmnissen für das vertikale Wachstum des zukünftigen Städtebaus.

3 INSTRUMENTE DES VERTIKALEN BAUENS

Jener Prozess ist als Schaubild unter dem Namen Instrumente des vertikalen Bauens dargestellt (vgl. Abbildung 1). Die Instrumententafel dient als Wegweiser für potenzielle Vorhaben, dessen Realisierbarkeit zu prüfen, zu planen und den Nutzen zu erkennen.

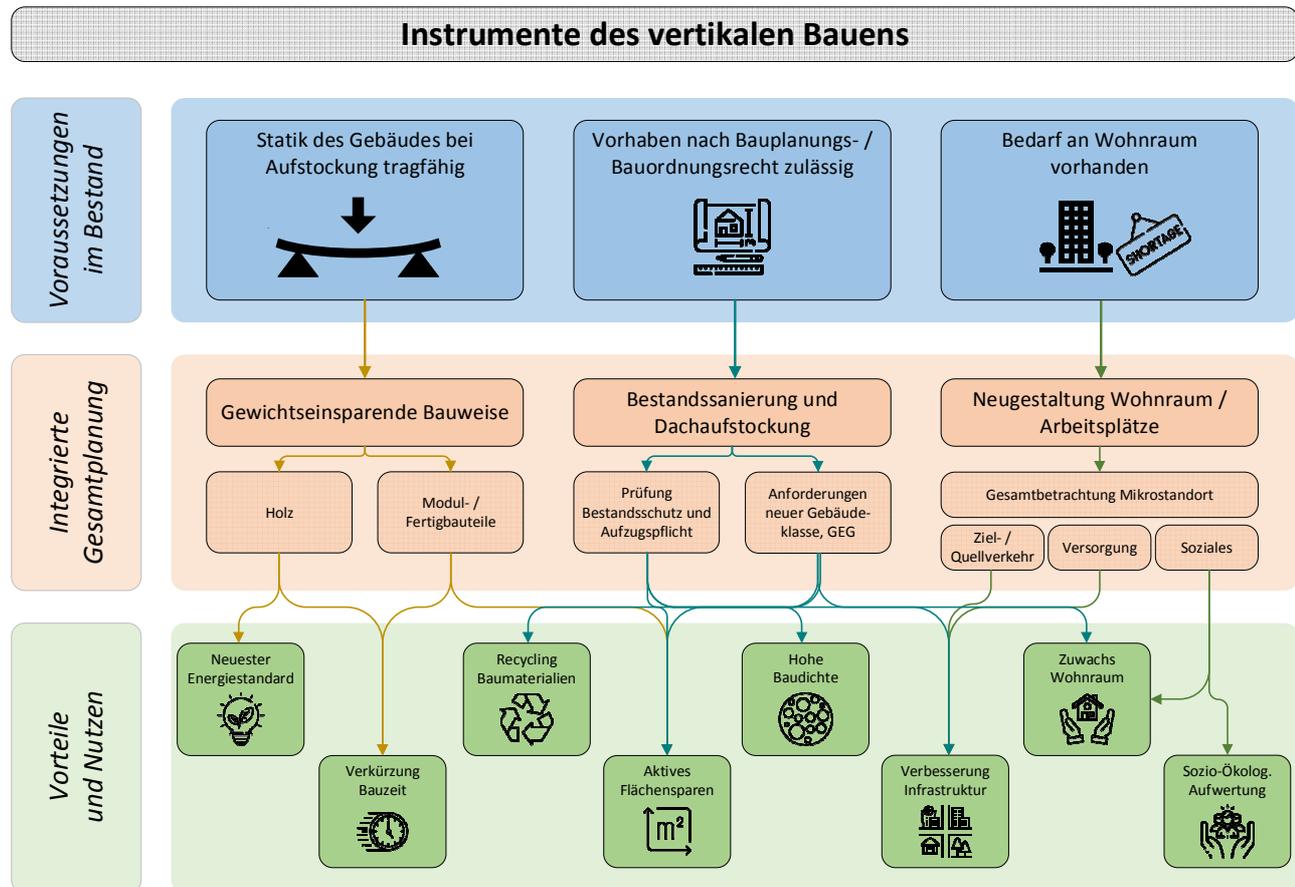

Abbildung 1: Instrumente des vertikalen Bauens.[3]

Im blau hinterlegten Feld sind die technisch-planerischen sowie rechtlichen Voraussetzungen skizziert, die für jede individuelle Dachaufstockung zu erfüllen sind. Ein stabiles Fundament legt den Grundstein für die Zusatzlast eines oder gar mehrerer Geschosse auf dem Bestandsbau. Qualitativ anspruchsvolle Bauweisen, Massen von Beton oder historisch belastbare Bausubstanzen zählen zu denjenigen Hauseigenschaften, aus denen hohe Traglastreserven resultieren. Daher charakterisiert das Bundesinstitut für Bau-, Stadt- und Raumforschung (BBSR) vor allem Häuser der 1950 bis 1960er Jahre mit dem größten Potenzial für zukünftige Dachaufstockungen.[4] Der Bestand dieser Baualtersklassen beläuft sich auf insgesamt 11 Millionen Wohnungen in Deutschland.[5] Weiterhin hängt die konstruktive Rahmenbedingung der Tragfähigkeit von den berücksichtigten Verkehrslasten ab; ändert sich beispielsweise die Nutzungskategorie des Gebäudes von Gewerbe zu Wohnraum, sinkt die Nutzlast gemäß DIN 1055-3von fünf auf zwei Kilonewton pro Quadratmeter. Folglich ergeben sich anhand der geringer anzusetzenden Nutzlasthöhere Tragreserven, welche die Zusatzlasten durch ein- oder mehrfache Geschossaufstockungen aufnehmen können. Für diese Schritte sind sowohl ein qualifizierter Tragwerksplaner als auch ein Sachverständiger für die Prüfung der Standsicherheit zu beauftragen.

Das Bauplanungsrecht mit den Vorschriften des Baugesetzbuches sowie der Baunutzungsverordnung und das Bauordnungsrecht in den jeweiligen Landesbauordnungen regeln die Zulässigkeit eines Bauvorhabens. Die Genehmigung kann je nach Gebiet des Weiteren vom Denkmal-, Naturschutz- oder Wasserrecht abhängig sein. Generell wird eine Erweiterungsstrategie nach Kombination mit Sanierung der Gebäudehülle oder Durchführung der Einzelmaßnahme ohne zusätzliche Modernisierung differenziert. Im ersten Fall

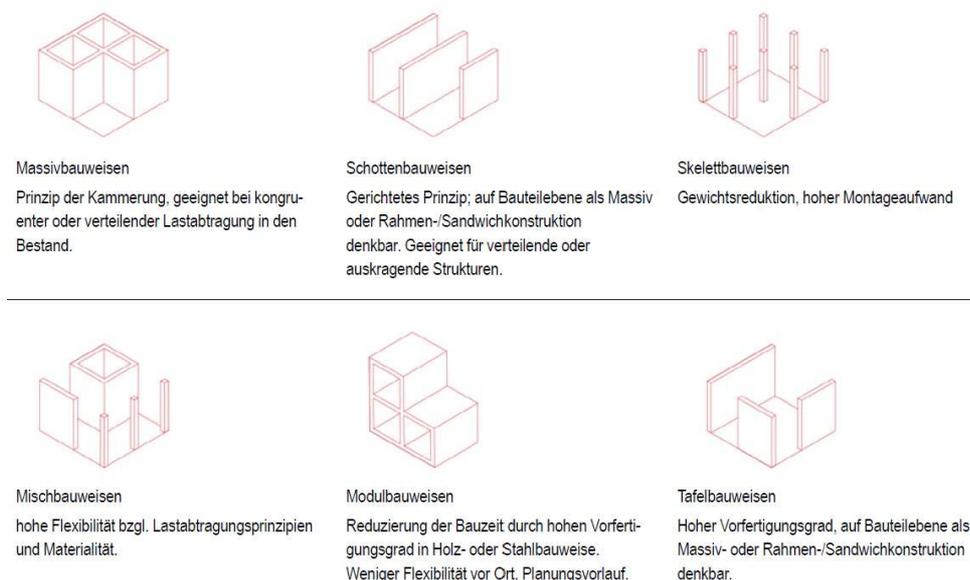
---

[3] Reinhard (2022).
[4] BBSR (2016), S. 34.
[5] Pestel-Institut (2023), S. 19.

erfolgt ein Eingriff in den Bestand durch eine oder mehrere Baumaßnahmen (z. B. Herstellung eines baurechtlich konformen Treppenaufgangs ins Dachgeschoss). Folglich verfällt der Bestandsschutz und das gesamte Gebäude muss mit dem aktuell geltenden Recht in Einklang stehen – es ist wie ein Neubau zu behandeln und muss somit auch die neuesten Anforderungen im Gebäudeenergiegesetz erfüllen.[6] Der zweite Fall findet sich häufig in denkmalgeschützten Gebäuden wieder, deren Außenfassade je nach Bauvolumen, Stil und Proportion einer geplanten Aufstockung nicht beeinträchtigt werden darf. Das BBSR kritisiert die rechtlichen Vorgaben bei der Zulässigkeitsprüfung einer Bauerweiterung und sieht deutliche Hemmnisse in der Realisierung von Dachaufstockungen und -ausbauten. Investoren würden vor allem durch den Wegfall des Bestandsschutzes, erhöhte Anforderungen durch die Änderung der Gebäudeklasse sowie die Einhaltung der Energieeinsparverordnung (seit 08/2020: Gebäudeenergiegesetz) für Neubauten finanziell zurückgehalten.[7]

Der Bedarf an Wohnraum lässt sich jährlich anhand der Geburten- und Sterberate, den Wanderungen über die Bundesgrenze sowie der zukünftigen Bevölkerungsentwicklung aufstellen. Das Pestel-Institut hat für das aktuelle Kalenderjahr ein Defizit von 700 Tausend Wohnungen ermittelt– welches der größten Wohnungsnot seit 20 Jahren entspricht. Die Gründe für das hohe Defizit liegen an den jüngst entstandenen Problemen: Energiekrise, Materialknappheit, Lieferkettenengpässe, steigende Baukosten und Fachkräftemangel. Der Wohnungsbau scheitert allerdings auch an langwierigen Genehmigungsverfahren, die bereits vor dem Russland-Ukraine-Konflikt publik waren.

Die integrierte Gesamtplanung im orange gefärbten Feld baut im Folgeschritt auf den zu erfüllenden Voraussetzungen auf. In Abhängigkeit von Bausubstanz, Traglastreserven und weiteren statischen Bedingungen erfolgt der Einsatz von Holzkonstruktionen oder Modul- bzw. Fertigbauteilen aus Leichtbeton. Im ersten Fall steigen Zusatzlasten infolge eines Dachausbaus nur um ein geringes Maß, da lediglich ein Austausch des Dachstuhls stattfindet – z.B. durch den Bau von Gauben und Flachdächern, deren Lasten durch neu angerichtete Holzbalken abgetragen werden(vgl. Abbildung 2, Skelettbauweise; Abbildung 3, Strategie 1). Als Alternative bietet sich der Einsatz von Modul- bzw. Fertigbauteilen an, welche auf der Baustelle vor Ort über einen Schwerlastkran an den vorgesehenen Platz gehoben und anschließend final verschraubt werden(vgl. Abbildung 2, Modulbauweise).



Massivbauweisen

Prinzip der Kammerung, geeignet bei kongru-enter oder verteilender Lastabtragung in den Bestand.

Schottenbauweisen

Gerichtetes Prinzip; auf Bauteilebene als Massiv oder Rahmen-/Sandwichkonstruktion denkbar. Geeignet für verteilende oder auskragende Strukturen.

Skelettbauweisen

Gewichtsreduktion, hoher Montageaufwand

Mischbauweisen

hohe Flexibilität bzgl. Lastabtragungsprinzipien und Materialität.

Modulbauweisen

Reduzierung der Bauzeit durch hohen Vorferti-gungsgrad in Holz- oder Stahlbauweise. Weniger Flexibilität vor Ort. Planungsvorlauf.

Tafelbauweisen

Hoher Vorfertigungsgrad, auf Bauteilebene als Massiv- oder Rahmen-/Sandwichkonstruktion denkbar.

Abbildung 2: Typologien zur Erweiterung von Dachgeschossen[8]

Innerhalb der zweiten Planungsstufe wird das vertikale Wachstum zwischen Bestandssanierung und Dachaufstockung differenziert. Abbildung 3 verdeutlicht den Betrachtungswinkel zwischen bestehender Gebäudehülle und der Erweiterungsstrategie, wobei die „Aufstockung als Building Envelope" eine

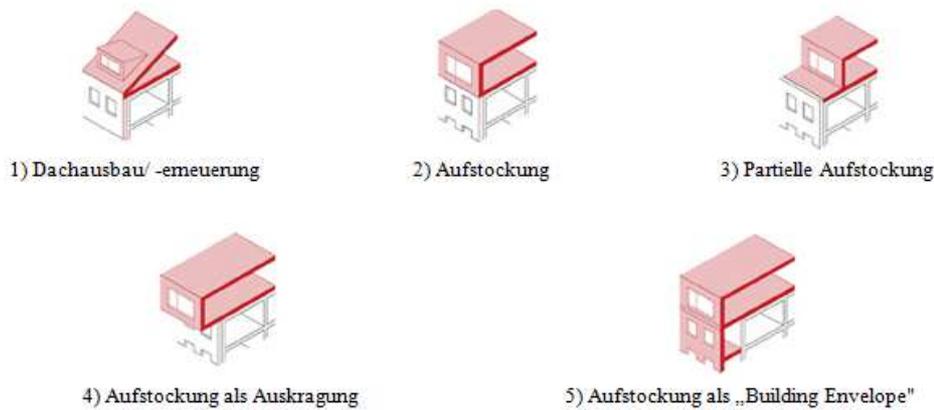
Koinzidenz von Sanierung und Aufstockung darstellt. Die Strategien eins bis vier decken die alleinstehende Aufstockungsmaßnahme ab; sie unterscheiden sich vor allem im Ausmaß der neu erschlossenen Wohnfläche.



1) Dachausbau/ -erneuerung   2) Aufstockung   3) Partielle Aufstockung

4) Aufstockung als Auskragung   5) Aufstockung als „Building Envelope"

Abbildung 3: Strategien der Bestandserweiterung (Bestandsbau weiß, Neubau rot markiert)[9]

Überschreitet das gesamte Gebäude nach der geplanten Erweiterungsmaßnahme eine Gebäudehöhe von sieben Metern, ändert sich die Gebäudeklasse und der Bestandsschutz verfällt. Fortan bestehen dann strengere brandschutztechnische Anforderungen an die Bauteile (von „feuerhemmend" zu „hoch feuerhemmend", §§ 2, 26 MBO). Weiterhin ist die Einhaltung der Abstandsflächen zu beachten, um eine ausreichende Belichtung und Belüftung, den Brandschutz und einen Sozialabstand zu gewährleisten (§ 6 MBO). Die nach GEG vorgeschriebenen Wärmedämmungs-, Schallschutz- sowie energetischen Maßnahmen im Neubau müssen dann in den bestehenden Geschossen nachgerüstet werden. Für die Sanierung sieht dass BBSR den Bestand der 1950 bis 1960er Jahre ebenfalls im Vorteil, da durch den standzeitbedingten Sanierungsbedarf und die geometrisch unkomplizierten Fassaden der neueste Energiestand mit einfach technischen Mitteln erreicht werden kann.[10] Durch die Vorgabe von zwei unabhängigen Rettungswegen je Geschoss (§ 33 MBO) ist für die Erschließung der ausgebauten Dachgeschosse häufig ein neues Treppenhaus notwendig, da die durch ein Rettungsgerät erreichbaren Stellen zu hoch oder von Baumkronen verdeckt sind. Als zusätzlicher Prüfschritt steht der Kostenfaktor "nachträglicher Einbau eines Personenfahrstuhls" an; die nationale Aufzugspflicht besteht ab einer Gebäudehöhe von 13m (§ 49 Abs 4. MBO) bzw. in den Landesbauordnungen überwiegend ab fünf (Berlin: vier) Vollgeschossen. Mit Abschluss dieses integrativen Planungsabschnitts muss folgende Frage beantwortet sein: Ist es für den Investor wirtschaftlich betrachtet sinnvoll, neuen Wohnraum zu finanzieren, der eine komplexe Sanierung der "alten" Wohnflächen bedingt?

Sind die technischen und rechtlichen Planungsfragen abgeschlossen, müssen die sich mit den neugewonnen Wohnflächen bzw. Arbeitsplätzen einstellenden Bedürfnisse geplant werden. Dazu ist eine Gesamtbetrachtung des Mikrostandortes notwendig, um die Lebensgrundfunktionen rund um ein städtisches Viertel zu analysieren. Im Schwerpunkt werden hierbei soziale Belange, die Nahversorgung sowie die Mobilität in Form von Ziel- und Quellverkehr untersucht. Der Sozialgedanke lässt sich zum Einen am Verhältnis zwischen alten und neuen Bewohnern des Hauses messen. Andererseits stellen sich Sickereffekte auf dem Wohnungsmarkt ein: Durch den Zuwachs an Wohneinheiten können vergleichsweise kostenintensive Mietobjekte im Dachgeschoss Besserverdienenden überlassen werden, welche aktuell den durchschnittlich teuren Wohnraum für Bürgerinnen und Bürger der Unter- und Mittelschicht blockieren. Die Berücksichtigung beider Komponenten stellt eine Lösung dar, aktiv gegen das Problem der Gentrifizierung zu handeln und auf die sozialen Interessen aller Menschen im Viertel einzugehen. Hinsichtlich der Versorgung und Mobilität liefert POPELKA mit dem Ausdruck einer positiven Dichte das Stichwort, welches die notwendige Kapazität der vorhandenen Infrastruktur aufstellt.[11] Handelt es sich bei vertikalem Wachstum im Sinne einer flächensparenden Verdichtung von zusätzlichem Wohnraum, so nimmt die Einwohnerzahl am Mikrostandort nur geringfügig zu. Als Resultat sollte die existierende Infrastruktur die neu hinzugekommenen Versorgungs- und Mobilitätsbedürfnisse aufnehmen können – sofern die Dichte

---

[9] BBSR (2016), S. 31.
[10] ebd., S. 27.
[11] Popelka (2021).

positiv und die Beliebtheit eines Ortes hoch bleiben. Zum Schluss der zweiten Reihen im Schaubild "Instrumente des vertikalen Bauens" gilt es folgende Fragestellungen zu erörtern:

Ist der neu erschaffene Wohnraum so groß, dass er genügend Fläche für Tätigkeiten im Homeoffice bietet? Befinden sich am zu verdichtenden Mikrostandort genügend Arbeitsplätze in der Umgebung, sodass potentielle Mieter durch die Aufstockungsmaßnahme das Prinzip Stadt der kurzen Wegerealisieren können? oder: Wird das vertikale Wachstum in Erwägung gezogen, weil ein Wohnraumbedarf aus der Errichtung neuer Arbeitsplätze entsteht?

Im abschließenden Feld der Instrumententafel erfolgt das Resultat der vorherigen Schritte: die grün hinterlegten Vorteile und Nutzen, welche sich aus den drei Faktoren des integrativen Planungsprozesses ergeben. Der neueste Energiestandard wird zusammen mit der Leichtbauweise und den Anforderungen des GEG erreicht, Sonnenkollektoren oder Solaranlagen unterstützen in diesem Zuge die Nachhaltigkeit und Energiebilanz des neuen Wohnraums. Weiterhin kann die Umsetzung von Dachaufstockungen durch den Einsatz von Fertigbauteilen beschleunigt werden, sodass sich ein reibungsloser Bauablauf und ein gleichzeitiger Schutz der Bestandsbewohnerinnen und -bewohner durch Lärmvermeidung einstellt. Die beim Bauen anfallenden Abfallmengen können durch den Erhalt und die Pflege von Bestandsgebäuden deutlich minimiert, aber nicht vermieden werden; der geringfügige Bedarf neuer Baumaterialien im Zuge einer Aufstockung steht für eine Ressourcenschonung. Ferner besteht das Potenzial, die Wiederverwendbarkeit der aufzustockenden Bausubstanzen zu prüfen; Pfetten und Sparren können beispielsweise je nach Zustand recycelt und an anderer Stelle eingesetzt werden, ohne ein Downcycling zu erfahren. Im Zusammenspiel von Sanierung der Gebäudehülle und vertikalem Wachstum können Grünelemente sowohl an der Wand als auch auf dem Dach wertvolle Versickerungsflächen bieten; durch ihren Beitrag im ökologischen Städtebau der Zukunft eröffnen sich gar neue Wege, wie alte Bestandsfassaden eine klimafreundliche Aufwertung erfahren können, der Vorteil einer hohen Baudichte schließt den weiteren Nutzen des Flächensparens ein. Das Verhältnis von Mensch zu Nähe bleibt weiterhin positiv– die sozioökonomischen Differenzen dürfen durch die Beliebtheit eines Ortes jedoch nicht zunehmen. Die Installierung eines Supermarkts oder einer Mobilitätsstation zählen zu den Synergieeffekten, die eine Verbesserung der Infrastruktur infolge vertikalen Wachstums nach sich ziehen können. Gleichzeitig besteht auch der Vorteil einer sozioökologischen Aufwertung, wenn das Zusammenleben eines Bezirkes durch die Kommunikation zwischen alten und neuen Bewohnerinnen und Bewohnern gefördert wird. Der größte Nutzen durch vertikales Wachstum ist der Zuwachs an Wohnraum ohne Neuversiegelung einer Fläche. Die Entwicklung von Gebäude-, Frei- und Verkehrsfläche zeigt im Vergleich zu fertiggestellten Neubauten, dass der Flächenverbrauch stark in Abhängigkeit zur Bautätigkeit steht.[12] Der Bausektor in Deutschland dient daher als einer von mehreren Stellschrauben, die je nach Ausrichtung das vorgegebene Flächensparziel der Bundesregierung von unter 30 Hektar täglichen Verbrauchs nachhaltig beeinflussen zu können.

4   WOHNRAUMPOTENZIAL AM FALLBEISPIEL DER KÖLNER FORDSIEDLUNG

Das Potenzial des durch vertikales Wachstum erschaffenen Wohnraums lässt sich anhand verschiedener Kriterien messen. Die Wirtschaftlichkeit der Baumaßnahme steht in Abhängigkeit zur gewählten Erweiterungsstrategie (vgl. Abbildung 3). Die Arbeitsgemeinschaft für zeitgemäßes Bauen stellt im Kostenvergleich die wohnraumschaffenden Maßnahmen Neubau, Modernisierung und Umbau gegenüber (vgl. Abbildung 4). [13] Die neubaugleiche Modernisierung gilt als kostenintensivste Möglichkeit, als kostensparende Alternative besteht die Option einer Vollmodernisierung in kleineren Interventionen mit der bestehenden Bausubstanz. Der Umbau von Büroflächen stellt die günstigste Option dar, in diesem Fall ist der Aufwand und Materialeinsatz am geringsten. Der in diesem Paper aufgestellte Schwerpunkt eines Dachgeschossausbaus bzw. Aufstockung sticht mit knapp 1000 Euro pro Quadratmeter Einsparung gegenüber dem Neubau eines Wohnhauses hervor; die nachhaltige Verdichtung ist vor allem aufgrund des Kostenfaktors "Grundstückserwerb" ein sparsames Mittel zur Wohnraumschaffung.

Abbildung 4: Baukostenvergleich wohnraumschaffender Maßnahmen (Vergleich der gemittelten Bruttokosten für verschiedene Möglichkeiten der Wohnraumschaffung im 4. Quartal 2021)[14]

Wie setzen sich die Baukosten für die Erweiterungsstrategie einer Aufstockung zusammen? Den größten Anteil bildet die Kostengruppe (KG) 300 für die allgemeine Baukonstruktion eines oder mehrere Vollgeschosse. Hinzu kommen die KG 400 für technische Kosten und die KG 500 für Außenanlagen. Um die Traglast der obersten Geschossdecke zu schonen und die hinzukommenden Lasten über die Außenwände abzutragen, ist gegebenenfalls eine Ertüchtigung der bisherigen Konstruktion von Nöten. Ein weiterer Kostenpunkt kann der bereits erwähnte Personenfahrstuhl sein (vgl. S. 4), eine nachträgliche Installation an der Außenfassade gilt hier als denkbare Umsetzung.

Zur weiteren Bestimmung des Wohnraumpotenzials sind die nationalen Bestandsgebäude zu differenzieren. Je nach Baualtersklasse, Dachfläche und Bundesland ergeben sich unterschiedliche Potenziale für zusätzliche Wohnflächen bzw. Wohnungen. Sinnvolles Aufstockungspotenzial befindet sich vor allem in Metropolregionen und Ballungsräumen, in denen ohnehin ein erhöhter Wohnungsbedarf festzustellen ist. Demgegenüber weisen ländliche Regionen einen zu hohen Gebäudeleerstand auf, der sich vor allem aufgrund der Urbanisierung eingestellt hat. Wie bereits im vorherigen Abschnitt erwähnt, weisen Gebäude der Bauperiode ab den 1950er Jahren eine hohe Eignung für eine Gebäudeerweiterung auf (vgl. S. 4). Gemessen an den drei Kriterien stellt das Pestel-Institut in seiner Deutschland-Studie 2015 fest, dass der Gebäudetyp "Baujahr 1960 bis 1969, drei bis zwölf Wohnungen je Gebäude, alte Bundesländer im nördlichen Teil Deutschlands) mit 198 Quadratmetern Dachfläche im Durchschnitt die beste Grundlage für das vertikale Wachstum bietet.[15] In der übergreifenden Bauperiode 1950 bis 1969 stehen in den neuen Bundesländern durchschnittlich 110 Quadratmeter Dachfläche zu Verfügung, welche als niedrigster Wert in die Gesamtberechnung einbezogen wird. Aus dieser ergibt sich laut der Studie ein Wohnungspotenzial von1.5 Millionen Wohnungen[16] durch Gebäudeaufstockung, wovon 317.000 Wohnungen im Besitz von Wohneigentumsgemeinschaften sind.[17]

Durch die Option der Anpassungsfähigkeit der neu entstehenden Grundrisse kann eine effiziente Nutzung der Wohnfläche sichergestellt werden. Im Zeitalter einer globalen Pandemie blüht das Homeoffice auf, der Bürotisch wird durch die Küchentheke ersetzt, das hauseigene WLAN auf Belastungsspitzen geprüft – diese Adaptivität war in den vergangenen Jahren von Arbeitnehmerinnen und Arbeitnehmern in ihren eigenen vier Wänden gefordert. Vergleicht man den Trend der Telearbeit und die Entwicklung des Wohnflächenbedarfs, ergibt sich eine Parallele: steigende Bedürfnisse benötigen mehr Raum, ergo werden bei aktuellen Bauprojekten mehr Quadratmeter für Single-Haushalte und allgemeine Wohneinheiten veranschlagt. Die Bundesstiftung Baukultur sieht in der räumliche Qualität hingegen keine wechselseitige Beziehung zu dem Flächenausmaß; vielmehr sei ein intelligenter Grundriss und die Anordnung der Möblierung durch erfahrene Innenarchitektinnen und Innenarchitekten ein neuer Lösungsansatz.[18] Dieser wird durch eine Studie im Auftrag der Vereinigung der Bayerischen Wirtschaft (vbw) gestützt, da die Energieeinsparung bei

[18] Neue Umbaukultur (2023).

Reduzierung der durchschnittlichen Wohnfläche um 15 Prozent auf 40,5 Quadratmeter pro Kopf insgesamt mehr als zehn Megatonnen CO_2-Äquivalent betrage.[19] Daran anknüpfendbesteht durch das vertikale Wachstum die Möglichkeit, Grundrisse des neu zu erschließenden Wohnraums in Abhängigkeit von lokaler Wohnraumnachfrage durch Studierende, Familien oder Wohngemeinschaften adaptiv zu gestalten. Das folgende Fallbeispiel verdeutlicht die effiziente Nutzung der Wohnfläche, die auf einem rechteckigen Bestandsgebäude je nach Bedarf angepasst werden kann.

Wie Wohnraum durch vertikales Wachstum samt Gebäudesanierung behutsam und zugleich bedarfsgerecht erschaffen werden kann, zeigt das mit dem Bauherrenpreis prämierte Projekt von ARCHPLAN. Die Kölner Fordsiedlung liegt inmitten des Grüngürtels der Stadt, die günstige Lage erweist sich durch die Nähe zum Stadtzentrum, dem Rheinufer und mehreren Arbeitsstätten. Die dreigeschossige Zeilentypologie wies in ihrem Bestand aus den 1950er Jahren310 Wohneinheiten mit durchschnittlich 47 Quadratmeter Wohnfläche auf, ehe die Aufstockung der elf Wohnblöcke einen Zuwachs von 6.350 Quadratmeter erzielte. Das wirtschaftliche Ergebnis lässt sich anhand eines 45-prozentigen Wohnflächenzuwachses messen, insgesamt erhielt die Fordsiedlung durch das vertikale Bauen 81 neue Wohneinheiten mit großzügiger geschnittenen und familiengerechteren Grundrissen. Der in Abbildung 5erkennbare Instandhaltungsbedarf wurde mithilfe einer umfassenden Sanierung der Gebäudehülle gelöst. Der Sanierungskatalog enthält vor allem Wärmeschutzmaßnahmen: Dämmung von Außenwänden undGeschossdecken, Einbau moderner Fenster und Türen mit dreifacher Verglasung, Isolierung der bestehenden Gebäudehülle auf KfW60.

Abbildung 5: Bestandsgebäude und Objekt nach Sanierung und Aufstockung im Vergleich.[20]

Die vertikale Erweiterung wurde mithilfe von vorgefertigten Holzbauelementen realisiert, der nachhaltige Baustil wurde im 3-Liter-Standard (KfW 40) durchgeführt. Reduzierte Energiekosten durch Modernisierung des Bestandsgebäudes, Verschönerung und Erweiterung von Freiflächen zwischen den Wohnblöcken, Heterogenität zwischen neuen und alten Bewohnerinnen und Bewohnern – all diese Kernelemente gaben 75 Prozent der langjährigen Mieterinnen und Mietern Anlass, während des Bauprozesses in ihren alten und neuen vier Wänden wohnhaft zu bleiben. Demnach baute das Jury-Urteil des Bauherrenpreises[21] auf den entsprechenden Instrumenten des vertikalen Bauens auf: neuester Energiestandard, aktives Flächensparen, Wohnraumzuwachs, sozioökologische Aufwertung (vgl. Abbildung 1).

5 HERAUSFORDERUNGEN IN DER GESETZGEBUNG

Im Zuge der rechtlichen Thematik gilt es zunächst, die Begrifflichkeiten voneinander abzugrenzen. Denn der Umbau an sich ist von anderen Eingriffen in den Bestand zu differenzieren: Die Wiederherstellung eines früheren Zustands charakterisiert eine Restaurierung, wohingegen durch eine Renovierung lediglich kleinere Mängel ausgebessert werden. In der Verordnung über die Honorare für Architekten- und Ingenieurleistungen (HOAI) ist die Modernisierung als „bauliche Maßnahme zur nachhaltigen Erhöhung des Gebrauchswertes eines Objekts" paraphrasiert. Alle drei Bestandseingriffe sind letztlich von dem vertikalen Wachstum zu unterscheiden: der Umbau in Form von Erweiterungsbauten wird als „Ergänzung eines vorhandenen

---

[19] VBW (2020), S. 97.
[20] ARCHPLAN (2011).
[21] GDW et al. (2011), S. 37.

Objekts" definiert. Dabei verändert jener Umbau, der mit „wesentlichen Eingriffen in Konstruktion oder Bestand" einhergeht, auch die räumliche Struktur. Folglich verliert das Objekt seine Identität, da durch die Änderung etwas anderes, ein „aliud", entstanden ist.

In Bezug auf das vertikale Wachstum sieht die aktuelle Genehmigungspraxiseines baulichen Eingriffs wie folgt aus: Beabsichtigt ein Hausbesitzer bzw. eine Besitzerin einen Dachausbau oder eine Aufstockung auf seinem bzw. ihrem Bestandsgebäude zu realisieren, so ist eine Genehmigung bei der zuständigen Baubehörde einzuholen. Die Erteilung jener Baugenehmigung verbinden die Bauämter häufig mit Nachbesserungen im Bestand. Die sogenannten Anpassungsverlangen zielen darauf ab, das nicht nur der geplante Ausbau, sondern auch das übrige Gebäude im Nachhinein auf den neuesten Stand der Technik modernisiert werden soll. Im Umkehrschluss ergeben sich durch die zusätzliche Forderung seitens Bauamt höhere Investitionskosten, die von den Bauwilligen im Zuge der Kostenaufstellung nicht einkalkuliert wurden – sodass die Absicht der Gebäudeerweiterung und somit der Bauantrag zurückgezogen werden. Summiert man die Quadratmeterpreise der wohnraumschaffenden MaßnahmenAufstockung und Vollmodernisierung (vgl. Abbildung 4: 5.010 Euro pro Quadratmeter) und vergleicht diese mit den Baukosten eines Neubaus, wiegt die reine Neuerrichtung ohne Grundstückskosten für Investorinnen und Investoren aus finanzieller Sicht deutlich attraktiver.

Im Zuge der Voraussetzungen im ersten Abschnitt der Instrumente des vertikalen Bauens wurde bereits die Erschließung der neuen Aufstockungsfläche als Hauptgrund für den Wegfall des Bestandsschutzes thematisiert (vgl. S. 3).Je nach Ausprägung des vertikalen Wachstumsentfällt jener Schutz ebenso durch die Änderung der Gebäudeklasse (GK): Überschreitet die Gebäudehöhe im Sinne der Fußbodenoberkante des höchstgelegenen Geschosses durch die Erweiterung beispielsweise den Wert von sieben Meter, so ist fortan das gesamte Objekt der GK4 zuzuordnen. Es gelten dann strengere brandschutztechnische Anforderungen an Geschossdecken sowie Zwischen- und Außenwände. Auch ein Feuerwehreinsatz ist ab diesem Zeitpunkt nicht mehr mit Steckleiter, sondern einer Drehleiter von Nöten. Als Lösungsansatz sieht das BBSR hier die Option, den Bestandsschutz infolge eines Dachausbaus oder einer Dachaufstockung lediglich für bestimme Teilbereiche des bestehenden Objektes entfallen zu lassen;[22] z.B. für das an die Erweiterungsmaßnahme angrenzende Geschoss. Weiterhin sind pro Geschoss zwei unabhängige Rettungswege zu gewährleisten, Fluchtwege über einen befestigten Weg entlang des Daches werden häufig von den örtlichen Feuerwehren als genehmigende Stelle abgelehnt – unabhängig davon, ob die politischen Zielsetzungen der Stadtentwicklung erreicht werden und man sich dabei auf brandschutztechnische Alternativen einlassen müsste.

Neben den drei hervorgehobenen Problematiken in der Rechtsgebung bestehen mit Abstandsflächen (§ 6 MBO), Ausgleichsmaßnahmen bei Überschreitung der Geschossflächenzahl, einer Stellplatz- und Aufzugspflicht weitere Faktoren, welche die Realisierung einer Dachaufstockung im Interesse eines nachhaltigen Städtebaus erschweren oder gar verhindern. Es lässt sich feststellen, dass die aufgezeigten Regelungen allesamt aus der Musterbauordnung stammen und je nach Bundesland gar in einer strengeren Landesbauordnung festgehalten werden.

Einerseits verlangt das Baugesetzbuch eine „städtebauliche Entwicklung vorrangig durch Maßnahmen der Innenentwicklung (§ 1 IV BauGB), verbunden mit einem schonenden und sparsamen Umgang von Grund und Boden, um eine Verringerung der zusätzlichen Inanspruchnahme von Flächen zu erzielen (§ 1a II BauGB). Andererseits legen die Regeln der Landesbauordnungen sowie die Genehmigungspraxis der Bauämter potentiellen Investoren wortwörtlich die Steine in den Weg, um ihren eigenes formulierten, im Gesetzbuch verankerten Zielen näher zu kommen. Dabei besitzen jene Genehmigungsstellen ausreichend Ermessensspielraum, um vor allem in Regionen mit angespannten Wohnungsmärkten mittels vereinfachten Genehmigungsverfahren für Entlastung zu sorgen.

6 DISKUSSION

Während die Baubranche das Potenzial von Bestandsbauten und die Erweiterungsoption derer unlängst erkannt hat, hemmen Gesetzesbücher und Verordnungen die großflächige Anwendung in der Praxis. Welche Schritte sind folglich notwendig, um häufiger Wohnraum dort neu zu erschaffen, wo die Infrastruktur bereits vorhanden ist?

---

[22] BBSR (2016), S. 37.

Zu Beginn gilt es, die Bedeutung und auch den Wert des Baubestandes zu schätzen. In diesem Zuge konstatiert die Bundesstiftung Baukultur: "Eine selbstbewusste Auseinandersetzung mit dem Vorhandenen"[23] sei von Nöten, um weg von der Denkweise hoher Betonblöcke in den Agglomerationsgürteln der Stadt, hin zu vereinzelten, mit architektonischer Intelligenz lückenfüllenden Wohnräumen auf solchen Objekten zu errichten, die bereits dem Flächenetat einer Stadt angehören. Dazu ist die bereits thematisierte Vereinfachung von Baugenehmigungen erforderlich, welche unter anderem auch mit politischen Forderungen mehrerer Bauverbände untermalt wurde.[24] Verfolgten im Jahr 2016 oftmals Kommunen „eine explizit auf Nachverdichtung ausgerichtete Stadtentwicklungsstrategie" durch eher großzügig ausgelegte Ermessensentscheidungen[25], so änderten Nordrhein-Westfalen und Bayern ihre Landesbauordnungen im Interesse der Bauherrn: nach § 63 BauO NRW bzw. Art.58 BayBO ist die „Änderung und Nutzungsänderung von Dachgeschossen zu Wohnzwecken einschließlich der Errichtung von Dachgauben" fortan genehmigungsfrei. Als nächste Handlungsanweisung ist es von nun an unabdingbar, eine stärkere Aufklärung über die Voraussetzungen, den Ablauf und die entstehenden Kosteneiner Gebäudeaufstockung zu betreiben. Der eingangs erwähnte Vorreiter bildet hier der Internetauftritt der Stadt Wien, die hiesige „Begutachtung eines Dachausbaus" stellt von Bedingungen über Fristen und Termine, den zuständigen Stellen bis hin zu den erforderlichen Unterlagen alles an Informationen barrierefrei bereit, die ein möglicher Investor bzw. eine Investorin für sein bzw. ihr Vorhaben benötigt.[26] Jener Handlungsleitfaden steht vor allem für die Ursache, warum das Projekt Dachaufstockung in der österreichischen Landeshauptstadt eine hohe Beliebtheit erfährt.

Je nach Wohnungsmarktlage können dann Großstädte genauso wie Kommunen entscheiden, ob die flächenschonenden Wohnbaumaßnahmen über finanzielle Anreize beworben werden. Denkbar sind an dieser Stelle die Forderungen der Bauverbände von 2015, wie sie bereits für den allgemeinen Wohnungsbau übernommen wurden: steuerliche Sonderabschreibungen, Investitionszulagen sowie Förderprogramme (z.B. KfW).[27] Infolgedessen können größerer Wohnungen durch das vertikale Wachstum aufgrund lokaler Nachfragen nachgesteuert werden, die sich beispielsweise durch das Redevelopment Homeoffice ergeben. Neben den drei Funktion im Wohnungsbau ergibt sich für das zeitgemäße Wohnen der Zukunft somit eine vierte Komponente, die in neuzugestaltenden Grundrissen berücksichtigt werden muss.

Die letzte Zutat für eine großflächige Anwendung von nationalen Dachaufstockungen ist die Kooperation zwischen der Bauindustrie und den mit Aufstockungen vertrauten sowie erfahrenen Architekturbüros. Zwar sind die identifizierten Objekte der Baualtersklassen (vgl. S. 4) mit hohem Potenzial für eine Erweiterung individuell und unterschiedlich, jedoch ist, wie am Fallbeispiel der Kölner Fordsiedlung gezeigt (vgl. S. 5),eine industrielle Vorfertigung der aufzustockenden Wohneinheiten auf mehreren Wohnblöcken ein Ansatz, der auf langfristige Perspektive durch eingespielte Produktionsstraßen Baukosten senken und Produktionszeit sparen kann. In diesem Zuge ist auch der Einsatz recycelter Bauteile denkbar.

7 FAZIT

Dachaufstockungen und Dachausbauten können in Zukunft einen Beitrag zur Deckung des nationalen Wohnbedarfs und damit zur Entlastung angespannter Wohnungsmärkte leisten. Sie dienen ebenso als Ventil, behutsames Wachstum bei gleichzeitigem Schutz des Umweltguts Fläche in den Städten zu integrieren. Die Nutzung des hochwertigen Raumes hoch über den Dächern der Stadt darf allerdings nicht zur Luxusplattform werden, woraus die Gefahr der Gentrifizierung und damit verbundenen sozioökonomischen Differenzen in neuaufkommenden Szenevierteln drohen.

Die Maßnahme der Gebäudeerweiterung lässt sich anhand der Instrumente des vertikalen Bauens (vgl. Abbildung 1) von Voraussetzung über Planung bis hin zu den entstehenden Nutzen charakterisieren. Hervorzuheben ist hier die Differenzierung zwischen Bestandssanierung und Gebäudeaufstockung, die vor allem in der Genehmigung jener Baumaßnahme ihre jeweiligen rechtlichen Probleme bergen. Verfällt der Bestandsschutz des Objektes, entstehen durch die Anforderung des neuesten Energiestandards zusätzliche Sanierungskosten. Auch die Änderung der Gebäudeklasse kann aus der anfangs beabsichtigten

Dachaufstockung eine kostspielige Erweiterung für die Investorin oder den Investor bedeuten. Dennoch sind durch die Novellierung der Bauordnungen in Bayern und Nordrhein-Westfalen genehmigungsfreie Dachausbauten möglich, die schnell und einfach Wohnraum schaffen. Weiterhin kommt es sanierungsbedürftigen Gebäuden wie den Wohnblöcken der Kölner Fordsiedlung zugute, wenn durch eine Gebäudeerweiterung auch der Bestand eine Aufwertung durch Modernisierung erfährt.

Der Bau in die Vertikale stellt zusammenfassend eine nachhaltige Lösung dar, wie die Lücken auf dem Wohnungsmarkt nachhaltig minimiert werden können. Um die vorhandenen Reserven auf den Dächern unseres Gebäudeetats aktiv für neuen Wohnraum zu nutzen, ist eine selbstbewusste Auseinandersetzung mit jenem Bestand unerlässlich; es gilt fortan, das Aufstockungspotenzial zu werben, zu fördern und schließlich die Industrie für eine nachhaltige Serienfertigung mit recyceltem Baumaterial vorzubereiten.

BlueGreenStreets – Adapting Urban Streets for Climate Change

Jochen Eckart, Wolfgang Dickhaut, Michael Richter

(Prof. Dr. Jochen Eckart, Hochschule Karlsruhe, jochen.eckart@h-ka.de)

1 ABSTRACT

Strategies for the adaptation of cities to the consequences of climate change such as dry periods, heat waves and urban flooding are needed. As urban streets account for about 25% of the area in inner-city neighbourhoods, they also have to be included. In the project BlueGreenStreets concepts are being developed to increase the resilience of cities by means of blue-green infrastructure in urban streets. The basic philosophy is to develop streets as 'multi-talents', taking into account not only the traffic function but also the requirements of urban drainage and green infrastructure. Concepts for the multidimensional redesign and retrifiting of existing streets in urban neighbourhoods are being developed, and tested in pilot projects. Two innovative solutions "the street as a drain" and "stormwater tree pits" are presented in detail.

Keywords: streets, blue-green infrastructure, cities, climate change, urban neighbourhoods

2 CLIMATE ADAPTATION OF URBAN STREETS

Urban citizens and greenspaces are suffering the consequences of climate change. There is a growing number of heavy rainfall events exceeding the design capacity of the urban drainage systems, resulting in urban flooding. The consequences of climate change also include the increased occurrence of urban heat islands and prolonged dry periods. Thus, the vitality of urban greenspaces and especially street trees is affected by the drought periods. These already existing challenges are expected to intensify in the near future as climate change progresses. Solutions for the adaptation of cities to the consequences of climate change are required. There is the need to adapt urban streets to these challenges, which account for about 25% of the area in inner-city neighbourhoods. Conflicts of use are particularly prevalent in street spaces, as there are spatial demands from many users and there is limited space. In dense cities, the street space is one of the large reserves of space for the provision of open space and the qualification of the quality of stay in the residential and living environment of the residents. Accordingly, there will be a demand in the future to develop the street space as a 'multi-talents' to create a win-win situation that promotes environmentally friendly transport, traffic calming climate adaptation and quality of life. Within the framework of the R&D project BlueGreenStreets (BGS) pilot projects and tangible solutions to multifunctional climate-adapted streetscape design are tested and the results summarised as guidelines for practitieners (BlueGreenStreets 2022). In addition in-depth research on technical design and effectiveness of blue-green elements in streetscapes is conducted.

3 MULTIDIMENSIONAL STREETS

Initial approaches for water-sensitive, multifunctional streetscape design have been discussed in various publications (Benden 2014; Klimakvarter 2013; Dörr & Schöning 2014; ReStra 2014 and Deutscher Städtetag 2015) as well as in R&D projects such as MURIEL, KURAS, SAMUWA and RISA. These publications from the field of urban water management stress the increasing importance of land use and in particular street space for the adaptation to climate change In a white paper on urban green (BMUB 2017), the strategies of multi purpose, water-sensitive and heat-adapted urban space is presented, but remain very general. Bridging the disciplines between urban water management, landscape design and traffic planning has been attempted sporadically with Benden 2014 and Eckart & Blaszczyk 2017 but is still predominantly at the conceptual level and has not yet reached the level of detail required for the practical design of streets. Solutions for water-sensitive streetscape design, adapting to heavy rainfall events and droughts, discussed in the field of urban water management have not yet been taken up in the design of streets. Also heat-sensitive street design with potentials for evaporation, cooling and shading have not yet played a role in practice. So far, there is a lack of tangible approaches on how a climate adaptive street design could function. This gap was addressed by the R&D project BlueGreenStreets which developed concepts to increase the resilience of cities by means of blue-green infrastructure in urban streets. The basic philosophy is to develop streets as

'multi-talents', taking into account not only the traffic function but also the requirements of urban drainage and green infrastructure.

In Germany, the concept of decentralised rainwater management has been established since the 1990s, which aims at surface retention, storage, evaporation, infiltration and delayed discharge of rainwater. Decentralised rainwater management uses an established repertoire of solutions such as water-permeable pavements, infiltration swales, trough infiltration, trough-rigole systems etc. The strategy of BlueGreenStreets builds on these concepts of decentralized rainwater management, but adds new perspectives:

- Overall planning of flow path: Decentralized rainwater management was based on a small-scale "parcel principle" draining single properties, which no longer meets the challenges of flood protection during heavy precipitation. The decentralised rainwater management is expanded to include an overall planning of the flow paths for heavy precipitation and urban flooding, taking into account streets, playgrounds and sports fields as well as open spaces (Kruse 2015).

- Multipurpose land use: For climate adaptation of urban streets, it is not longer sufficient to add up the different space demands of pedestrians, cyclists, parking flowing car traffic, street trees, rainwater management etc. as in many existing streets not sufficient space is available. Rather streets design are required, which combined the different functions of streets at the same space. For example, areas that primarily serve another main use such as the roadway or parking spaces can temporarely be used specifically as retention space or flow paths for a short time during heavy precipitation.

- Balancing water and micro climate: The elements of BlueGreenStreets aim to restore all dimensions of the natural water balance and micro climate. Thus, in addition to reducing runoff and favouring infiltration, also retention, evaporation as well as the harvesting and use of rainwater are considered. BlueGreenStreets are thus simultaneously the solution to both heat and flooding problems by integrating planting into stormwater management. In addition, the use of rainwater becomes more important for dealing with drought events and evaporation becomes more important to reduce local heat islands.

- Integrated planning: In BlueGreenStreets, different interests such as traffic safety, underground infrastructures, rainwater management, parking management, biodiversity, micro climate and human well-being come together. Through innovative approaches to the design and integration of these demands in urban streets, the vitality of the street green can be improved, water management and urban climate concerns be addressed and valuable ecosystem services can be preserved and improved. In order to realise the possibilities of multidimensional design of urban streets there is the need to overcome the inherent logics of subject-specific planning. The cooperation between different disciplines such as urban water management, urban planning, landscape planning and traffic planning is required.

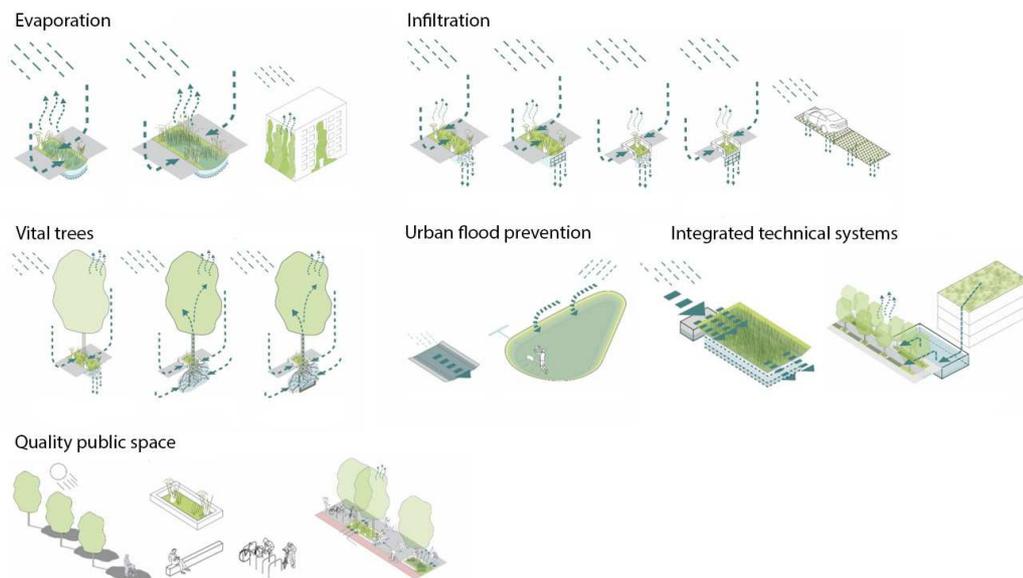
Within the framework of the project BlueGreenStreets, concepts for the multipurpose redesign and retrofiting of existing streets in urban neighbourhoods are being developed, and tested in pilot projects. The results are compiled in a toolbox as a practice-oriented guideline (BlueGreenStreets 2022). The tried and tested solutions of decentralised rainwater management continue to be suitable for the collection, retention, infiltration and evaporation of rainwater of urban streets. This includes elements such as water-permeable pavements, infiltration swale, trough infiltration, trough-rigole systems, street trees greened central reservations, green walls and green facades (compare figure 1). However, BlueGreenStreet design also requires solutions that have so far been used less frequently in practice, such as the use of streets for the temporary drainage of heavy rainfall events or stormwater tree pits . These two innovative solutions are described in more detail below.


Fig. 1: Extract of the BlueGreenStreets toolbox with green infrastructur for the redesign of urban streets (BGS, bgmr Landschaftsarchitekten GmbH)

4 THE STREET AS A DRAIN

As a result of climate change, in the future heavy rainfall events will increasingly exceed the design capacity of urban drainage systems. The runoff will flow on the surface following the topography often using urban streets as the "natural" flow paths in urban settings. As result there is the danger, that urban flooding events will impact urban land uses worthy of protection. Increasing the capacity of the urban drainage infrastructure is not a realistic solution for many municipalities because of ecological and economical considerations. Up to now, mainly technical retention basins of various types have been used to manage the impact of heavy rainfall events. A new strategy to reduce flood damage in urban streets is the multidimensional use of streets for controlled temporary emergency drainage and retention of heavy rainfall (Benden 2014, Valée and Benden 2010, Günthert and Faltermaier 2016). In other words, the street is temporary used as a drain. The strategy of planned joint use of traffic areas for controlled temporary emergency drainage and retention of heavy rainfall events is being analysed in the R&D project BlueGreenStreets.

For the strategy of the street as a drain, the obligation to ensure road safety must be observed. The costs due to possible detours or accidents should be lower than the benefits of avoided damage costs from flooding. Based on an analysis of accidents during heavy rainfall events in the cities of Bretten, Karlsruhe, Solingen and Hamburg as well as video-based traffic conflict analyses a framework for the safe design of the street as a drain are identified.

- If the vehicle fording depth of passenger cars of usually 30 cm (Kramer et al. 2015) is exceeded, the cars are damaged due to the penetration of water into the engine. The traffic conflict analysis of flooded roadways shows that from water depths of more than 20 cm (plus the wave impact of the vehicles), there is a significant increase in such single-vehicle accidents (Mettmann et al. 2016). In addition the danger of slipping of pedestrians increases at water levels above 20 cm (Shu et al. 2011). Safe driving and walking on flooded roadways is therefore possible at water levels of up to 15 to 20 cm. If the water level exceeds this, the roadways must be closed.

- Depending on the water level and tyre profile, aquaplaning of cars can occur at speeds above 60 km/h (Reed et al. 1984). In order to avoid these dangers, the temporary retention of rainwater in roads with a maximum permitted speed of over 50 km/h should be avoided. The analysis of the speed driven on flooded road sections shows that most road users drive at a maximum of 30km/h (Mettmann et al. 2016). Road users thus compensate for the adverse road conditions by reducing their speed appropriately for the situation (Kyte et al. 2000). Also the accident analysis does not show more accidents on urban streets during heavy rainfall events. Hence the strategy of the street as a drain is suitable for urban streets with a maximum permitted speed of 50 km/h or even better 30 km/h.

- In order for drivers to be able to react to the flooded roadway, sufficient visibility for stopping and space for possible manoeuvres is required (Mettmann et al 2016). The road section should also not have any obstacles that are covered by water on the roadway and are not visible to road users.

Taking into account the information on road safety, concepts for the design of "streets as a drain" can be developed. In most cases, simple structural adjustments to the road profile are sufficient. High curbs, generously dimensioned gutter systems or sills are suitable for directing rainwater and keeping it away from land uses worthy of protection. The flow cross-section and retention volume of a "street as a drain" is defined by the height of the lowest trailing edge of the pavement. The retention volume of the road space can be increased by using centre channels (V-profile of the roadway) and increasing the cross slope. Swales or depressions in the road gradient should be avoided. In addition, an emergency overflow is to be provided to areas, where the flooding does not cause any damage.

The possibility of the street as a drain was investigated in BlueGreenStreets as part of a pilot project in Solingen. The goal for pilot project was to design it multifunctionally street, combining the temporary retention of rainwater on the street with the provision of additional green infrastructure in the street. The reduction of the maximum permitted speed from 50 km/h to 30 km/h allows for a reduction of the roadway width and the large intersections can be reduced. Together with a reorganisation of the parking cars, space can be provided for the design of infiltration ditches combined with trees. In addition, the profile of the roadway is redesigned in a V-shape, so that can be retained during heavy rainfall events.

5 STORMWATER TREE PITS

The vitality of the street green can be improved through innovative approaches for the design and integration of multifunctional green spaces in the streetscape. Street trees play an important role in multifunctional streetscape design. They provide a whole range of ecosystem services to the urban environment, such as reducing the urban heat island effect, filtering air pollutants, increasing urban biodiversity and having positive effects on the quality of stay. In addition, trees have important influences on urban stormwater management. They reduce stormwater runoff and soil erosion through direct retention on or wetting of leaves and branches with water (interception), drainage of water through trunk (stem runoff), and infiltration through the soil (Elliott et al. 2018). Additionally, substrates filter pollutants from stormwater before it infiltrates into groundwater (CRWSA 2009). However, urban and especially street trees often face more difficult site conditions due to various environmental factors. According to Embrén et al. (2009), the most common problems for the development of urban tree populations include lack of space (root zone), lack of oxygen, and lack of water. Drought stress, in particular, is already causing loss of vitality today. Climate change may lead to increased mortality of street trees due to an increase in extreme events (Savi et al. 2015). One possible solution is to identify tree species that can cope well with urban stresses, including heat and water shortage. Another approach is to modify tree locations and conditions to increase the vitality of urban street trees. Adapting planting sites to meet the needs of urban trees can be done primarily through the design of the planting pit and/or the composition and layering of planting substrates. Combining street trees with stormwater management measures can, in some circumstances, both increase tree vitality and reduce flooding risk by directing stormwater into tree pits (Grey et al. 2018). In terms of technical feasibility, there are several options for combining decentralized stormwater management and tree pits. Two systems have become established, so-called box or cell systems and structural soils. In Europe, the "Stockholm model", a structural soil with a coarse soil content of > 100 mm grain size, is established in several countries (f.e. Sweden, Austria, Switzerland, Denmark).

The suitability of different systems in urban locations depends on different environmental factors and objectives. The origin of the rainwater (e.g. street or roof water) plays a decisive role for the possible unproblematic use from the point of view of tree vitality and groundwater protection. The substrates or planting systems used must provide sufficient air and water storage capacity (pore distribution and volume). In addition, compaction must not occur, which is ensured by either structural soil substrates or cellular systems.

In the BGS project, different stormwater tree pit systems were planned, built and evaluated. In order to make statements on the functionality with regard to rainwater infiltration and tree vitality, monitoring of the water (level, water content and water tension) and soil air (O_2, CO_{22}) balance is carried out in the pilot projects. Long-term results demonstrating improved tree vitality in such elements or effectiveness as a stormwater

982

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

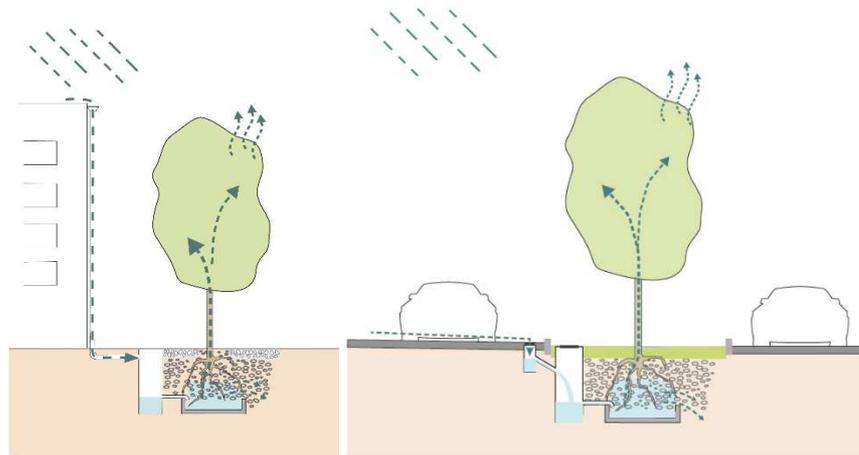
management measure, especially during heavy rain events, are not currently available. In the long term, the diversity of the pilot projects in terms of substrates and technical/structural elements should help to close the gaps in knowledge regarding water and oxygen supply to tree roots. In addition, the interrelationships between the discharge of additional rainwater from traffic and/or roof areas and the vitality of the trees planted in them will be investigated by measurements. In 2020 and 2021, different types of tree pits with and without underground water storage were built in Hamburg. The structurally similar types in Hölertwiete in Hamburg-Harburg and Am Beckerkamp in Hamburg-Bergedorf are supplied with rainwater from the roof or the street (Fig. 1). To store more water for dry periods, underground water reservoirs were built and their functionality is tested.


Fig. 2: Stormwater tree pits in Hamburg-Harburg (left) and Hamburg-Bergedorf (right) with underground storage elements and drainage from roofs and streets (© HCU, BGS).

The construction methods of the pilot sites differ in terms of substrates, waterproofing and drainage areas. In the Hamburg-Harburg, 2 tree pits (+ 2 reference tree pits without additional stormwater drainage) were constructed with underground bentonite waterproofing, conventional tree substrate (after FLL 2010) and an underground supply of stormwater from roof areas (Fig. 1). The tree infiltration trenches Hamburg-Bergedorf (3 + 3 reference sites) have a similar design, but are supplied from street stormwater and have a substrate mix based on the Stockholm model.

The tree pit systems showed high water management effectiveness during the first years of operation. At the site in Hamburg-Harburg, for example, < 10% of the stormwater runoff from the roof areas was discharged to the sewer system via the emergency overflow. Waterlogging, which could affect tree roots as a result of heavy rain, was effectively prevented by lateral infiltration of excess water. The stormwater tree pits and reference tree pits showed little difference in dynamics of water contents and tensions, O_2 and CO_2 contents at different depths in the first two years (2020 & 2021), as rooting to areas > 40 cm was probably not yet achieved. In deeper areas > 70 cm, desiccation hardly occurred and, accordingly, relatively low O_2 contents prevailed in stormwater and reference tree pits. The vitality parameters stomatal conductance, leaf chlorophyll content, and leaf chlorophyll fluorescence also showed no significant differences between stormwater tree pits and references in the first two stand years. However, in the third growing season, a difference in rooting depth became apparent, possibly due to the summer drought. At the tree trench sites, several parameters indicate deeper rooting in 2022, which may indicate more effective water supply from the water storage elements. Further monitoring over as many years as possible will probably highlight the differences between stormwater tree pits and references and describe the possible effects of the increased water supply for the trees.

6 CONCLUSIONS AND MANUAL

It still seems largely unclear how trees will react in the long term to the targeted infiltration of rainwater in stormwater tree pits and how much water will be available to the trees, especially during dry periods. Technical options such as additional storage elements are currently being investigated to hold water for dry periods and make it available to the trees. Currently, there are no technical standards for such tree-rainwater systems, which makes it difficult to implement in day-to-day planning outside of pilot projects. Further categorization or standardization of built systems may be another step toward technical codest. Additional

research into the effects of different systems on the urban (soil) water balance and flood and heat prevention is just as essential as gaining knowledge about the long-term effect on the vitality of different tree species.

The strategy "street as a drain" seems to be a promising solution to reduce the risk of urban flooding caused by heavy percipitation events. The minor impairment of traffic safety through flooded streets could be offset by the reduction of damages caused by urban floods. Cost estimates indicate, that the cost for designing streets as a drain are much lower than the costs for adapting the urban drainage infrastructure to increasing rainfall events. Further questions on the operation and maintenance of streets as a drain have to be investigated pilot projects. The above mentioned requirements for the traffic safety on flooded streets can help to design and implement such pilot projects.

In the BlueGreenStreets project, a guideline "BlueGreenStreets toolbox" (BGS 2022) was created from the experience gained in pilot projects with the planning and implementation of blue-green elements in streets. It presents the current state of knowledge on such elements and is intended to contribute to the integration of water-sensitive design in planning. In the ongoing second phase of the project this guideline will be tested and evaluated in new pilot projects. Goal is the transfer of the results to practice.

Building Land Register – an Important Step towards Effective Space Management

Barbara Černič

(Barbara Černič, Geodetic Institute of Slovenia, Jamova cesta 2, 1000 Ljubljana, barbara.cernic@gis.si)

1 ABSTRACT

Space is a limited natural resource that is subject to many pressures, such as the expansion of building land to agricultural land, whereas building land within settlements often remains vacant and unused. The reasons for this are the many constraints to the development of these areas, such as inadequate plots and ownership structures, inadequate communal infrastructure, or the dilapidation of this infrastructure, which needs to be renovated (MES PILOT, 2022).

Currently, there is no adequate register of building land and its properties in Slovenia, which would provide insights into the current state of the land and provide a basis for the implementation of land policy instruments. As a result, spatial planning is not in line with the principles of sustainability as defined in the Slovenian spatial planning legislation; that is, the treatment of space as a limited good that requires comprehensive treatment, coordination, and management of its social, environmental, and economic aspects (Spatial Planning Act - ZUreP-3). The lack of data is reflected in the reckless direction of settlement and placement of investments, whithout taking into account the possible acitvation of empty building land, possibility of revitalisation of brownfields, and without foreseeing possible negative impact on the living and natural environment.

In response to the described problem of urban management in the country, the idea of creating a systematically regulated spatial data record, called The Building land Register, was developed. The Building land Register contains data on the existing state of built-up land and vacant building land. Based on the properties of the land, it will be possible to determine the presence of degradation of the built-up land; therefore it will be possible to identify areas where, by activating the already occupied space, its functionality would be restored. According to their characteristics, vacant building land is classified into land development phases, which define the possibility of actual land construction. Spatial planing Act (ZUreP-3) defines five cetegories of land development phases: 1 – unbuildable land, 2 – spatially disordered land, 3 – building land without urban ifrastructure provided, 4 – unorganized buildable land and 5 – buildable land. In order to classify land into these five categories, it is necessary to know the current state of communal infrastructure, planned spatial development, and limitations in space (ZUreP-3, explanation to Article 142.)

Establishing Building land Register is the first step in effective urban management at all levels (local, regional, and national). To achieve this goal, collaboration of all levels of urban management is necessary, in addition to providing high-quality data about the building land.

This article states the reasons for the establishment of the Building land Register, the importance of data in the management processes of space, the content of the Building land Register and the method of its establishment provided for in the Slovenian spatial legislation.

Keywords: development phases of vacant building land, actual use of built-up land, building land register, land policy, urban management

2 CIRCUMSTANCES AND REASONS FOR IDEA OF BUILDING LAND REGISTER

All users of the space usually ask themselves similar questions. What does it offer us, where can we build, what can we build, and what are the costs of planned investments? Where should the development of settlements and activities be directed? Spatial planners and investors want to establish a safe and stable environment for work and living. To achieve this, a targeted development of activities is necessary, which requires knowledge of the situation in the area. Sustainable spatial management needs to be based on legally backed data that enable different stakeholders to make decisions that facilitate the focused, harmonized, and rational use of space. Credible data play an important role in spatial and urban policy planning, implementation of land policies, and real estate valuation.

Spatial planning is the responsibility of municipalities in Slovenia. Municipalities are autonomous administrative territorial systems that operate relatively independently of the state. Self-governing local communities are independent in decision-making and implementation within their original powers, and must act in accordance with law (Tasks of municipalities, 2023). The main tasks of municipalities in space

management are spatial planning, planning communal infrastrucure, determining the actual use of land, managing land in the public interest, and implementing land policy measures. On the other hand, the state determines the goals of spatial development; determines the starting points, rules, and guidelines; and implements spatial measures and land policy tasks at the state level (Spatial planing act – ZureP-3). At the same time, by performing tasks related to the operation of the spatial information system and monitoring the state of spatial development, tries to follow the trends of the digitalization of space and related data.

For municipalities and the state to carry out their tasks in a high-quality way and manage land efficiently, it is necessary to understand the situation in the area. Information is needed on the fund of already used building land on the one hand and the fund of vacant building land on the other hand. It is necessary to know the properties of building land and the necessary inputs for the development of these lands to achieve their suitability for planning purposes.

A already mentioned, there is no adequate register of building land and its properties in Slovenija, which would provide insights into the current state of the land and provide a basis for the implementation of land policy instruments. As a result, spatial planning is not in line with the principles of sustainability as defined in the Slovenian spatial planning legislation; that is, the treatment of space as a limited good that requires comprehensive treatment, coordination, and management of its social, environmental, and economic aspects (Spatial Planning Act - ZUreP-3). The lack of data reflects on poor spatial planning, the reckless direction of settlement and placement of investments, whithout taking into account the possible acitvation of empty building land, possibility of rehabilitating brownfields, and without foreseeing possible negative impacts on the living and natural environment.

2.1 From idea to implementation

In response to the described problem of urban management in the country, the idea of creating a systematically regulated spatial data record, called The Building land Register, was developed. The first step from idea to implementation began at the national level, within the framework of the eProstor project program, under the common slogan "one space for all". The project was led by Surveying and Mapping Authority of the Republic of Slovenia and Spatial Planning, Construction and Housing Directorate under the Ministry of Natural Resources and Spatial Planning in the years of 2016 to 2022. The basic purpose was to increase transparency and efficiency in spatial planning, construction, and real estate management for local and state governments. At the same time, the goal was to make it easier for individuals, engineers, designers, and domestic and foreign investors to edit real estate documents and to have better and more transparent access to standardized spatial data collections. With this aim, the activities were carried out to cut red tape and allow paperless e-commerce in public sector, private sector, and public administration resulting in easily accessible official data on real estate and space (One space for all. Brochure, 2019). Under the Spatial Planning Act, Slovenia introduced the establishment of a digital environment in the fields of spatial planning, building construction, and real estate registration into its legal system. This regulates the operation of the spatial information system, within which, among other things, data on the Building land Register is managed. The Building Land Register is intended to serve as a multi-purpose database containing data on built-up land and vacant building land and providing information on development stages and other features of building plots. The records of building land retain data regarding: land area, land characteristics, connection with real estate an other information required for record-keeping (Building land register, Spatial information system, 2023).

Reliable data on built-up land is a prerequisite for the determination of vacant building land. As part of the project of mass capture of inhabited land, a record of the actual use of inhabited land was established in which data on the types of more detailed actual use of inhabited land were kept. Data on the actual use of built-up land were entered into the land cadastre of real estate and are publicly available (Recordes of the actual use of inhabited land. Spatial information system. 2023).

Spatial data on the actual use of built-up land hdad been captured for all municipalities in Slovenija, which was the first step toward creating a building land register made by the government. The second is to identify vacant building land and its characteristics. This is the part that is supposed to be taken by municipalities until the end of the year 2026. Since it is a completely new field of work, a methodology was created for the purpose of implementation to support municipalities in their work. The document describes in detail the key steps in the process of establishing an Building land Register, and it was created based on a pilot

implementation of the establishment of an Buliding land Register in which the municipality of Kranj actively participated. The task was carried out by the Geodetic Institute of Slovenia as part of the large-scale Pilot MOP project, which was led by the Ministry of Natural Resources and Space. The main purpose of the Pilot MOP was to establish the conditions for the successful implementation of many innovations introduced by the current spatial and construction legislation in the field of spatial and real estate management and to establish better cooperation between the state and local communities as carriers of spatial planning (MES PILOT, 2022).

Fig. 1: Records of the actual use of inhabited land (Insights into the building land records, 2023).

3 DATA CONTAINED IN BUILDING LAND REGISTER

As mentioned before, the Building land Register contains data on built-up land (Chapter 3.1) and vacant building land (Chapter 3.2). It provides information on the development stages and other features of building plots (Figure 2).

3.1 Built-up land

Built-up land consists of land of public road and railway infrastructure, inhabited land and construction plots.

For existing buildings, built-up land was determined using mass capture of data. Built-up land includes the area that a facility uses for its operation in nature. Built-up land is determined on the basis of data on the actual state of nature with man made and natural boundaries, the condition of registered real estate and ist ownership and the intended use of space in accordance with the provisions of spatial planning acts. For each piece of land, its actual use was also determined (Methodology for mass capture of inhabited land, 2019). The types of more detailed actual land use are taken from the Decree on Actual Land Use (Official Gazette of the Republic of Slovenia, nos. 43/18 and 35/19) and is kept in the land cadastre. Figure 3 shows an example of determining the area of inhabited land for residential and agricultural buildings.

Fig. 2: Data contained in Building land Register (Image material of the project MES PILOT 2022).

Fig. 3: Example of determining the area of inhabited land (Image material of the project MES PILOT 2022).

Building plot represents the land utilized by regular use of the building. By the new legislation it is obligatory to identify the building plot for new buildings, which is usually recorded as a single land parcel with arranged plot boundaries. By recording it in the Building land Register, the building plot represents an instrument for maintaining data on built-up land. By accurately recording real rights and restrictions on the plot, the building plot represents an instrument of spatial planning that connects real estate evidence with other spatial data (Spatial planning act – ZureP-3).

988

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

In addition, in the future, data will be kept for areas of built-up land on the possible devaluation of the space. Like many other countries around the world, Slovenia faces brownfields. Brownfields are degraded areas that have lower value due to inappropriate use or lack of settlements and can have a negative impact on the environment, society, economy or the visual image of the space. The areas are built and often equipped with communal infrastructure, but do not fully fulfill their original function (Methodology of derelict areas. MES PILOT, 2022). The basis for the determination of devalued areas as part of the Building land Register is the data of derelict land, which were obtained in the framework of the target research project entitled Comprehensive methodology for the inventory and analysis of abandoned land, the implementation of a pilot inventory and the establishment of an up-to-date register (Lampič et al., 2017). To direct the development of these areas, it is necessary to determine their quantity and characteristics. By recording in the systematically regulated spatial data record Building land Register, the possibility of activating the brownfield becomes more perspective.

Fig. 4: Example of Brownfield - An area that is built but does not fulfill its original function (Author: Barbara Lampič).

3.2 Vacant building land

Slovenian spatial legislation defines vacant building land as a plot or several plots or their parts, which are intended for the construction of buildings by the Municipal Spatial Implementation Act and are not built-up land. Spatial planning Act (ZUreP-3) defines five categories of land development phases: 1 – unbuildable land, 2 – spatially disordered land, 3 – building land without urban ifrastructure provided, 4 – unorganized buildable land and 5 – buildable land. In order to classify land into these five categories, it is necessary to know the current state of communal infrastructure, planned spatial development, and limitations in space (ZUreP-3, explanation to Article 142.)

Fig. 5: An example of vacant building land, which is classified into one of five categories of land development phases, depending on the current state of communal infrastructure, the planned spatial development and the limitations in the space (Image material of the project MES PILOT 2022 and Insights into the building land records, 2023).

It should be noted that the level of the development phase does not determine whether construction is permissible or not, but rather, based on the collected data on the space, an assessment is given of the stage of

development the land is in, according to its construction purpose. The fact that a piece of land is classified as building land does not mean that it can be built on; many other parameters affect the buildability of the land, in particular, the provision of communal infrastructure, compliance with the regulations of the spatial act, and the possible existence of space restrictions, which are thus determined for the purpose of preserving nature, protecting cultural heritage, protecting the environment, protecting agricultural land, protecting forests, water management, protecting human health, defending the country, protecting against natural and other disasters, and protecting economic and public infrastructure.

The important information provided by the Building land Register is not only the development levels determined for individual plots of land. An essential contribution of the record is all data on the condition of the space, collected accurately per plot. Such a detailed identification of the condition of the land provides a basis for decision-making in all spatial planning processes, from planning, equipping, building, and using the public space to the maintenance and renovation of its components at all levels of operation – local, regional, and national.

Qualitative and legally valid data will be the basis for the valuation of building land. Through the process of development, undeveloped building land gains in value. First, appropriate spatial acts are prepared for them, which define the possibility of construction. Subsequently, subdivision procedures are carried out, and if necessary, consolidation procedures are carried out to create a structure of building land that enables the spatial arrangements foreseen by the spatial act. In each step, certain resources are invested in the land, which increases its value. For land to be suitable for construction, it is necessary to provide it with communal infrastructure, which is the highest investment in land in the process of its development to the level of buildable land. This also increased the value of the land to the greatest extent. However, buyers and sellers currently do not have detailed, publicly available information, as Building land register will provide. This situation is reflected in the sale prices of real estate, as the data show that the price of building land does not follow the actual value of the land or does not increase in the same proportion as the value of land. It is assumed that high-quality and legally formally supported data provided by the Building land Register will be the basis for the regulation of current prices in the real estate market, which will be a reflection of the actual value of land and at the same time, a measure for the valuation of land and duties related to it, which, taking into account quality data, will be allocated more fairly.

4 BUILDING LAND REGISTER ESTABLISHMENT PROCESS

Establishing a building-land register involves several phases (Chapter 3.2). Currently, the first phase has been completed, wherein a proposal for inhabited land and its actual use have been prepared as part of the mass capture of inhabited land. As previously mentioned, the proposal for inhabited land was prepared by the Ministry of Natural Resources and Spatial Planning. Municipalities are taking over data management now. They have to determine the amended proposal for inhabited land and the proposal for vacant building land. To determine the amended proposal for inhabited land, the municipality will use data from the proposal for inhabited land, which is the result of mass data collection, data on building plots, data on associated land of public roads and public railway infrastructure, and other data on built-up land. Data on degraded areas will be also considered when determining the final proposal for the extent and characteristics of build-up land. After this activity, they will identify vacant building lands and their characteristics. It is an extensive and complex process in which it will be necessary to use a multitude of datasets to determine the properties of individual lands. In their work, municipalities will use at least data on real estate cadastre parcels, economic public infrastructure, spatial acts, spatial restrictions, and many others. These data will be collected for each vacant building land and these plots will be classified into one of the development levels based on the collected characteristics (Methodology for mass capture of inhabited land, 2019 The register of building land. Spatial information system, 2023).

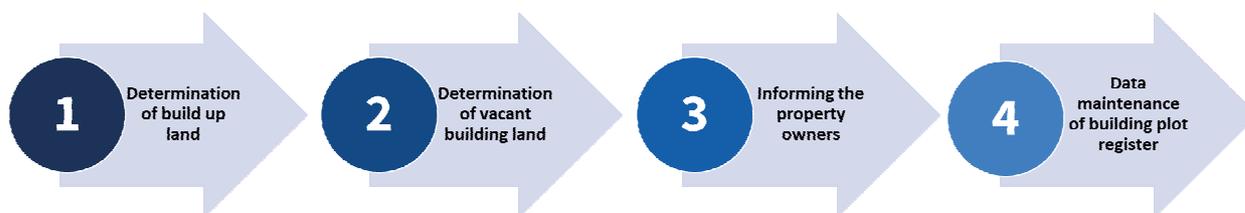
The preparation of the first proposal for built-up land and vacant building land will be followed by informing property owners. Based on the comments of the owners and views of the municipality, a final proposal for the data will be prepared. The municipality will then submit data on inhabited land, associated land of public roads and public railway infrastructure, and vacant building land with development levels to the register of building land at the state level.


Fig. 6: The process of setting the Building land Register.

This is the moment when the real-life building land register will be started. Data from the building land register will be maintained based on changes resulting from the adoption of individual or general legal acts in the field of spatial planning, construction, or public finance (Spatial Planning Act, ZureP-3).

5 CONCLUSION

Sustainable management and land use (space) are priorities for sustainable development. Land, especially agricultural and forest land, is recognized as a non-renewable natural resource, which, when lost, is very difficult (and expensive) to replace. Many strategic documents and policies at different levels address the necessity of changes in approaches to the location of activities and the management of space and, at the same time, point to the critical consequences of the development of the last decades. The report on the environment (2015) of the European Environment Agency points out two things in this connection: a) the extremely rapid loss of (mostly agricultural) land due to construction and b) the great threat to soils and related ecosystem services due to soil "sealing," erosion and pollution (Methodology of derelict areas. MES PILOT, 2022).

The development of system-driven evidence, such as Building land Register, is a long-term and extremely complex process that involves various actors and a multitude of data sources. The implementation began with mass collection in 2017, and the Building land Register is currently in a phase where it is waiting for the municipalities to take it over in their administration and upgrade the data with properties about vacant building land.

With a detailed identification of land properties, the Buidling land register will provide a basis for decision an policy making in all spatial planning processes, from planning, construction, and use of space to maintenance and renovation of its components and at all levels of operation–local, regional, and national. Building land Register will offer greater transparency over the situation in the area and answer questions about where I can build, under what conditions, and whether the land on which we can build is equipped with the necessary infrastructure.

The article draws knowledge and information from the projects of mass capture of inhabited land, eProstor, and Pilot MOP, in which the Geodetic Institute of Slovenia participated as a contractor. We believe that with our work, we have taken important steps towards effective, balanced and sustainable management of space with improved quality of life for all.

1 ABSTRACT

Within the Cool-down Güssing project, measures for sustainable cooling of existing buildings were investigated. While in new buildings the heat input can be reduced by intelligent construction and passive cooling measures can be integrated relatively easily by installing surface cooling system (e.g. concrete core activation), the situation in existing buildings is much more difficult. Nevertheless, with suitable measures, sustainable cooling, or at least a significant reduction of the residual cooling demand, can be achieved. It has been shown that there is no universal solution for all different types of existing buildings. For example, different measures are suitable for large production halls of companies compared to private households. Therefore, the buildings were divided into several categories, like private households, companies and public buildings.

Different types of night ventilation have shown good potential for public building and companies to reduce room temperatures by at least a few degrees. This can be done either by means of decentralized ventilation units or automatic window openers, or by intelligent control of existing infrastructure such as fire ventilation systems which is especially suitable for production halls. Especially for public buildings, financing is often a major challenge, so that suitable financing models must be found. In addition, the heat input should be reduced as far as possible. This can be achieved by external shading and by reducing internal loads. Proper user behavior should also not be underestimated. The remaining electricity demand should be covered as far as possible with electricity from renewable generation. If the installation of an own photovoltaic system (PV) is not possible, energy communities offer the possibility to purchase local renewable electricity at favorable conditions.

Keywords: public buildings, companies, private households, existing buildings, sustainable cooling

2 INTRODUCTION

In Austria, as well as in many other countries, there has been a massive increase of hot days. The number of days above 30 °C has doubled to tripled in recent decades.[GeoSphere Austria, 2022] What used to be a record a few years ago has become average now. In connection with the rising temperatures, the energy demand for cooling has also increased steadily in the recent years. This is problematic, as the operation of conventional cooling devices is very energy-intensive and can thus contribute to a further advance of the climate change. Moreover, due to (currently) high electricity prices, the operation of such cooling systems can cause significant costs. While in new buildings the heat input can be reduced by intelligent construction and passive cooling measures, which can be integrated relatively easily by installing surface cooling system (e.g. concrete core activation), the situation in existing buildings is much more difficult. Surface cooling respectively surface heating systems can only be retrofitted at great constructional and financial expense as part of a comprehensive renovation. To enable climate-friendly cooling in these buildings, therefore, not only new technologies are needed, but also new and, above all, holistic approaches that combine different measures and evaluate their suitability for the use in existing buildings.

Therefore, the Cool-down Güssing project[1] investigates different measures based on nine pilot buildings. The pilot buildings are composed of companies, private households and public buildings in order to take into account a broad cross-section of different requirements and initial situations. The cooling should be carried out as sustainable as possible. In the first step, this means reducing the required cooling energy as much as possible. Various measures to reduce the heat input (insulation, sun protection films, installation of external shading elements, construction of canopies, etc.) were investigated and their suitability for the use in existing buildings was evaluated. Furthermore, the potential for intelligent (night) ventilation was investigated, that the cooler air during the night hours can be used to lower the temperature in the interior spaces. Only if the

---

[1] https://smartcities.at/projects/cool-down-guessing/

use of passive cooling technologies is not (economically) possible or the required cooling capacity cannot be achieved with them, the use of active cooling technologies was examined. If this was the case, the energy demand should at least be supplied with renewable electricity. Especially photovoltaic systems are very well suited to supply cooling devices due to their simultaneity with the occurring cooling demand. In addition to the installation of own photovoltaic systems on the roof of the pilot buildings, renewable energy communities offer stakeholders without photovoltaic systems the opportunity to obtain renewable electricity locally at advantageous conditions in order to operate their cooling equipment. Furthermore, this offers the possibility to use additionally available photovoltaic electricity within the energy community for other purposes. These measures were combined with an extensive stakeholder involvement for demand assessment, awareness raising and training for an optimal user behavior.

The right choice of measures always depends on the individual circumstances. No company, public institution or private household is exactly the same as another. Therefore, general valid solutions are difficult. However, it could be shown that there are many similarities, especially within the respective building categories, where recommendations for measures could be derived from.

3 PUBLIC BUILDINGS

3.1 General conditions

Public buildings are often characterized by large glass surfaces, such as large window fronts or glass-covered staircases. A shading or cooling concept was usually not considered, especially in buildings constructed in the second half of the twentieth century. Although this creates a pleasantly bright indoor climate, many of these buildings are now affected by overheating in summer due to rising temperatures. An example of this is the BORG in Güssing, which is one of the pilot buildings. Already in early summer, temperatures beyond 30°C were measured in some classrooms, which have a negative impact on the students' ability to concentrate.

A second characteristic of public buildings is the difficulty to finance cooling measures. The necessary budget is usually only available to a very limited extent or, in some cases, not at all. Depending on the type of public buildings, there are different stakeholders, which often have a very limited radius of action. Significant changes to buildings often involve a high planning effort, as various committees have to be passed through. Depending on the owner of the building, the responsible parties can be found at the municipal, state or federal level. As a result, this type of building requires particularly cost-effective solutions, both in terms of investment and operation. In the rarest of cases, those responsible for the individual buildings are in a position to implement extensive cooling measures on their own. Therefore, an overriding strategy is required that promotes or finances cooling measures in schools and other public buildings. Otherwise, the implementation of an extensive cooling concept will rarely succeed.

3.2 Recommendations for public buildings

In the case of public buildings, measures to reduce solar radiation and intelligent night ventilation concepts have proved particularly suitable. Although the installation of a central cooling system would be desirable, it is usually beyond the financial scope. The operation of decentralized cooling units causes high operating costs, which in turn burden the budget. In addition, the air conditioning units used are not optimal from an ecological point of view. It is therefore advisable, if not already done, to install external shading options for the window surfaces. In most public buildings, the rooms are used during the day. So, there is nothing to be said against operating the shading manually. However, consistent and early shading is important. If rooms are used only occasionally, a time control can help to carry out the shading. Sun protection films also offer another possibility to minimize solar radiation without completely darkening the rooms. Removable solar protection films also make it possible to take them off in winter to avoid negative effects in terms of heating requirements.

With intelligent night ventilation, the cooler night temperature can be used to cool the building during the night hours, so that temperature peaks during the day can be reduced or at least postponed. Either decentralized ventilation units installed in the respective rooms or automatic window openers are suitable for this purpose.

Automatic window openers can be easily retrofitted to many windows and are cheaper to purchase than decentralized ventilation units. Windows are opened automatically in the summer months as soon as the outside air temperature drops below the temperature inside the building. Rain sensors enable the windows to be closed automatically in case of bad weather. An additional timer control also makes it possible to lock the automatic window openers for certain times to reduce the potential risk of injury from trapped fingers. This can be particularly relevant for schools or kindergartens. Basically, a distinction is made between window openers that tilt the window and those that open the window completely. The wider windows are opened, the higher the air exchange and thus the cooling effect. However, since public buildings are usually not used during the night hours, burglar protection must be taken into account in this regard. Automatic window openers are therefore particularly suitable for higher floors. Optimal are rooms that have windows on several sides or concepts that combine several rooms by means of wall openings or open doors. Another issue are animals such as birds or bats that can get into the building when the windows are open, setting off alarms. Meshes mounted in front of the windows can remedy this, but also reduce the air exchange rate.

Decentralized ventilation units are more expensive to purchase and have, albeit slightly, higher operating costs. On the other hand, the windows remain closed and all the problems associated with open windows are eliminated. In addition, they offer the advantage of providing controlled ventilation during the day, depending on the CO_2 content, thus ensuring that there is no higher heat input than absolutely necessary during the ventilation process. In winter, these ventilation units can also be used to reduce heating costs through integrated heat recovery. Furthermore, it is often possible to retrofit cooling modules in case they are needed later on.

3.3 Example: BORG Güssing

This pilot building houses the BORG and the ECOLE HLW Güssing. The students and teachers suffer from far too high temperatures in the classrooms as early as May. Although the building has external blinds, they are not sufficient as a stand-alone measure to prevent overheating in summer. The classrooms on the south and east sides of the building are particularly affected. A glass roof also causes additional heating of the stairwell.

Measurements have shown that 30 degrees and more are not uncommon. It has also been shown that even during comparatively cool nights, temperatures in the classrooms cool only slightly, as can be seen in Fig 1. While outside air temperatures drop below 13 degrees during the night, indoor temperatures do not drop below 25 degrees. It was therefore decided to equip two of the particularly affected classrooms with decentralized ventilation units for night ventilation. Automatic window openers have not be an option in this case because there is a heating plant in the immediate vicinity, from which a stronger dust input must be assumed in unfavorable wind conditions.

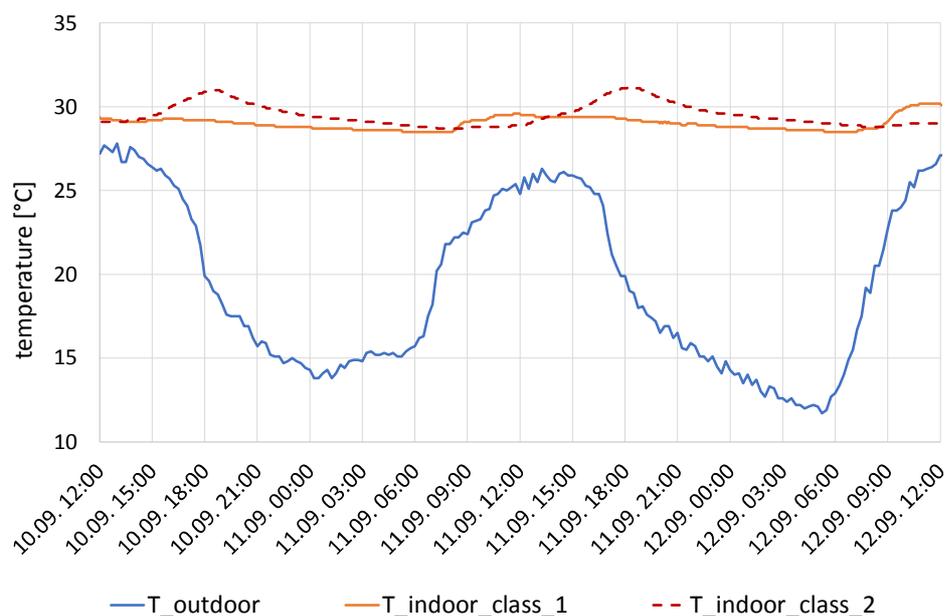

Fig. 1: Temperature profile in the school building measured in the year 2020.

The units will be installed in the summer of 2023. It is assumed that there will be a significant reduction in room temperatures during the night hours, which should result in a much more pleasant indoor climate, at least in the mornings. In addition, an outdoor class (see Fig. 2) has been installed to escape the hot classroom on particularly hot afternoons.

Fig. 2: Picture of the outdoor class of the BORG Güssing

The financing of the cooling units was achieved by sponsoring from an executing company, as this would not have been possible from the school's budget alone. Within the framework of the project, further financing models were developed (crowdfunding, leasing, events), on the basis of which schools can generate further income for cooling measures. However, the integration of a comprehensive cooling concept is only possible through the provision of financial resources and subsidies from a higher authority (in this case the Bundesimobiliengesellschaft). Such measures are urgently needed and should be rolled out nationwide, as the BORG Güssing is by no means an isolated case.

4 COMPANIES

4.1 General conditions and recommendations for companies

Companies were divided into office areas and production halls, as these are subject to very different requirements. In the case of office areas, parallels can be found with public buildings, although the financial constraints are usually less pronounced. The first step is to minimize solar heat gain. External shading options and solar protection films are suitable for this purpose. The installation of canopies can also reduce solar radiation. Optimally, these are combined with photovoltaic systems so that renewable electricity can be generated at the same time to operate cooling equipment. Cooling can also be provided by night ventilation, as described in chapter 3. In addition, roofs of commercial buildings are usually well suited for the installation of PV systems, so that, if necessary, the power supply of conventional air conditioning units can be covered with local renewable electricity.

The cooling of production halls is usually a major challenge if it has to be achieved at reasonable cost. As shown in chapter 4.2 on the example of the Guttomat company, the control of the already installed fire ventilation for night ventilation has proven to be a cost-effective measure, with which the temperatures in the halls could be significantly reduced overnight. How quickly the halls warm up again during the day depends on the structure of the building and its use, but in many cases the time of severe overheating can be postponed by at least a few hours. If possible, an earlier start to work in the summer months can also be considered to take advantage of the cool morning hours. Another option for cooling production halls is adiabatic cooling. Adiabatic cooling is based on the evaporation process. The water evaporates in the air as the air stream passes over the water. The air cools down because the thermal energy required for this is extracted from the air. The advantages lie in the relatively low energy input and low maintenance requirements. The performance depends on the outside air temperature and the humidity. Humid air is more difficult to cool than dry one. Nevertheless, the cooling capacity is significantly higher than the cooling capacity of night ventilation, especially at high outdoor air temperatures during nighttime, but adiabatic cooling also involves significantly higher investment costs.

In addition, it is advisable to take a look at the internal loads. In many cases there are devices that emit heat. Often this heat input can be reduced by suitable insulation measures or by targeted heat dissipation.

4.2 Example: Guttomat[2]

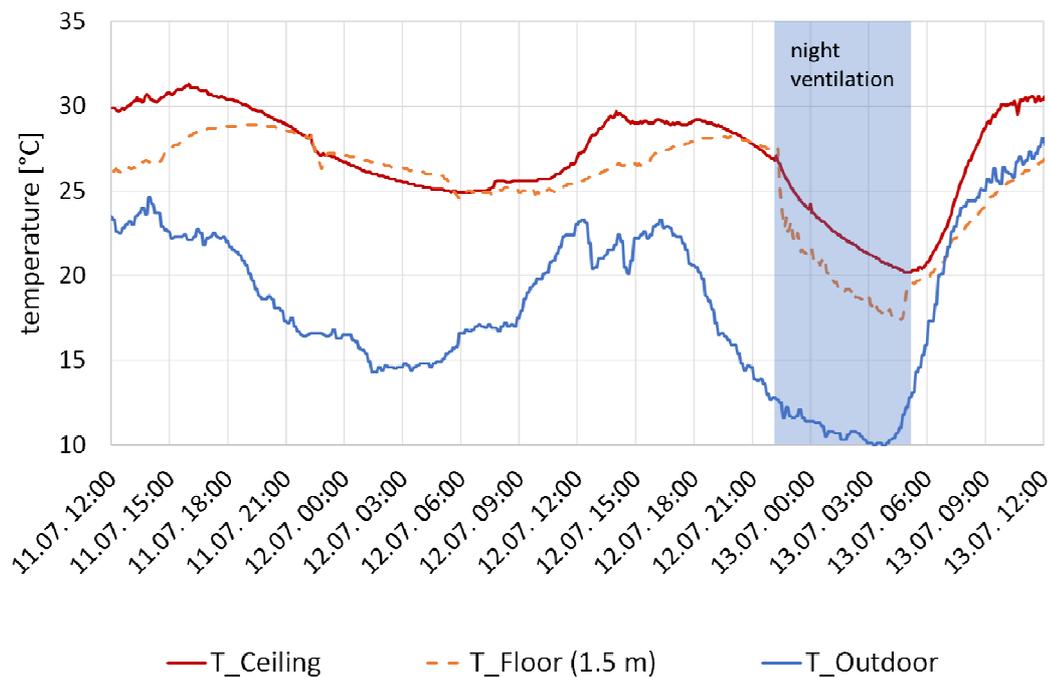
Guttomat is a production company for overhead, sectional, tilt-up and industrial doors. Overheating occurs in the summer months due to the structural conditions and large windows in the production halls as a result of direct solar radiation as well as heat input via the roof surfaces. In this case the existing fire ventilation system (smoke and heat extraction) was adopted to be used for natural ventilation. The fire ventilation system at Guttomat consists of louvre and hood ventilators. In addition to the fire ventilation function the system is designed to provide natural ventilation by utilizing the thermal load within a building as a function of pressure or temperature difference. Based on a test operation, the potential of night ventilation could be confirmed. An example of this is shown in Fig. 3.


Fig. 3: Effects of the night ventilation test by using the fire ventilation system.

In this case, night ventilation was activated by means of a fire ventilation system on the 13th of July at 10 pm. It can be seen that an immediate reduction of the inside air temperature, especially the one near the floor was dedicated. The temperature drops continuously until the night ventilation was stopped at about 4 o'clock due to precipitation in order to avoid moisture ingress. Despite the early termination of the night ventilation, significantly lower temperatures could be reached in the morning hours than for example on the 12th of July where no night ventilation was carried. It has to be mentioned, that the outside air temperature on the 13th of July was lower than on the 12th of July which might have an additional beneficial effect on the indoor temperatures on the 13th of July, but nevertheless the effects of the night ventilation test are shown clearly. According to the employees who are in this area, the night ventilation brought a noticeable improvement especially in the morning hours. After that, a renewed heating of the hall occurred, but the time of overheating could be postponed for several hours. This solution was preferred to adiabatic cooling because of the significantly lower investment costs.

5   PRIVATE HOUSEHOLDS

Private households differ from other building types in terms of hours of presence. Solutions for automatic night ventilation, which are advantageous for public buildings and companies, are usually not needed for private households, as the occupants are usually at home during the cool night hours and can carry out the ventilation manually. If this is not the case, such solutions are of course an option. Furthermore, private

---

[2] https://www.guttomat.at/

households in the Cool-down Güssing project were divided into single- and multi-party residential buildings. Depending on ownership and dedication, different options are available to residents.

If single-family homes are heated with a heat pump, or if a heating system replacement is imminent, it makes sense to use the heat pump for cooling in the summer months. Ground source heat pumps are particularly well suited for cooling, as the cooling circuit can be used for passive cooling in summer (i.e. without operating the heat pump itself). In the case of air-source heat pumps the heat pump can be operated as a chiller. This requires a higher energy input, but especially in combination with a PV system, it is still a comparatively effective solution. If no heat pump is available, ground heat exchangers with air flow can be used to precondition the supply air in combination with a ventilation unit.

In multi-apartment buildings, the individual residents usually have only limited options available to them. In most cases, a conventional air-conditioning split unit is the only possibility to realize cooling. Tenant power models, i.e. common PV systems installed on the roof of multi-party apartment buildings, as well as participation in an energy community offer possibilities to supply them with local renewable electricity.

Proper user behavior should also not be underestimated. Ventilation procedures should be carried out as shock ventilation. The windows should not remain open longer than necessary. CO_2-sensors can help determine the correct ventilation time. Windows should be shaded in good time with external shading measures. Before leaving the house or apartment, it is recommented to shade all windows where a direct exposure to sunlight may occur. Automated systems, such as Smart Home, can support this but are not mandatory.

6 CONCLUSION

The installation of sustainable and at the same time affordable cooling solutions in existing buildings is a major challenge if no comprehensive renovation will be carried out. The installation of conventional air conditioning split units is often the much simpler solution. Nevertheless, with suitable measures, sustainable cooling, or at least a significant reduction of the residual cooling demand, a cooling effect can be achieved. In public buildings, which usually have a particularly limited budget, automatic window openers and decentralized ventilation units have proven to be particularly suitable. These are characterized by low investment and low operating costs. In this case, the cool night air is used to cool the classrooms during the night hours. The performance of night ventilation is limited by the outside air temperature, but in many cases it helps to improve the situation significantly and to postpone overheating at least for a few hours. In production halls, the cool night air can also be used for cooling. For this purpose, the fire ventilation system, which is installed in many cases anyway, can be used. Another option is the installation of an adiabatic cooling system. In addition, internal loads should be identified and reduced. In the case of private houses or apartments, automatic night ventilation is usually not expedient, since people are usually present during the night hours and can carry out night ventilation manually. For houses, the combination of cooling with the heating system is a good option. Especially geothermal heat pumps are well suited for this purpose. Air-source heat pumps can also be used for cooling, although in this case the energy rate is higher. A combination with a PV system is a good way to cover the electricity demand with own renewable electricity and to reduce the operating costs. In apartments, where often only the installation of a conventional split air conditioner is possible, the electricity consumption can be covered by a common PV system on the roof of the apartment building (tenant electricity model) or by joining a renewable energy community with local renewable electricity at more favorable conditions.

These solutions should always be combined with measures to reduce solar gain, e.g. in the form of external shading measures. During the day, ventilation should only be as much as necessary and should be carried out as shock ventilation.

1 ABSTRACT

Öffentliche Straßenräume erfüllen vielfältige Funktionen: Sie sind Orte der Kommunikation/Interaktion, des Konsums, des Aufenthalts und nicht zuletzt unserer Mobilität. Ein Blick auf die derzeitigen städtebaulichen und verkehrlichen Realitäten/ Verhältnisse (Flächenkonsum und rechtliche Vorrangstellung des motorisierten Individualverkehrs (MIV)), lässt jedoch Zweifel an der Funktionsvielfalt und nicht zuletzt am Schlüsselbegriff des „Öffentlichen" sowie an einer damit einhergehenden am Gemeinwohl und Lebensqualität orientierten Stadt- und Verkehrsplanung aufkommen.

Vor diesem Hintergrund beschreibt der Artikel einen dreistufigen kollaborativen Beteiligungs- und Planungsprozess mit der Zivilgesellschaft, der Stadtverwaltung und der Kommunalpolitik für den Umbau einer Quartiersstraße in Dortmund (Deutschland). Ziel des Prozesses war es, die Zieldimensionen Verkehrswende, Aufenthaltsqualität und Klimaresilienz (Blau-Grüne-Infrastrukturen) integriert zu betrachten, um eine gleichermaßen ambitionierte wie gesellschaftlich tragfähige Planung zu entwickeln. Der Artikel beschreibt hierbei nicht nur die empirischen Arbeiten und Befunde, sondern stellt vor allem dar, wie die Rückmeldungen aus dem Beteiligungs- und Planungsprozess in die Planungsentwürfe integriert wurden.

Ausgehend von dem Fallbeispiel diskutieren die Autorinnen und Autoren die Relevanz von temporären Straßenexperimenten für einen dauerhaften Umbau zu lebenswerten Straßen und Städten.

Keywords: Kollaboration, Straßenexperiment, Lebenswert, Beteiligung, Straßenumbau

2 HINTERGRUND

Städte in Deutschland – aber auch in fast allen Industrieländern - sind in den letzten Jahrzehnten stark vom Leitbild der „autogerechten" Stadt geprägt worden. Um den ökologischen, sozialen und ökonomischen Herausforderungen des 21. Jahrhunderts gerecht zu werden, gilt es den urbanen Raum zu transformieren. Daher fordern die Vereinten Nationen, dass Städte „inclusive, safe, resilient and sustainable" (SDG 11) sind bzw. dahingehend entwickelt werden. Ebenso plädiert die Neue Leipzig-Charta für eine gemeinwohlorientierte, integrierte und nachhaltige Stadtentwicklung. Die Klimakrise mit den bereits heute erkennbaren Klimafolgeschäden für urbane Räume verdeutlicht zudem die Notwendigkeit für ein rasches und radikales Umsteuern. Daher haben die Vereinten Nationen auch die 2020er Jahre zur „Dekade der Umsetzung" ausgerufen.[1]

Dem Straßenraum kommt im Kontext dieser urbanen Transformationsprozesse eine besondere Bedeutung zu, da dieser Raum durch Stadtverwaltungen direkt adressiert werden kann. Er spiegelt heute vielfach ein ausgedientes stadt- und verkehrsplanerisches Leitbild wider, nachdem der Verkehr, d.h. der MIV, möglichst ungestört von einem zu einem anderen Ort fließen kann. Versteht man ihn jedoch nicht allein als Verkehrs-, sondern als öffentlichen Raum, besitzt er das Potenzial multifunktionale Flächenansprüche zu erfüllen. Dadurch können sich Städte an die Folgen von Starkniederschlagereignissen und Hitzeperioden anpassen, aktive Mobilität und damit auch Gesundheitsschutz befähigen, Nachbarschaften durch Teilhabe und Interaktion zu stützen oder auch um lokale Ökonomien fördern zu können.

Auch wenn diese Ansprüche an den öffentlichen Raum heute immer stärker in der Planungspraxis berücksichtigt werden, bestehen dennoch hohe Barrieren und Beharrungskräften, die grundlegende strukturelle Veränderungen behindern. Wie kann es gelingen, diese Barrieren abzubauen, so dass sich die Alltagsroutinen der Stadtgesellschaft verändern und sie sich gleichzeitig mitgenommen und nicht überfordert fühlt? TemporäreStraßenexperimente (tactical urbanism, street experiments, street reclaiming) können hierfür ein wichtiger Baustein sein. Sie stellen einen schnellen, kostengünstigen und umsetzungsorientierten Ansatz dar, um für städtebauliche und/oder verkehrliche Problemlagen im Straßenraum zu sensibilisieren und zukunftsgerichtete Lösungen zu erproben. Das Experimentieren erlaubt eine frühzeitige Partizipation der

---

[1] https://www.un.org/sustainabledevelopment/decade-of-action/

Stadtbevölkerung, um mögliche Fehlplanungen bzw. Konfliktlinien zu identifizieren und auf diese kommunikativ wie planerisch einzugehen. Um den Mehrwert von Straßenexperimenten zu heben, gilt es jedoch diese intelligent in Beteiligungs- und Planungsprozesse zu integrieren.

3   TEMPORÄRE STRAßENEXPERIMENTE ALS PLANUNGSINSTRUMENTE

Der Umbau von Stadtstraßen erfordert in Deutschland häufig eine formelle Bürgerinnen- und Bürgerbeteiligung im Rahmen eines sogenannten Planfeststellungsverfahren. Da dieses jedoch meist erst recht spät im Planungsprozess ansetzt, setzten Kommunen häufig in frühen Planungsphasen auf informelle Beteiligungsformate, um frühzeitig die Planungen zu erläutern und rückzukoppeln, Konflikte zu identifizieren und ggf. Planungen dahingehend anzupassen.

In den letzten Jahren haben sich, international (z.B. Superblocks/Barcelona, Piazze Aperte/Mailand, Grätzloasen/Wien) aber auch in Deutschland (z.B. Ottensen Macht Platz/Hamburg, Friedrichstraße/Berlin, Piazza Zenetti/München), temporäre Straßenexperimente als weiteres Element einer Bürgerinnen- und Bürgerbeteiligung im Planungsprozess zunehmend etabliert. Straßenexperimente sind allerdings keineswegs ein neues Phänomen: Bekannte Beispiele sind die Ciclovía, die 1974 in Bogotá, Kolumbien, ins Leben gerufen wurden und der mittlerweile international etabliertePARK(ing) Day, der erstmals 2005 in San Francisco, USA stattfand. Diese Straßenexperimente der ersten Stunde zielten vor allem auf eine Sensibilisierung der Bürgerinnen- und Bürgerschaft für die negativen Auswirkungen einer autogerechten Stadtentwicklung ab. Der konkrete Straßenumbau, d.h. die dauerhafte Umverteilung des öffentlichen Straßenraums, stand jedoch nicht im Mittelpunkt des Interesses.

Im Zuge der in den letzten Jahren immer deutlicher werdenden Klimakrise und vor allem durch die Covid-19-Pandemie, haben Straßenexperimente als kurzfristig realisierbarere Straßenraumumnutzung als Zwischenschritt hin zu einem dauerhaften Umbau bzw. zur Erprobung der Wirksamkeit eines dauerhaften Umbaus an Bedeutung gewonnen. Heutige radikale Stadtumbaupläne wie in Paris, Mailand oder Barcelona sind das Resultat eines Zusammenspiels aus Notwendigkeiten (Klimakrise, Covid-19) und politischem Mut. Die positiven Erfahrungen aus Straßenexperimenten (z.B. Pop-up-Bikelanes) können in diesem Kontext wichtige Impulsgeber sein. Bertolini (2020) definiertStraßenexperimenteals "intentional, temporary change of the street use, regulation and/or form, aimed at exploring systemic change in urban mobility, away from 'streets for traffic', and towards 'streets for people'".

Die Vorteile von Straßenexperimenten für Stadtverwaltungen liegen dabei auf der Hand. Durch die vorübergehende Veränderung des Straßenbildes ermöglichen sie Stadt- und Verkehrsplanerinnen sowie Stadt- und Verkehrsplanern, aktuellen räumlichen wie auch sozialen Anforderungen gerecht zu werden. Gleichzeitig bieten sie die Möglichkeit, Lösungsansätze für langfristige Herausforderungen wie Luftverschmutzung, Lärm, Verkehrsunfälle und Staus zu testen. Straßenexperimente "aim to provide a glimpse of a drastically different future scenario, wherein streets are for mixed uses including socializing, playing, and exercising – that is, 'for people' (Gehl, 2010) - rather than for traffic" (Van Hoose et al., 2022). Sie sind dabei deutlicher schneller und zu deutlich niedrigeren Kosten als ein dauerhafter Umbau zu realisieren und eignen sich als Beteiligungsformat, um a) ortsspezifisches Wissen frühzeitig in den Planungsprozess einzubinden, b) mögliche Konflikte zu antizipieren und aufzulösen, um so die Planungen sowie die Akzeptanz dafür zu verbessern.

Damit Straßenexperimente all diese Funktionen erfüllen können, gilt es jedoch, sie intelligent in den Planungsprozess einzubinden. Das nachfolgende Beispiel zeigt hierfür einen möglichen Weg auf.

4   METHODISCHE VORGEHENSWEISE

Der dargestellte Beteiligungs- und Planungsprozess war angeleitet von dem normativ-konzeptionellen Leitbild einer ‚lebenswerten Straße'. Als solches werden Straßenräume bezeichnet, bei denen die Zieldimensionen Verkehrswende, Klimaresilienz durch blau-grüne Infrastrukturen und Aufenthaltsqualität integriert betrachtet werden, sodass Straßen für Menschen und nicht für Autos entstehen (März et al., 2020). Dieses Leitbild wurde auf die Dortmunder Quartiersstraße „Neuer Graben" angewendet. Das betrachtete 560m lange und circa 16m breite Teilstück befindet sich im Dortmunder Kreuzviertel und umfasst bereits heute Elemente einer lebenswerten Straße. Es existiert ein alter Baumbestand, die Straße ist insgesamt aufgrund zahlreicher Cafés, Restaurants und Einzelhandelsgeschäften belebt und die Bewohnerinnen und Bewohner sind vielfach zu Fuß oder mit dem Rad unterwegs. Allerdings ist das Straßenbild insgesamt stark

vom ruhenden Verkehr geprägt. Im Straßenraum parken, zu relevanten Anteilen nicht StVO-konform, bis zu 220 Pkw. Anlass für die Auswahl waren anstehende grundhafte Kanalsanierungsarbeiten (März et al., 2022).

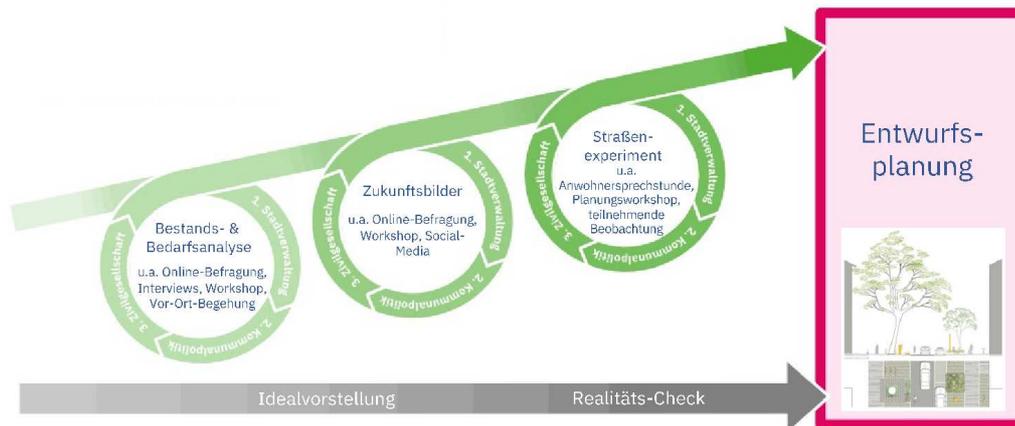
Im Rahmen des LesSON-Projekts hat ein Forscherinnen- und Forscherteam ein Straßenexperiment in einen rund eineinhalb Jahre andauernden Planungsprozess integriert, bei dem sowohl die Stadtverwaltung, die Kommunalpolitik als auch die Zivilgesellschaft mehrfach bei der Ideenentwicklung für einen zukunftsfähige Straßenumbau aktiv eingebunden wurden. Das Ziel war die Entwicklung einer gleichermaßen ambitionierten wie gesellschaftlich tragfähigen, d.h. mehrheitsfähigen Planung für den Neuen Graben. Der kollaborative Planungsprozess gliederte sich insgesamt in die drei Phasen Bestands- & Bedarfsanalyse, Zukunftsbilder und temporäres Straßenexperiment und kennzeichnet sich durch ein iteratives Vorgehen. In jeder Phase wurde zunächst die Stadtverwaltung, anschließend die Kommunalpolitik und im Anschluss die Zivilgesellschaft eingebunden, um die jeweiligen Planungsschritte auf eine breite Basis zu stellen (vgl. Abbildung 1).


Abbildung 1 Schematischer Ablauf des Beteiligungs- und Planungsprozesses

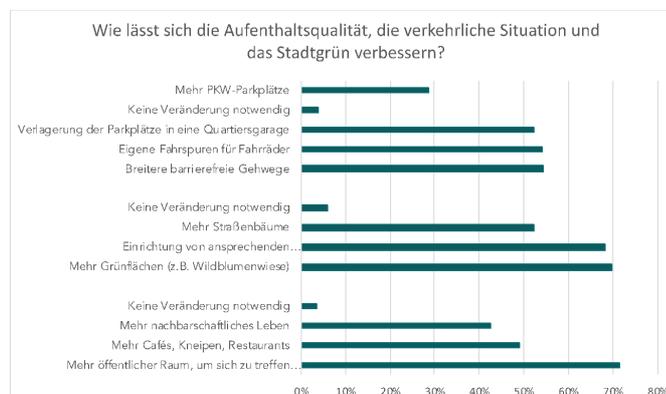
Nachfolgend werden die verschiedenen Phasen mit Blick auf deren Einfluss auf den Planungsprozess kurz dargestellt.[2]


Abbildung 2 Zentrales Feedback für eine Zukunftsvision des Straßenraums

5 ERGEBNISSE

5.1 Bestands- und Bedarfsanalyse

In der Bestands- und Bedarfsanalysen erfolgten verschiedene Analysen mittels klassischer Methoden der empirischen Sozialforschung und Verkehrsplanung (u.a. Interviews, Online-Befragungen, Vor-Ort-Begehung, Parkraumzählung). Die mittels Geo-Targeting durchgeführte Online-Befragung (n=709) unterstrich den hohen Parkdruck, die Unzufriedenheit damit und den Wunsch nach einer Qualifizierung des öffentlichen Straßenraums durch Stadtgrün und attraktive Verweilorte (im Grünen) (vgl. Abbildung 2). Das Ergebnis bestätigt andere Studien (z.B. Zoderer et al., 2021), nach denen die hohe Wirksamkeit grüner Infrastrukturelemente (insb. bei Erhöhung des Grünanteils) hinsichtlich ihrer Ökosystemdienstleistungen wie

---

[2] Der Fokus liegt im Rahmen dieses Papers auf der zivilgesellschaftlichen Beteiligung und nicht auf den Arbeiten mit der Stadtverwaltung bzw. der Kommunalpolitik.

u.a. die Regulierung des Mikroklimas oder eine verbesserte Biodiversität sowie der positiven Eigenschaften für das menschliche Wohlergehen als erstrebenswert angesehen werden.

5.2 Zukunftsbilder

Aus den abstrakten Anregungen der Anwohnerinnen- und Anwohnerschaft wurden zwei Zukunftsbilder abgeleitet in eine Vorplanung übersetzt und visuell aufbereitet (Abbildung 3). Im Wesentlichen unterscheiden sich die „Fahrradstraße" (minus 75% ruhender Verkehr) und der „Shared-Space" (minus 100%) im Ambitionsniveau bzgl. der Reduktion des ruhenden Verkehrs und der damit verbundenen Umwidmung der freiwerdenden Verkehrsfläche. Im Rahmen der zweiten digitalen Anwohnerinnen- und Anwohnerbefragung konnten die Varianten bewertet und diskutiert werden. Beide Zukunftsbilder wurden mehrheitlich deutlich besser bewertet als der aktuelle Status quo. Während der Status Quo auf einer 10-stufigen Likert-Skala eine mittlere Bewertung von 3,93 erhielt, wurden die Zukunftsbilder mit 6,67 (Fahrradstraße) bzw. 6,17 (Shared Space) bewertet.[3] Allerdings variierte die Beurteilung zwischen den untersuchten Subgruppen teils signifikant. Sowohl die Zustimmung von Personen, die einen privaten Pkw im Haushalt besitzen, sowie von Personen, die diesen ebenfalls häufig nutzen, fällt in Bezug auf beide Zukunftsbilder signifikant geringer aus.[4]

Abbildung 3 Status-Quo (oben links), Zukunftsbilder „Shared-Space" (unten links) / „Fahrradstraße" (unten rechts) und eine Vorzugsvariante (oben rechts) für den Neuen Graben (Bildrechte: MUST Städtebau GmbH)

5.3 Temporäres Straßenexperiment

Ausgehend von den überaus positiven Rückmeldungen der bisherigen Beteiligungsformate, erfolgte im August 2021 (31.07 bis 14.08) ein Straßenexperiment in Anlehnung an das „Shared Space"-Zukunftsbild. Zwar blieb die Fahrbahn im gesamten Zeitraum regulär nutzbar, auf den Flächen des ruhenden Verkehrs (ca. 40 Pkw-Stellplätze) wurde jedoch mittels verschiedener atmosphärischer und grüner Elemente (u.a. Rollrasen, Pflanzkübel, Liegestühle, Sitzbänke etc.) ein lebenswerter Raum geschaffen. Begleitet wurde das Straßenexperiment durch vielseitige Partizipationsformate, um sowohl analog wie digital in den direkten Dialog (Anwohnersprechstunden, Planungsworkshops, Online-Workshop) zu treten, als auch anonymes Feedback (Fragebogen, Briefkasten) einzuholen.

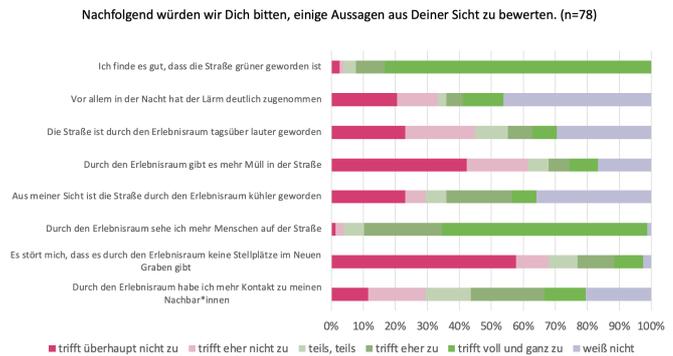
Die positiven Bewertungen aus vorangegangenen Beteiligungsformaten trafen während des Straßenexperiments auf z.T. konträre Alltagsrealitäten. Zwar fiel die Bewertung insgesamt überwiegend positiv aus. Die Wahrnehmung divergierte jedoch entlang der drei Faktoren 1) Alter, 2) Pkw-Besitz und 3) direkte Anwohnerschaft. Aufgrund der Konkretheit des räumlichen Experiments konnten frühzeitig nicht-intendierte Nebeneffekte identifiziert werden wie bspw. eine hohe Lärmentwicklung oder vermehrte

---

[3] n = 1.545

[4] Eine detaillierte Beschreibung der Umfrageergebnisse erfolgt bei März et al. (2022).

Verschmutzung durch die intensive Nutzung des Experimentierraums. Ebenso wurde der komplette Wegfall der Pkw-Stellplätze, trotz Ausweichstellplätzen, die Ausweitung der Außengastronomie oder die Spielmöglichkeiten entlang der Straße kritisch gesehen.

Abbildung 4 Impression des temporären Straßenexperiment (links) und Bewertung (rechts) (Bildrechte:T.Weyland)


5.4 Anpassungen der Planungsentwürfe im Rahmen des kollaborativen Beteiligungsprozesses

5.4.1 Motorisierter Individualverkehr und ruhender Verkehr

Der MIV, aber vor allem der ruhende Verkehr dominiert heute das Straßenbild des Neuen Grabens, obwohl bereits heute rund ein Viertel der Haushalte im Quartier kein eigenes Auto besitzen. Insgesamt parken in den Abendstunden bis zu 220 Pkw im Straßenraum, obwohl nur rund 140 legale Parkplätze existieren. Die Zukunftsbilder skizzierten daher eine Straßennutzung, in der der MIV nur noch Gast ist. Die Bilder sollten bewusst provozieren, um eine Debatte anzustoßen und so den Möglichkeitsraum zu verschieben. Ausgehend von dem Straßenexperiment wurde schließlich eine Kompromiss gefunden, bei dem rund 50 % der legalen Stellplätze umgewidmet werden. Da das heute weitgehend geduldete Falschparken durch planerische Eingriffe (z.B. Poller, Beete) nicht mehr möglich sein wird, reduzieren sich die heutigen Stellplatzflächen um bis zu 75 %. Die verbleibenden Parkplätze werden baulich so gestaltet, dass eine spätere Nutzungsumwidmung mit geringem Aufwand und Kosten verbunden ist.

5.4.2 Umweltverbund

Der Fußverkehr spielt bereits heute eine wichtige Rolle. Die Beteiligungsphasen haben seine Rolle weiter gestärkt, in dem in den Entwurfsplanungen die Gehwege barrierefrei und 2,50m breit geplant werden. Zudem werden Nutzungskonflikte mit der Außengastronomie und auf dem Gehweg parkenden Autos vermieden. Das Fahrrad ist ebenfalls bereits heute ein wichtiges Verkehrsmittel, allerdings existiert keine adäquate Infrastruktur. Lediglich 9 % der Haushalte im Viertel besitzen kein eigenes Rad. Ausgehend von den Rückmeldung aus der Bestandsanalyse wurde das Rad in den Zukunftsbildern zum wichtigsten Verkehrsmittel, zu Lasten des MIV. Das Straßenexperiment verdeutlichte jedoch, dass solch eine radikale Veränderung der Verkehrsmittelpriorisierung, den gesellschaftlichen Rückhalt deutlich negativ beeinflussen würde, zumal im direkten Umfeld des Neuen Grabens ein Radschnellweg in Planung ist. Es wurde sich daher gegen ein Shared-Space, Fahrradstraße oder Fahrradzone entschieden. Vielmehr wurde die Straße in eine mind. 4m breite Einbahnstraße, die für den gegenläufigen Radverkehr freigegeben ist, in der Entwurfsplanung umgewandelt. Zudem wurden Radabstellanlagen für 300 Räder geschaffen. Die Straße wird nicht durch den ÖPNV bedient, allerdings sieht die Entwurfsplanung Car- und Bikesharing Stellplätze vor.

5.4.3 Blau-Grüne Infrastrukturen

Der Erhalt der heutigen Baumstandorte sowie der Wunsch nach zusätzlichem Stadtgrün durchzogen alle Beteiligungsphasen. Entsprechend wurde in der Entwurfsplanung der Baumbestand gesichert und insgesamt 16 neue Baumstandorte definiert. Es ist ein Wasserspiel vorgesehen.

5.4.4 Interaktionsräume/Aufenthaltsqualität

Der ursprünglich identifizierte Bedarf nach mehr öffentlichen, nicht kommerziellen Aufenthaltsräumen zum Verweilen oder auch zum Spielen wurde durch ein Wasserspiel, Sitzecken, Spielgeräte sowie eine

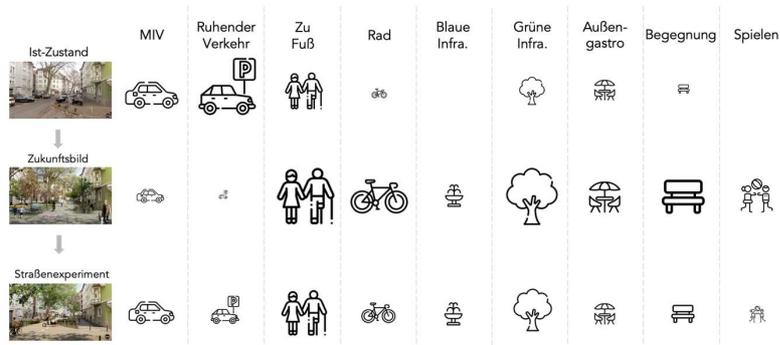
Ausweitung der Außengastronomie in den Zukunftsbildern umgesetzt. Das Straßenexperiment deckte jedoch nicht intendierte negative Auswirkungen (Gesprächslärm, Müll) auf. Zudem zweifelten Eltern an der Sicherheit und Notwendigkeit der Spielgeräte im Straßenraum, aufgrund der unmittelbaren Fahrbahnnähe sowie vorhandenen Spielplätzen in der Nachbarschaft. Daher enthält die Entwurfsplanung zwar noch Sitzmöglichkeiten (zur Pause beim zu Fuß gehen), aber keine größeren Sitzecken oder Spielgeräte mehr. Auch die Außengastronomie wurde nicht erweitert, sondern nur vom Gehweg weg verlagert, um Nutzungskonflikte mit Fußgängerinnen und Fußgängern zu vermeiden.


Abbildung 5 Schematische Darstellung der Veränderungen der Planungsentwürfe im Beteiligungsprozess

6 DISKUSSION

Insgesamt war das Straßenexperiment ein wichtiger Baustein im kollaborativen Beteiligungs- und Planungsprozess, da es neue Perspektiven auf die heutige wie zukünftige Straßennutzung erlaubte. Insgesamt ziehen die Autorinnen und Autoren folgende Schlussfolgerungen:

- Temporäre Straßenexperimente erlauben stärkere Diskussion auf Augenhöhe

In formellen wie informellen Beteiligungsformaten werden Planungen häufig über Lagepläne oder Schnitte dargestellt. Dies setzt jedoch ein gewisses planerisches Verständnis bei der Zivilgesellschaft (und Kommunalpolitik) voraus. Durch die Verortung von Planungen bzw. Planungselementen im Raum wird die Verständlichkeit erhöht, sodass Diskussionen stärker auf Augenhöhe erfolgen können.

- Temporäre Straßenexperimente helfen neue/zusätzliche Zielgruppen zu erreichen und fördern das Demokratieverständnis

Durch Straßenexperimente verlagern sich Diskussionen an die Transformationsorte. Dies erhöht nicht nur den Grad der Konkretheit von Diskussionen, sondern verringert auch die Einstiegshürden in die Diskussion. Menschen werden dort abgeholt, wo die Planungen später wirken. Dies schafft Transparenz und verringert den Eindruck, dass Planungen "irgendwo" am Schreibtisch entstehen. Der öffentliche (Straßen-)Raum wird dadurch öffentlich "produziert", wodurch sich auch die Identifikation mit den Planungen erhöhen kann.

- Temporäre Straßenexperimente sind kein Allheilmittel

Viele Städte haben in den letzten Jahren Straßenexperimente umgesetzt. Dafür braucht es finanzielle und vor allem personelle Ressourcen. Letztlich binden Experimente Ressourcen, die an anderer Stelle womöglich fehlen. Gleichzeitig wecken sie Erwartungen, z.T. auch falsche Erwartungen. Daher gilt es sich die Intention von Straßenexperimenten klar zu machen und kritisch zu reflektieren, ob das Experiment hierfür die richtige Methode ist. Dies gilt umsomehr, da Straßenexperimente Wirkungen von Planungen bzw. Umbauten immer nur andeuten können. Gerade die positiven mikroklimatischen Effekte von NBS lassen sich nur sehr eingeschränkt darstellen.

- Temporäre Straßenexperimente "nur" ein Baustein eines kollaborativen Planungsprozesses

Die Eignung und der Zeitpunkt des Einsatzes von Straßenexperimenten für Planungsprozesse hängt stets vom jeweiligen Einzelfall ab. Im Fallbeispiel hat es sich als zielführend erwiesen, das Straßenexperiment zu nutzen, um die artikulierten Bedarfe und daraus abgeleiteten Zukunftsbilder dar- und damit zur Diskussion zu stellen. Dadurch wurden die bisherigen Planungen qualifiziert. Das Experiment diente jedoch auch der Stadtverwaltung und Kommunalpolitik zur Selbstvergewisserung, dass die Planungen nicht nur planerisch möglich sind, sondern auch gesellschaftliche Akzeptanz finden. Das Straßenexperiment war folglich eines

1004

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

von mehreren Bausteinen, bei dem Stadtverwaltung, Kommunalpolitik und Zivilgesellschaft kollaborativ die Zukunft des Straßenraums gemeinsam entwickelten.

7 FAZIT

Das Fallbeispiel des Neuen Grabens, Dortmund, hat gezeigt, dass Straßenexperimente als Teil eines Beteiligungsprozesses die Qualität von Planungsentwürfen verbessern können. Sie ermöglichen eine verbesserte Diskussionskultur mit den Akteurinnen und Akteuren vor Ort und bieten Gelegenheit, Planungsideen frühzeitig im Feld zu testen. Sie sind jedoch mit einem nicht zu vernachlässigen personellen, zeitlichen und finanziellen Aufwand verbunden. Ihre Nutzung sollte daher kein Selbstzweck sein, sondern immer vom Einzelfall abhängig gemacht werden. Richtig eingesetzt, können sie jedoch die gesellschaftliche Akzeptanz veränderter Planungsparadigmen und notwendiger urbaner Transformationen erhöhen, damit Straßen und Städte zukünftig wieder zu lebenswerten Orten für Menschen werden.

1 ABSTRACT

The recently developed microscale model for urban applications PALM-4U was used to simulate the thermal variability in Vienna on different spatial scales and to evaluate its ability to capture thermal characteristics in real urban environment.

The model simulations cover the entire city of Vienna with a spatial resolution of 20 m. The static data related to geographical information and urban infrastructure are based on GIS data provided by the city administration of Vienna, available as spatial multi-purpose maps (Flächen-Mehrzweckkarte - FMZK), street tree cadastre, Digital Elevation Model and Digital Surface Model, which were combined with the national land cover data (Land Information System Austria - LISA) to account for the unresolved vegetation and Open Street Map to include building properties in the surrounding region (Lower Austria) of the model domain. The simulations were performed for a selected clear-sky hot day in August 2022.

The results for hourly air temperature were evaluated with conventional weather stations of the national weather service and the city of Vienna and with quality-controlled data from citizen weather stations from the company NETATMO. The results show high intra-urban variability during daytime, but distinct spatial patterns at night with higher air temperatures in urban regions. In addition, spatial patterns of surface temperature were compared to remote sensing data from ECOsystem Spaceborne Thermal Radiometer Experiment on Space Station (ECOSTRESS) and with the modelling results from previous studies, but with coarser grid spacing (e.g. urban climate model MUKLIMO_3 with 100 m spatial resolution).

The results indicate that the microscale model PALM-4U shows general agreement with observations and is able to simulate atmospheric processes in urban regions. However, during the night a strong temperature inversion is present in the model, which can be related to the choice of model configuration and requires further investigations. The spatial patterns in urban-rural temperature gradient are similar as found in coarser scale model simulations and remote-sensing data, but show higher variation in surface temperature amplitude.

Keywords: surface temperature, climate modelling, urban heat island, simulation, palm-4u

2 INTRODUCTION

Due to the modified energy balance in built-up environment, urban areas are generally warmer than their surroundings (e.g. Oke, 2019; Oke et al., 2017), an effect known as the Urban Heat Island (UHI), or Surface Urban Heat Island (SUHI), when surface temperatures are considered. Building materials often have low reflectivity, high heat capacity and thermal conductivity, which enhances the absorption of solar radiation during the day and the excess heat is being slowly released during the night. Especially in densely built areas, with lack of vegetation and appropriate ventilation, the heat is being trapped in street canyons. Large water surfaces and green areas, usually provide regulating function in reducing the temperature extremes, through evaporative cooling and enhanced ventilation, in case of water, and shading, in case of trees. However, diversified relief, land use and land cover of cities, as well as characteristics of built-up structures, make the distribution of urban temperatures spatially inhomogeneous. Mapping of areas with extreme heat or cool zones and understanding the development of UHI became an important issue in urban planning in order to protect the beneficial natural areas, decrease the impact of existing and avoid generation of new hot-spots through further urban development.

As a measure to reduce negative aspects of urban climate, the City of Vienna developed an UHI strategic plan (UHI MA22, 2015) including a number of urban planning measures for buildings and open spaces, particularly measures based on green infrastructure. The strategic plan was based on various data sources and climate studies assessing urban climate of Vienna (e.g. Schwab&Steinicke, 2003; Zuvela-Aloise et al. 2013; Stiles et al., 2014). Additional heat vulnerability map of Vienna was published in 2019 based on the thermal infrared sensor from Landsat 8 with a spatial resolution of 100 m, which was used to derive a weighted

average surface temperature for Vienna, covering the years 2015 to 2019 and combined with information on distribution of vulnerable age classes and a vegetation index (Bhattacharjee, 2019). An updated urban climate analysis map was provided in 2020 based on a GIS procedure and illustrates thermal characteristics, but also the cold air flow during the night. All studies of urban climate in Vienna indicate higher heat load in the densely built urban centre and lower temperatures in forested areas westward and along the river Danube. However, detection and exact localization of hot-spots, as well as selection of appropriate measures to reduce the UHI effect remained an issue. Various background data, spatial resolution and different mapping techniques lead to uncertainties in resulting urban heat maps.

One of the main tools for analysing UHI development are the urban climate models that take into account both urban morphology and meteorological data and can be used for climate assessment, as well as for evaluation of urban planning measures and spatial development plans. Newly developed urban microclimate model PALM-4U (Maronga et al. 2020) allows simulation of entire cities with a very high-resolution enabling detection of small-scale temperature variations on a building-scale. However, the model has not been tested yet in various urban environments and an evaluation of model performance is needed to quantify possible uncertainties.

In this study the urban climate model PALM-4U was applied to simulate the UHI in Vienna with grid-resolved building and vegetation canopy on a spatial resolution of 20 m. The simulations are compared to existing modelling simulations with the MUKLIMO_3 model used in previous studies (Hollosi et al. 2021; Zuvela-Aloise et al., 2022) and observational data. The modelled surface temperature was compared with the remote sensing data from ECOsystem Spaceborne Thermal Radiometer Experiment on Space Station (ECOSTRESS) and the near-ground air temperature was evaluated against monitoring data from citizen weather stations.

3 DATA AND METHODS

3.1 Urban climate simulations

The open-source modelling system PALM (PArallelized Large-Eddy Simulation Model) with recently developed additional modules for urban boundary layer (PALM-4U) is a new modelling tool for high spatial resolution simulations of urban environment based on the large-eddy simulation (LES) technique (Raasch and Schröter, 2001; Maronga et al., 2015; 2020). In this study, the PALM-4U model was applied for the city of Vienna to evaluate the model performance and was compared with the established modelling approach based on urban climate model MUKLIMO_3 (Sievers, 2016). In comparison to PALM-4U, the MUKLIMO_3 model uses RANS-type turbulence parametrization, parametrization of buildings and land use based on a tile approach and has typically a lower spatial resolution (20 - 100 m). The simulations were performed for August, 16-17, 2022, as a representative hot day with clear-sky conditions. The models were initialized at 06:00 UTC with the initial vertical profiles of meteorological variables from the AROME numerical weather forecast model in operation by GeoSphere Austria.

Both models use information on terrain, land use and land cover, building and vegetation properties, however, in different format and spatial detail. In case of the PALM-4U model, the static information was provided from Digital Elevation Model and Digital Surface Model for the City of Vienna and Lower Austria, land cover data from Land Information System Austria (LISA), Open Street Map, street tree cadastre (Baumkataster) and spatial multi-purpose maps (Flächen-Mehrzweckkarte - FMZK) of the City of Vienna. The spatial information was prepared in a raster format with 20 m spatial resolution according to Heldens et al. (2020). In case of the MUKLIMO_3 model raster data with 100 m spatial resolution were provided for terrain height, land use types based on Copernicus Urban Atlas enriched with LISA land cover data, building height, wall area index of buildings, building density, tree cover and proportion of sealed surfaces based on High-Resolution Layers of Copernicus Land Monitoring Services.

3.2 Observational temperature data

The standard meteorological monitoring network in Vienna includes about a dozen of official semi-automatic weather stations, so-called TAWES stations, and additional environmental monitoring stations employed by the city administration departments (MA22). In order to evaluate the modelling results with high spatial resolution, a higher density of monitoring stations is needed. For this purpose, the monitoring

1008

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

data from a network of over 1000 private weather stations available in Vienna provided by the company NETATMO was used. To minimize the uncertainty associated with the non-standardized temperature measurements, a statistical quality control as proposed in Napoly et al. (2018) was applied. As previous studies for Vienna have shown (Hammerberg et al. 2018, Feichtinger et al. 2020), a rigorous quality control which detects outstanding temperature observations, can help to reduce sources of errors and the data can be used to investigate the intra-urban air temperature variations.

The remote sensing data for surface temperature were provided by ECOsystem Spaceborne Thermal Radiometer Experiment on Space Station (ECOSTRESS) mission. The ECOSTRESS Land Surface Temperature and Emissivity Daily L2 Global 70m V001 dataset (Hook & Hulley, 2019), which is part of the ECO2LSTE Version 1 data product providing atmospherically corrected land surface temperature and emissivity (LST&E) values derived from five thermal infrared bands including layers of LST, emissivity for bands 1 through 5, quality control for LST&E, LST error, emissivity error for bands 1 through 5, wideband emissivity and Precipitable Water Vapor were used. The dataset has a spatial resolution of about 70 m. In this study, the LST and corresponding quality control data for LST layers available for August 16, 2022 were considered. A short overview of data used in model validation is shown in Table 1.

	MUKLIMO_3	**PALM-4U**	**ECOSTRESS**	**NETATMO**
Type of data	RANS microscale model output	LES microscale model output	satellite imagery	private weather stations
Spatial resolution	100 m	20 m	70 m	over 1000 stations with quality-controlled data
Time output	hourly	hourly	snapshot	30-min to hourly
Air temperature	reference at 2 m, defined vertical model levels	reference at 2 m, defined vertical model levels	not available	variable
Surface temperature	temperature of soil, streets, building roofs and top of vegetation (trees)	temperature of soil, streets, building roofs and the soil under the vegetation (trees)	temperature of surface visible by satellite (excluding clouds)	not available

Table 1: Overview of meteorological data used in the study.

4 RESULTS

The observational data for air temperature based on quality-controlled measurements from NETATMO private weather stations show distinct pattern of the UHI island in Vienna during the night. Higher temperatures are found in the city centre and lower temperatures in the surroundings (Fig. 1). The model results show similar large-scale pattern, however, small-scale variation in temperature and temperature inversion with height are more pronounced in the PALM-4U model compared to the model with lower spatial resolution (MUKLIMO_3).

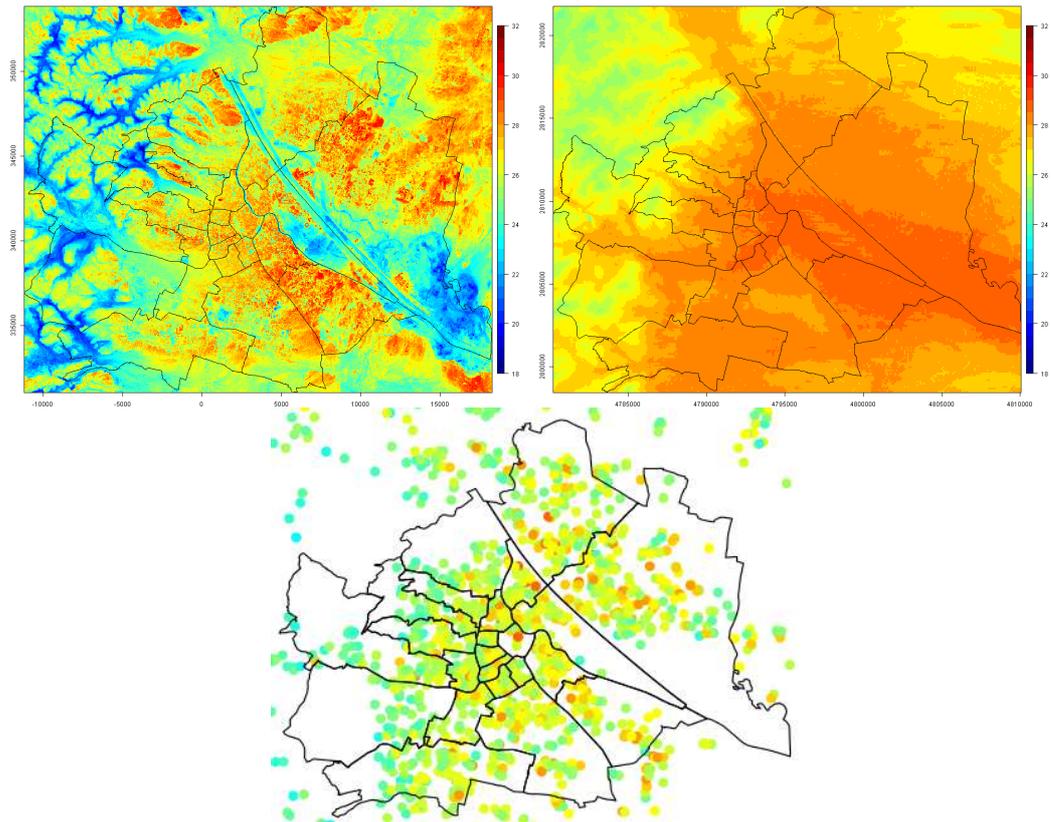
The spatial patterns in surface temperatures based on remote sensing (Fig. 2), show an urban-rural temperature gradient as well, with higher temperatures found in built-up areas and lower temperatures in forested areas and near water. However, agricultural areas in south and east show high surface temperatures during the day as well. This effect is most likely caused by high exposure of low vegetation and free soil to solar radiation and low soil moisture during the heat wave and is well captured by the models. The PALM-4U model overestimates the surface temperatures in urban areas, which can be partially explained by variations in temperatures due to the higher model resolution, but requires further investigation.


Fig. 1: Air temperature (°C) in Vienna on 16. August 2022 at 19:00 UTC calculated by PALM-4U model (top left), MUKLIMO_3 model (top right) and derived from quality-controlled monitoring dataset of NETATMO private weather stations (bottom).

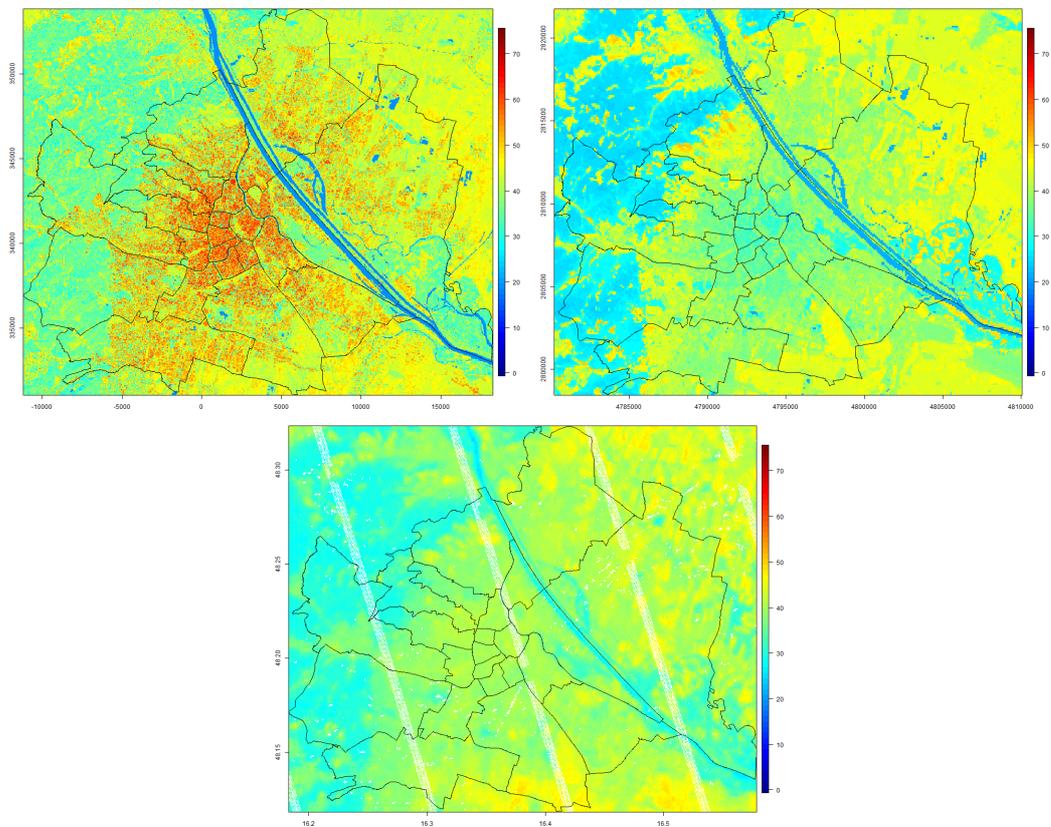

Fig. 2: Surface temperature (°C) in Vienna on 16. August 2022 at 12:00 UTC derived by PALM-4U model (top left), MUKLIMO_3 model (top right) and provided by ECOSTRESS (ECO2LSTE.001, day: 228; time: 11:38:39 UTC) remote sensing dataset (bottom).

5 CONCLUSION

This study investigated the perfomance of the PALM-4U model to simulate the development of the UHI in Vienna during summer conditions. By using models with higher resolution, small-scale processes such as turbulence, shading by buildings and vegetation, interaction between the atmosphere and urban surfaces and building materials are better represented. Increasing the model resolution enables more detailed analysis of inner-city temperature variations and allows detection of additional heat or cool zones in the city. The modelled spatial distribution of near surface air temperature and surface temperature was compared with observational data and lower resolution model results from existing studies.

The results of the PALM-4U model show typical spatial variations of urban heat with higher temperatures in built-up areas and lower temperatures in surroundings, particularly forest and water areas, which is found in previous studies and can be confirmed by observational data. The spatial distribution is different during the day and night-time. The UHI effect is more pronounced during the night, while during the day high local variations in temperatures are found.

When comparing the modelled air temperatures with measurements from NETATMO citizen weather stations, the PALM-4U model shows higher spatial variations than the MUKLIMO_3 model. Large temperature variations are also found in the observational dataset during the day. However, the correlation between the PALM-4U model and observations is not necessarily higher than the MUKLIMO_3 model. The reason is that the temperature variations in the NETATMO dataset during the day are probably related to the specific positioning of stations and influence of local factor such as shading, exposure to radiation and viscinity of buildings which could not be filtered out during the quality control completely.

At night, the spatial patterns between the models and NETATMO temperature measurements are more similar. It indicates that the strong small-scale variation diminishes and the NETATMO temperature measurements become more representative for a larger area. However, a strong temperature inversion during the night is found in the PALM-4U model, which can be related to the choice of model configuration and needs further investigation.

Comparison of ECOSTRESS LST remote sensing data with PALM-4U model simulations shows higher variability in modelled surface temperature than observed, which is partially related to higher spatial resolution of the model. The forest areas are warmer than observed. However, the results can not be directly compared since the model output reflects the surface soil level under the trees, rather than tree tops as observed by the remote sensing. While agricultural areas are well represented by the model, the built-up areas, i.e. building roofs, show very high temperature values ($> 60°C$) that require further analysis.

1 ABSTRACT

Urban morphology and human population distribution are two interrelated aspects of our urbanization that play a critical role in shaping the sustainability, resilience and liveability of cities. In recent years, the advent of global datasets with 3D information derived from Earth Observation (EO) technologies has revolutionised our ability to study and analyse these two aspects of urbanisation, providing information that is essential for designing cities that can accommodate the needs of their residents while minimizing their environmental impact.

One such dataset is the novel World Settlement Footprint 3D (WSF3D) produced by the German Aerospace Center (DLR). The WSF3D was the first global dataset providing detailed information of the fraction, area, average height and total volume of buildings, at unprecedented spatial resolution, coverage and consistency. Since its development, researchers from different organizations (e.g. WorldBank, United Nations, WorldPop) have employed the dataset as input data for large-scale studies in urban morphology and population distribution, with a level of detail that was previously impossible.

In this paper we present a selection of WSF3D-driven applications with the objective of demonstrating how the new data can be used to support urban planning and management. First, the WSF3D has been employed to demonstrate how the four layers of the dataset can be used to determine a building's functional use, and how this information can be leveraged to improve large-scale models of population distribution at large-scale. Thereafter, the WSF3D has been used to determine the relationships among building height/volume, population density and income, which can provide insights into the efficient use of space (e.g. crowding vs layering) on the one hand, and shed light into infrastructure disparities and variations, on the other. With that being said, due to the global nature of the WSF3D dataset, the previous analyses were conducted from local to regional scales, which can also help identify opportunities for interventions that can be replicated across different locations.

Overall, with the results of this research, the authors aim to provide planners and policy-makers with valuable insights into usability of the globally available WSF3D dataset. By demonstrating its potential as reliable and robust input data, this study seeks not only to empower evidence-based decision-making, but also to advocate for the widespread adoption of geospatial layers in the implementation of strategies towards sustainable development strategies of the built environment.

Keywords: Sustainability, World Settlement Footprint 3D, Earth Observation Data, Large-scale Population Distribution, Large-scale Urban Morphology

2 INTRODUCTION

Understanding of how cities are structured and how populations are distributed is crucial for the development of sustainable, resilient and liveable cities. On the one hand, from a socio-economic perspective, being able to identify areas of high population density and areas with high building density (2D and 3D), can promote efficient planning and utilization of resources like water, energy, transportation and waste management (Chokhachian et al., 2020; Wang et al., 2021b). This allows creating more vibrant cities, which in return, attract business, tourists and investments, generating an economic boost that enables social equality and inclusivity. On the other hand, from an environmental point of view, knowledge on these two factors aids in designing cities that minimize urban sprawl and population crowding, promoting compact, secure and eco-friendly urban centres (Lall et al., 2021; Wang et al., 2021a). For example, with up-to-date and precise information, governments and planners can conduct better hazard and environmental assessments that aim at reducing pollution levels and habitat fragmentation and loss, as well as promoting cities that are more

resilient to climate-related impacts like sea-level rise, flooding or extreme heat (Cai et al., 2021; Carpio et al., 2021; Mills et al., 2021; Scheba et al., 2021).

In this framework, with the advancement of Earth Observation (EO) technologies (e.g. remote sensing) and artificial intelligence (e.g. machine and deep learning), the development of geospatial datasets has revolutionised our ability to study and analyse urban morphology and population distribution (Chen et al., 2023) . Global-scale datasets, in particular, allow for cross-regional comparisons that enable researchers and planners to understand similarities and differences among cities and countries, helping identify best practices and solutions that can be applied in different contexts (Wang et al., 2023).

In this paper, we present the novel World Settlement Footprint 3D dataset (WSF3D) produced by the German Aerospace Center (DLR) (Esch et al., 2022), and showcase a series of insightful applications that can be performed with the data. Our research objectives are twofold: Firstly, we emphasize the dataset's potential for enhancing large-scale population modelling by leveraging volume and building use information exclusively from the WSF3D dataset. To achieve this, we explore the capabilities of a machine learning algorithm to categorize buildings into residential and non-residential classes, using the fourWSF3D layers: building area, height, fraction, and volume. Additionally, we provide accuracy results obtained from other population modelling methods, demonstrating the significant improvements attained through the utilization of the new WSF3D. Secondly, we conduct analyses across diverse spatial domains to investigate how the WSF3D dataset can be employed to compare and contrast different urban patterns, such as crowding versus layering across cities, countries, and regions. Moreover, we examine how infrastructure disparities and variations relate to income data. The primary focus here is to demonstrate the capability of combining the WSF3D with other information sources to facilitate the derivation of crucial statistical analyses that can be replicated across various locations.

3   APPLICATIONS BASED ON THE WORLD SETTLEMENT FOOTPRINT 3D

The WSF3D was the first global dataset providing detailed information of the fraction, area, average height and total volume of buildings. The dataset has unprecedented spatial resolution (~90m at the Equator) and is open-and-free for download at https://geoservice.dlr.de. In regards to its processing framework, the WSF3D was generated using a combination of a modified version of the ~10m WSF binary settlement mask derived from S1-S2 data (Marconcini et al., 2021) and ~12m digital elevation data and radar imagery collected by the TanDEM-X mission (Zink et al., 2014). Its production relied on three automatic workflows: one to estimate the building fraction and areas, a second to estimate the mean building height, and a third to estimate the total built-up volume. For a more detailed description of these three modules, please refer to Esch et al. (2022).

Figure 1 illustrates a subset of the four main layers that compose the WSF3D.

Fig. 1: WSF3D for the city of Munich, Germany. a) Building height [m], b) Building Fraction [%], c) Building area [m2] and d) Building Volume [m³]. Image reference: Palacios-Lopez et al. (2022)

3.1 Large-scale gridded population modelling

Gridded population datasets model human population distributions using a dasymetric modelling approach, in which census counts are disaggregated from administrative units into a reference grid, using different geospatial layers as determinants of allocation. While gridded population datasets have been produced for more than 20 years, recently we have witnessed a significant breakthrough in the field, as current products have begun incorporating 3D and functional use information into their models, thus reducing underestimation errors in rural regions and overestimations in urban areas

In this section we show how the WSF3D can be used to improve the qualitative and quantitative accuracy of residential population estimations without relying on any other data source. The analyses presented here are based on the research of Palacios-Lopez et al. (2022), where the authors apply the same methodology at a Pan-European scale.

First, using a Random Forest (RF) classifier and training data collected from the Urban Atlas 2018 , we show how spatial metrics derived from the WSF3D dataset are sufficient to identify large industrial/commercial areas in the built-up environment. In particular, the use of the mean, median and stdev. of the four WSF3D-layers, are enough to accurately recognise these areas. Using the city of Ljubljana in Slovenia as an example, Figure 2 shows outcome of this classification. At the country level, the classification achieves an overall accuracy (OA): 86.31% and a Kappa coefficient (K) of 0.7. According to the results presented in Palacios-Lopez et al. (2022), at a Pan-European scale the average OA and K can achieve average values of 84.43% and 0.68, respectively.

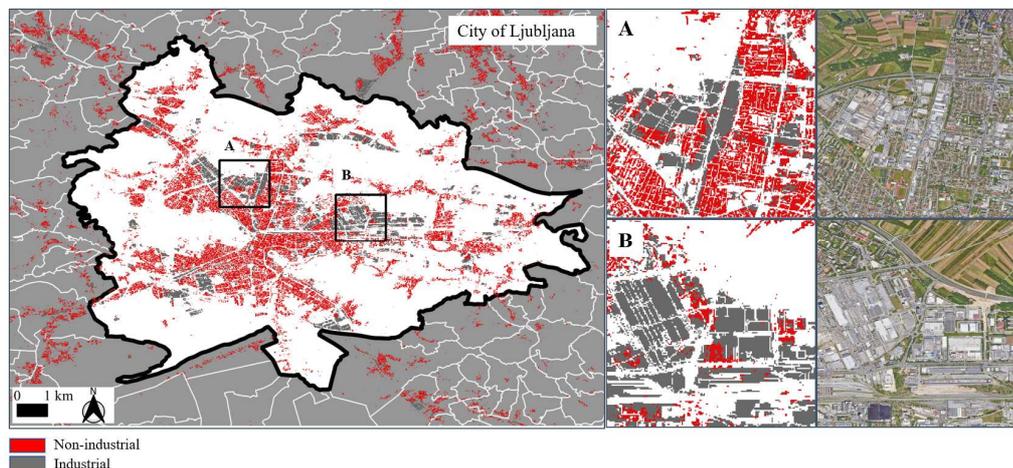

Fig. 2: Industrial/Non-industrial classification based on spatial metrics derived from the WSF3D and RF algorithm.

Using this binary classification, as a second step we evaluate how the accuracy of gridded population maps improves by incorporation building volume and building use information into the modelling framework. We compare our results with methods that are based on general 2D proxies and no building use information, which represent methods that are still largely employed (Leyk et al., 2019). For the city of Ljubljana (NW-area), Figure 4 shows the outcome of population distribution maps produced on the basis of a binary settlement layer (BM), a fraction layer (BF), a volume layer (BV) and volume + use layer (BV-IS).

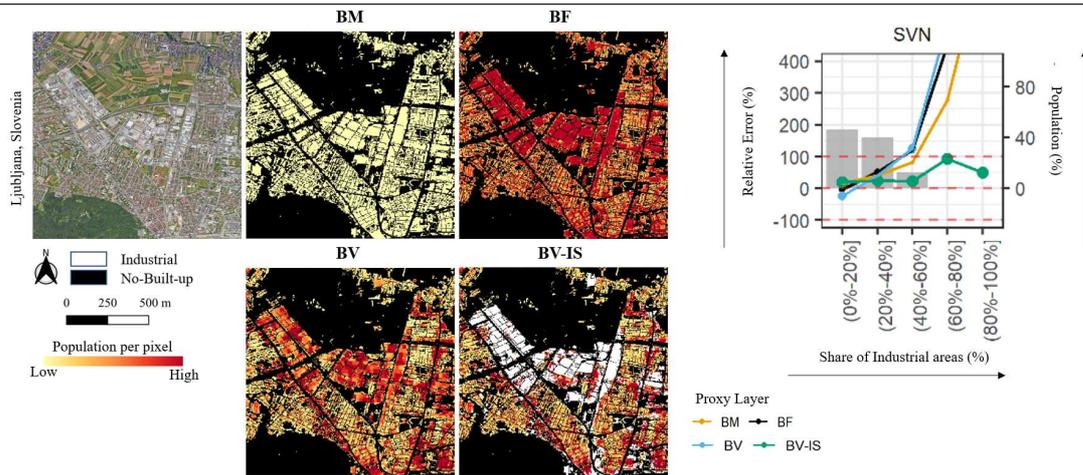
As observed, gridded population maps based on the BM proxy layer show homogeneous distributions, with each pixel having the same population. In contrast, maps using BF, BV, and BV-IS proxies exhibit more spatial heterogeneity, following changes in density and volume values. Without settlement use information, BF and BV maps allocate a large population proportion to industrial areas. The BV proxy, however, minimizes this effect, allocating more population to dense non-industrial areas compared to BF, where populations in both dense non-industrial and industrial areas seem balanced. By comparing the relative error produced by the layer, it is clear that the BV-IS delivers the best results. In areas where a large share of industrial areas are found, overestimations are minimized by more than 500%. Comparably, in areas where the share of industrial areas is less (e.g. residential areas), the BV-IS also produced errors closer to 10%.


Fig. 3.

3.2 Analysis of urban morphology

In the following two subsections we present a set of applications that demonstrate how the WSF3D can be integrated with different data sources, to understand the correlations that might exist between urban morphology and socio-economic development. Analyses are carried-out in two spatial domains:

(1) at the country level using the GADM v4.1 polygons and socio-economic data downloaded from the WB development indicators catalogue.

(2) at the urban cluster level (globally) using the GHS Urban Clusters, which provide socio-economic information at the level or urban areas,

For each spatial domain the following variables have been collected/used: average building height and total built-up area from the WSF3D, and population, income group, and GDP.

3.2.1 Analysing "Crowding vs Layering"

Figure 4 provides a graphical representation of each country's position concerning its population (x-axis), average height (y-axis), and built-up area (bubble size), coloured according to their income group. The chart categorizes countries based on their tendencies towards "layering" (top-left) or "crowding" (lower-right) based on their urban development patterns.

Analysing the chart, we observe that high-income (HIC) countries predominantly cluster towards the top-left quadrant, indicating their inclination to construct buildings with greater height and extensive built-up areas compared to lower-income (LIC), lower-middle income (LMIC), and upper-middle-income (UMIC) countries. The behaviour of HIC, coupled with their relatively smaller populations, suggest that they offer more space to their citizens (including industrial and commercial buildings), contributing to a lower population density and -presumably - less crowding.

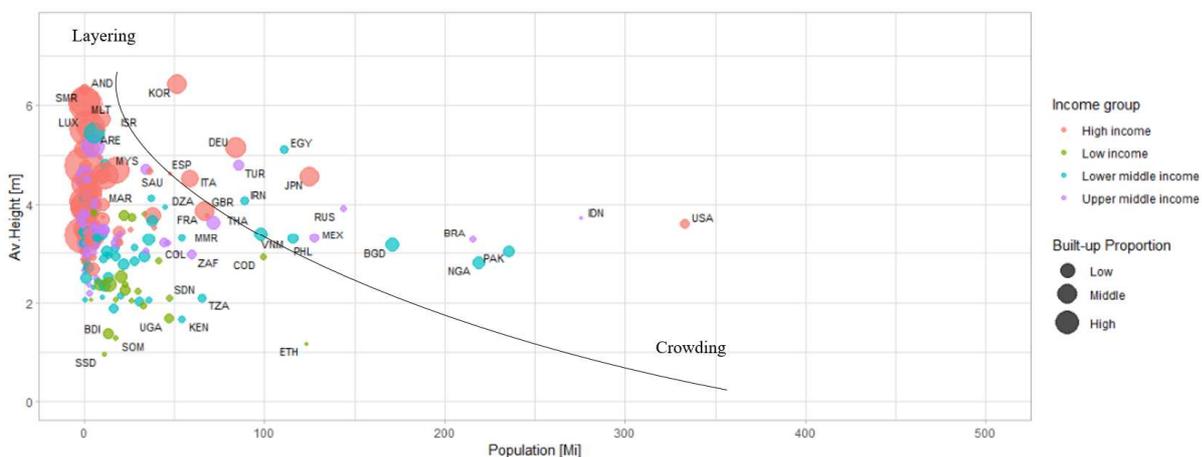

Fig. 4: Country-scale representation of "layering" and "crowding" trends. Total population and income group represent the year 2022.

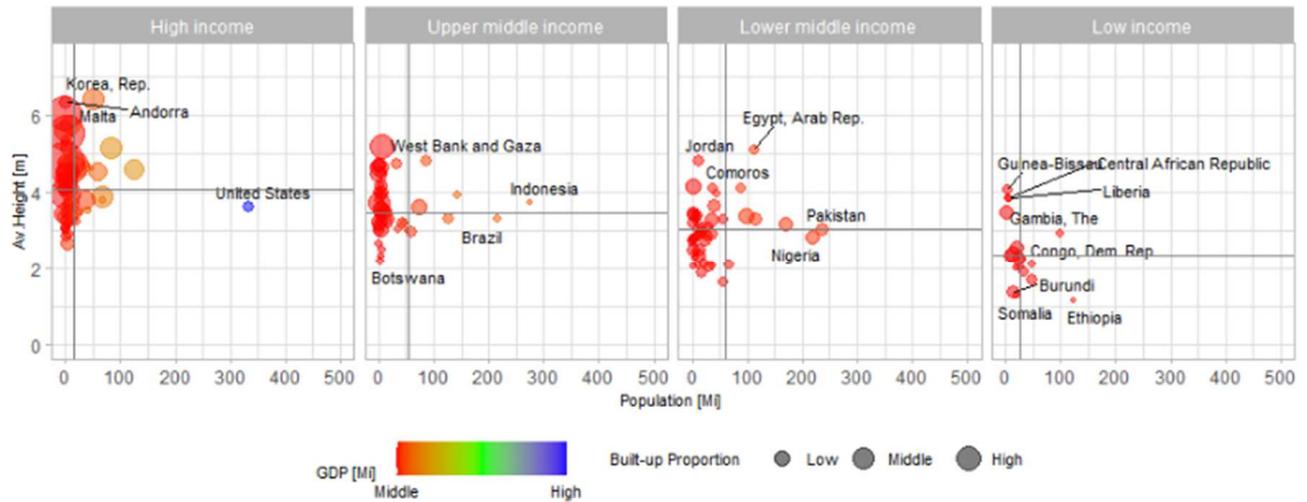
Comparably, the same data can also be displayed as shown in Figure 5. Here for example, it can be seen that countries that are located in different income groups, but that have similar populations and similar GDP, do not necessarily offer the same space to people. These differences can also be appreciated for countries within the same income group, where the amount of GDP does not necessarily play a role in built-up space. While somehow simple, information like this can help, for example, to shed light into how building policies and financial resources are being implemented to define building space, as well, as well as to understand how possible geographical restrictions including, being an island or having coastal areas, might influence infrastructure development.


Fig. 5: Country-scale distribution of av. height, built-up area and population with respect GDP and income group.

3.2.2 Analysing "Infrastructure disparities"

While the continental-scale analyses presented in the previous section can be found already useful to define some correlations between morphology and economic development, the use of the WSF3D can also help to analyse infrastructure disparities at the city level. For a number of selected countries, Figure 6 shows the position of different urban clusters in relation to their average height and built-up area proportion.

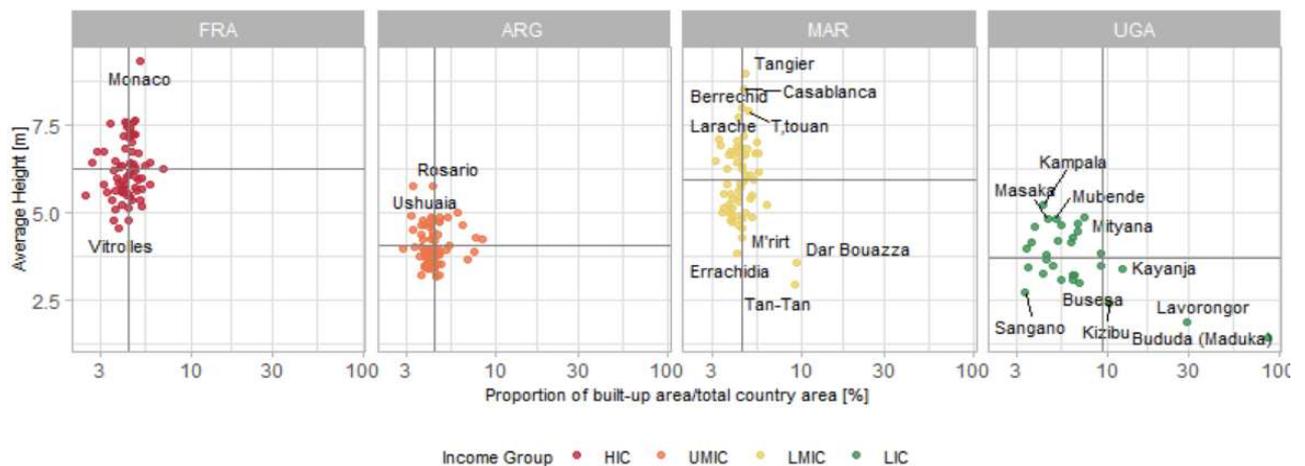

Fig. 6: Urban Cluster distribution in terms of av. height and built-up proportion for France, Argentina, Morocco and Uganda. Each country belongs to a different income group.

Notably, at the country level, France and Morocco display strikingly similar patterns in terms of average height and built-up proportion, as indicated by the horizontal and vertical black lines. This suggests that income levels may not be the sole determining factor influencing infrastructure choices. Surprisingly, Argentina, despite being classified as an upper-middle-income country, exhibits lower average building heights compared to Morocco and appears relatively close to Uganda, which falls into a lower-income group.

In contrast, analysing within-country disparities reveals a different narrative. Within each country, cities exhibit greater variation in their morphological characteristics, as depicted by the spread of points in both the

x and y directions. This variation is notably pronounced among Ugandan cities, indicating that local policies and institutional forces play a significant role in shaping urban development patterns within the country

4 CONCLUSION AND DISCUSSION

Accurate knowledge of the 3D characteristics of the built-up environment and population distribution holds significant potential to enhance aspects of sustainability and resilience in urban planning and related decision-making processes. However, a major obstacle in advancing our understanding of these factors on a large scale has been the scarcity of data with sufficient accuracy, spatial detail, and consistency.

This paper introduces and showcases a series of applications that leverage the WSF3D dataset. First, we demonstrate how this data can improve existing population models by integrating volume and functional use information of the built-up environment, leading to more precise population estimates. The key advantage of this approach lies in achieving higher quantitative and qualitative accuracies over binary and density approaches using a single dataset, thus eliminating the technical complexities associated with gathering extensive data. As we continue to develop a multi-temporal WSF3D layer, our outlook is to produce and openly release a global-scale, multi-temporal population dataset with unparalleled accuracy and spatial resolution (approximately 10 meters).

Furthermore, we illustrate how the WSF3D dataset can be employed to comprehend the complex correlations between economic and institutional forces with urban morphology. We highlight how patterns and trends vary depending on the spatial domain of analysis. For example, the observed similarities in urban morphology between countries with different income levels highlight the need to consider various factors beyond income when formulating urban development strategies. Moreover, the substantial variation in urban morphology within a single country underscores the importance of context-specific policies and governance in shaping the built environment. These insights provide valuable guidance for policymakers and urban planners to foster equitable and sustainable development practices, tailoring solutions to address the unique challenges and opportunities presented by different urban contexts.

In conclusion, due to the remarkable versatility and seamless integration of the WSF3D with other data sources, our main goal in presenting these results is to encourage further exploration and utilization of this dataset to address diverse spatial and socio-economic challenges worldwide. By leveraging this valuable resource, researchers and policymakers can make informed decisions that foster sustainable urban development and enhance the overall well-being of communities globally.

Hochauflösendes Monitoring der Flächennutzungsentwicklung in Städten und Regionen mit dem IÖR-Monitor

Gotthard Meinel

(Dr.-Ing.Gotthard Meinel, Leibniz-Institut für ökologische Raumentwicklung, Weberplatz 1, 01217 Dresden, g.meinel@ioer.de)

1 ABSTRACT

Es wird der Monitor der Siedlungs- und Freiraumentwicklung (IÖR-Monitor) und seine Entwicklung vorgestellt. Er visualisiert die Flächennutzungsentwicklung in einem interaktiven Viewer. 90 Indikatoren in 15 Indikatorkategorien stehen zur Verfügung und werden in Form von Karten, Tabellen, Statistiken und Entwicklungsgraphen visualisiert. Die Indikatorwerte werden für administrative Gebietseinheiten vom Bund bis zu den Gemeinden und Gemeindeteilen und in unterschiedlicher Rasterauflösung bis zu 100 m-Rastern gezeigt. Die Zeitreihen beginnen ab 2000 und umfassen inzwischen 18 Zeitschnitte. Exportfunktionen ermöglichen vertiefte statistische Auswertungen und WebGIS-Dienste die Einbindung der Daten in Geoinformationssysteme. Der Beitrag geht anfänglich auf die wichtigste Datengrundlage ein, das Amtlich Topographisch-Kartographische Informationssystem (ATKIS Basis-DLM). Dieses beschreibt die topographischen Objekte der Landschaft im Vektorformat nach der AAA-Modellierungsvorschrift der AdV flächendeckend für Deutschland in hoher räumlicher Auflösung. Diese Datengrundlage hat viele Vorteile im Flächennutzungsmonitoring gegenüber den Nutzungsinformationen des Liegenschaftskatasters ALKIS, welches Grundlage der amtlichen Flächenstatistik ist. Am Ende wird auf ausgewählte Indikatoren zur Beschreibung der Nachhaltigkeit der Entwicklung eingegangen. Das betrifft die Zeitreihe zur Flächeninanspruchnahme, zur Siedlungsdichte, zur Entwicklung der Flächen für Freiflächen-Photovoltaik und die bauliche Entwicklung in Überschwemmungsgebieten.

Keywords: Flächennutzungsmonitoring, Quantitative Indikatoren, Nachhaltige Entwicklung, Städte- und Rgionenvergleich, Flächensparen

2 PROBLEM FLÄCHENVERBRAUCH

Immer noch wird weltweit zu viel Freiraumfläche umgewandelt in Siedlungs- und Verkehrsflächen. Dieser Prozess ist verbunden mit dem Verlust natürlicher Böden, die überbaut und zu großen Teilen damit auch versiegelt werden. Dieser Prozess ist in aller Regel irreversibel. So werden in Zukunft Flächen fehlen für eine ökologische Landwirtschaft, die mehr Fläche benötigt als eine Konventionelle. Zudem bedingt eine Bodenversiegelung städtische Überwärmungen, verhindert die Wasserspeicherung im Boden, befördert einen schnellen Wasserabfluss, Hochwassergefahren usw..

Natürlichen Böden kommt eine Schlüsselrolle in der Nachhaltigkeitstransformation zu. So formuliert der Wissenschaftliche Beirat der Bundesregierung Globale Umweltveränderungen (WBGU) in seinem Hauptgutachten: „*Nur wenn sich unser Umgang mit Land grundlegend ändert, können die Klimaschutzziele erreicht, der dramatische Verlust der biologischen Vielfalt abgewendet und das globale Ernährungssystem nachhaltig gestaltet werden.*" (WBGU 2021).

Inzwischen wurden für alle administrativen Ebenen Begegnungsziele formuliert, beginnend mit der weltweiten Agenda 2030 mit den SDG-Nachhaltigkeitszielen. So wird im Kapitel „Nachhaltige Städte und Gemeinden" das Ziel verfolgt, Städte und Siedlungen inklusiv, sicher, widerstandsfähig und nachhaltig zu gestalten (SDG 11). In Europa wird das „No Net Land Take-Ziel" verfolgt, den Flächenverbrauch bis 2050 auf Netto-Null zu senken (EU 2011). Auch in Deutschland soll bis 2050 nach dem „Klimaschutzplan 2050" eine Flächenkreislaufwirtschaft verwirklicht werden (BMUB, 2016).

Ein konkretes Ziel zur Reduktion der Flächenneuinanspruchnahme in Deutschland wurde erstmals im Jahr 2002 in der Deutschen Nachhaltigkeitsstrategie formuliert. Ausgehend von dem damaligen hohen Wert von mehr als 120 Hektar pro Tag wurde für das Jahr 2020 das Ziel von maximal 30 Hektar pro Tag definiert (Bundesregierung, 2002; Jakubowski & Zarth, 2003). Nachdem sich abzeichnete, dass dieser Wert bis 2020 nicht erreichbar sein würde, enthielt die Neuauflage der Nachhaltigkeitsstrategie von 2016 die Formulierung der Erreichung eines Wertes von „weniger als 30 Hektar pro Tag" bis zum Jahr 2030, allerdings ohne konkrete Bezifferung des anzustrebenden Wertes (Bundesregierung, 2017).

In Deutschland sind Flächensparziele formliert in der Nachhaltigkeitsstrategie der Bundesregierung (weniger als 30 ha/Tag bis 2023) bzw. im Klimaschutzprogramm der Bundesregierung eine vollständige

Flächenkreislaufwirtschaft bis 2050 (Bundesregierung). Auch viele Bundesländer in Deutschland verfolgen eigene Flächensparziele (Tab. 1).

Bundesland	Flächensparziel [ha/d]	Flächenverbrauch (2022)
Baden-Württemberg	3	5,2
Bayern	5,00	8,9
Berlin		0,0
Brandenburg		1,4
Bremen	0,1-0,3	0,1
Hamburg		0,0
Hessen	2,5	2,1
Mecklenburg-Vorpommern	1,2	4,0
Niedersachsen	3,0	11,9
Nordrhein-Westfalen	5,0	4,8
Rheinland-Pfalz	1,0	3,2
Saarland	472m²/Einw.	0,7
Sachsen	2,0	2,1
Sachsen-Anhalt	1,3	0,6
Schleswig-Holstein	1,3	1,2
Thüringen		0,7
Deutschland gesamt	< 30	46,7

3 FLÄCHEN(NUTZUNGS)MONITORING

Um den Erfolg flächenpolitischer Maßnahmen zu messen, bedarf es eines verlässlichen Monitorings der Siedlungs- und Verkehrsfläche. Wichtigster Indikator dabei ist die Flächenneuinanspruchnahme (FNI) oder „Anstieg der Siedlungs- und Verkehrsfläche" gemessen in ha/Tag. Mit diesem Indikator kann der Zielerreichungsgrad und die Wirksamkeit flächenpolitischer Maßnahmen beurteilt werden. Seine Bestimmung sollte dafür so aktuell, genau, räumlich hochauflösend und vor allem auch in seiner Veränderung für eine robuste Zeitreihe sicher bestimmt werden. Wie hoch die Anforderungen an die Genauigkeit des Indikatorwertes ist, der derzeit bei ca. 55 ha/Tag (Destatis) liegt bzw. bei 47 ha/Tag (IÖR-Monitor), wird bewusst, wenn man diesen in Beziehung zu dem SuV-Flächenanteil setzt. Denn diese erhöht sich bei einer Zunahme um 50 ha/Tag nur um 0,1 % pro Jahr. In allen Monitoringsystemen werden leider die Veränderungen nicht direkt, sondern nur als Differenz der Flächennutzungenwerte im Jahresvergleich gemessen. Eine direkte objektscharfe Auswertung aller Neubauten über die primären Bauerfassungsbögen ist leider derzeit durch das Hochbaustatistikgesetz nicht möglich. Denn die Adressen der Neubauten sind ein Primärmerkmal und dürfen darum weitergegeben werden. Sie dienen innerhalb der Statistik zur Aggregation der einzelnen Bauaktivitäten auf Bundeslandebene. Die Einzelauswertung der Bauerfassungsbögen aber würde eine viel verlässlichere Indikatorwertbestimmung des Flächenverbrauchs ermöglichen (Meinel, 2017). Eine fernerkundlichen Erhebung der Flächennutzung ist derzeit nur mit einer max. 95–98 % Klassifikationsgüte möglich, eine Veränderungsdetektion wäre noch ungenauer. Damit sind verlässliche Aussagen und Bewertungen der Veränderungsrate in robusten Zeitreihen bis heute nicht möglich.

Prinzipiell ist die Erfassung des Flächenverbrauchs primär- oder sekundärstatistisch möglich (Meinel 2023). Bei der Primärerfassung ist das Erhebungsprogramm direkt auf die Erfassung der Flächennutzungsveränderung ausgerichtet. Vertreter davon sind die Arealstatistik Schweiz (Bundesamt für Statistik 2023 und Meinel 2023) und das Bodenbedeckungs-/ Bodennutzungsstatistik-Programm LUCAS (Eurostat, 2023). Sekundärstatistische Erhebungen zeichnen sich dadurch aus, dass der Flächenverbrauch nicht das ursächliche Ziel der Erhebung ist. Damit fehlt sekundärstatistischen Erhebungen die erforderliche Methodenkonstanz, da die Programme immer wieder ihren Hauptanforderungen angepasst werden. Ein

1022

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Beispiel dafür ist die amtliche Flächenerhebung in Deutschland. Einen Vergleich von primär- und sekundärstatistischer Flächenerhebung zeigt Tab. 2. Bei der Messung der Flächenneuinanspruchnahme sind Nutzungsänderungen flächenscharf und nicht nur kumulativ zu bestimmen. Da sich in der Vergangenheit die Erhebungsmodelle zum Teil grundlegend geändert haben und dies in Zukunft voraussichtlich wieder passieren wird, ist dies vor dem Hintergrund einer insgesamt geringen Veränderungsdynamik besonders herausfordernd.

	Primärstatistische Flächenerhebung	**Sekundärstatistische Flächenerhebung**
Auswertemethodik	statistische Hochrechnung	Kumulation von Flächen, Pufferung von Linien bzw. Punkten
Aufwand	hoch	mittel
Methodenkonstanz	Weitestgehend, da keine anderen Anforderungen zu erfüllen sind	Gering, da primäre andere Anforderungen zu erfüllen sind
räumliche Auflösung der Analyseeinheiten	Gering, durch statistische Hochrechnung	hoch, da Erhebungseinheit=Analyseeinheit
zeitliche Auflösung	gering (3, 6 oder 12-jährig)	hoch (2-3 Jahre, Tendenz jährlich)
thematische Genauigkeit	Hoch, durch Vororterhebung oder sehr genaue stereometrische Erhebung	Gering, durch Abgrenzungsunsicherheiten
Homogenität	hoch, da wenige Interpreter	gering, da viele Interpreter
Stabilität der Zeitreihen	Hoch, durch Methodenkonstanz	Niedrig, durch methodische Veränderungen

Tabelle 2: Vergleich von primär- und sekundärstatistischer Flächenerhebung (Quelle: https://doi.org/10.5281/zenodo.8115880)

Ergebnisse einer vergleichenden Untersuchung zur Erhebung der »Tatsächlichen Nutzung« in ALKIS und der daraus abgeleiteten Zeitreihe zur Flächenneuinanspruchnahme sind hier zu finden (Blechschmidt & Meinel, 2022)

4 FLÄCHENNUTZUNGSMONITORING IM IÖR-MONITOR

Seit seiner Einführung im Jahr 2010 werden im Monitor der Siedlungs- und Freiraumentwicklung (IÖR-Monitor) Indikatoren zu Struktur und Dynamik der Flächenentwicklung in Deutschland veröffentlicht. Am Beginn der Arbeit stand eine Untersuchung geeigneter Datengrundlagen (Schumacher und Meinel 2009). Viele Gründe sprachen für die Nutzung des ATKIS in seiner höchsten räumlichen Auflösung, dem Basis-DLM (AdV 2023). Seine hohe räumliche und thematische Auflösung, seine zyklische flächendeckende Grund- und Spitzenaktualisierung, seine freie Verfügbarkeit und seine gegenüber dem Kataster vergleichsweise geringen Migrationsartefakte und Inhomogenitäten ermöglichen ein verlässliches Flächennutzungsmonitoring. Allerdings verlangen seine digitale Ablage eine Flächenpriorisierung und seine nur linienhafte Führung von Verkehr und Gewässern deren Pufferung mit den jeweiligen Objektbreiten. Die Methodik dazu wird hier detailliert beschrieben. Ausgangspunkt für die Indikatorenberechnung ist eine Rasterkarte der Flächennutzungsarten in einer Rasterweite von 2,5 m (Krüger et al. 2013).

Sowohl das thematische Spektrum der Indikatoren, die Funktionalität der interaktiven Webanwendung als auch die Daten- und Dienstbereitstellung durch Exportdienste wurden seit 2010 kontinuierlich ausgebaut und werden stetig weiterentwickelt (Meinel et al. 2021 und Meinel 2023).

Im Jahr 2020 wurde der IÖR-Monitor vom Rat für Sozial- und Wirtschaftsdaten (RatSWD) als Forschungsdateninfrastruktur akkreditiert. Dies hat seine Nutzung auch auf sozialwissenschaftliche Fragestellungen ausgedehnt und belegt die gesellschaftliche und wissenschaftliche Relevanz seiner bereitgestellten Indikatoren.

Neben Messgrößen zur Flächennutzungsstruktur (Flächenanteile unterschiedlicher Landnutzungskategorien) werden auch komplex berechnete Indikatoren bereitgestellt, beispielsweise zur Landschaftsqualität (z. B. Fragmentierung der Landschaft, Hemerobie), dem räumlichen Muster von Siedlungen (z. B. Zersiedelung) oder zum Flächenbedarf für nachhaltige Energiegewinnung (Windpark- und Solarenergieflächen).

5 AUSGEWÄHLTE ERGEBNISSE

Im Folgenden werden ausgewählte Ergebnisse gezeigt, die Belege für die Nutzung des IÖR-Monitors in der raumanalytischen Forschung und der Planungspraxis sind.

5.1 Flächenneuinanspruchnahme

Abb. 1 zeigt die Entwicklung des Nachhaltigkeitsindikators „Anstieg der Siedlungs- und Verkehrsfläche" für Deutschland im Vergleich der amtlichen Flächenstatistik mit den Werten des IÖR-Monitors. Die Werte des IÖR-Monitors liegen immer unter dem Wert der amtlichen Flächenerhebung, wobei sich die Differenzen zwischen 2010 bis 2020 stetig verkleinern. Allerdings laufen die Kurven ab 2021 wieder auseinander, was u. a. auf die Berücksichtigung von Vormigrationen im IÖR-Monitor zurückzuführen ist. Für 2022 liegt bedingt durch Erhebungsverzögerungen seitens der amtlichen Flächenerhebung noch kein Wert vor.

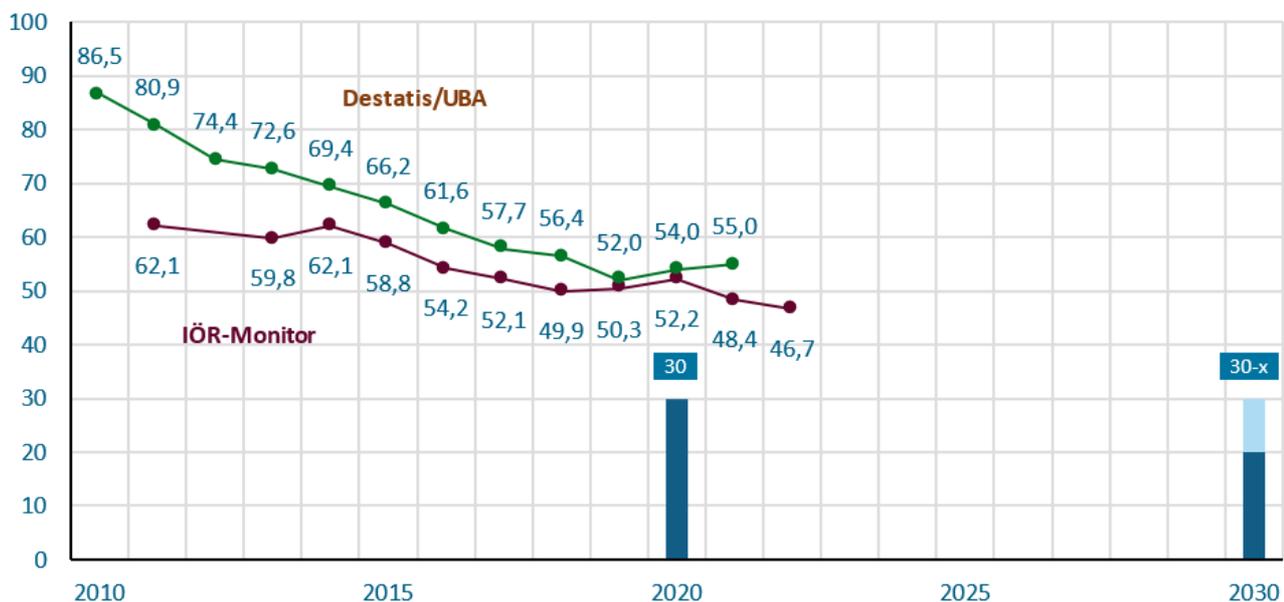

Abb. 1: Entwicklung der Flächenneuinanspruchnahme (grün=amtliche Flächenstatistik, braun=IÖR-Monitor) (Quelle: https://doi.org/10.5281/zenodo.8115880)

5.2 Entwicklung der Siedlungsdichte

Abb. 2 zeigt die Entwicklung des Nachhaltigkeitsindikators „Siedlungsdichte" seit 2010. Dieser Indikator wurde seit 2016 mit der Neuauflage der Nachhaltigkeitsstrategie der Bundesregierung und im Zuge der Anpassung an die weltweiten SDGs neu aufgenommen (Bundesregierung 2016). Die „Siedlungsdichte" beschreibt, wie viele Einwohner auf einem Quadratkilometer Siedlungs- und Verkehrsfläche leben. Anders als die Einwohnerdichte kann damit die Effizienz der Siedlungsflächennutzung bewertet werden. Ziel der Bundesregierung ist eine Stabilisierung der Siedlungsdichte auf den Wert des Referenzjahres 2000 (Bundesregierung 2016). Der Kurvenverlauf zeigt allerdings, dass dieses Ziel verfehlt wird. Dabei ist die Siedlungsdichte in Landkreisen stärker rückläufig als in kreisfreien Städten. Aber auch dort sank die Siedlungsdichte gegenüber dem Jahr 2010. Weiterführende Details sind publiziert in (Hübsch 2017).

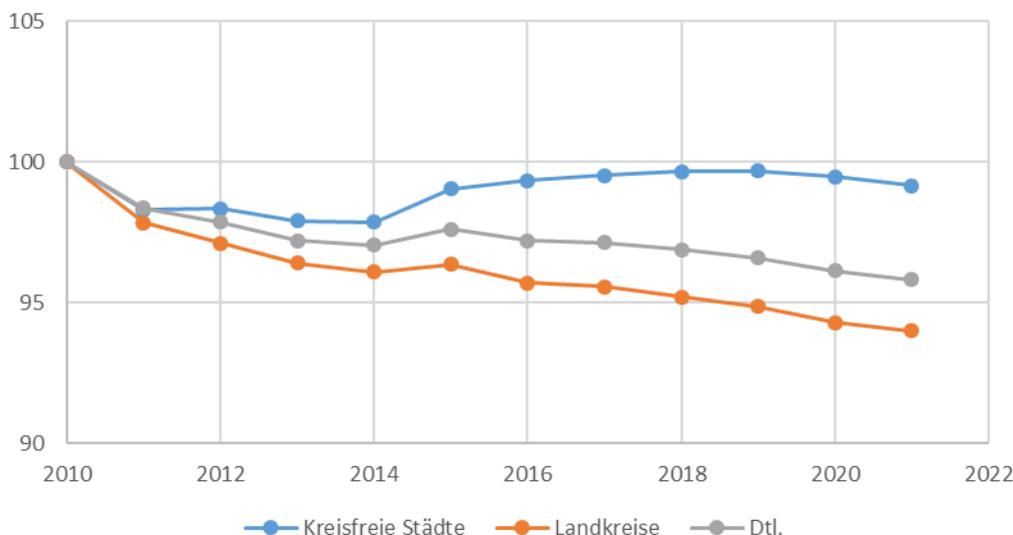
REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities


Abb. 2.: Entwicklung des Nachhaltigkeitsindikators Siedlungsdichte (Quelle: IÖR-Monitor)

5.3 Energieflächeninanspruchnahme durch Freiflächenphotovoltaik

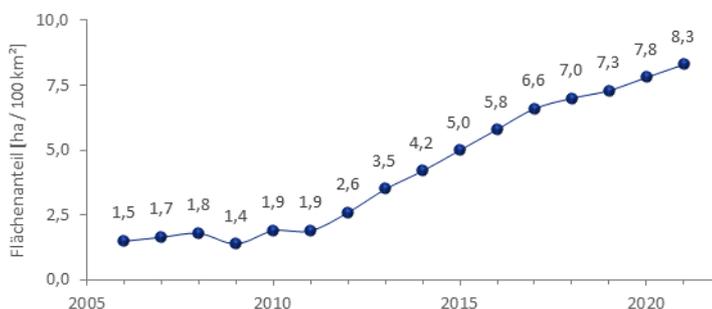
Der Bedarf an Flächen für Freiflächenphotovoltaik (FF-PV) ist gewaltig. Auch wenn diese für die Energiewende gebraucht werden, ist der damit in der Regel verbundene landwirtschaftliche Flächenverlust problematisch zu sehen. Das gilt insbesondere dann, wenn hochwertige Böden mit FF-PV überbaut werden. Selbst wenn unter den Anlagen noch eine Beweidung erfolgt, ist die ackerbauliche Nutzung nicht mehr möglich. Lösung wäre hier eine multifunktionale Flächennutzung, wie die Agro-PV oder die Aqua-PV (Kern 2023). Abb. 3 zeigt die rasante Flächeninanspruchnahme durch FF-PV in Deutschland.


Abb. 3: Entwicklung der Freiflächen-PV in Deutschland (Quelle: IÖR-Monitor?)

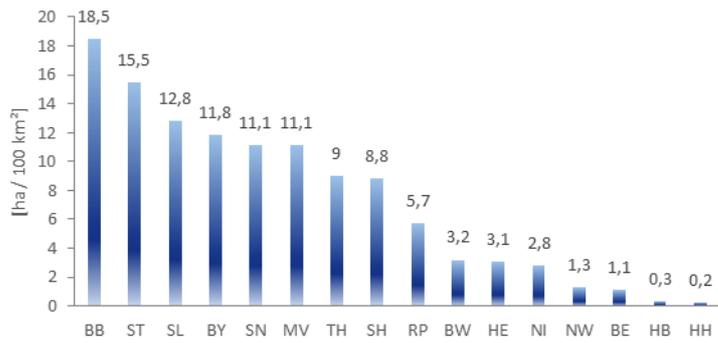
Die Abbildungen 4 und 5 zeigen die unterschiedliche Ausbausituation in den Bundesländern. Ersichtlich ist der höhere FF-PV-Flächenanteil im Osten und Südosten Deutschland gegenüber dem Westen und Norden (Walz et al. 2022). Dort dominiert die Windkraft, wie im Indikator „Anteil Windparkfläche an Gebietsfläche" im IÖR-Monitor in einer Karte auf Kreisbasis von 2022 gezeigt: https://monitor.ioer.de/?rid=4359) Weitere Details sind Krüger et al. 2023 und Lipfert 2023 zu entnehmen.


Abb. 4: Flächenanteile PV-FFA für die Bundesländer (Quelle: IÖR-Monitor)

Abb. 5.: Anteil der FF-PV an den Gebietsflächen der Kreise Deutschlands (Quelle: IÖR-Monitor)

5.4 Bauliche Entwicklung in Überschwemmungsgebieten

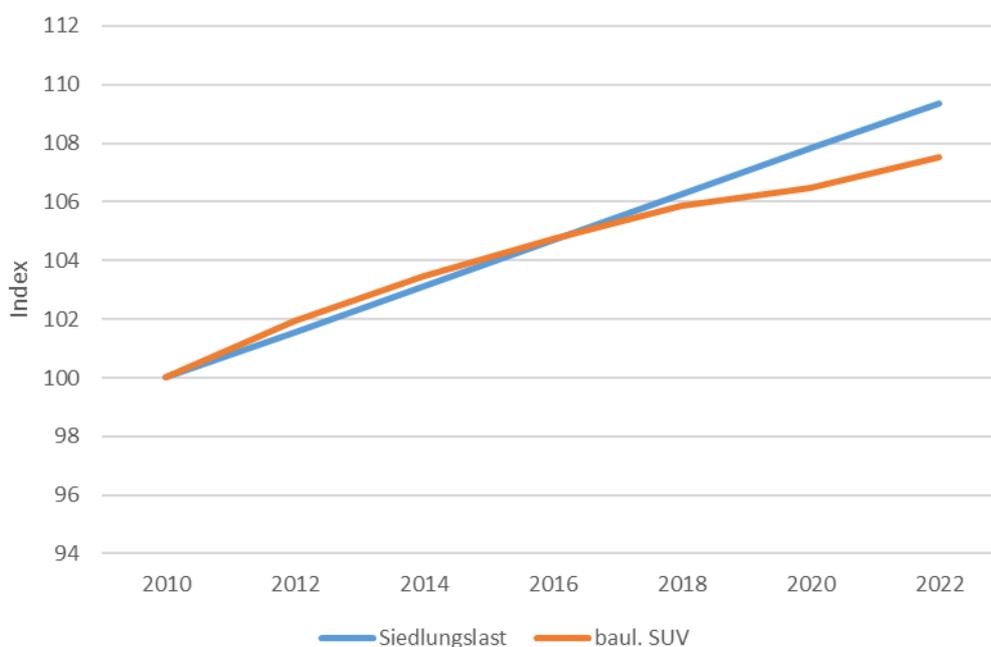
Abb. 6 zeigt die im IÖR-Monitor visualisierte bauliche Entwicklung in amtlich festgesetzten Überschwemmungsgebieten (Indikator Siedlungslast der Kategorie Risiko, Kreiskarte 2022: https://monitor.ioer.de/?rid=4358). Die Siedlungslast berechnet sich dabei aus dem Flächenanteil des amtlich festgesetzten Überschwemmungsgebietes, der von baulich geprägter Siedlungs- und Verkehrsfläche eingenommen wird. Obwohl amtlich festgesetzte Überschwemmungsgebiete eigentlich frei zu halten sind vor baulichen Entwicklungen, zeigt die Abb. 6, dass die bauliche Entwicklung in Überschwemmungsgebieten (blau) höher ist als die allgemeine Siedlungsentwicklung (orange). Selbst die öffentliche Hand ist in dieser Hinsicht oft kein Vorbild. So wurde beispielsweise das Dresdner Kongresszentrum wegen der Attraktivität des Standortes unmittelbar an der Elbe errichtet, obwohl die Fläche in einem festgesetzten Überschwemmungsgebiet liegt.


Abb. 6.: Bauliche Entwicklung in amtlich festgesetzten Überschwemmungsgebieten (Quelle: IÖR-Monitor)

6 SCHLUSSFOLGERUNG

Das Flächennutzungsmonitoring ist und bleibt eine große Herausforderung. Erst lange robuste Zeitreihen ermöglichen die sichere Bewertung der Veränderungstendenzen der Flächennutzung. Sowohl ALKIS (optimiert für den Grundstücksverkehr) als auch ATKIS (optimiert für geotopographische Visualisierungen) sind beide nicht ursächlich für ein Flächennutzungsmonitoring und eine daraus abgeleitete Flächenstatistik konzipiert. Beide Systeme werden sich mit der Umsetzung der GeoInfoDok NEU (AdV, 2023) zum 31.12.2023 verändern. Während die Flächenerfassung in ALKIS sehr inhomogen ist und noch verschiedene methodische Veränderung vor sich hat, sind die ATKIS-Daten homogener und die Analysen führen zu robusteren Zeitreihen.

Beste Ergebnisse werden mit einer Primärerhebung der Flächennutzung erzielt, wie die Arealstatistik in der Schweiz zeigt. Nur mit einer über Jahrzehnte nahezu unveränderten Methodik einschließlich der genutzten Basisdaten, können präzise flächenstatistische Analysen und flächenpolitische Schlußfolgerungen gezogen werde. Allerdings nur für vergleichweise große Gebietseinheiten (Kantone) und auch nur über lange Zeiträume (12 Jahre).

Die amtliche Flächenstatistik in Deutschland ist hinsichtlich robuster Zeitreihen des Kernindikators „Anstieg der Siedlungs- und Verkehrsfläche" schon auf Bundeslandebene im räumlichen und zeitlichen Vergleich problematisch. Aber auch Städte und Gemeinden brauchen für ihre Bebaungsplanung und Flächenhaushaltspolitik verlässliche Zahlen zum Flächenverbrauch. Mit dem IÖR-Monitor werden verlässliche Daten angeboten. Allerdings sind es Daten aus der Forschung, denen der Stempel der Amtlichkeit fehlt, was die Arbeit und Zitation dieser Daten in der Praxis erschwert. Die Perspektiven des IÖR-Monitors werden in (Meinel 2022) aufgezeigt.

Die Indikatorwerte des IÖR-Monitors zeigen einen stabilen Abwärtstrend der Flächeninanspruchnahme auf Bundesebene im IÖR-Monitor. Dagegen sprechen zum einen die deutliche Verfehlung des 30-Hektar-Ziels im Jahr 2020, zum anderen die Trendumkehr zu steigenden Werten seit 2018 und eine fehlende verbindliche Kontingentierung des Bundesziels auf der Ebene der Planungs- und Entscheidungsträger. Ohne rechtsverbindliche Flächenkontingentierung wird das Fernziel einer Flächenkreislaufwirtschaft nicht zu erreichen sein. Zu groß sind die Triebkräfte des Marktes.

Die Einbeziehung der Primärdaten der Erhebungsbögen der Bautätigkeitsstatistik als Referenzdaten neuer Gebäude könnte die Qualität der Erhebung und der Zeitreihen wesentlich verbessern (Meinel, 2019). Anzustreben wäre auch die Erstellung eines Referenzdatensatzes der Flächennutzung einschließlich dessen

zyklischer Aktualisierung für eine Teilfläche. Nur so könnte die Güte von Flächennutzungserhebungsmethoden bestimmt bzw. ein Training neuer KI-basierte Klassifikatoren erfolgen.

1 ABSTRACT

Bottom-up initiatives by citizens and communities are essential to increase acceptance of, and engagement in climate related actions. Yet, conventional approaches for raising awareness often fail to provoke a change in perspectives and actions. The CLEANcultures project conducts disruptive interventions in neighbourhoods to stimulate transformative learning processes to tackle climate change bottom-up at the neighbourhood level. The aim is not only to provide the neighbourhood with facts about the climate crisis, but also to trigger the citizens' emotions and attitudes, ultimately encouraging individual and collective action. Building on Transformative Learning Theory, local knowledge shall be activated, accepted norms questioned and alternative narratives of change co-created. A mixed-methods approach in two urban districts of Graz and the rural municipality of Admont combines 14 stakeholder interviews and a standardised postal survey of about 770 households with unconventional and interactive discussion formats involving 20 to 30 citizens per intervention.

In the urban districts, commuter traffic, increasing heat stress, soil sealing and the decline of green spaces pose the biggest challenges. By contrast, the rural area struggles with insufficient public transport and lack of protection against extreme weather events. In line with Transformative Learning Theory, residents were first invited to critically assess their prevalent practices, prejudices and assumptions. Residents were confronted with the perceived climate-related threats in their direct surroundings as they appeared in the interviews and survey results, in order to generate reflection and self-examination. Next, the residents were engaged in iterative and interactive phases of stimulus, discussion, and reflection to discover local capacities to address the identified issues. The goal is to point out to the neighbourhoods their own possibilities for action and to strengthen their collective efficacy. The first intervention consisted of an impromusical play in which the climate-related problems were conveyed and reframed in a humorous way. The second intervention involved representatives of different religions who discussed various perspectives on ethics of climate responsibility with local citizens. Both interventions invited the audience to engage in an interactive and open discourse.

As part of the transformative learning process, people realised that they were not alone in their thoughts and fears, and they were supported in developing ideas on how to get personally involved in their neighbourhood. Many mentioned that they were surprised by the relevance of climate-related issues in their residential surroundings. While citizens as individuals often do not feel heard and hardly see options for meaningful and effective contributions, the sense of belonging to a like-minded group can be empowering to explore new roles, relationships and actions. Working closely with (local) politicians also illustrated to decision makers the importance of the climate crisis in their neighbourhood and reinforced joint discourse. In all, unconventional interventions provide a promising entry point for introducing neighbourhood-level transformation processes in terms of climate change awareness, empowerment, and citizen involvement in decision-making.

Keywords: neighbourhoods, climate learning, transformative learning theory, mixed-methods approach, citizen engagement

2 INTRODUCTION

Many countries and communities have declared a climate emergency, but the desired results in reducing greenhouse gas emissions have not been achieved (Gills & Morgan, 2022). The main reasons for this policy failure are:

- Policy actions do not reach the ground level of individual behaviour.

- Top-down measures are proposed without engaging local citizens.

Thus, the research project CLEANcultures focuses on neighbourhood-level climate change issues and implements interventions to challenge existing assumptions and norms. The project conducts case studies in nine neighbourhoods across Austria, Finland, Norway, and Italy, aiming to promote sustainable practices within communities. This paper presents the results of the Austrian case studies.

3 THEORETICAL FRAMEWORK

3.1 The neighbourhood approach

Although "neighbourhood" is widely used as a category for social analysis, it is a complex construct. A neighbourhood can be viewed as a cohesive unit where individuals live close to one another and hold a sense of community, but can also be characterized by various dimensions. These dimensions include physical aspects (e.g., land use patterns and infrastructure), administrative boundaries, socio-demographic factors (e.g., similarity of residents in age, income, and education level), social aspects (e.g., cohesion and community engagement), and cultural elements like shared values, traditions, and religions (Komeily & Srinivasan, 2016). A comprehensive consideration of all these dimensions is essential to gain insights into climate-relevant behaviour in the context of neighbourhoods.

According to Bronfenbrenner's ecological theory (1979), an individual's development and well-being are influenced by interactions within multiple interconnected systems, from direct interactions with the immediate environment, including family, peers, and neighbours (microsystem), to broader cultural factors like government, media, and cultural values (macrosystem), and historical events in an individual's environment (chronosystem). Examining neighbourhoods as a unit of analysis may link the micro- and macrosystem dimensions of contemporary urban and rural communities.

3.2 Transformative Learning Theory

Mezirow's (2008) Transformative Learning Theory (TLT) explains how individuals can undergo profound personal and cognitive transformations through the process of changing their frames of reference, that is, the structures of culture and language that shape our perceptions, beliefs, and intentions. Transformative learning involves recognising and challenging problematic frames of reference, leading to a more inclusive, reflective, and emotionally open mindset that is better able to adapt and change. The theory proposes that transformative learning occurs through a series of stages:

(1) Disorienting dilemma

(2) Self-examination with feelings of fear, anger, guilt, or shame

(3) Critical assessment of assumptions

(4) Recognition that one's discontent and transformation are shared

(5) Exploring alternatives

(6) Planning for action

(7) Acquiring knowledge and skills

(8) Provisional trying of new roles

(9) Building competence and self-confidence

(10) Reintegration into one's life based on a new perspective

TLT highlights the importance of critical reflection, dialogue, and experiential learning, all of which may occur throughout a person's lifetime. CLEANcultures centres on stage 1–5 to foster a process of activating local knowledge, challenging accepted norms, and co-creating alternative narratives.

4 METHODOLOGY

The paper examines three case studies in Austria: two districts of Graz, Eggenberg and Jakomini, and the rural municipality of Admont in Upper Styria. To assess the initial situation of the climate culture and local climate-related issues in each neighbourhood, a mixed-methods approach was employed: Fourteen

1030

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

stakeholder interviews were conducted with key actors in the respective neighbourhoods, and a standardised postal survey was carried out in which 767 households participated.

In order to operationalise the psychological concepts underlying the TLT, survey data were aggregated into a set of variables using an exploratory factor analysis (Hamann et al., 2021; Stern, 2000; Steg & Vlek, 2009):

- Participatory efficacy refers to an individual's belief in their ability to actively contribute to achieving a collective goal by collaborating with other people in the neighbourhood (3 items, Cronbach's Alpha α=.72).
- Collective intention represents a shared commitment and motivation among community members to engage in certain actions (1 item).
- Collective awareness encompasses the shared understanding that the decisions and behaviours within the neighbourhood have direct consequences for future conditions (2 items, α=.75).
- Social norms refer to the perceived expectations of other community members about what behaviour is considered acceptable and appropriate (3 items, α=.62).

Subsequently, unconventional and interactive intervention formats were utilised, involving groups of 20–30 citizens per intervention, to explore how disruptive interventions in neighbourhoods can stimulate climate learning. After conducting interventions, participants were interviewed in a semi-structured qualitative format about their experiences, and the project team reflected on interactions and reactions.

5 RESULTS AND DISCUSSION

5.1 Initial situation

5.1.1 Climate Change Beliefs

The belief that climate change is happening, is caused by humans, and is already having visible local consequences is generally high in all neighbourhoods surveyed. Among urban respondents, 93% say that climate change is definitely or probably happening, compared to 94.5% in the rural area. In terms of cause, 70.2% of urban respondents attribute climate change mainly to human activities, in comparison to 60.8% in the rural neighborhood. While 65.3% of urban respondents report they definitely or probably observe changes in their local environment, this percentage is slightly lower in the rural area (61.1%).

However, as the interviewed local stakeholders pointed out, climate change is not considered a central concern in people's daily lives. Although climate-friendly actions are seen as potentially enhancing the quality of life, many individuals feel limited in their ability to make a significant impact on their own. There is a prevailing sense that insufficient actions are being taken to address the issue. Additionally, there is a lack of cooperation and collective effort within neighbourhoods towards addressing climate change.

5.1.2 Collective Drivers

Figure 1: Collective drivers (means with 95% confidence intervals; 0=weak, 4=strong; N=695)

For taking action against climate change on the neighbourhood level, participatory efficacy, collective intention, collective awareness, and social norms could be of central importance. In terms of collective drivers (Figure 1), social norms related to climate action were ranked lowest, indicating limited expectations and support for climate-related efforts within the community. Collective intention to engage in local climate action ranked second, indicating a medium level of commitment to collective climate-related efforts. While social norms and collective intention have similar measures in the urban-rural comparison, participatory efficacy (indicating that residents recognise the impact of their joint actions on climate change) and collective awareness (indicating that residents recognise the impact of their actions on climate change) differ. In the urban neighbourhood, both variables were ranked higher compared to the rural case study, and collective awareness slightly higher than participatory effectiveness. Conversely, in the rural neighbourhood, participatory efficacy was ranked marginally higher than collective awareness.

### 5.1.3   Priority areas of improvement in the neighbourhoods

Figure 2: Priority areas of improvement (means with 95% confidence intervals; 0=not important, 4=extremely important, N=735)

Figure 2 demonstrates the top 5 areas of improvement based on the survey results. In urban areas, environmental protection and climate change are the most significant concerns, followed by economic development. Public transport ranks fifth in importance. According to the stakeholder interviews, urban districts face challenges like commuter traffic, rising heat stress, soil sealing, and reducing green spaces.

By contrast, in rural areas, public transport takes the top priority. Economic development and jobs come in second place, followed by environmental protection and climate change. In rural neighbourhoods, the focus lies in enhancing local infrastructure, with less attention given to climate and environmental concerns. The interviews also highlighted the importance of adapting to extreme weather events. In this analysis, energy costs are neglected due to the influence of sharply increased energy prices during the 2022 energy crisis.

5.2 Intervention design

The project's interventions involve linking abstract climate change induced problems to participants' real-life experiences and providing thought-provoking impulses in unexpected ways. Residents participate in iterative and interactive periods of impulse, discussion, and reflection to unlock the local capacity to address climate change induced problems. Three interventions were designed:

5.2.1   Intervention 1: Survey Presentation and Impromusical Play

After introducing the participants to the topic of climate change and perceptions in the neighbourhood by presenting and discussing the survey results, a theatre group transformed the previously discussed content as well as spontaneous reactions of the audience into improvised musical performances. The artists engaged the audience in a spontaneous conversation in which there was space for worries, concerns, fears and hopes regarding the climate crisis. By means of music, climate-relevant topics were conveyed in a respectful but also humorous way.

5.2.2 Intervention 2: Multi-ethical Polylogue

Representatives of different religions discussed the ethics of climate responsibility with local citizens. The aim of this intervention was to promote a deeper understanding of climate change from an ethical perspective and address questions such as morally appropriate action in times of climate crisis, collective responsibility for climate protection, and humanity's relationship to nature. Speakers' contributions from Christianity, Buddhism, Islam, and Judaism enriched the discussions and contributed to a comprehensive exploration of ethical responsibility in times of the climate crisis.

5.2.3 Intervention 3: Throwing Game "Hit Climate-Friendly Decisions"

This game is designed to engage children, teens, and their parents in reflecting on climate-friendly behaviours. In a throwing gallery, participants attempt to hit targets that represent climate-friendly decisions (e.g., vegetarian diet, no flying, buying local food); the harder the decision is to implement in daily life, the smaller the target. By posing complex climate change related choices in an interactive and playful environment, the game is designed to prompt reflections on current habits and to foster a sense of personal responsibility towards the climate.

Figure 3: Impressions of intervention 1, 2 and 3 in Graz (Source: JR/LIFE)

5.3 Intervention experiences and link to Transformative Learning Theory

Based on TLT, the interventions initiate a learning process by presenting participants with a disorienting dilemma, challenging their existing assumptions and norms about climate change. Through self-examination and critical assessment, participants reflect on their attitudes and contributions to climate change issues. The interventions evoke emotions and trigger critical reflection, empowering individuals to explore new roles and possibilities for climate action. They also discover that they are not alone in their fears and receive support to generate ideas for personal involvement in their local community.

Through the interventions, many participants were surprised to realise the relevance of climate-related issues in their own neighbourhoods. Participants were also able to connect with local politicians and community organisations and explore new roles and actions within their neighbourhood.

5.3.1 Intervention 1: Survey Presentation and Impromusical Play

The intervention's informal atmosphere fostered open discourse, making discussions on climate change related topics approachable and engaging. Playing improvised songs about the neighbourhood reinforced the connection to one's surroundings, and the positive environment encouraged participants to dance together, fostering a sense of unity and community spirit. Additionally, the intervention's low entry threshold attracted and engaged new audiences, broadening the reach of climate-related initiatives and promoting a more diverse and inclusive approach to climate learning. While initially met with scepticism in the rural community, participants eventually opened up to the approach.

5.3.2 Intervention 2: Multi-ethical Polylogue

Participants realised that their climate-related concerns were widely shared, which created a sense of belonging. Many expressed surprise at discovering ethical responsibility as a common theme across various religions, gaining new insights from the diverse perspectives presented. The polylogue provided a platform for critical self-examination of ethical beliefs and values in relation to climate responsibility, deepening participants' self-reflection and awareness.

5.3.3 Intervention 3: Throwing Game "Hit Climate-Friendly Decisions"

The experience with the climate game showed a high level of enthusiasm and engagement among the – mostly – children who played the game. The incorporation of gamification elements, such as rewards,

challenges, and social interaction, contributed to sustained interest and motivation to explore climate-friendly behaviours beyond the game itself. By awarding points in certificates depending on the hit CO2 saving targets, a competitive spirit was perceived by many children. The game also encourages reflection on personal actions, such as "I don't go on holiday" or "I am already a vegetarian".

6 OUTLOOK

The project expects to yield results at three distinct levels, contributing to the understanding of small-scale societal system dynamics (micro level), offering a transferable methodology (meso and macro level), and providing recommendations for climate policy-making. A follow-up survey will be conducted in spring 2024 to compare the perception of climate change before and after the interventions in a longitudinal study. In addition, the results of the case studies in Austria will be compared with those in Finland, Norway, and Italy.

The CLEANcultures concept can also make a valuable contribution in other areas, such as spatial planning. With regard to citizen involvement in the development of urban and rural areas, participatory processes can be loosened up by creative thematic interventions and create a low-threshold, open access for residents to get involved. The use of creative and interactive methods can attract a diverse range of individuals, ensuring a more inclusive representation of the community's perspectives and ideas. Addressing emotions empowers citizens to question existing norms and take an active role in shaping their neighbourhoods, fostering a sense of ownership, e.g., towards collaborative approaches of nature based solutions such as community gardens. Incorporating participatory processes enables drawing on community knowledge, tailoring projects to local needs, and fostering citizens' meaningful engagement in creating sustainable communities.

7 CONCLUSION

The findings of the CLEANcultures project underline the importance as well as the potential of unconventional interventions for initiating transformative climate learning and promoting bottom-up climate action at the neighbourhood level. The designed interventions demonstrated their effectiveness in triggering emotions, stimulating critical reflection, and empowering individuals and communities. The results also shed light on the particular challenges faced by urban and rural neighbourhoods, highlighting the need for tailored intervention strategies. In the future, incorporating neighbourhood-level perspectives, fostering community engagement, and co-creating solutions in policy-making will be critical for climate change mitigation and adaptation and for creating sustainable and resilient neighbourhoods.

1 ABSTRACT

Nature is our ally in solving all kinds of social problems. This was well understood by the researchers of the ongoing URBiNAT (2018-2023) project, with focus on the regeneration of under-served urban neighbourhoods[1], through the co-creation of Nature-Based Solutions. Combining physical and infrastructural – green - solutions with social and economic practices, this project aims at creating collective awareness and contribute to a better understanding of human and non-human dimensions of our urban environments by conducting research, exploring case studies and implementation in several cities. How can these results and working methods also apply to trees and better conservation of the tree stock[2], which also play a key role in many challenges society is facing? Trees are essential in tackling climate change through mitigation and adaptation. They are natural and free air conditioners, they purify the air, provide carbon storage and biodiversity in the soil/underground and they fulfil a landscape or social role in villages and cities. Moreover, they provice a green counterweight to the increasing use of space in Flanders[3], something that could be experienced first-hand during the corona crisis. Yet trees still often disappear to make room for other space claims in Flanders. Today, citizens and permit providers (mainly municipalities) make an important mark on the above-ground use of space: recent research by the Department of Environment & Spatial Development Flanders shows that most applications for tree felling are submitted by citizens, and that municipal authorities approve nearly every application. In this new research proposal, integrating the approach of the URBiNAT project in order to prevent the disappearing tree stock in Flanders, we want to know why trees are cut down and how we can co-create collective awareness on the benefits of trees with the stakeholders involved in Flanders.

Keywords: awareness, co-creation, ecosystem services , trees, nature-based solutions

2 INTRODUCTION AND PURPOSE OF THIS STUDY

In this research proposal, we consider whether the URBiNAT method can be used to increase collective awareness for tree preservation and for biodiversity conservation, given the benefits of trees and biodiversity (ecosystem services). After all, a previous study on tree felling and planting and vegetation changes of trees outside the forest in Flanders (Peeters et al, 2022) shows that trees still have to make room for other space claims.

The research of Peeters et al (2022) was carried out in connection with trees outside the forest because there are few reliable and area-wide figures available on the evolution of the number of trees outside the forest. In addition, the felling of trees outside the forest context is regulated by different regulations than for trees in the forest. In the first instance, the felling of trees outside the forest is regulated by the Decree on nature conservation and the natural environment of 21.10.1997 and the rules on spatial planning from the Flemish Spatial Planning Codex. For trees within the forest, this is regulated by the Forest Decree of 13 June 1990.

In section 2.1 we first explain the results of this previous research on tree felling and planting and vegetation changes (Peeters et al, 2022) and the recommendations we will focus on. In section 2.2. we explain the URBiNAT project, NBS (Nature-Based Solutions) and the SROI tool (Social Return on Investment). In section 2.3, we screen the potentially relevant information from a completed research on the felling and planting of trees, that can be combined with the URBiNAT method. To what extent can this method help to increase support for the preservation of trees?

The goal of this study is to explore the application of the URBiNAT method to increae support for tree preservervation and biodiversity conservation. But this research proposal is also innovative, because it

---

[1] among other suburbs

[2] Since the generic SROI instrument of URBiNAT has so far evaluated the socio-economic-spatial impact of a Nature-Based Solution (focused on public spaces), where trees also play a role.

[3] Flanders is the northern region of Belgium and is also the most dense and urbanized part of it.

proposes a new research method, with a new tool (the SROI tool), which is still being developed. This research could help to further optimise the SROI tool.

2.1 Tree felling: a screening of the permit system

There are many initiatives to expand the tree stock. Both local and supralocal authorities recognise the importance and value of trees, and in their policy documents, they emphasise the many benefits and functions of trees in the living environment and in rural areas. The Flemish Coalition Agreement 2019-2024 contains several goals for the tree area in Flanders. The most specific goal is planting 1 million additional trees in the Flemish Periphery around Brussels. At the beginning of 2020, Flemish Minister of The Interior Bart Somers proposed the Local Energy and Climate Pact, which included the ambition to plant 3,300 km of hedges and 6.6 million trees – or 1 tree for each inhabitant of Flanders – in cooperation with local authorities by 2030. Flemish Minister for the Environment Zuhal Demir endorses the importance of these goals and the many benefits and functions of trees in the living environment and in the countryside, first in the "Vlaams Bosuitbreidingsplan" [the Forest Expansion Plan Flanders] (2020) and later in the "Vlaams Klimaatadaptatieplan" [the Flemish Climate Adaptation Plan] (Vlaams Overheid, 2022). The intention is to stimulate the planting of tall trees by means of a Flemish regulation or another instrument in the (re)construction of well-known urban heat islands such as car parks and squares, as well as the introduction of trees in climate-adaptive agriculture. But also on local level, many municipalities have expressed commitments for the expansion of their tree area. This is reflected in the signing of the Covenant of Mayors[4], an European project, or 'het bomencharter'[the Tree Charter][5] (a citizens' initiative). Parties signing the Tree Charter commit to planting 1.7 million additional trees by 2024 (Peeters et al. 2022).

If we aim at a net growth the tree stock in Flanders, we have to plant new trees, but also preserve the existing tree stock. In order to investigate this, the Flemish Department of Environment & Spatial Planning carried out a first research in order to gain insights into the felling and planting of trees outside the forest, in order to support policy (Peeters et al, 2022). The research consisted of a quantitative and qualitative analysis of data derived from the Flemish permit systems. The input of permit providers was also requested. Additionally, this report also describes the impact of other dynamics that influence the felling and/or preservation of trees. A number of methods have been explored for mapping the felling of trees without a permit requirement.

For trees in gardens, an application for a felling permit is usually filed. 75% of the applications are submitted by private individuals, and more than half are located in residential areas (according to regional land use plans). Compared to the Flemish average (8 applications/km²), the number of applications in gardens (24/km²) and residential areas (34/km²) is significantly higher, with outliers in residential parks[6], where even than ten times more tree fellings are requested.

According to the above-mentioned research, these figures indicate that 'nuisance' caused by trees around homes is one of the most common reasons why trees have to dissappear. Examples of nuisance are leaves and fruits falling of trees, or the loss of light and vision.

Since gardens make up more than 12%[7] of Flanders and 9 out of 10 applications for tree felling are approved, it is understandable that private individuals are an important stakeholder in the preservation of the tree stock. Therefore, we want to investigate what the real reason is why these trees are cut down, and later we want to examine how we can sensitize these stakeholders (to arrive at a mindset that understands and appreciates the importance of trees).

According to this study, what are the reasons for cutting down trees in relation to trees outside the forest? The competent municipal authorities estimate that the most common causes (average score on a scale of 1 to 5) are: buildings (3.7), nuisance (3.3), pavement (3.2), safety (3.1), making way for other functions (2.5) and gardens (2.4). The estimate of the number of trees that will be destroyed for buildings, pavement and other

---

[5] Through the Tree Charter, cities and municipalities commit themselves to obtain a certain number of additional trees ('the target') on the territory of the city/municipality: bomencharter.be, retrieved 27 July 2023.

[6] In Flanders, a residential park is intended as a residential area, intended for living in greenery. This specific type of zoning area accomodates many trees, on avarage more than in other residential areas.

[7] calculations based on the GARMON-project, retrieved on 26 July 2023

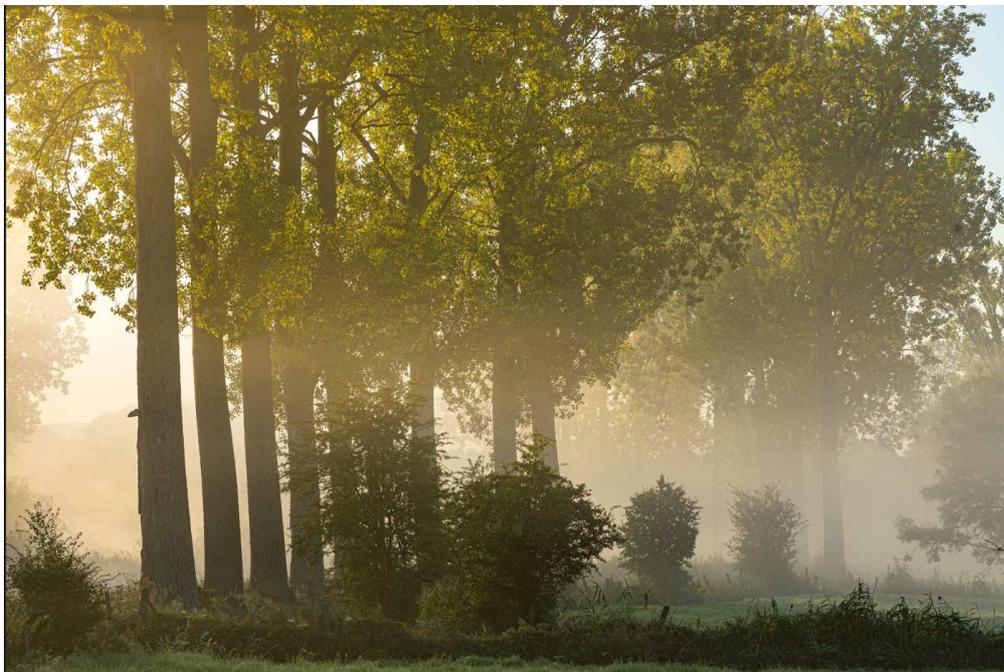
functions is admittedly (too) high compared to the share of permit applications within a larger project and therefore seems to be an overestimation.

Nuisance can take many different forms, but from the complaints that municipalities receive about trees, this appears to be mainly about leaf fall and fruits. Shadow casting on solar panels is mentioned as an emerging complaint. Other current reasons for felling are illness or loss of vitality in coniferous trees (due to damage by the type setter), safety nuisance around railways (often after complaints from the Belgian Railroad Company), and (fear of) storm damage.

An important observation from the discussions with municipal officials is that many municipalities indicate that the reasons for cutting down trees that are described in permit applications certainly do not always correspond to the real reason for the felling.

There are also a number of specific cases[8] where trees are cut down without a permit being required. These are difficult to quantify due to a lack of data. In order of estimated importance, these are: tree fellings around roads and pipes by the road and pipeline managers, felling of trees on the public domain (mainly redevelopment of streets and public space) and fellings of trees that pose an acute danger (e.g. after storm damage).

In order to draw up a policy to reduce the felling of trees, it is important to know why trees are cut down. Research into this can be done both by delving deeper into the reasons described in the application files, and by going through more files (submitted applications) than possible within the time frame of the previous research about trees mentioned before (Peeters et al, 2022). Research that examines the imposed conditions by delving deeper into the files can also be an added value. The other way is to question the applicants (and other actors) for tree felling (sociological research). URBiNAT is a possible way to conduct this research. That is why we will in the next section first briefly describe what this project and this method exactly entails.

Other ways to reduce the tree fellings according to the study are: stricter regulations, fewer felling permits and good communication ('what is the use of trees?'). Good commication may be important for sensitisation, but the two other possibilities are beyond the scope of this study, and we will not discuss it here.


Gert Arijs 2019

---

[8] Trees of less than one metre trunk circumference and trees within a radius of 15 metres around a licensed building may be freely cut down. This also applies to trees that are included in a management plan, and under certain conditions also to trees that pose an 'acute danger', trees on public land, trees in the context of agroforestry, trees that are cut down by railway managers and pipeline managers, etc

2.2 The URBiNAT method in a nutshell

URBiNAT (2018-2023) is an innovative European project that focuses on co-creation in urban environments. The project, funded by the European Union's Horizon 2020 programme, aims to transform the concept of urban development through the active involvement of citizens, stakeholders and various interest groups. The main goal of URBiNAT is to promote sustainable and inclusive cities in which people are central. The project focuses on developing and implementing new approaches to urban planning and design, with co-creation at its core. This means that all parties involved, including residents, businesses, municipal authorities and academics, work together to find solutions to urban challenges and create liveable and resilient cities. URBiNAT has three front runner cities based on their innovative use of public space through Nature-Based Solutions (NBS): Nantes, Sofia and Porto.[9]

The URBiNAT project defines Nature-Based Solution (NBS) in view of the Healthy Corridor (HC) concept.[10] The HC is situated on a macro-scale (i.e. certain urban districts/areas) consisting of various NBS positioned on a lower or micro-scale (i.e. in parts of urban districts/areas) (WP 5.4[11]).

To evaluate the socio-economic-spatial impact of a Nature-Based Solution (NBS) in urban Healthy Corridors (HC), a generic Social Return on Investment (SROI) instrument has been developed (WP5.4). The Social Return on Investment (SROI) measures the social, environmental, and economic value created by a project. SROI considers both the financial returns generated by an investment and the social and ecological outcomes it produces.

The more traditional concept of Return on Investment (ROI) is a well-known concept within the discipline of economy to assess the (relative) profitability of an organization and/or its economic investments. The nature of the SROI is clearly metric as it involves the collection of quantitative data (i.e. ratio variables) on the basis of which one ratio or indicator is calculated. The Social Return on Investment (SROI) is the present value of the actual and future social impact relative to the investments made, based on both qualitative and quantitative information.

The different phases of the SROI tool are shown in figure 1 below.

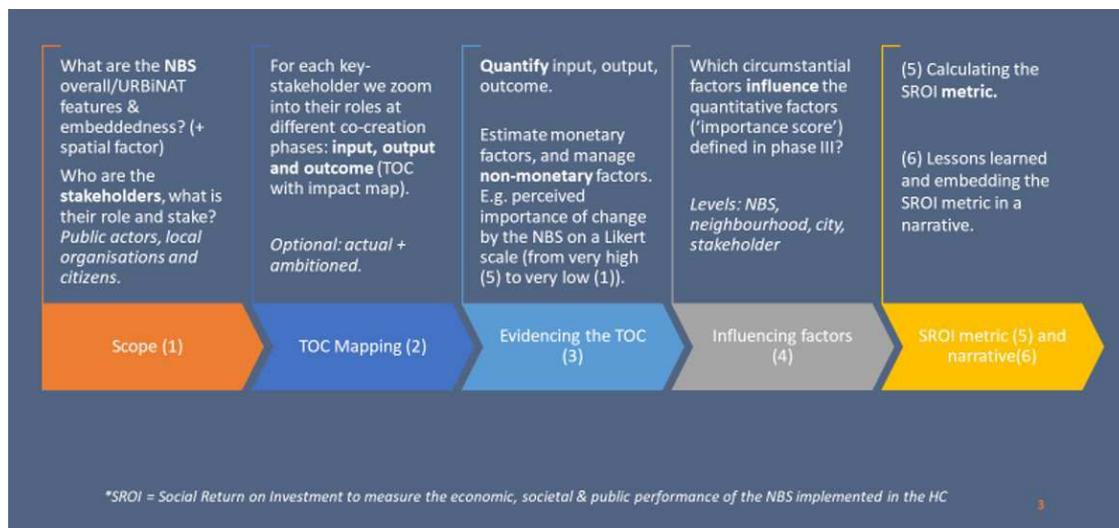


Fig. 1: Phasing the implementation of the SROI instrument (based on WP 5.4).

What are the different phases of the SROI instrument (fig. 1)? Firstly, Phase 1 describes the "scope" and "major (key)stakeholders". Secondly, in Phase 2, the researchers look at the roles of the different stakeholders in the different co-creation phases as a first screening. It is called mapping of "inputs",

---

[9] The aim of these cases is to regenerate the public space in urban districts by means of project interventions or initiatives that focus on (i) the public space within these districts/areas and on (ii) the co-realization of so-called innovative nature-based solutions (NBS). Urbinat - Healthy corridors as drivers of social housing neighbourhoods for the co-creation of social, environmental and marketable NBS., retrieved on 27 July 2023.

[10] www.URBiNAT.eu, retrieved on 27 July 2023.

[11] URBiNAT Project. WP5.4. Social & Economic Impact. The development of a generic SROI instrument to evaluate the socio-economic-spatial impact of a Nature-Based Solution (NBS) in urban Healthy Corridors (HC). (Unpublished – in development). (Expected in 2023)

"outputs" and "outcome", the mapping of the theory of change (TOC-mapping). In Phase 3, the researchers will evidence outcomes and give "values" (at this phase they will paste a number). Other factors influencing the result of Phase 3 are being looked at in Phase 4. The SROI ratio is then calculated (Phase 5). Finally, what are the lessons learned (Phase 6)? From now on, the embedding and using of the SROI-ratio of metric is possible.

In the proposed research project, we will only focus on the first three phases of the SROI tool, partly due to the fact that the SROI tool is still under development.

2.3 How can we use the SROI tool for awareness around tree conservation?

Throughout Europe, people are working on Nature-Based Solutions, complex or not. For example, simply planting a tree or not cutting it down is already a quick-win and already has many advantages. We are thinking of the many ecosystem services provided by trees: for example, wood production, noise buffering, climate regulation, regulation of hydrological processes and filtering air quality. The paper 'Het verhaal van bomen (kappen) in Vlaanderen' [The story of (felling) trees in Flanders] examines why, despite the many policy initiatives to plant trees, so many trees and other greenery still disappear in Flanders - preserving the existing tree stock and greenery is at least as important as planting new trees if we want a net growth of the number of trees (Vandevenne et al, 2023). To understand that, the authors of this aforementioned paper argue that deeper digging is needed. In their paper, starting from the figures on felling applications, the authors try to better understand the history and motives behind the felling of trees in Flanders (the so-called 'felling behaviour'), and to look for a number of causes and solutions through thinking in systems. It is first and foremost necessary to increase awareness, since there is apparently too little support for the preservation of trees. We think that with the SROI tool (from URBiNAT) we can gain insight into possibilities for creating more support for the preservation of the existing tree stock and other greenery, starting with the first phases of SROI.

We could take a wider perspective and not only limit ourselves to trees, but involve different 'types' of greenery, such as low greenery (<3 m), and high greenery (>3 m) for example. Because there, too, there is a lack of sufficient support for its preservation. Spatial aspects are also important. In the first place, executing Phase 1 of the SROI tool, we will investigate who the various stakeholders are when trees are cut down. There are different categories of stakeholders involved in the system: citizens, several authorities, farmers, schools, etc.

In the second place, in a kind of stakeholder mapping, we can analyse their influence and their role in the different co-creation[12] phases (Phase 2 of SROI tool). What is the input, output and outcome? For example, we can apply this to planting a tree in a garden.

Finally, in Phase 3 (of SROI tool), the input, output and outcome of Phase 2 will be quantified by monetary and non-monetary factors. In this phase, we could for example use the Likert-scale as a survey aid.[13] What is the importance of change by the NBS on a Likert scale (if we preserve the greenery)? This scale is an answer scale, with which data that are difficult to express in numbers can be retrieved and measured. A likert scale is used, among other things, to investigate the opinions and behaviour of respondents. In other words, we will have to list all the benefits of trees and other greenery. And this from different angles.

3 CONCLUSION

Too many trees are being cut down in Flanders, despite the many policy initiatives to plant new ones. One of the conclusions drawn from the previous research on felling and planting trees and vegetation changes outside the forest (Peeters et al, 2022), is that there is too little support for the preservation of trees and that further research is needed.

In this paper, we propose to apply the URBiNAT's SROI method to gain insight into the possibilities for creating more support and awareness. This could then be worked out in a follow-up assignment of the research on felling and planting trees, which was mentioned above. In the paper we already put forward a suggestion on how to proceed with this. But a deeper investigation will show whether this method is possible and whether is the best choice. During this future research, we may find certain limitations and/or

---

[12] Co-creation is a form of collaboration in which all participants have an influence on the process
[13] Likert scale – Wikipedia, retrieved on 26 July 2023.

points for improvement in connection with the SROI method or we may find better and other possibilities to increase support. But before we come to any conclusions, we need to work on a final draft of this research proposal an implement this method.

Microclimate-Related Human Comfort as Aspect in Urban Planning: Indication of NBS Interventions to Increase Quality of Cycling Networks

1 ABSTRACT

Climate change and environmental challenges affecting cities encourage them to reduce negative impacts of environmental challenges on human comfort and respond with sustainable spatial solutions such as Nature-based solutions (NBS). While spatial analyses are often limited in analysing dynamics between space–environmental characteristics and human comfort, there is a challenge to exploit new technologies (ICT) as the potential for the development of more inclusive analyses and monitoring. This paper reflects on one particular portable device for a simultaneous dynamic microclimatic data gathering, and by a protocol for microclimate street assessment evaluates microclimate-related comfort of cycling lanes in Ljubljana, Slovenia. By identifying correlations between spatial elements and microclimate conditions in different spatial settings, the study defines cycling lane sections of various levels of comfortability. The results suggest that ICT innovations for in-situ measurements can help urban analytics to gather and urban planners to interpret detailed microclimate-related information and can help to assess places according to microclimate issues such as high temperature, poor air quality, incrised humidity, but also disturbing noise levels. Collected data are interpreted within human comfort zones and can be linked with rates/levels of comfort. Thus, the paper contributes to urban planning by the provision of fine-grain localised data, with precise data spatial and temporal resolution. As the gathered data is geopositioned, it can be presented on a map enabling a linkage of environmental conditions within a spatial context.

Keywords: Urban planning, Nature-based solutions, Information and communication technologies, Human comfort, Microclimate

2 INTRODUCTION

Microclimate in urban areas is increasingly being affected by the impacts of climate change. As human comfort is directly reflected in human behavior, activity patterns, space usage [1, 2, 3], and microclimate-related human comfort become a crucial aspect in urban planning when designing solutions to address contemporary societal challenges. To improve the quality of living and mitigate the adverse effects of climate change, cities are trying to implement various innovative approaches and develop climate-change-resilient sustainable solutions. Urban planning plays a crucial role not only in climate mitigation by reducing global warming but also in designing solutions that facilitate natural processes, leading to the creation of pleasant microclimate conditions.

Nature-based solutions (NBS), a planning concept addressing various societal challenges, holds a promising potential for incorporating the aspect of microclimate-related human comfort in design solutions. Solutions based on mimic natural processes can directly address the societal challenges of cities [4]. However, to implement sustainable solutions that are as self-sustained as possible and deliver the desired environmental outcomes, it is crucial to integrate microclimate knowledge into the design process based on urban analyses of site specific conditions. Following Goličnik Marušić et al. [4], further, it is important to recognise local characteristics to identify the resources that are needed and/or available for the functioning of the NBSs so that NBSs can enhance/exploit the given sites' characteristics to the greatest possible.

The development of new Information and Communication Technologies (ICT) represents the potential for conducting comprehensive analyses, as well as exploring the interpretation of locally-based information of microclimate from a human perspective. Here, we specifically refer to portable ICT devices that enable the acquisition of detailed environmental data with precise spatial and temporal resolution. These devices have the potential to reveal the hidden dynamics between environmental characteristics and spatial context, which could assist urban planners in identifying areas where NBS interventions may be needed.

In this sense, this paper follows a pilot research that uses a particular ICT device for dynamic microclimate-related data gathering and, by using a protocol for microclimate street assessment, explores the microclimate-related comfort of cycling lanes in Ljubljana, Slovenia. Besides providing a few preliminary

examples of microclimate assessment, the paper addresses the following research question: How can ICT devices for in-situ measurements aid urban analytics in gathering detailed microclimate-related information and assist urban planners in assessing places based on microclimate-related challenges?

Summing up, the research follows a bottom up aproach, of locally based environmental data collection, such as air temperature (°C), relative humidity (%), noise level (dBA), and particulate matter (e.g. PM 2.5 (μg/m³)). It developes the aproach to analyse cycling lane as comfortable and discomforatble areas, representing a first step towards identifying possible microclimate-related challlange. Such an analysis is recognised as having potential for prioritising and selecting spatial interventions that may be needed to achieve or improve the quality of a space. Since this research is still ongoing, this paper cover only one segment of the entire research. The quality of data plays an important role in urban planning, so the paper comments on data gathered in relation to usefulness of such data for urban planning analytics. By providing a few examples of analysed cycling lanes section it illustrates what kind of data can be gathered and demonstraits the potential of such data for defining comfortable and uncomfortable cycling lane sections as well as for identifying possible microclimate challange and/or suitable NBS for improvement.

2.1 Data Characteristics

To assess spaces in terms of human comfort and microclimate-related challenges, data characteristics must be understood within the context of urban planning. To interpret microclimate conditions from a human perspective and cycling experience, urban planners should work with fine-resolution data that reflect site-specific environmental conditions.

Considering that microclimate conditions in urban areas vary between 1 to 100 meters [5], it is crucial to address the appropriate spatial resolution of microclimate-related data. Therefore, the minimum recommended accuracy for distinguishing environmental conditions is approximately 100 meters; however, achieving an optimal level of accuracy would require data with a resolution as fine as 10 meters. Data spatial resolution also plays an important role, as cyclists occupy space at different time intervals during a day, and microclimate changes within a 24-hour period [5]. Therefore, the data should reflect the environmental variability that cyclists might experience at different time intervals throughout the day. In terms of microclimate-related human comfort, it is crucial to recognize that microclimate conditions arise from dynamic interactions between various microclimate parameters. These interconnected relationships significantly influence human comfort. Therefore, when conducting microclimate assessments focused on human comfort, it is essential that the data enable urban planners to interpret such simultaneous influences of microclimate parameters. Also, in practical terms, urban planning relies on map-based approaches. Therefore, graphically geolocated data in the form of maps becomes crucial.

2.2 Presentation of the Tool

The tool was developed by the University of Deusto in Bilbao, Spain. It serves for gathering and analyzing microclimate-related data at a user-experience level, focusing on site-specific environmental details. The tool enables the tracking of movement, making it usable for walking or cycling, and can be utilized in all publicly accessible spaces. The tool consists of two components: hardware (Figure 1 and Figure 2) and software.

The hardware comprises sensors for the simultaneous collection of environmental data, including air temperature (°C), relative humidity (%), barometric pressure (kPa), particulate matter (PM 1.0, PM 2.5, and PM 10.0 (μg/m³)), CO_2 gas, and noise level (dBA). The hardware is connected to a user interface (software) and is part of the publicly accessible platform called Bike Intelligent Centre. The platform provides feedback to the user and can be accessed at http://bizkaiabikeintelligence.deustotech.eu/en/datacentre (accessed on 10 April 2023). The platform offers a range of functions for analyzing microclimate parameters. The tool allows for the measurement of each mentioned parameter and subsequently presents the environmental data on a map. The data is displayed using different colors corresponding to each parameter. These colors are assigned based on a threshold classification system, where each color represents different levels of data values. The query function on the platform (software) enables the selection of specific dates and time intervals of interest for analysis. Within the platform, there is an underlying spatial map that includes essential information, such as land use and the occupation level of bicycle paths.

Fig. 2: User interface (software), a platform, consisting of different functions to analyse the collected data.

3 METHODOLOGY

This study adopts a case study approach, with the fieldwork conducted along the cycling lanes in Ljubljana, Slovenia. The data gathering process was carried out as an integral part of the research methodology, where the main objective was to evaluate the microclimate-related comfort of cycling lanes in the urban area.

The paper also explores the potential of ICT for assessing the level of comfort of cycling lanes regarding microclimate-related challenges and investigates the potential to identify correlations between spatial elements and microclimate conditions in different spatial settings. In that sense, we explored the potential of this ICT tool considering the following data characteristics:

- Spatial resolution,
- Temporal resolution,
- The interpretation of environmental data through human comfort parameters,
- The interpretation of environmental data within different levels of comfort zones,
- Map-making and linking environmental conditions with a spatial setting,

3.1 Field work

Data gathering was performed using the protocol for microclimate-related street assessment, consisting of several steps, which were already defined in our previous work [6]. Beside the tool, the necessary equipment for data gathering is a bicycle. Additionally, the appropriate cycling speed for data collection in relation to the frequency of the device's data capturing was set to 8 km/h to enable precise data temporal and spatial resolutions.

3.1.1 Protocol for microclimate-related street assesment

The protocol is composed of four main steps: deffinition of the measurement area and the measurement period, selection of parameters to be measured and evaluated, definition of measurement time intervals, and analysis of collected data. They are conducted as following:

1. Definition of the Measurement Area and Measurement period

The data gathering campaign is condicted on highly occupied bicycle lanes in the urban area; in this paper applied in the case of the city of Ljubljana.

Within this first step also the duration of the measurement is defined. In our case, there were some limitations related to readiness of the device. However, as a period of observation the month of August was selected, significant for high temperatures as climate-related characteristics.

2. Selection of parameters to be measured and evaluated

To identify comfortable and uncomfortable sections and possible microclimate challenges, the microclimate-related human comfort parameters must be included in the analyses. In that sense, based on a literature review, the following microclimate parameters were selected: (a) air temperature, (b) solar radiation, (c) humidity, (d) wind velocity, and (e) air quality. In assessing human comfort, we also considered the following set of parameters: (f) level of noise, (g) human perception, and (h) other subjective parameters, such as human activity and clothing [7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17].

3. Definition of measurement time intervals

As we are specifically interested in the conditions under which people cycle for their daily commute, the data gathering was scheduled for working days (Monday to Friday) between 7:30 a.m. and 9:00 a.m., and 3:00 p.m. to 5:30 p.m. The planned campaign was set for every day in August 2022, yet data gathering was not been performed on rainy days.

4. Analysing the collected data

This is the most complex step of the protocol, comprising three levels:

(1) Data visualisation to transfer gathered data on a map to provide links between environmental conditions within a spatial context.

(2) Descriptive analysis to identify areas that offer comfort or discomfort to their users.

(3) Data interpretation to identify areas where microclimate challange is present and NBS intervention is needed.

The first step, data visualisation enables linking environmental conditions within a spatial context and must be done with the tool enabling to visualize microclimate through a medium where urban planning operates—mapping.

The second step, descriptive analyses must allow for interpreting data within the range of human comfort zones, with varying colors indicating comfortable spaces, as shown in Table 1. Currently, the descriptive analysis is based on the Bike Intelligent Centre platform, (part of the tool system), enabling to analyse data within absolute values of collected data. However to interpret the value of the difference of microclimate parameters within individual cycling sections, the data interpretation within relative values must be adressed. Another important step of discriptive analyses is related to the layering of the gatered data. First, different microclimate parameters are analysed separatedly. To identify uncomfortable areas for each microclimate parameter separately, individual gathering sessions are layerd and merged into the final maps of places with uncomfortable conditions (separating the morning and afternoon sessions for each microclimate parameter). Further step is related to the comfort rating in terms of simultaneous and integrated analysis of microclimate-related comfort parameters. Within this step the maps related to uncomfortable areas of individual parameters are merged into cumulative maps to define areas that are uncomfortable in terms of two or more parameters simultaneously.

The third step is related to data interpretation to identify areas where microclimate challange is present and NBS intervention is needed. Apart from simultaneous and integrated analysis of microclimate-related comfort parameters, this step requires a definition of a criteria referring to spatial analysis and other relevant data to consider when determining the NBS intervention.

	<0	<40	<10	/

Table 1: Legend to interpret microclimate data in relation to human comfort values (parameter threshold classification of comfort zones). The definition of a threshold for the temperature parameter was proposed by the experts who designed the ICT tool and is based on the average temperature values for Spain [18]; noise-level thresholds are based on the environmental noise guidelines for the European Region [19]; air-quality thresholds are based on the World Health Organization's air-quality guideline values [20]; and humidity levels are based on general recommendations for indoor and outdoor humidity in European climates.

4 RESULTS

Results are presented in two parts. The first part shows some illustrative examples of data gathering, indicating the potential of such a tool for defining comfortable and uncomfortable cycling lane sections. In the second part, the results are related to the quality of data, covering aspects of spatial and temporal resolution, data characteristics related to interpretation within human comfort zones, and the ability to use map-making for identifying and interpreting the correlations between space and environmental conditions.

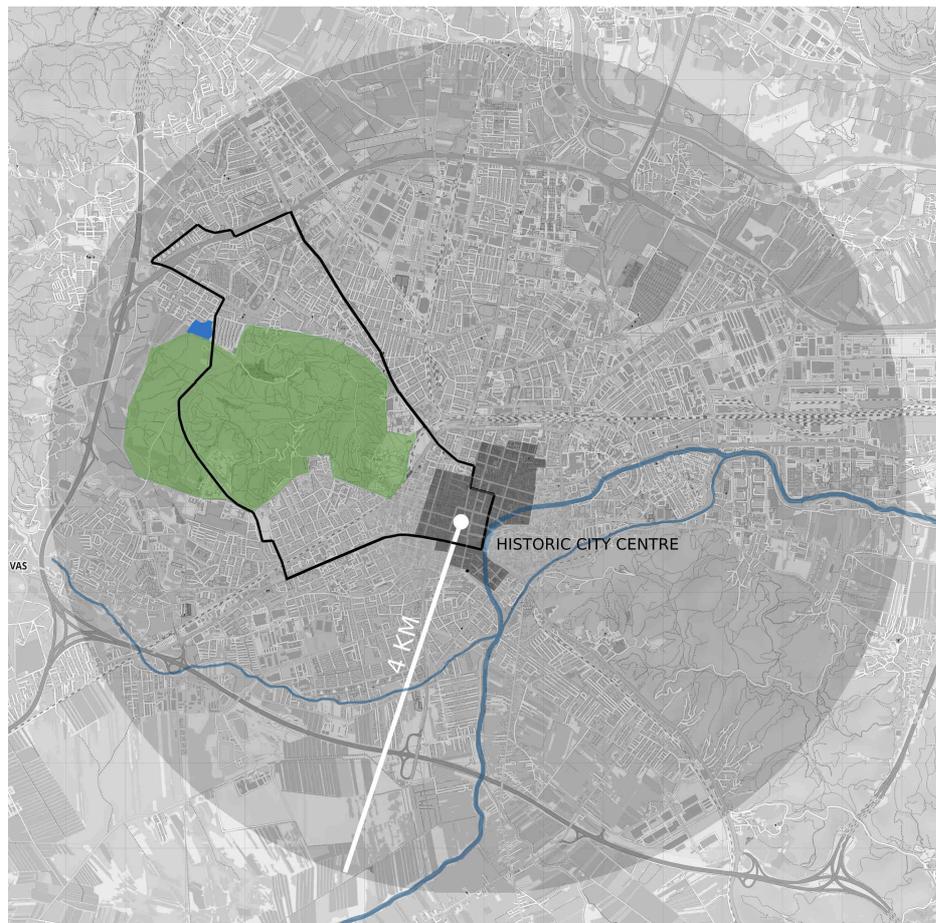

Fig. 3. Data gathering routh.

4.1 The practical performance of data gathering and illustrative examples of identifying comfortable and uncomfortable sections

Data gathering was performed almost every day in August 2022. The pre-planned route (12.5 km) led through different parts of the city, covering a variety of urban structures, including a densely built-up historic

urban area, a densely built-up urban area, and a relatively compact urban pattern with areas of low density. According to the land-use plan, the cycling paths most often crossed areas of central activity, residential areas with accompanied activities, areas of green spaces, and forest areas. Natural morphological features were related to flat terrain, open spaces, forests, clusters of trees, water areas, and artificial non-agricultural green areas, such as urban tree lines and small-sized green surfaces.

4.1.1 <u>Illustrative examples of data gathering, and the potential of such a tool for defining comfortable and uncomfortable cycling lane sections.</u>

This subchapter illustrates which microclimate-related parameters can be interpreted and how such microclimate-related human comfort related data can be used within urban planning analytics.

The illustrative example of data gathering was performed in Ljubljana on Friday, August 5, 2022, between 16:06 and 16:18. Cycling Lane section led through different spatial setting, characterised by densely built-up urban tissue and densely built-up historic urban tissue. The most common natural morphological features are related to flat terrain, urban tree lines, small-sized green surfaces and also a river.

The device enabled the collection of the following parameters: air temperature, relative humidity, noise level, and particulate matter (PM 2.5), which represents the potential of identifying possible microclimate challenges in urban areas. The inclusion of these parameters is sufficient to understand the environmental conditions from an objective–numerical standpoint, which address only the physical conditions.

The gathered data is presented trough a software of the tool, a map-based platform. The routh of data gathering is represented by a track of movement, where the microclimate values are graphically represented with dots of different colors. These colors are assigned based on a threshold classification system, where each color represents different levels of data values, indicating the level of comfort (see Table 1). Such data interpretation enables to differentiate sub-areas regarding the level of comfort.

For example, the temperature parameter on the following cycling lane section (Figure 4) is mostly represented with red colour, indicating uncomfortable conditions, varying between 35.1°C and 37.2°C. Yet, cycling lane subsection following through a historic part, near the city river, the temperature values are represented with orange colours, indicating still uncomfortable conditions, yet with a lower temperature value (varying between 34.7°C - 35°C). In terms of data precision, the data enables to interpret variable microclimate conditions every 10m, enabling to identify changeable microclimate conditions on a pedestrian level. The data related to temperature indicate that every 10 meters temperature can changes between 0.1 °C and 0.8°C. Continuing with the humidity parameter, conditions are represented with yellow colour. Such colour representation is indicating comfortable conditions, varying from 35.6% and 40.2%. Every 10 meters, the humidity value can change between 1% and 1.4 %.

The level of noise is represented with three different colours, indicating subsections are different in terms of comfort level. Green colour is indicating comfortable conditions, varying between 40–60 dBA, yellow colour is indicating uncomfortable conditions, varying between 60–70 dBA and orange colour is indicating uncomfortable conditions between 70–80 dBA. Every 10 meters, the level of noise can change for 0.1 dBA and 16 dBA.

Air quality values are comfortable during the whole section (green colour), where conditions are varying between 9–17 µg/m³. Every 10 meters values differ from 1 – 8 µg/m³.

4.2 The tool's potential for urban analysis of assessing human comfort related to microclimate challenges

The findings indicate that the data's spatial resolution is accurate in capturing the changeable environmental conditions that cyclists may encounter within a few meters. While cycling at an average speed of 8 km/h, measurements were recorded by the device at 5-second intervals, resulting in data collection approximately every 10 meters. Taking into account that environmental conditions can vary between 10 and 100 meters [5], the utilization of the ICT tool enables the generation of sufficiently detailed data. Moving on to the temporal resolution, the tool facilitated data collection at any given time period throughout the day. Given that microclimate conditions change within a 24-hour cycle [5], and assuming that a commuter cyclist travels a minimum of two times per day, the results indicate that the 5-second resolution could help identify the environmental conditions experienced by cyclists during their commute. With the tool, we achieved the

1046

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

capability to collect a comprehensive set of human comfort parameters. The data obtained were then visualized across various human comfort zones, providing valuable insights into the comfort levels of a given space.

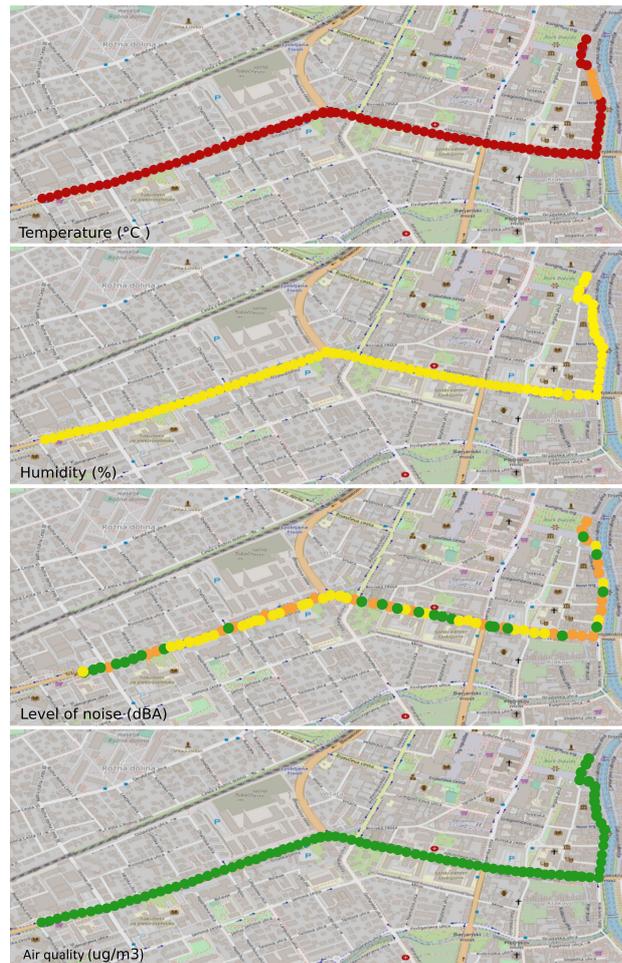

Fig. 4. The practical performance of data gathering and illustrative example of identifying comfortable and uncomfortable sections to demonstrate the potential for identifying possible microclimate challenge.

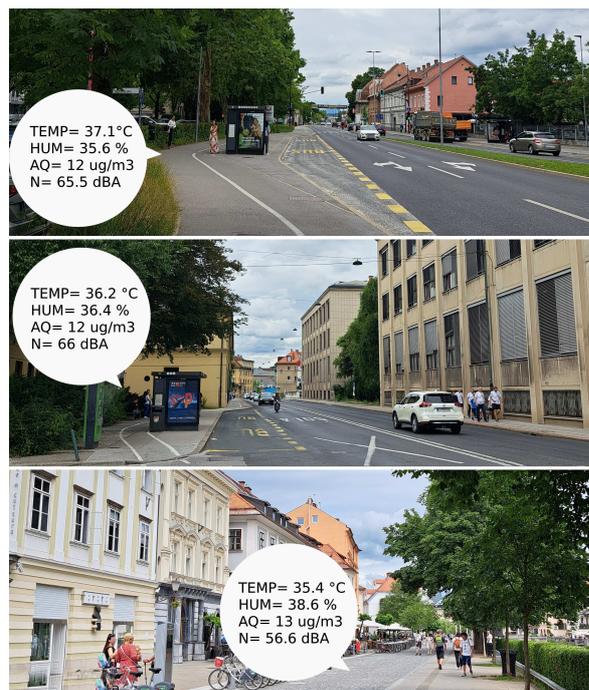

Fig. 5. Illustrative example of data gathering in real places demonstrating detailed microclimate-related information for identifying variable microclimate conditions at a pedestrian level.

The implications of these findings are seen within urban analyses of assessing spaces in terms of microclimate-related human comfort and for identifying microclimate challenges, including high temperature, air quality, humidity, and noise level. Furthermore, in terms of its map-making capabilities, which facilitate the correlation of environmental conditions with specific spatial settings, the results indicate that the platform offers a user-friendly and visually intuitive approach to conducting environmental assessment analyses.

The findings demonstrate the potential of such data in conducting urban analyses. This valuable information can be utilized to identify and allocate necessary spatial interventions or to monitor existing sustainable solutions, ensuring their long-term environmental benefits.

5 DISCUSSION AND CONCLUSION

This paper is based on the premise that considering the microclimate in the design process of sustainable solutions can lead to improvements in environmental quality, affecting environmental conditions and supporting human comfort. However, conventional urban analyses might prove inadequate in thoroughly examining the connections among microclimate conditions, environmental characteristics, and human comfort. In that sense, the paper explores the potential of one ICT tool for assessing human comfort in a case study of cycling lanes in Ljubljana, Slovenia. Based on a microclimate-related street assessment and simultaneous dynamic environmental data gathering, the paper defines sections that are comfortable and uncomfortable, representing a first step towards identifying possible microclimate challenges.

The results suggest that ICT innovations, for in-situ measurements, can help urban analytics gather and urban planners interpret detailed microclimate-related information and assess places according to microclimate challenges. The ICT tool enabled the production of data with characteristics that support better consideration of microclimatology in urban planning. The collected data have precise temporal and spatial resolutions, enabling the identification of variable microclimate conditions within a few meters, every five seconds. In terms of data characteristics related to comfort, the results indicate that the data can be interpreted through the main microclimate parameters: air temperature, relative humidity, particulate matter (PM 1.0, 2.5, and 10.0 µg/m³), noise level and additional ones; barometric pressure (kPa), and CO_2 gas, thereby assessing the comfort of the space. The findings also suggest that the data are presented through a map-based visual representation of spatial assessment, a linkage of environmental conditions within a spatial context.

Such innovative tools for analysing site-specific environmental characteristics represent a potential within urban planning of NBS, where the data's potential is seen in urban analyses, prioritizing, and selecting spatial interventions to achieve or improve the microclimate-related human comfort of a space.

1 ABSTRACT

Densely built urban environments experience extremely high temperatures during summer heat waves. Nature-based Solutions (NbS), such as increasing green infrastructure by replacing sealed surfaces with vegetation, installing green roofs and especially planting trees can ameliorate severe heat conditions by providing cooling through evapotranspiration and shading. This study analyses the effectiveness of NbS to reduce the summer maximum temperatures in Vienna using an urban climate modelling approach that takes into account NbS performance criteria on micro-scale and upscales the application of NbS for the entire city.

Using existing data of the Viennese urban structure, status-quo urban climate simulations were performed. Further, based on evidence on NbS performance criteria different climate scenarios for implementation of NbS were designed. A densely-built area in Vienna, for which the possibility of implementation of NbS was analysed, was chosen as a study area for micro-scale simulations. The adaptation measures included: 1) reduction of soil sealing, 2) increase in surface reflectivity of sealed surfaces, 3) implementation of green roofs, 4) new park areas with trees and low vegetation and 5) a combination of all NbS.

The modelling simulations were performed for a representative clear-sky heat day for NbS scenario first for the selected area with the ENVI-met model and later for the entire city of Vienna with the MUKLIMO_3 model. The extent of NbS was proportionally scaled for the city-level simulations and the measures were applied for all densely-built areas in the city.

The results show the highest cooling effect for the combination of NbS with a similar intensity of cooling found both in microscale and city-scale simulations. In case of city-scale simulations, the results show mean difference in daily maximum temperature of about 0.1°C and maximum difference of about 1.4°C. The effect is strongest in the densely-built areas where the measures were applied. However, the cooling effect can be detected in the surrounding areas as well.

The robustness of the urban scale results was tested using different modelling setups, varying the parameters describing land-use properties, such as variations in land use mapping, soil sealing, building density and tree coverage. Different representation of land use characteristics in the model leads to variations in spatial pattern of heat load. The cooling effect also varies spatially, dependent on the possibility to implement the adaptation measure. However, the results confirm similar efficiency of NbS regardless of the background data and method applied.

Keywords: urban heat island, urban climate, nature-based solutions, microclimate, climate modelling

2 INTRODUCTION

Urban environments are particularly sensitive to negative impacts of climate change. Especially, increasing occurrence of extreme weather events like heat waves poses a serious threat for urban regions (e.g. EEA 2012), since the prevailing structures increase the the experienced heat due to the Urban Heat Island (UHI) effect (e.g. Oke et al. 2017). Regulating urban climate by reducing the UHI effect and extreme temperatures during heat waves has become an important issue in sustainable and climate sensitive urban planning. One approach towards UHI mitigation is the implementation of the so-called Nature-based Solutions (NbS), such as parks, forests, water bodies, green roofs, green facades and other green and blue infrastructure, that have positive effect on reducing temperature peaks and provide multiple other ecological and social benefits (e.g. Nesshöver et al. 2017).

In case of Vienna, strong increase in temperature and heat-related climate indices has already been observed and further intensification in urban heat is expected in the next decades (Chimani et al. 2016; Bokwa et al. 2018; Bokwa et al. 2019). This can cause severe impact on public health by increasing the level of heat-

related mortality (Muthers et al. 2010). The climate trend towards higher temperatures relates also to growing energy demand for cooling of buildings (Bird et al. 2019). The energy consumption depends on the building performance as well as specific microclimate conditions. The NbS can provide further benefits in reducing cooling energy demand by reducing outdoor temperatures as well as regulating indoor temperatures through insulation of buildings, for example by implementation of green walls and roofs.

As a measure to reduce the negative aspects of urban climate, the City of Vienna developed an UHI strategic plan (UHI, 2015) to implement various climate adaptation measures on buildings and open space including urban ecology measures based on planning tools and instruments on different governance levels. The scientific data base for the strategic plan are a number of climate studies providing an urban climate assessment, future climate scenarios and possible impacts, climate function map including thermal imaging, as well as strategic papers and information on the physical implementation of actions such as green space networks, green roofs, living walls and rainwater management.

As a supporting evidence for strategic plans for climate adaptation and sustainable urban development, many modelling applications have provided estimates on efficiency of NbS to reduce the UHI effect in Vienna. Most of the studies (e.g. Orehounig et al. 2014; Vuckovic et al. 2018) were focused on a specific building block and considered possible implementation and optimization of adaptation measures to find best-suitable solution for the particular study area, for example unsealing of paved surfaces and planting trees considering the orientation of streets and building geometry to enhance the shading effect. The quantitative results of these studies were difficult to transfer on other areas in the city, as well to draw general conclusions for implementation on a strategic level.

Another modelling approach considered implementation of adaptation measures on a city-scale, however, with limited spatial detail. For example, the implementation of blue and green infrastructure (Žuvela-Aloise et al. 2016) and application of green roofs and albedo modifications (Žuvela-Aloise et al. 2018) was modelled for Vienna and the results show that moderate to strong cooling effects can be achieved by extensive implementation of NbS. However, these studies calculated the cooling effect of NbS in terms of theoretical potential based on existing urban morphology, but not considering realistic application and actual urban development plans.

One of the main challenges of urban planning response to climate change impacts is that adaptation measures need to be implemented consistently at different planning levels and that the right amount of NbS needs to be identified in order to achieve a sufficient cooling effect as well as to engage appropriate planning instruments for the implementation (Reinwald et al. 2021). In the study of Reinwald et al. (2021) a combined approach with micro-, local- and meso-scale climate simulations and a green and open space factor was adopted to assess current and future urban heat stress and to evaluate the cooling effect of NbS in a standardized way on different spatial and planning levels.

Similar climate modelling approach was used in this study with a goal to identify appropriate NbS specifically for densely built urban environments, which are most severely affected by the UHI effect and quantify their cooling effect on the micro- and city-scale. The study examines a typical building block in dense urban environment in Vienna and considers different adaptation measures, including reduction of soil sealing, increase in surface reflectivity of sealed surfaces, implementation of green roofs, new park areas with trees and low vegetation and a combination of all NbS above. The modelling simulations are performed with a micro- and city-scale urban climate model and the results are analysed in the context of climate change adaptation for the use case example of "Supergrätzl" and the strategic plan on the level of the city of Vienna.

3 DATA AND METHODS

3.1 Micro-scale model

The state-of-the-art microclimate model ENVI-Met was selected to simulate status-quo and "resilience" scenario on a micro-scale level. ENVI-Met provides the possibility to design buildings, vegetation, surfaces, pollutant sources or waterbodies on a 3D grid and simulate atmospheric and surface interaction processes (ENVI-Met, 2023). Buildings and trees are explicitly resolved, thus enabling representation of adaption measures on a granular scale. The model domain focuses on a demonstrative quarter called "Supergrätzl" in

1052

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

the 10th district of Vienna and expands to 792 x 476 x 60 m with a spatial resolution of 2 m and higher resolved vertical resolution of 0.4 m within the lowest 5 model levels. The meteorological boundary conditions were chosen from a clear-sky hot day (19.07.2014), with fixed low wind direction from West to represent an autochthon weather situation. Around 350 m of the domain in the Western part are considered as buffer zone to account for effects induced by boundary conditions.

For the NbS scenario, different streets in the domain have been redesign with NbS. Surrounding streets of the quarter have been greened with additional trees and sealed parking lots have been unsealed or adapted to grass pavers. One street has been paved with higher albedo plaster and adjacent buildings gained façade and roof greening where applicable. Some streets received façade greening, removed and unsealed parking lots, additional trees, street greening, water features and higher albedo plaster, while others have been refurbished with technical solutions like sun sails, fog showers and as well higher albedo plaster to compare NbS and technical solutions (Fig. 1).

Fig. 1: Domain overview and depiction of status-quo and planned measures (left) and implemented measures (right) for urban quarter ("Supergrätzl") in the micro-scale simulation.

3.2 City-scale model

The simulations of urban climate for the city of Vienna were performed with the urban climate model MUKLIMO_3 (in German: 3D Mikroskaliges Urbanes KLImaMOdell) developed by the German Weather Service (DWD). The thermo-dynamical version of the model described in (Sievers, 2016) with model updates released in 2020 was used. The model is based on Reynolds-averaged Navier–Stokes (RANS) equations and includes parametrisation of vegetation and building morphology. The modelling approach takes into account terrain elevation, land use types and spatial distribution of land use parameters such as building density, building height and wall area index, sealing fraction and tree cover. The model domain covered the City of Vienna and its immediate surroundings with a grid size of 314 x 239 points and horizontal grid spacing of 100 m. The vertical resolution of the 3D model with 39 levels varied from 10 to 100 m with higher resolution near the ground and maximum height of about 1000 m. The simulations were conducted for a chosen clear-sky hot day (19.07.2014) representative for heat conditions during a summer period in Vienna, adopted from (Reinwald et al. 2021).

3.3 NbS assessment

The calculation of NbS cooling effect was performed by comparing the model results for mean and maximum air temperature between the reference simulation with current urban structure and the NbS scenario. In the NbS simulation the land-use parameters that are used as model input, as well as their spatial distribution, were adjusted to account for reduction of sealed surfaces and increase in vegetation (Table 1).

	Reference	NbS Scenario
Building area	43.6%	43.6%
Green roof area	0.0%	5.0%
Streets	53.7%	35.5%
Unsealed surface	0.0%	15.2%
Vegetation (low vegetation and tree trunks)	2.7%	5.7%
Number of trees	84	231

Table 1: Percentage of different land use areas in reference simulation and the NbS scenario as input parameters for the model simulations.

Realistic values of available surface area and possible greening measures were estimated on the example of Supergrätzl (Fig. 2). In case of the city-scale simulations the measures were applied in all densely built areas

in Vienna. To account for increase of number of trees that could not be simulated in the city-scale model due to the low spatial resolution, a park area was assigned to grid cell with buildings for every ninth grid-point of the dense built-up area. Additionally, albedo value of sealed surfaces was increased by 30%, as the existing street areas where considered to be partially replaced by higher reflective concrete and porous pavement.

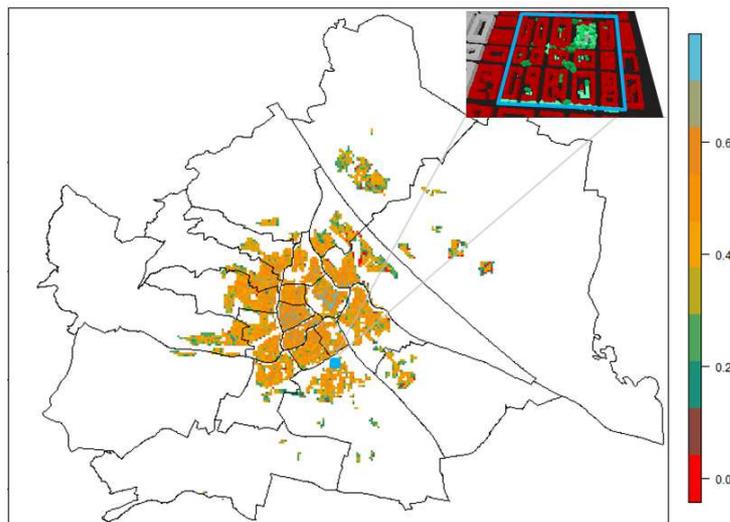

Fig. 2: Building density in Vienna for the dense built-up areas (land use typology: Blockrandbebauung; Green4Cities/GREENPASS, 2018, adapted from Reinwald et al. (2021)) and the location of the Supergrätzl.

4 RESULTS

4.1 Micro-scale simulations

Evaluation and comparison of NbS scenario with status-quo has been carried out for the parameters air temperature and mean radiant temperature (MRT) on pedestrian level. During the entire course of the day, NbS demonstrated stronger cooling capacities than technical solutions with averaged 0.8°C vs. 0.4°C during the day and 0.6°C vs. 0.3°C during the night for air temperature over the entire urban quarter. The cooling effect on air temperature is stronger during the day than during the night as differences of surface temperatures are higher during daytime (Fig 3, left, middle). Shading function of trees and evapotranspiration of vegetation are the main drivers of the temperature reduction. Sun sails only fulfil a partial shading function, as they can not be applied over the entire street scape for ventilation reasons. On the contrary, increased albedo on sun exposed areas even lead to higher MRT due to reflection of solar radiation (Fig 3, right).

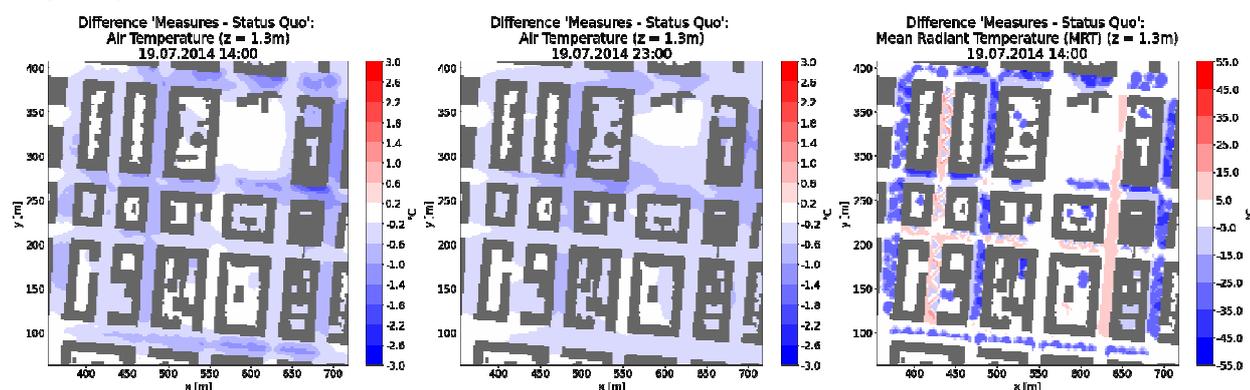

Fig. 3: Difference plots between scenario measures and status-quo of simulations for urban quarter ("Supergrätzl"). Left plot shows air temperature difference at 14:00, middle plot at 23:00. Right plot shows mean radiant temperature difference at 14:00.

4.2 City-scale simulations

A reference simulation based on the current urban morphology (Fig. 4, top) shows a typical development of the UHI in Vienna, characterized by higher temperatures in the densely built city-centre and lower temperatures in the surroundings, especially the elevated forest areas in the West and the national park Donau-Auen in East. By applying the NbS in densely built areas, a moderate cooling effect is found (Fig. 4

1054

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

bottom). The maximum difference in mean air temperature was 0.7°C and 1.4°C in maximum air temperature. The mean difference is, however, lower and yields to 0.1°C in maximum temperature. The cooling effect varies spatially and depends on the availability of open spaces where NbS can be implemented. The cooling is most effective in the areas where the NbS is applied. However, due to the prevailing wind from Northwest, the cooling effect can propagate further Southeast and the surrounding areas where no measures where applied.

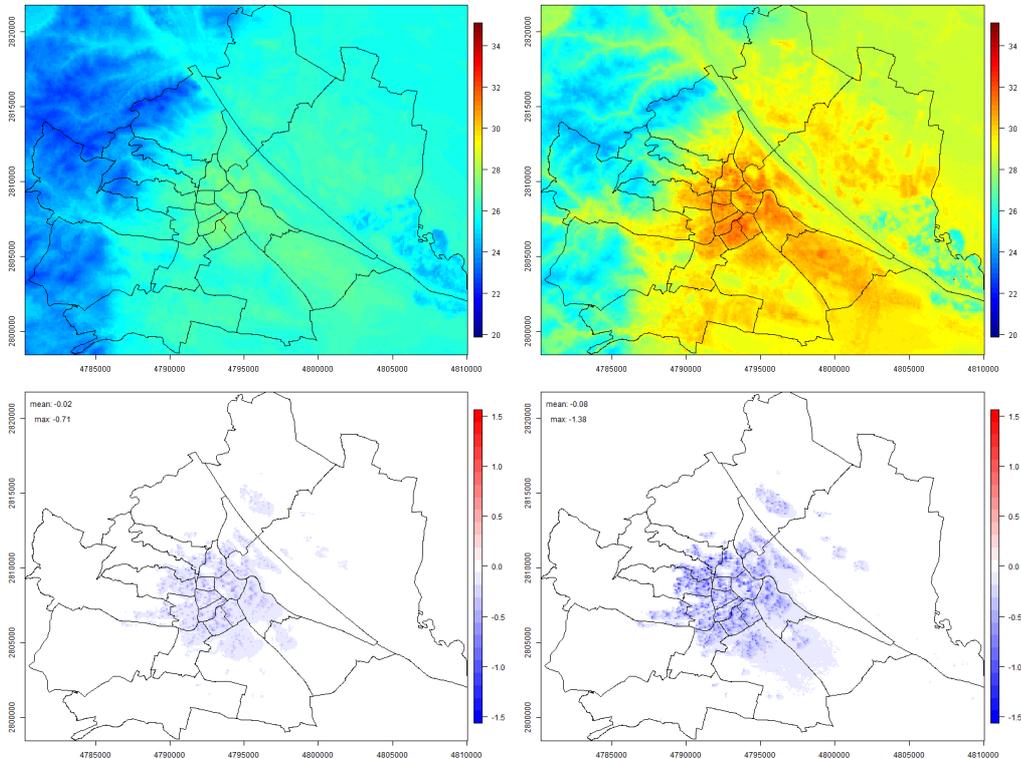

Fig. 4: City-scale simulations of air temperature (°C) in Vienna for July 19, 2014. Upper panel indicates daily mean (left) and daily maximum temperature (right) values for the reference simulation. The lower panel shows the difference in respective temperatures between the NbS simulation and the reference simulation.

5 CONCLUSION

This study demonstrates the cooling effect of NbS applied in a densely built environment based on the micro-scale and city-scale model simulations. The results from both modelling approaches confirm similar efficiency of NbS. The maximum cooling effect when different greening measures are applied is a difference in maximum air temperature of about 1.5°C. The cooling effect is limited by the availability of free spaces in densely built environment.

On the micro-scale the cooling effect of NbS is stronger than of technical solutions like sun sails or fog showers. The applied measures show stronger cooling effects (absolute) during the day than during the night. On the city-scale, the highest cooling effect is achieved by implementing green areas with trees (ΔT_{max}~1.2°C), while unsealing of surfaces has minor effect (ΔT_{max} ~0.3°C). The effect of green roofs, which was limited to 5% in the study area, is negligible (ΔT_{max} ~0.1°C). With higher availability of green roofs (30%) a larger, but still minor, cooling effect (ΔT_{max} ~0.4°C) could be achieved.

These results show that the NbS has a moderate cooling effect even in densely built environment, where their implementation is physically limited. As such, the NbS are an important instrument to address negative impacts of climate change and particularly to reduce the UHI effect. In further steps, the results of this study will be analysed in scope of climate risk assessment, where social aspects and vulnerability of urban population will be considered. These results can help improve existing urban development plans and accelerate the urban adaptation to climate change in Vienna.

Small Lexicon on Ecology (for those Interested in Cities)

Olivier Lefebvre

(Dr Olivier Lefebvre, Olivier Lefebvre Consultant, 4 rue Rollin 75005 Paris France o.lefebvreparis05@orange.fr)

1 ABSTRACT

Some notions about ecology show that if there is not a corpus there is an interesting and pertinent debate. We quote: on the environment itself, negative commons, mistake of the isolated system, dealing with the symptoms and not the causes (the tragedy of the horizons), and on the Opinion, Great Reversal, laws of opinion, greenwashing and the return of enclave economy. The cities are concerned by the two different stakes, adaptation and mitigation. Also, the question is posed of the places where ecological awareness can appear.

Keywords: cities, adaptation, urban policy, ecology, mitigation

2 INTRODUCTION

The ecological and climatic crisis has burst out in a society which was already a consumers society where Opinion is all powerful. Opinion is also elusive and arbitrary, according to the French philosopher Castoriadis. He compares it to a "magma" (Castoriadis, 1975). In some aspects, it is reassuring, since Opinion cannot be programmed, at least in democratic countries. Also, it is risky. If we distinguish, like the German sociologist Tonnies, two opinions, one "gaseous", volatile, sentimental, the other stable, educated (in progress like a Parliament learning during years, thanks to accumulated experience) we fear a too slow "learning" of the stable opinion. The pace of learning cannot be too slow, since the global warming worsens threatening to go out of control. Tonnies uses also the words "essential will" and "arbitrary will". The essential will is in conformity with the identity of a group, often a tribe. The arbitrary will is able to trigger decisions taking into account some evolution of the society, which is understood (Tonnies, 2012). Therefore, the fear can be described with the words of Tonnies: the disaster is if the pace of climatic change is faster than the pace of appearance of an arbitrary will (which is needed, to trigger the struggle against climatic change). That is why in in this "lexicon" we insist on what concerns the Opinion: Laws of Opinion, Great Reversal, Greenwashing.

Also of interest is the mental representation of Nature, and its evolution. Here we refer to the French theorist George Sorel, who distinguished "artificial nature" and "natural nature" (Sorel, 2019). In the industrial society knowledge was accumulated on "machinic systems". Nature was considered as a provider of energy and the goal was to avoid the waste of this energy (degradation of energy because of frictions). "Will" was needed to struggle against the machines' wear. Nature itself was forgotten. It is "natural nature". It is not only that artificiality of the city won around 1900. The famous urban planner Patrick Geddes wanted that the pupils of the schools in the cities take trips in the countryside, to learn what Nature is (otherwise, they never saw it). It is also that the relationship Man/Nature was not an interesting topic (only the "will", justifying productivism and extractivism). Before the industrial era, the relationship Man/Nature was taken into account, but on the religious mode (before the Newtonism in the 18 th century). The historian Wittfogel has described how in Old China, the Emperor was a half god responsible for the weather. He was guaranteeing the good working of the Universe. If there were disastrous floods, the dams being broken, he was at least removed. Recently a procession was seen in a city of the South of France, to get rain. To put an end to irony, we need to pay attention to Nature, and, of course, taking into account Science (climatology, scientific ecology, biology …).

What is of interest in the notion of "artificial nature"/"natural nature" is that the two knowledges, knowledge of causes (Science) and knowledge of reasons (sentiments, beliefs) are considered. Speaking of sentiment at the time of productivism / extractivism, it was "will". That there are debates in Science and on beliefs, both, has been theorized by the French sociologist Tarde, commenting on the works of the French philosopher Cournot (Tarde, 2012). It is interesting to understand the shift of the two knowledges when the era of productivism/extractivism ends, while the era of Sustainable Nature begins. Concerning the knowledge of causes, the sciences which matter are no more thermodynamics, mechanics, the science of motors (fluid dynamics …) but climatology, scientific ecology, biology, studies on health etc. And concerning the sentiment, one passes from "will" to "prudence". Indeed, the precautionary principle is the pilar at the time

of sustainable nature. It matters because we have understood that the impact of human activities on Nature is disastrous and cannot be neglected like in the past. And the indispensable science allowing to understand this impact does not (yet) exist. We are obliged to suppose the worse, when the impact of an activity on the environment is unknown. And, of course, we have to give up any project if its consequences on environment, that current science does not understand, or understands not enough, are possibly disastrous.

Now one can give the plan of this paper:

- First, some articles concern more the environment itself: negative commons, mistake of the isolated system, dealing with the symptoms and not the causes.

- Other articles concern Opinion, and economic or political topics: Laws of Opinion, Great Reversal, Greenwashing and return of the enclave economy.

- In the conclusion, we shall examine how the stakes of the ecological transition concern the cities.

3 ARTICLES CONCERNING THE ENVIRONMENT ITSELF

3.1 Negative commons

They are places where waste is illegally put: ocean floors, underground dumps, illegal burials etc. At the time of Soviet Union, the floor of the White Sea was used as a dump by the military nuclear industry. On the floor of the Tyrrhenian Sea, in Italy, is put waste from industry (this is under the control of an Ecomafia). Etc. If a user has waste to evacuate, he can make a gain by choosing the illegal way. There are rules concerning waste: they have to be burnt, or stored in some conditions, or recycled etc. If one avoids these rules, the cost is less and there is a profit. Think of an owner who destroys a building and wants to evacuate the waste. Until today, the waste in the building industry was not a problem. But this changes. The dumps are full. In some regions, where there is much wind, the wind carries dust from the dump far away. The materials used to build houses are complex and need recycling. Etc.

- A negative common works thanks to a "group of actors":

- The user makes a gain because the price for the evacuation of the waste is less.

- Some civil servants are bribed.

To find the people who carry out the illegal task itself is easy. According to the American economists Akerlof and Schiller, fraud works like the capitalism: if there is an opportunity of fraud, there are always the people who will launch this fraud, and benefit from it. It is like in the capitalism, if there is an opportunity to invest in some way, and win money, this investment occurs (Akerlof, 2016). The "group of actors" appears, and acts in coherence. Of course, it is because the rules are not enforced, and are not tough enough (only fines …). The society could "capitulate". That is to say, one tolerates the negative commons. In this case, the opportunity to make a gain thanks to a negative common, is open to anybody. It is the characteristic of a common. This common is negative because of the pollution of waters, air, soils … is aggravated.

3.2 Mistake of the isolated system

We simplify when we pose the problem of struggling against pollution. One considers one pollution, separately, and the goal is to eliminate it. Often, the struggle against a pollution creates another pollution, or hampers the struggle against some other pollution. There are many examples:

- Aerosol: These airborne particles often reflect the solar light and mitigate the warming of the atmosphere. But they are toxic pollutants. One has to remove them, even if they have a favorable impact on the warming of the atmosphere.

- Chlorofluorocarbons: After the Montréal Protocol (1987) one has ceased to produce chlorofluorocarbons, which destroy the ozone in the stratosphere (useful to protect against UVs). They have been replaced by the HFCs, hydrofluorocarbons … but these products strengthen the greenhouse effect… Finally, currently one removes the HFCs also.

- Methane: This gas in the atmosphere contributes to the greenhouse effect. Curiously, when one removes the gases NOx from the air in the cities because they are toxic for people, it hampers the

1058

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

struggle against methane … because the presence of NO_x in the air triggers chemical reactions which make methane molecules break.

- etc.

All is interdependent in the environment. This makes the methodology, when one studies the impact of chemical products on environment, very complex. For instance, it is not enough to study impact of some product. It would be necessary to study the impact of cocktails of products or their metabolites (the products into which a product breaks down in the water).

Awkward problems arise. For instance, conflicts are possible between experts in public agencies (who give advices on the danger of some products being diffused in the environment) and scientists (who make the scientific studies on the danger of some products). The experts could simplify while the scientists reckon that the methodology has to take into account the complexity of the problem. All this advocates for the precautionary principle.

3.2.1 <u>Dealing with the symptoms and not the causes</u>

We have to distinguish "adaptation" and "mitigation". "Adaptation" means measures taken and infrastructures created or upgraded to cope with the negative consequences of global warming in cities. The goal is to maintain livable the cities. The short term is considered. Are concerned networks of refrigerated water (to refresh buildings during hot summers), measures to deliver potable water even when there are droughts, measures against the disastrous effects of floods (which will be more frequent), raised dams etc. "Mitigation" of global warming concerns the long term. It is to deal with the causes themselves (too many emissions of CO_2 in the atmosphere).

One has coined the term "tragedy of the horizons" to describe the possible mistake. To deal with the symptoms, forgetting the causes, would be a mistake. As the worse is besides the horizon (an unbearable increase of the mean temperature of the atmosphere), and there are preoccupations in the present, one is tempted to give the priority to adaptation forgetting mitigation.

Since in this paper we explore the hypothesis of an Opinion all powerful, elusive and arbitrary, we cannot avoid to discuss this possible evolution: "adaptation" is taken in charge efficiently, the Opinion is reassured and this leads to the stake of "mitigation" neglected. This, because the consequences of adaptation are visible, while the consequences of mitigation are invisible (but matter very much). Obviously, if we lose time to carry out mitigation, it becomes more and more costly. The Stern[1] report (2006) has stated that mitigation of climatic change, carried out more lately, will be costlier. During the lost time, the expenses for adaptation would increase. Finally, the Humanity would cope with a double investment wall: for adaptation and for mitigation (this, without speaking of a possible no return point).

Take the example of water in Paris. The works to master the problems of water in Paris started a century ago. One has created several water reservoirs (lakes) upstream of Paris, to master the flow of the river Seine (to retain water in winter, to deliver water in summer). After, the works have reached a pharaonic size. One has promised the Parisians to allow swimming in the river Seine in 2024, year of the Olympic Games in Paris. For that, the water treatment plants upstream of Paris have been upgraded. The cleanness of the water in the river is threatened when there are storms, because the rainwater and the wastewater overflow the sewage system. One builds two huge reservoirs connected by a tunnel to collect these waters, which will be released in the river lately, after a treatment cleaning them. Notice that the promise (to Parisians that swimming in the river Seine will be possible) has already been made for the year 2000 … without effect. Now suppose that the promise is kept. Concerning another recreational activity, fishing in the river Seine, it is definitively lost, because of chemical pollution in the river Seine. One corrective action (swimming) is possible and costly, while another one (fishing) is impossible. Again, this shows that the precautionary principle should be applied.

---

[1] Nicholas Stern is a British economist.

4 ARTICLES CONCERNING OPINION

4.1 Great reversal

Again, given our hypothesis on the Opinion which is all powerful, elusive and arbitrary, one has to consider the possibility of a turning back in environmental matters. Already some European leaders claim a "pause" in environmental legislation. In the Nederland, a political party claiming to maintain the productivist agriculture has made significant electoral gains. In the European Parliament a law poised at restoring the totally or partially destroyed ecosystems in the EU, has been voted by a narrow majority, after many articles have been cancelled. However, it is absurd. One cannot limit the ambitions of the struggle against global warming to a decarbonated economy at a certain date (2050). We have also to maintain the carbon sinks. To limit the emissions of CO_2 in the atmosphere while destroying carbon sinks (forests, wetlands, meadows …) is absurd. In an impossible rational approach, we should choose at each time the less costly means: either to reduce emissions of CO_2, either to strengthen or to restore a carbon sink. Again, it is the precautionary principle: we should reduce the emissions and restore the carbon sinks.

Even, one can imagine that in case of success, the opponents to environmental legislation get that one gives up on decarbonated economy.

One knows, at the time of the social networks, that there are techniques to manipulate the Opinion. One displaces the "Overtone window"[2] alongside an axis marked from "unthinkable" to "policy" via "radical" and "acceptable". It is done step by step. Of course, it is purely empirical. To use the words of the American author Cass Sunstein, there is an "entrepreneur in availability". One cannot know in advance if he will succeed or fail, but if he succeeds one cannot know if he has worked on the "gaseous" opinion (the triggered change is temporary) or on the "stable" opinion (the triggered change is definitive). In the same vein, the famous "nudging" should concern only a change of the gaseous opinion or a change explained by the evolution of the stable opinion in some field.

Let us comment on the examples of "battlegrounds" where proponents of comprehensive environmental rules and opponents, struggle: oil and gas, vehicles electrification, industry.

4.2 Oil and gas

Are concerned the NOCs (National Oil Companies). They want to benefit from the resources they have in their reserves, oil, and they say it. Notice that the production of oil increased every year except during the pandemic. And the emissions of CO_2 have not started to decrease! However, the NOCs are in an awkward dilemma. If they choose as a strategy to produce very much oil, the price will decrease and their proceeds will diminish. And if they choose to shrink the production, the high price will favor the renewable energies, which substitute to fossil energies.

4.3 Electrification of vehicles

We live in a "society of the supermarket" (Fourquet, 2022). So, the logistics has become a huge activity (Fourquet, 2020). The goods sold to consumers have to be carried as far as the supermarkets, or, in case of electronic commerce, the door of the customer' home. Only trucks are useful for this task, and are used. Trains are used mainly to carry heavy products. As it has been said by Jean Marc Jancovici[3], there is this negative consequence, from an environmental point of view, of the consumers society: the cars (and mainly the heavy cars) being fashionable, one is committed to electrification of cars, and electrification of trucks, which would be of great benefit for the environment, is forgotten.

4.4 Industry

Manufacturers, in recent years, have made many efforts to save energy. So, their emissions of CO_2 were reduced (industry is not the main source of emissions, it is transport). It is the notion of "good cost": a good cost is when one euro spent generates a revenue of more than one euro. The industry, by saving energy, increased its profits. But the reduction of emissions of CO_2 from industry is not enough. One has decided to levy a carbon tax. The "good cost" becomes: one euro spent generates more than one euro in carbon tax which is not paid.

---

[2] The overtone window is the list of the positions currently accepted in the society.
[3] He is a voice on ecology in France.

4.5 Laws of Opinion

One has to be cautious when Laws of Opinion are concerned. At best, these laws allow identifying an evolution of Opinion when it has started a long time ago. The French specialist of Opinion Jérôme Fourquet gives the example of sexual minorities in France. One has seen a sequence of reforms, changes in laws and in the society itself: homosexual rights (1981), civil solidarity pact (for homosexual couples also, allowing a usual fiscal status, but not adoption of a kid), same sex marriage (allowing adoption of a kid), and assisted procreation technology (for married women also). At every stage, there was an opposition sometimes ferocious. To explain the sequence, Fourquet proposes ratchet effect, domino effect and catalyst (Fourquet, 2020):

4.6 Ratchet effect

When some law is passed, the reform is decided and finally the change is accepted.

4.7 Domino effect

Every law passed, reform made, creates the conditions for the following step. The evolutions of Opinion come one after another.

4.8 Catalyst

The catalyst is the legal environment, that is to say all the laws already passed. It is an encouragement for the Opinion to evolve in some direction, to accept many changes of the same kind, in the same field.

But there is no absolute certainty when Opinion is concerned. Take this example: in France the law on free abortion (1976) is sacrosanct. But in the USA, one has seen an offensive against free abortion. It could fail but, in any way, it is a kind of alert.

The hope is that the laws passed in the European Parliament in the context of the European Green Deal will create a shock setting out a model imitated in the entire world. This sequence of laws should be helped by the ratchet effect, the domino effect and the catalyst. It remains to be confirmed that the change concerns the "stable" opinion in Europe (see the article "Great reversal").

4.9 Greenwashing

Decades ago, the French author Jacques Ellul, a proponent of political ecology, noticed that advertisers have taken the side of technology. Since this time greenwashing has appeared. The risk is an invisibilisation of environmental stakes. To explain that, we have recourse to the theories of the French sociologist Jean Baudrillard. There are two stages, naturalization and greenwashing:

Naturalization. In "The consumers society" Baudrillard defines it: "the signs of Nature restored while capitalism destroys it" (Baudrillard, 1986). After Baudrillard, the consumers buy signs, mainly, the use value of the consumed objects being secondary. "Naturalization" means that the consumers buy the signs of restored Nature (when they buy care articles, food, trips etc.).

Greenwashing. Now the signs are that of the saved Planet. Advertising creates this consumer's belief: buying a good, he contributes to save the Planet. A simulacrum is seductive (Baudrillard, 1988). And a simulacrum is to simulate that one has that one has not. Greenwashing is the simulacrum of having a safe environment thanks to consumption.

Take just an example: the car. The democratization of the car is explained by its popularity. Someday, the consequence of this democratization of the car, the traffic congestion in metropolises, threatened the car with unpopularity. The reaction of advertising was the denial. Advertisers and designers in the car industry refused the obvious solution, the small car. At the opposite, they promoted the large and heavy car. And this, notwithstanding the alerts on global warming. Around 2010, it was obvious that there was the victory of the model of the large car, the small cars being bought by only a few customers. Even when the cars are electrical, large cars are not the good choice: the carbon footprint of a large car is more than that of a small

car, not because of the use (provided that green electricity is used) but because of the manufacturing.[4] Add to this the fact that electrical trucks are neglected (see the article Great Reversal).

Greenwashing has created in the mind of the public, such reactions, that one can fear an invisibilisation of the environmental stakes. And this could contribute to a possible Great Reversal. In other words: greenwashing has persuaded the consumers that there is nothing to worry about environment, since the issue has been addressed, thanks to the purchase of goods.

4.10   The return of the enclave economy

Enclave economy was theorized by the Brazilian sociologist Cardoso. It was due to a powerful country investing in a poor country getting a grip on the government of this country. Later, it was due to multinational firms. And today, two new causes have appeared, "liquid Nature" and militarism:

"Liquid Nature". It has been theorized by Naomi Klein. In some project (1) Nature is a resource, monetized, of course (2) Nature is presented as kept safe, preserved (3) Nature is at the core of the project, and is a justification (Klein, 2010). For instance, a village in Italy losing its population, is "saved" by a single vocation, three-star tourism. An example of enclave is when a foreign country buys the land in an entire region, in a poor country, to cultivate it on a large scale.

Militarism. Militia control mines and get a revenue from them. The militia can be from the country itself (Libya, Sudan). Or in African countries the militia are from foreign countries. They trade military services for the revenues from the controlled mines. And this, when the countries importing raw materials want to control the conditions in which they are extracted, the environmental conditions and how the workforce is treated.

5   CONCLUSION

In conclusion, we shall insist on two points: adaptation and mitigation, and the places favorable to some ecological awareness.

The cities are concerned by two stakes, adaptation and mitigation, which are very different. Either adaptation strengthens mitigation, either they are not linked, and possibly they are in conflict. Let us comment on a few examples:

Adaptation strengthens mitigation. Energy efficient refurbishment is adaptation and mitigation, both. Renovated buildings are fresher in summer (one makes economies of energy, avoiding air conditioning) and hotter in winter (economies of heating). Therefore, the buildings will emit less CO_2 in the atmosphere. Another example is low emissions zones. It is adaptation (upgrading quality of air in metropolises) and struggle against global warming (there are less emissions of CO_2 from thermic motors, people walking or using the public transport).

Adaptation and mitigation are not linked. Huge works on infrastructures in cities (to raise dams to avoid the consequences of floods, to dig large reservoirs for rainwater like in Paris and London …) are poised to make cities livable and safer. But nothing is made for mitigation. Soon or later, if global warming continues, the new infrastructures will become insufficient … Opinion in cities could be reassured (since the cities remain livable) and forget the necessity of long-term objectives like struggle against the global warming … It would be to treat the symptoms and not the causes.

Adaptation and mitigation are in conflict. District cooling is an example. Of CO_2, it makes the cities livable in summer, but it requires huge amounts of energy, hence emissions of CO_2 (as far as the electricity is not decarbonated). Desalinization is another example. One can solve the problem of bringing potable water to cities, but it is costly, requires very much energy and degrades environment, since large quantities of brine are rejected.

The metropolises are the places where are labs and universities. Here, the knowledge on environment develops. But again, knowledge of causes and knowledge of reasons matter, both.   The places for knowledge of beliefs, sensitivity to threatened environment and degraded Nature, are small cities and countryside. They are near Nature. Beside the "right to the city" there is a "right to the village" (Fourquet,

---

[4] Today the metals industry uses fossil energies. In the future, when it uses electricity, the large and heavy car will trigger a waste of energy.

2021). Take an example in France, the lower part of the Drôme valley. The place is called Biovallée (Bio valley). There live many newcomers having left cities, bio farmers or growers of aromatic plants. They are proponents of ecology and biopharming. They are networked. Among them some work at the University of Lyons, which is near, as teachers or researchers. Ecology requires knowledge of causes, science (in cities) and experience, sensitivity to Nature (in small cities and countryside).

1 ABSTRACT

The "Health Targets Austria" from 2012 define, among other things, an increase in healthy life years in Austria. These are the years of our lives that we do not spend in illness. According to Eurostat, the average EU citizen over the age of 65 still has 10.3 healthy years of life. In comparison, Austria has only 7.7 healthy years. Now, a report by the Austrian Court of Audit has criticized the fact that this target has not been met because the number of healthy years of life from the age of 65 is falling significantly despite various measures that have been taken to date. Healthy life years are closely related to a lack of physical activity. The World Health Organization (WHO) recommends 150 minutes of moderately intensive exercise per week. In Austria, only about half of adults meet these recommendations. According to the WHO, children and adolescents between the ages of 5 and 17 should engage in at least 60 minutes of moderate to vigorous physical activity daily.

Encouraging in active mobility during young ages holds tremendous potential for preventing later diseases associated with physical inactivity. In Austria, one of the most frequent causes of death are cardiovascular diseases. These are closely linked to a lack of physical activity. Research shows, the positive effects on personal health are a decisive motivator to achieve a lasting change in behaviour towards active mobility. Sufficient physical activity in old age has an enormous impact on extending "quality years" and can help prevent dementia. In addition, active mobility prevents obesity, osteoporosis and various types of cancer. Active mobility thus also reduces the likelihood of belonging to one of the risk groups mentioned above.

In addition, the developments in the choice of means of transport in recent decades from active mobility to passive jeopardize the promotion of active forms of mobility. Especially the increase of so-called "parent cabs" and the reduction of free play in the residential environment due to the increased traffic volume contribute to this. The increased traffic volume also causes a higher health burden due to noise and pollutants.

Among the factors that can influence health is physical activity, which has a positive effect on the physical and psychological development of children and adolescents. As an area of physical activity, active mobility also plays an important role alongside sport in achieving a health effect. Active mobility in everyday life (walking or cycling) is the key to changing this.

Active mobility is also conducive to healthy sleep patterns (sufficient sleep and quality of sleep) and subsequently has a positive effect on subjectively perceived well-being and stress levels. Other positive effects of active mobility include a better attention span compared to peers with little to no physical activity. This also results in better school performance among children and adolescents who are physically active. These are just a few reasons why it is important to promote active forms of mobility among children and adolescents.

Keywords: physical activity, adolescents, children, health, active mobility

2 POSITIVE EFFECTS OF ACTIVE MOBILITY ON HEALTH

Active mobility significantly contributes to several of Austria's health goals such as creating health-promoting living and working conditions (Health Goal 1), enhancing health literacy (Health Goal 3) as people become more aware of the health benefits associated with mobility. Furthermore, active mobility, when pursued collectively (e.g. Pedibuses), foster social cohesion which in turn strengthens health (Health Goal 5). More general, active mobility plays a crucial role in providing a healthy upbringing for children and adolescents (Health Goal 6). Another essential aspect is promoting safe and healthy movement in daily life (Health Goal 8). In addition, encouraging children to explore their surroundings and experience things actively rather than relying on passive transportation also fosters psychosocial health (Health Goal 9). These factors highlight the value of active mobility in achieving Austria's health goals while co-creating a health-promoting and socially supportive environment. (BMGF, 2017)

2.1 Physical health

In Austria, one of the most frequent causes of death are cardiovascular diseases. These are closely linked to a lack of physical activity. Research shows, the positive effects on personal health are a decisive motivator to achieve a lasting change in behaviour towards active mobility. Sufficient physical activity prevents obesity, osteoporosis and various types of cancer. According to the World Health Organization (WHO), obesity is considered a disease and the WHO even speaks of a global epidemic of the 21st century. Obesity can lead to a number of secondary diseases: In addition to psychological consequences, shortness of breath an increased risk of high blood pressure and cardiovascular diseases, an increase in the probability of strokes and an increased risk of diabetes are possible effects (Voitl, 2004).

According to statistics, Austria is in line with the Central European trend in terms of overweight among children and adolescents. One in four adolescents is classified as overweight and just under nine percent as obese. The strong rates of increase over the observed period are particularly drastic. (The Lancet, 2017)

Everyday trips in particular can often be done by bike or on foot, and at little cost. Studies show that the positive effects on personal health are a decisive motivator for a lasting change in behavior toward active mobility. In addition, active mobility prevents obesity, osteoporosis and various types of cancer. According to Statistics Austria, one in four adolescents in Austria is overweight and almost nine percent are already obese. Habits learned in childhood and adolescence are usually maintained into adulthood. (Lohaus, 1993) This transfer of behavior is also known as the tracking effect. Thus, the literature also indicates that physical inactivity in childhood is also highly likely to lead to an inactive lifestyle in adulthood. (Völker, 2008)

As an area of physical activity, active mobility, along with sports, also plays an important role in achieving a health effect.

The development of transport mode choice in recent decades from active mobility to passive (MIV) puts a particularly heavy burden on children. In one of his studies (Children's travel behavior and its health implications), Mackett (2013) investigated the positive effect of an actively completed walk to school on the consumption of calories and contrasted this with a usual physical education class (2 hours per week). Older children aged 12 to 13 years burned more calories walking to and from school than during physical education classes. This indicates a physical activity advantage to walking (Mackett, 2013).

It was also shown that the positive effect of active walking to school could not only be attributed to the activity itself (walking versus driving), but positive effects were also found later in the day. For example, children who walked to school behaved more energetically across all subsequent activities than children who were taken by car. This effect could be observed not only on the way to school, but also on the modal split over the entire daily life of the children.

However, walking or biking actively to school and gym time at school cannot be compensated by any extracurricular behaviors. Yet, considering that children and adolescents cover a defined route during 40 school weeks and 200 days per year while commuting to school, the cumulative duration of these active or inactive periods of movement becomes substantial (Schneider 2012). Therefore, it is imperative not to underestimate the significance of these additional activities in promoting overall physical activity levels, as mentioned by Goodman et al. (2011).

2.2 Menthal health

Active mobility also promotes healthy sleep patterns (sufficient sleep and quality of sleep), which in turn has a positive effect on perceived well-being and stress levels. A study with 152 primary school children in lower Austria shows a tendency how parents could observe that their children slept better, if their level of active mobility during the day was higher. On the other hand it showed, that children who moved by car during the day, were more irritated and had a tendency of an inner restlessness (Stark et al. 2018). Particular the connection with the aspect of well being, their health status and a good night sleep Schneider 2012 shows in her study that a certain tiredness has an affect on children´s self consciusness (Schneider 2012).

Furthermore, active mobility helps to counteract diseases. It also reduces Alzheimer's disease and dementia. Another positive effect is the reduction of risk for depression and anxiety.

It is clear that mobility influences children's psychological well-being at different levels, both in the short term (via direct experience and activation on the route itself) and in the long term (e.g. as a result of traffic

1066

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

accidents). Even though a predominant part of the influences on well-being is based on the external influence of traffic (traffic noise and accidents), the results indicate that the choice of means of transport additionally influences the psychological cognitive and social domain.

2.3 Cognitive and social skills

Active mobility has a positive effect on the attention span as well. Compared to peers with little or no physical activity the attention span is better. Physically active children and adolescents also perform better in school. Another positive aspect is the independence and the children have more social contacts. For instance, engaging in a pedibus, a joint walking initiative, offers numerous opportunities to fortify social bonds among children and adolescents, which in turn yields a wealth of profound health advantages. Social interactions at a young age play a pivotal role in shaping cognitive, emotional, and physical development, and walking together in a pedibus setting fosters an environment conducive to these beneficial connections (e.g. it combats feelings of loneliness, promotes a sense of belonging, enables to share experiences and a sense of teamwork which in turn fosters resilience).

3 CURRENT PHYSICAL ACTIVITY SITUATION OF CHILDREN IN AUSTRIA

The World Health Organization (WHO) recommends 150 minutes of moderately intensive exercise per week. In Austria, only about half of adults meet these recommendations. According to the WHO, children and adolescents between the ages of 5 and 17 should engage in at least 60 minutes of moderate to vigorous physical activity daily. (WHO, 2010)

A common measure to describe a burden of disease and its impact on the duration and quality of life is the DALY (Disability-adjusted life years) defined by the WHO. A DALY corresponds to the value of a lost "healthy" year of life resulting from the current state of health compared to an ideal situation (WHO, 2009). Across Austria, it is assumed that the risk factor physical inactivity is responsible for 6% of all deaths and for 3% of all DALYs. Risk factors and diseases are interrelated and are therefore included with different proportions in the total DALY burden. A healthy lifestyle as a preventive measure against the major risk factors of high blood pressure, tobacco and alcohol consumption, high cholesterol, overweight and obesity, too few fruits or vegetables, and physical inactivity can largely prevent diseases and leads to a reduction of the DALY burden by almost 30% (WHO, 2005).

Sedentary behavior among children and adolescents has been shown to have a negative impact on health. It can be assumed that the sedentary lifestyle contributes to the development of obesity. (Huber & Köppel, 2017). This study, which covers Germany, Luxembourg, and Austria, shows that the median sitting time of children and young adults aged 4 to 20 years is 10.6 hours on weekdays and 7.5 hours on weekend days. This is particularly alarming because at the same time it is shown that long sitting times of more than 8 hours have massive health effects and are associated with the risk of premature death. Furthermore, significant correlations between sitting times and the prevalence of many chronic diseases are shown, with the increased prevalence of obesity in adolescents still insufficiently researched.

3.1 Independent mobility among children as driver for active mobility

Regarding active mobility another term to put in connection is independent mobility of children. Independent mobility means that children are able to move in the residential environment without the accompaniment of an adult (Hillman et al. 1990 quoted after Seemüller et al.). The ability to manage schoolways independently is an component which influences the mobility behaviour of children in the long run. There is a tendency that independent and active trips of children can be associated with an increased physical activitiy (Oliver et al. 2016). Larouche et al. got an similar result: independent trips of children support physical activity (Larouche et al.). Furthermore independent mobility can contriubute to the well being of children. There are first results which are indicating a positive correlation (Stark et al. 2018). However, there is no causality to report here and in general the field of psychological well-being in connection with mobility is still a rather unexplored area. Altough it is known that independent mobility can have a positive impact on the mobility behaviour of children regarding active mobility the amount of children which are independet mobile is decreasing. In Germany the number was decrasing from 93% to 76% during the years 1990 ans 2010 (Shaw et al. 2013).

What steps are to be taken now to ensure that children are moving more actively and independently? There are different needs to consider. On the one hand regarding children´s needs in partcular – an individual factor

– and on the other there are factors from outside which have an effect on children: the social environment and infrastructure conditions.

3.2 Factors influencing the mobility of children

Figure 1 shows that the factors, which can influence the mobility behaviour of children is very diverse. An important factor is the infrastructure. To build and shape infrastructure in a way people and especially children are able to be mobile in a safe and independent way is one goal. Another important aspect is to build awarness and knowledge. Especially regarding new mobility services such as e-bikes and e-scooters.

In the study from Seemüller et al. is described which individual factors affect the urge to use active mobility. For the children motivation and personal attitude are beneficial. Nevertheless, a lack of knowledge about road traffic conditions could have a negative effect (Seemüller et al. 2022). Regarding this result safety is an important topic for children, which is also shown in the study from Landwehr and Kolip 2021 (Landwehr & Kolip 2021). This can be correlated if the outside factore infrastructure. If traffic infrastructure is designed poorly, it effects safety of children and their well-being regarding everyday ways (Seemüller et al. 2022, Landwehr & Kolip 2021). In addition, to consider is, as mentioned earlier, the outside factor social environment. Regarding children, it is their parents, which make up a large share of their social environment. Children want to be mobile in an independent way (Seemüller et al. 2022). Often their parents are concerned, and it is important to consider them, when talking about mobility during children. Needs of this particular target group are diverse and merge into eachother.

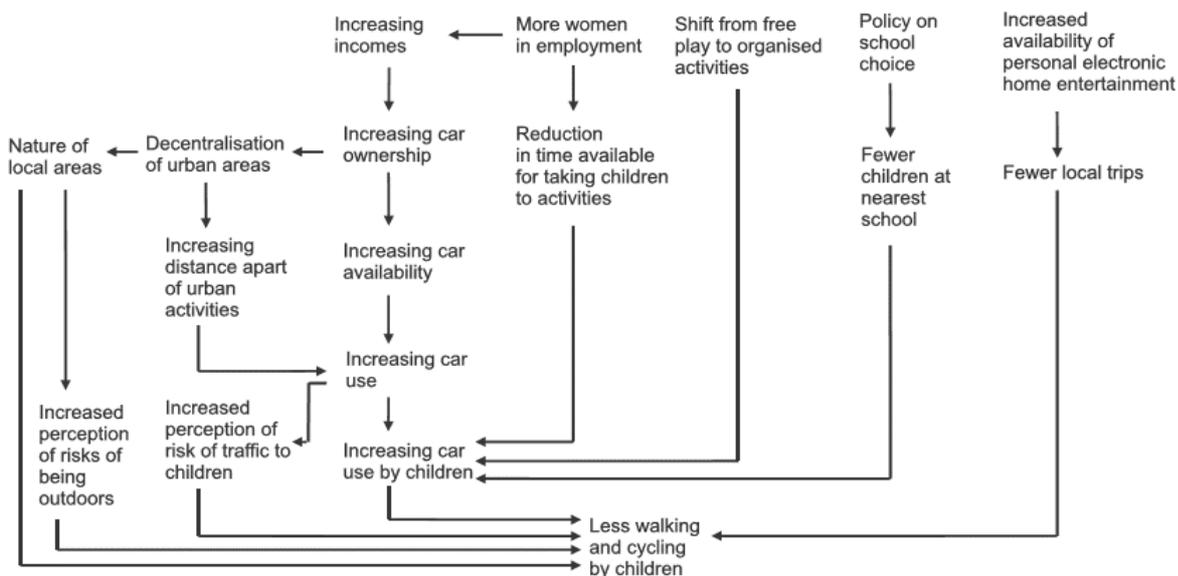

Figure 1: The influence of modern life on children's walking and cycling levels (Mackett, 2013, S. 68).

In the study from Seemüller et al. is described which individual factors affect the urge to use active mobility. For the children motivation and personal attitude are beneficial. Nevertheless, a lack of knowledge about road traffic conditions could have a negative effect (Seemüller et al. 2022). Regarding this result safety is an important topic for children, which is also shown in the study from Landwehr and Kolip 2021 (Landwehr & Kolip 2021). This can be correlated if the outside factore infrastructure. If traffic infrastructure is designed poorly, it effects safety of children and their well-being regarding everyday ways (Seemüller et al. 2022, Landwehr & Kolip 2021). In addition, to consider is, the outside factor social environment. Regarding children, it is their parents, which make up a large share of their social environment. Children want to be mobile in an independent way (Seemüller et al. 2022). Often their parents are concerned, and it is important to consider them, when talking about mobility during children. Needs of this particular target group are diverse and merge into eachother.

4   CONCLUSION

Active mobility and health are closely linked and play an important role for the development of children and adolescents. Different studies already showed that there is a positive correlation between active mobility and

health. Unfortunately the exercise recommendations are already not achieved and the trend does not seem to change soon either. Active mobility in everyday life (walking or cycling) is one key to change this.

If we want to change the travel behaviour towards more active mobility, it is necessary to start with the children.

1 ABSTRACT

Public participation in urban planning and design processes is becoming increasingly important in European cities to improve transparency, enhance decision-making, and encourage community engegamement. However, broad and inclusive participation faces a number of significant challenges. Typical participation processes rely on face-to-face interaction and are only able to reach small and non-representative groups of people. To this day, direct means of communication are important because of the high complexity of urban planning and design tasks and the multi-faceted demands on urban spaces, which can hardly be represented in online questionnairs and one-way information campaigns. Additionally, urgent measures to reduce heat in cities and to counteract other negative effects of the climate crisis need to be explained to gain the support of local communities. These challenges are often compounded by low budgets for participation processes and a lack of commitment to a thorough communication strategy.

Over the past few decades, new information and communication technologies have radically changed the way we communicate. The advent of smartphones and the institutionalization of the internet have made it possible to interact with many people simultaneously in real time and at a low cost. Today, powerful mobile devices and the emergence of virtual and augmented reality applications promise new ways to communicate spatial change and to interact with the urban environment. The exploitation of these new technologies to support climate-friendly urban design projects with broad public participation was the declared goal of the Green Living Augmented+virtual ReAlity (GLARA) research and development project. At the heart of the project was the development of the GLARA app, a mobile application that visualizes the spatial and microclimatic effects of urban design projects. Choosing between the virtual and augmented reality modes, users could explore the altered urban space from home or directly in the respective public space. In the latter case, the live image of the mobile phone camera (image of reality) was overlaid with 3D elements like trees, benches and more. This type of vizualisation provided a unique spatial experience of the proposed design project. At the same time, the results of a micro-climate simulation, which shows the effects on surface temperature, perceived temperature, and wind was visualized and made tangible via the app. Last but not least, the application allowed users to provide feedback on the design from anywhere at any time, decoupling participation from the need to be physically present at a specific place and time and allowing a wider range of people to contribute their opinions to the planning process. The GLARA app was combined with a selected set of face-to-face participation tools to form a holisitc participatory planning service for open spaces with green infrastructure.

The full GLARA service was tested in a case study in Vienna's 7th district, Neubau. The local district administration had plans to redesign a narrow residential street in the course of laying new water pipes. The GLARA team accompanied the planning process over a period of one and a half years with a balanced mix of analogue and digital participation tools including the GLARA app. The introduction of a second participation loop based on the preliminary landscape design for the street was a novelty for the administration but was well received by the participating residents. The design was visualized via the app and offered an immersive experience of future spatial change. However, a number of technical and practical challenges remain for future development of the app, including better ways for device localisation, operability on less powerful mobile devices, reducing the effort required to create the 3D visualisations, and further reducing barriers for less tech-savvy populations.

2   PARTICIPATION IN URBAN DESIGN: CHALLENGES AND GOALS

The importance of dialogue and citizen participation in urban planning and design has been increasingly recognized in recent years. In Austria, for example, the cities of Vienna and Graz have developed their own guidelines for citizen participation (MA18 2012; Stadt Graz 2014). In Vienna, the expansion of citizen participation was also anchored in the Smart Climate City Strategy (City of Vienna, 2022).

In order to create a solid knowledge base about the current challenges and restrictions in relation to broad citizen participation, the research team of GLARA (Green Living Augmented+virtual ReAlity)[1] conducted stakeholder interviews and focus group discussions with more than 30 people from the fields of city administration, urban planning, process design and politics. The analysis revealed some main challenges in the conception and implementation of participatory processes today:

- Budgets for participation are often limited while high demands are placed on quality.
- Contemporary approaches only reach a small, non-representative group of people.
- Communicating complex planning requirements and processes is a challenge.
- Participation often takes place at the beginning of the planning process without a follow-up in later stages.
- There is a lack of transparency about the outcomes of participatory processes and their impact on final development proposals.
- There is no standardized way of measuring the success of participatory processes.

In the face of climate change, radical urban transformations will be required in the coming years. The conversion of our cities into resilient and climate-friendly living spaces can be made much more efficient and sustainable if it is supported by a large majority of the population. This can only succeed through the consistent involvement and education of people.

The GLARA participation service aims to provide a low-threshold opportunity to participate in the design of streets and open spaces. It includes a digital component that simulates and visualizes the positive effects of greening and unsealing measures in public space. In the course of the research project presented here, the main challenges were identified, a comprehensive participation service was developed and tested using a real-life case study in Vienna.

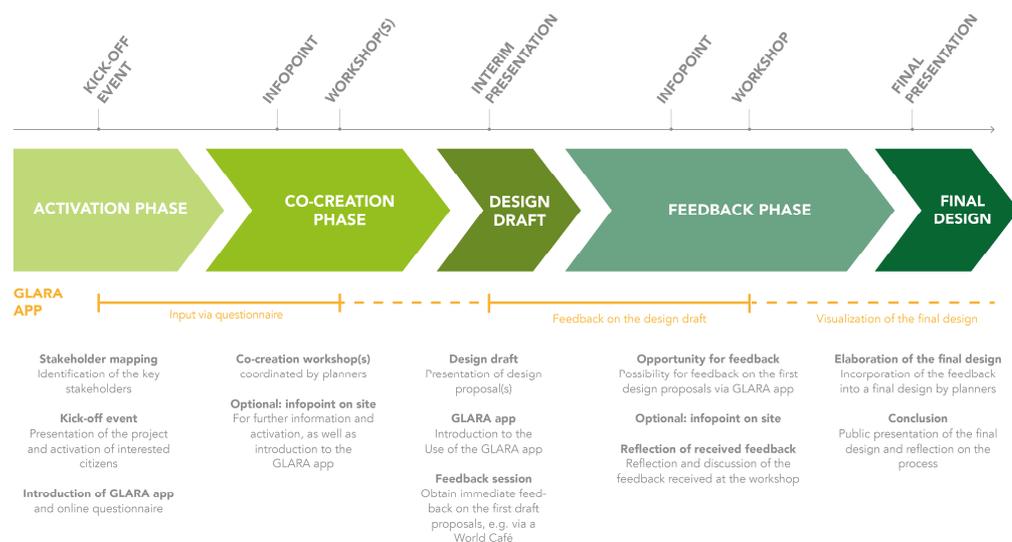

Fig. 1: Schematic process of the GLARA participation service, integrating analogue and digital methods.

3 THE GLARA PARTICIPATION PROCESS

In the GLARA participation service, the close interlinking of proven analogue methods and digital tools is central. A particular focus is on enabling as many people as possible to participate in the process. By removing time and space constraints, the GLARA app facilitates flexible participation as a digital tool in the process. This is supplemented by analogue and low-threshold participation on site to reach groups that would otherwise not have been involved in the process. A key feature of the GLARA process is the public interim presentation of a first design concept to allow feedback and possible changes before the design is finalized.

3.1 Analogue participation methods

The GLARA process is structured into several stages and starts with an activation phase. The goal here is to make users aware of GLARA and to win them over for workshops and for online participation. As a low-threshold method to reach people, a kickoff event (e.g. information evening) should take place. Parallel to this, there should be an online kickoff so that people who cannot join the event are informed. This will be followed by a co-creation phase with workshops (specific target groups or open) and information transfer (online/offline).

The portfolio of analogue methods that can be used is very large (for example, see participatory toolbox in Krebs & Mayr 2023). It should be adapted to the size and local characteristics of the project area. In addition, methods should be used that have proven themselves on site and that the local actors can handle well.

This is a selection of possible analogue participation methods, that have been used in the case study:

- Info points: The participation team meets the local community on the street. They gain the attention of people through placing some urban furniture, a large sign or other visible elements. In this way, qualitative feedback can be obtained right at the place in question and the actual users of the space are encouraged to participate in the design process.

- Workshops: These can be held with specific target groups like local entrepreneurs, children, and elderly people, or be open to all residents and interested stakeholders.

- Walkshops: Joint walk-throughs combined with co-creative methods.

- Information evenings: Large-scale information events that are announced well in advance. Politicians and administrators as well as planners should be present. Small workshop elements (e.g. written feedback with cards, post-it notes, group discussions...) can be integrated.

- Mailboxes: All neighbours receive a letter with a questionnair or feedback card and are encouraged to send it back (free of charge) to the participation team.

3.2 The GLARA app

The GLARA app is the digital component of the GLARA service. It is an innovative native application for iOS and Android that offers a new approach to green planning and its impact on the microclimate by integrating virtual reality (VR) and augmented reality (AR). The app allows for an intuitive understanding of complex issues and invites diverse audiences to explore and discover.

Fig. 2: The GLARA app's AR mode visualizing perceived temperature on a hot summer day in Bernardgasse, Vienna.

A main feature of GLARA's participatory process is providing easily understandable 3D models of the area, including the results of microclimate simulations. All are used in the app to visualize the proposed design as well as its impact on the area's microclimate. The most important factors for the perception of the environment - perceived temperature, surface temperature and wind speed - become visible as 3D overlays and can be intuitively understood by the public. A tutorial guides users and provides an overview of all features. The GLARA app marks an important step in bringing digital and analogue participation together and offers new opportunities to make green planning and its impact on the microclimate tangible.

Main functions include:

- Augmented reality: AR is a computer-based extension of the perception of reality. With the GLARA app, residents are able to immerse themselves in and move around the 3D environment with a smartphone or tablet in hand. The app uses the device's gyroscope and accelerometer sensors to track the user's movements and provide an immersive experience. On the screen, the live image from the phone's camera (a representation of reality) is overlaid with 3D elements. For example, people can walk through "bubbles" that visualize the perceived temperature on a hot summer day, or get an impression of the future of the alley with planning scenarios.

- Virtual reality: allows for an experience at any time and from anywhere. Similar to a computer game, 3D models with all relevant elements (buildings, street surfaces, furniture, plants, ...) can be explored. Users can switch between the status quo and the design, and see the effects of the redesign on the microclimate in the area. Thus, even people who cannot be there physically can get an impression of the planned changes through the app.

- Switching between different scenarios allows for comparison between the current situation and the proposed plans, as well as projected future scenarios (i.e. simulated temperature for 2050 or 2080, including the effects of the fully grown vegetation).

- Exploring the different climate parameters with the click of a button. Parameters are shown as 3D representations.

- Microclimate education: information about each parameter as well as the general microclimate situation in the area.

- Participation tools (in-app survey, picture based feedback tool).

4 CASE STUDY BERNARDGASSE

The GLARA participation service was tested in an urban regeneration project in the 7th district of Vienna. Due to the renewal of the water pipes, extensive construction works have to be carried out in one of the district's residential streets, Bernardgasse. The district mayor wanted to involve citizens in the design process and agreed to test GLARA as a new innovative tool for civic engagement.

4.1 Participation process Bernardgasse

The process was initiatied by a stakeholder mapping to identify relevant target groups and local actors. All residents were informed about the project through direct mail, additionally public awareness was raised through posters, flyers, and other media.

The first participation phase (October 14th to November 7th, 2021) focused on general challenges and ideas for the redesign of the street. Applied methods included an information evening with an interactive workshop part, questionnaires, on-site info points, and the use of the GLARA app. Emotional Mapping and Goals-Grid Analysis were used for qualitative feedback during the workshop. The survey assessed the current situation in Bernardgasse and design preferences of the citizens. The on-site info points helped to promote the use of the GLARA app and to test the AR mode in the street. In this phase, the app visualized the current micro-climatic conditions in the street and offered the opportunity for feedback through the integrated questionnaire. Moreover, the snapshot tool allowed participants to take pictures in the street, rate the situation and give comments for improvement. The results of the first participation phase were published in a comprehensive report and communicated to the landscape planners that won the design tender (GLARA, 2021).

1074

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Based on the citizen's feedback, technical framework conditions, and spatial planning strategies, a modular design concept was developed and discussed in the second participation phase (June 22nd to July 10th, 2022). Similar to the first stage, residents and entrepreneurs were invited to join an information event and workshop to provide feedback. On a large plan, stickers were used to indicate preferences for various functions and design modules. The GLARA app was used during a guided walk and at the on-site info points. The AR and VR modes visualized the design proposal and the simulated micro-climatic conditions, showing improvements where green elements, trees and impervious surfaces were proposed (see Fig. 3). Through the app, people could view the design remotely and provide their feedback via the online questionnaire. The results of the second participation phase were summarized and published in a report (GLARA, 2022). They substantially influenced the final design outcome that was presented in a concluding event in June 2023.

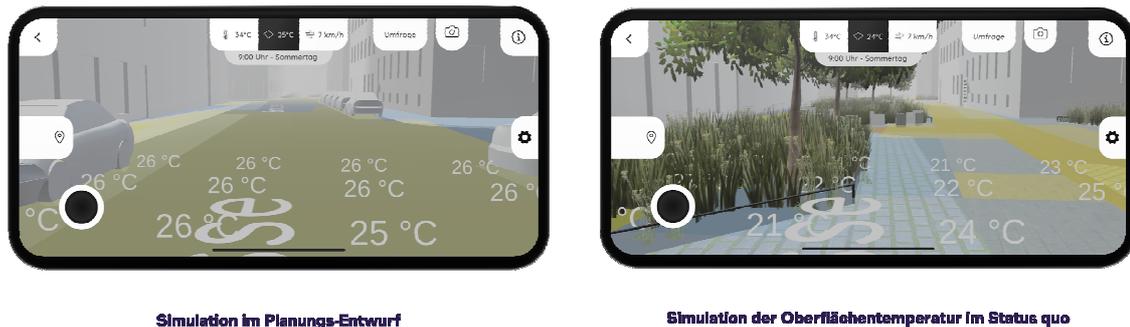

Fig. 3: The GLARA app's VR mode showing the status quo and design proposal with surface temperature for Bernardgasse, Vienna.

4.2 Feedback on the GLARA service

The case study in Bernardgasse was used to test the GLARA participation service and app in a real planning process and to collect feedback for further improvement of the service and methods. Overall, the participation was quite satisfactory. Out of the approximately 650 immediate residents in the street, 130 people attended the evening events and 160 participated at the on-site info points. In total, there were 280 responses to the questionnaire. The response rate was at 26 % in the first participation phase which is very high in comparison to other participation processes.The GLARA app recorded about 300 downloads throughout the whole process.

Participants were predominantly middle-aged residents with above-average education, as is often the case in participation processes. However, this may also be related to the general population composition in the 7th district that has a majority middle-class progressive population with a high level of education. The mix of digital and analogue methods however, has proven successful in addressing people with limited time budgets like parents or working people. The on-site participation was an integral element that established contact with people who could not attend the large events and was very well received.

In the course of the second participation phase, participants were also asked about their assessment of the process and the GLARA app. With 82 %, the participation process was rated positively by the majority of those surveyed. In personal communication, participants emphasized that the process has led to improved communication and new contacts and initiatives within the neighbourhood. This was also confirmed by the GLARA survey, in which 81 % stated that they knew more about the needs and problems of the residents and visitors of Bernardgasse after the participation process. At 56 %, a majority of app users in the survey also stated that they knew more about the effect of greening in the city after using the app. The most important result, however, is the satisfaction of the participants and residents with the final design. According to the GLARA questionnaire, 85 % like the presented vision of a green, traffic-calmed Bernardgasse.

5 REFLECTIONS AND LEARNINGS: TOWARDS MORE INCLUSIVE PARTICIPATION?

Civic engagement involves actors with different interests, with or without previous knowledge of urban planning processes. Therefore, the complex contents of planning must be well prepared and communicated simply and clearly. Visualization is considered key for successful communication and participation, as it provides participants with a shared basis for decision making. Virtual and augmented reality tools offer new

possibilities for visualizing a wide variety of data. They enable planners, policymakers and other stakeholders to experience and better understand the intended changes in the built environment and to identify potential conflicts before a development is implemented in practice (Tomkins and Lange 2020). In this context, GLARA presents the design proposals in a transparent and neutral way. The design is not exaggerated and "pretty" as is often the case with architectural renderings. The GLARA representation remains minimalist and concentrates on the essential and relevant factors of equipment, spatial distribution, microclimate, green and blue infrastructure. The GLARA app can thus empower citizens to give informed feedback on their preferences and help to make strategic urban planning decisions that are comprehensible for everyone.

Beyond the visualization of the design proposal, GLARA integrates and presents microlimatic simulations as well as a KPI-based evaluation and climate resilience analysis. GLARA is therefore particularly suitable for planning with a special focus on climate change adaptation and the construction of green infrastructure. In the case study, the GLARA app strongly supported the transfer of knowledge of climate data to the residents. It demonstrates how VR/AR tools can contribute to increasing the transparency and acceptance of climate mitigation and adaptation options among private actors and to improve the decision-making basis for politicians and planners (Othengrafen et al., 2023).

In the GLARA service, digital and analogue formats complemented each other in a meaningful manner. While digital tools can address new target groups that have been neglected so far through playful approaches and innovative forms of knowledge transfer, a holistic participatory process should also offer space and time for discussions in analogue formats. The tightly meshed, accompanying analogue formats also make key technologies such as AR and VR usable for people with a low affinity for technology. The low-threshold formats such as info points or online questionnairs ensure that all stakeholders can easily contribute their opinions.

In general, AR/VR tools have the potential to increase people's motivation to participate in planning processes by introducing innovative ways of visualization and playful means of interaction. At the same time, the acceptance of AR as a visualization and participation tool has, thus far, been rather low compared to analogue participation formats (Othengrafen et al., 2023, p. 62). The use of digital tools is still a barrier for those who are less comfortable with the use of smartphones or tablets. Moreover, the usability of high quality XR visualisations on all digital devices is still a technical challenge and representations have to be simplified to allow availability for all. These barriers, however, will diminish in the future with technical progress and higher rates of digital natives.

While the research team was confronted with technical challenges and limitations, there were also numerous ideas and approaches for even more interactive, inclusive and exciting ways to use VR/AR in planning and participation. An important question that arose in this context was how XR technologies could be used accross all planning phases, show planning options and enable a more dynamic exchange with local stakeholders. These issues will have to be addressed in the future where VR and AR applications will be applied in planning and participation processes more often and more effectively.

1 ABSTRACT

Reconstructing oder Revitalisierung? Vor dieser Entscheidung stehen aktuell zahlreiche gemeinnützige Wohnbauvereinigungen, wenn sie ihren mitunter großen historischen Wohnungsbestand modernisieren und den Anforderungen der Klimaschutzziele gerecht werden wollen. Während aus ökologischer Sicht eine umfassende Revitalisierung bestehender Wohnanlagen anzustreben wäre, erscheint aus wirtschaftlicher Sicht häufig Abriss und Neubau als die einfacher realisierbare Option. Auch das Wohnungsgemeinnützigkeits-gesetz WGG sieht vor, dass „insbesondere bei einem (…) hohen energetischen Sanierungsbedarf (...) in einer unternehmensinternen Kalkulation die Kosten einer umfassenden Sanierung den Kosten eines Abbruchs samt den Kosten der Errichtung einer Baulichkeit in räumlicher Nähe (...) gegenüber zu stellen" sind.

Das Projekt „ZUSIE – Zukunft Siedlung" möchte diese ausschließlich wirtschaftliche Betrachtungsweise in Frage stellen und – im Sinne des Smart-City-Konzepts – ergänzende soziale und ökologische Kriterien entwickeln. Dabei soll aufgezeigt werden, wie investive Maßnahmen in einer multidimensionalen Betrachtung von sozialen, ökologischen und ökonomischen Kriterien sowie unter der Berücksichtigung des gesamten Lebenszyklus von Quartieren neu bewertet werden können und so neue und alternative Entscheidungen möglich machen.

Das Projektvorhaben nimmt eine Siedlung der Ersten Gemeinnützigen Wohnungsgesellschaft (EGW), die in den 1940er Jahren in Erpersdorf in der Gemeinde Zwentendorf errichtet wurde, in den Blick. Sie ist Ausgangspunkt für neue Handlungsansätze – für die Siedlung selbst, aber auch für den großen Wohnungsbestand der EGW sowie weitere Bestandssiedlungen des gemeinnützigen Wohnbaus. „ZUSIE" wird von einem interdisziplinären Konsortium – bestehend aus der Stadtteilarbeit der Caritas Wien, die für Projektleitung, Partizipation und Kommunikation verantwortlich ist, dem gemeinnützigen Wohnbauträger EGW, dem Architekturbüro einszueins, dem Landschaftsplanungsbüro grünplan sowie dem Energie- und Umwelttechnikbüro e7 – gemeinsam umgesetzt.

Keywords: Ressourcen schonen, Gebäudebestand, Klimawandelanpassung, Mitgestaltung, Sanierung

2 EHEMALIGE ARBEITERINNEN- UND ARBEITERSIEDLUNGEN IM WANDEL

2.1 Ein großer Altbestand gemeinnütziger Wohnbauvereinigungen

Viele gemeinnützige Wohnbauvereinigungen haben einen großen Wohnungsbestand, der mittlerweile in die Jahre gekommen ist. Mit 971.050 Wohnungen befinden sich insgesamt rund 20% des Wohnungsbestands in Österreich im Wohnungs- und Verwaltungsbestand gemeinnütziger Wohnbauvereinigungen (Stand 2020). Ca. 489.020 Wohneinheiten dieses Bestands – dies entspricht heute ca. 10% des österreichischen Wohnungsbestands – wurden bis 1980 errichtet (Quellen: GBV 2021, Statistik Austria 2022).

Im aktuellen österreichischen Regierungsprogramm ist das Ziel, bis 2040 klimaneutral zu werden, verankert. Um dieses Ziel zu erreichen, sind insbesondere im älteren Gebäudebestand Sanierungsmaßnahmen zu setzen, die bestehende Wohnanlagen in Richtung klimaneutrale Quartiere entwickeln. Im „Rahmenprozess zur Modernisierung von Arbeitersiedlungen" wurden Arbeiterinnen- und Arbeitersiedlungen als eine Gebäudekategorie identifiziert, bei der besonderer Sanierungsbedarf insbesondere in Hinblick auf die Verbesserung von Energielösungen und Energieeffizienz besteht (vgl. Rainer, Lang, Schreiner 2021).

2.2 Revitalisierung oder Reconstructing im Rahmen der Wohnungsgemeinnützigkeit?

Bisher wurden allerdings kaum umfassende Sanierungen, die bauliche, ökologische, soziale und ökonomische Dimensionen gesamtheitlich berücksichtigen, umgesetzt. In Hinblick auf Arbeiterinnen- und Arbeitersiedlungen aus den 1920er bis 1940er Jahren wurden in der Recherche des Rahmenprozesses im gesamten deutschsprachigen Raum nur drei Beispiele für bestandserhaltende umfassende Modernisierung

identifiziert. In Österreich war dies die Sanierung der Burgfriedsiedlung in Hallein, die unter dem Titel „Wohnen findet Stadt" als Smart Cities Projekt gefördert wurde und, laut Bericht des Rahmenprozesses, das einzig dokumentierte Beispiel einer umfassenden, bestandserhaltenden Modernisierung mit Wohngebäuden aus der Zwischenkriegszeit darstellt. Die Siedlung umfasst Gebäude aus den 1930ern bis 1970ern. Im Zuge der Modernisierung konnten Maßnahmen der Gebäudesanierung im bewohnten Zustand, der Nachverdichtung durch Aufstockung, der Dämmung und Bauteilaktivierung sowie im Freiraum durchgeführt werden.

Aktuell wird hingegen vermehrt ein Trend zum Reconstructing (Abriss und Neubau) statt umfassender Revitalisierung beobachtet – der Endbericht gibt mehrere Beispiele u.a. aus Tirol und Kärnten dafür und auch Online Berichte aus der jüngeren Vergangenheit dokumentieren dies („Reconstructing-Neubau in Friesach" vom 26.07.2022 auf 5min.at oder „Reconstructing – die Zukunft des Bauens" auf der Website des gemeinnützigen Wohnbauträgers Fortschritt). Diese Entwicklung ist bei gemeinnützigen Bauvereinigungen u.a. auch auf gesetzliche Regelungen zurückzuführen, da das Wohnungsgemeinnützigkeitsgesetz WGG explizit vorsieht, bei umfassenden Sanierungen auch Abriss und Neubau als Alternative zu prüfen und den Kosten einer Sanierung wirtschaftlich gegenüber zu stellen.

Die Basis für die Bewertung investiver Maßnahmen ist dabei eine rein wirtschaftliche Betrachtungsweise. Im Sinne von ökologischer und sozialer Nachhaltigkeit soll im vorliegenden Projektvorhaben der Versuch unternommen werden, diese wirtschaftlichen Kriterien zu ergänzen, indem auch ökologische und soziale Kriterien entwickelt werden, die in Zukunft als Entscheidungsgrundlage in Hinblick auf investive Maßnahmen dienen können und einen Weg von der Bilanz zur Ökobilanz aufzeigen.

2.3 Herausforderungen und Hürden für umfassende Sanierungen von Arbeiterinnen- und Arbeitersiedlungen

Für die Modernisierung ehemaliger Arbeiterinnen- und Arbeitersiedlungen im Bestand gemeinnütziger Wohnbau-vereinigungen besteht die zentrale Herausforderung in der Finanzierung möglicher Sanierungsmaßnahmen (vgl. Rainer, Lang, Schreiner 2021). Einerseits sind häufig geringe bis keine Rücklagen vorhanden, da diese für gewisse bestandserhaltende Maßnahmen sowie Dämmung, Dach- oder Fenstertausch in den vergangenen Jahren bereits aufgebraucht wurden. Andererseits unterliegen die Mieten laut WGG strengen Obergrenzen, um insbesondere für Menschen mit geringem Einkommen leistbares Wohnen zu gewährleisten. Für umfassende Sanierungen sind daher weder die erforderlichen Finanzmittel angespart, noch können diese über künftige Mieteinnahmen refinanziert werden (ebd.). Es werden daher meist nur Schäden repariert, Teilsanierungen durchgeführt oder Wohnungen bei Neuvermietung wieder brauchbar gemacht und auf einen zeitgemäßen Standard gehoben. Die Anreize über die aus Landesmitteln gewährte Wohnbauförderung sind für diese Bestandsquartiere oft zu gering, wie im Bericht des Rahmenprozesses festgehalten wird. Hier gilt es, neue Rechts- und Finanzierungsmodelle zu finden und Fördermodelle zu entwickeln, um für Quartierssanierungen, die mehrdimensionale Maßnahmen in Richtung Klimaneutralität verfolgen, einen entsprechenden Rahmen zu schaffen. Konkrete Projekte fungieren in diesem Kontext auch als wichtige Anlässe, um Prozessinnovation und den Dialog mit Entscheidungsträgerinnen und Entscheidungsträgern voranzubringen.

2.4 Neue Dynamiken und Chancen für Arbeiterinnen- und Arbeitersiedlungen

Gleichzeitig verfügen ehemalige Arbeiterinnen- und Arbeitersiedlungen, insbesondere jene aus den 1920er bis 1940er Jahren, in vielen Fällen über besondere städtebauliche Qualitäten. Die Anlagen, die häufig angelehnt an das Konzept der Gartenstadt errichtet wurden, haben für die Bewohnerinnen und Bewohner eine angenehme Maßstäblichkeit und verfügen über großzügige Freiräume mit großen Potenzialen. Das Smart-Cities-Projekt „Transform Ternitz" (2021-2024), das ein Teil des Konsortiums bereits seit 2021 begleitet, zeigt wie gerade durch Aktivierung der Freiräume positive Dynamiken entstehen können (vgl. Kirsch-Soriano da Silva, Botzenhart 2022). Im Rahmen einer Summer School wurden – gemeinsam mit 20 Architektur Studierenden – gemeinschaftliche Möbel und Infrastrukturen in Holzbau errichtet. Diese eröffnen neue Möglichkeiten für Aneignung und soziales Leben und werden von den Bewohnerinnen und Bewohnern gerne genutzt.

Auch Nachverdichtung kann – falls es eine entsprechende Nachfrage nach Wohnraum in der Gemeinde oder Region gibt – eine Chance sein, zusätzlichen leistbaren Wohnraum sowie den aktuellen Bedürfnissen

1078

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

entsprechende Wohnformen zu schaffen, und leistet durch eine Reduktion der zusätzlichen Flächenversiegelung auch einen Beitrag zu einer klimagerechten Quartiersentwicklung.

Das Projekt „Smartes Wohnen für Generationen" (2018-2022), das in Wien umgesetzt wurde, bietet hier wichtige Anknüpfungspunkte, insbesondere auch in Hinblick auf die Entwicklung von innovativen generationen- und altersgerechten Wohnformen sowie Erfahrungen mit der Partizipation von Bewohnerinnen und Bewohnern bei Transformationsprozessen (Kirsch-Soriano da Silva et al. 2022). Im Smart Cities Projekt „ZuZugLeben" (2022-2025), das auch ein Teil des Konsortiums begleitet, wird ein Gesamtkonzept für eine Siedlung in St. Pölten entwickelt und die bestehenden, zum Teil „leer gewohnten" Gebäude der Siedlung zu attraktivem Wohnraum und Wohnumfeld für Mitarbeiterinnen und Mitarbeiter der ÖBB transformiert. Unter Einbeziehung von bestehenden und potenziell künftigen Bewohnerinnen und Bewohnern werden Konzepte für die Wohnnutzungen, die Attraktivierung der Freiräume sowie ein Klimaneutralitätsfahrplan für die Siedlung entwickelt. Zusätzlich werden Orte für Co-Working und Gemeinschaftsnutzung entwickelt, um auch Platz für „Neues Arbeiten" zu schaffen. Bei Modernisierungsmaßnahmen stellt sich dabei immer auch die Frage, wie klimaresilientes Wohnen – gerade im Sinne des gemeinnützigen Wohnbaus – leistbar bleiben und so genannte „Green Gentrification" verhindert werden kann.

3 NEUE HANDLUNGSANSÄTZE FÜR ERPERSDORF UND DARÜBER HINAUS

3.1 Die Siedlung in Erpersdorf

Die Siedlung wurde als Arbeiterinnen- und Arbeitersiedlung für die Pulverfabrik Skoda-Wetzler AG errichtet und bot in den folgenden Jahren auch Wohnraum für die Arbeiterinnen und Arbeiter im Chemiewerk der Donau-Chemie und im Raffineriewerk Moosbierbaum. Der Bau der Siedlung begann während der Zwischenkriegszeit und wurde in den 1940er Jahren fertig gestellt.

Historische Fotos der Siedlung in Erpersdorf: Abb. 1: Baustelle 1943, © HMZ. Abb. 2: Siedlung Erpersdorf 1968, © Franz Bauer. Quelle: zwentendorf.topothek.at

Bezeichnenderweise trägt die Siedlung bis heute keinen Namen – es wird nur von der „Siedlung" in Erpersdorf gesprochen – und steht so auch prototypisch für Siedlungen aus dieser Zeit. Die Anlage besteht aus zwei- und dreigeschossigen Gebäudezeilen und großzügigen gemeinschaftlichen Höfen dazwischen. Sie wurde weitgehend in Ziegelbauweise mit Holz-Dachstühlen und Holz-Stiegenhäusern errichtet. Die Energieversorgung erfolgt teilweise durch Fernwärme, die bei bereits erfolgten Sanierungsmaßnahmen angeschlossen wurde, teilweise über Einzelöfen. Die Siedlung aus den 1940er Jahren beinhaltet ca. 286 Wohnungen und die durchschnittlichen Wohnungsgrößen liegen bei ca. 60 m². In den 1990er Jahren kamen weitere Gebäudezeilen hinzu, sodass die Siedlung in Summe heute 424 Wohnungen beinhaltet und damit rund 20% der Wohnbevölkerung der Gemeinde Zwentendorf (mit rund 4.200 Einwohnerinnen und Einwohnern) ausmacht.

Die Wohnbevölkerung ist in Hinblick auf das Alter durchmischt – 20% sind jünger als 20 Jahre, 65% sind zwischen 20 und 64 Jahre alt und 15% sind 65 Jahre oder älter. Die Bewohnerinnen und Bewohner verfügen teilweise über geringere Einkommen als im Durchschnitt der Gemeinde. In den letzten Jahren zeigt sich

zudem ein steigender Anteil an Bewohnerinnen und Bewohner mit Migrationsgeschichte – 35% haben keine österreichische Staatsbürgerschaft und kommen u.a. aus den Ländern des ehemaligen Jugoslawiens, der Türkei, Ungarn, Slowakei, Rumänien, dem Irak und der Ukraine.

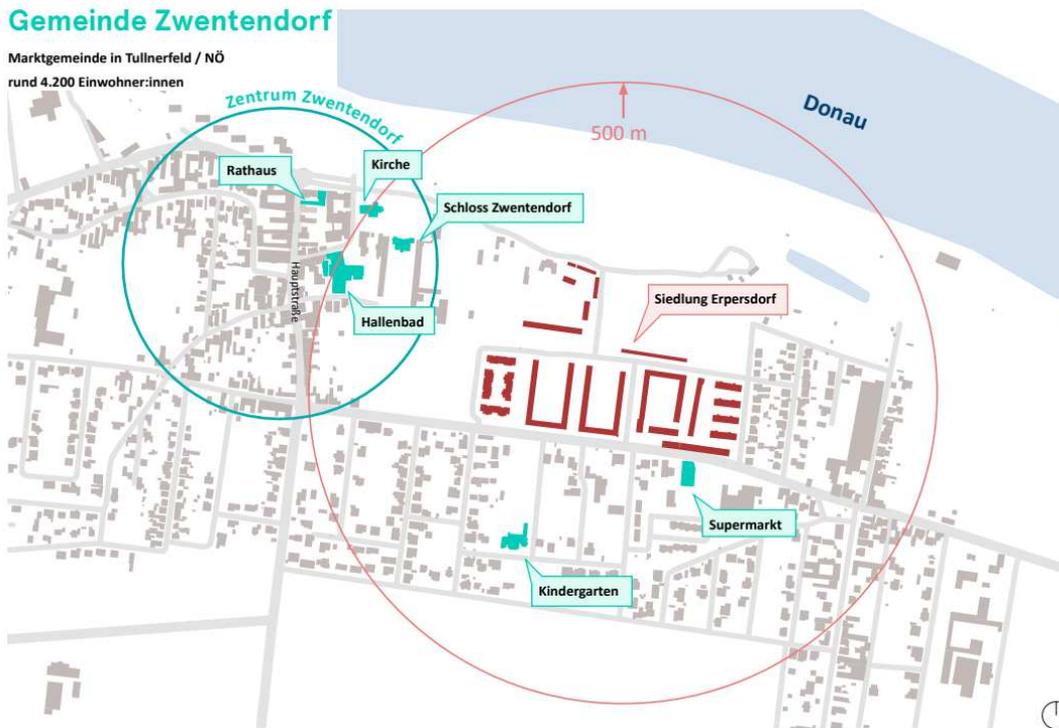

Abb. 3: Lage der Siedlung in der Gemeinde Zwentendorf. © einszueins

Abb. 4: Übersichtsplan der Siedlung. © einszueins

Für viele Menschen in Zwentendorf, insbesondere für jüngere Menschen, erscheint die Siedlung nicht mehr attraktiv. Es sollen daher neue Handlungsansätze entwickelt werden, um eine nachhaltige Weiterentwicklung der Siedlung zu einem zukunftsfähigen Wohnquartier zu ermöglichen. Neue nachhaltige Energielösungen, diversifizierte Wohnformen die aktuellen Wohnbedürfnissen entsprechen, Impulse für eine lebendige Nachbarschaft, Attraktivierung und klimaresiliente Gestaltung der Freiräume sowie alternative

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Mobilitätsangebote sind gefragt, um ein ökologisch und sozial nachhaltig gestaltetes Wohnumfeld zu schaffen.

Abb. 5 und 6: Aktuelle Fotos der Siedlung in Erpersdorf. © einszueins

3.2 Ziele und Maßnahmen im Rahmen des Projekts „ZUSIE"

Im Rahmen des Projekts „ZUSIE" werden folgende Zielsetzungen verfolgt und mit konkreten multi-dimensionalen Maßnahmenbündeln adressiert.

Die Identifikation mit der Siedlung wird gestärkt und eine Zukunftsvision partizipativ entwickelt.

Bewohnerinnen, Bewohner, Gemeinde und lokale Akteurinnen und Akteure haben eine aktive Rolle in der Entwicklung der Siedlung und bringen ihre Ideen dazu ein. Gestartet wird mit der partizipativen Formulierung einer gemeinsamen Zukunftsvision, wie klimafittes Leben in der Siedlung 2040 aussehen kann, und dem Finden eines Namens für die Siedlung. Aus Vertreterinnen und Vertretern von Gemeinde und Bewohnerinnen und Bewohnern wird ein Begleitgremium gebildet, das im gesamten Projektverlauf eingebunden wird und Feedback zu einzelnen Arbeitsschritten gibt. Vor Ort wird ein Zukunftsraum eingerichtet, in dem es aktuelle Informationen über das Projekt gibt und Ideen gesammelt werden, der als sozialer Treffpunkt und Kristallisationspunkt für neue Ideen und Impulse dient.

Prototypische Lösungen für eine klimaresilientere Gestaltung der Siedlung werden erprobt.

Klimaresiliente Lösungen für die Zukunft werden in prototypischer Form entwickelt und erprobt. Mögliche Prototypen sind ein „Klimabalkon" und eine „Klimapergola mit Mobilitätsstation". Beide kombinieren Elemente für klimafittes Planen (wie Begrünung, Grau-/Regenwassernutzung, Photovoltaik, Anschlüsse für E-Mobilität) zu einer neuen Lösung, können standardisiert und transferiert werden. Zudem werden auch prototypische Lösungen entwickelt, bei denen die Innovation stärker in der Prozessinnovation liegt, bspw. die Bildung einer selbstorganisierten Mitfahrbörse, die partizipative Neugestaltung von Freiräumen oder die Diversifizierung von Wohnungsangeboten durch Generationenwohnen oder Wohnen und Arbeiten im Rahmen der Modernisierung einer Gebäudezeile.

Ein Fahrplan für die umfassende Revitalisierung der Siedlung wird vereinbart.

Es wird ein Maßnahmenplan entwickelt, um die CO_2-Emissionen bis zum Jahr 2040 auf null zu reduzieren. Neben klimafitten Lösungen für Gebäude und Energieversorgung wird dabei auch auf frugale Lösungen gesetzt in Form von grün-blauen Infrastrukturen wie Vegetation und Wasserflächen. Zudem werden Finanzierungs- und Betriebsmodelle erarbeitet, mit denen die Maßnahmen realisiert werden können. Auf Basis des Konzepts wird eine Qualitätszielvereinbarung erarbeitet und von allen Beteiligten unterzeichnet. Sie dient als Grundlage für die Vorbereitung des Roll-outs auf die gesamte Siedlung.

Revitalisierung statt Reconstructing wird als Handlungsstrategie für Wohnbauvereinigungen gestärkt.

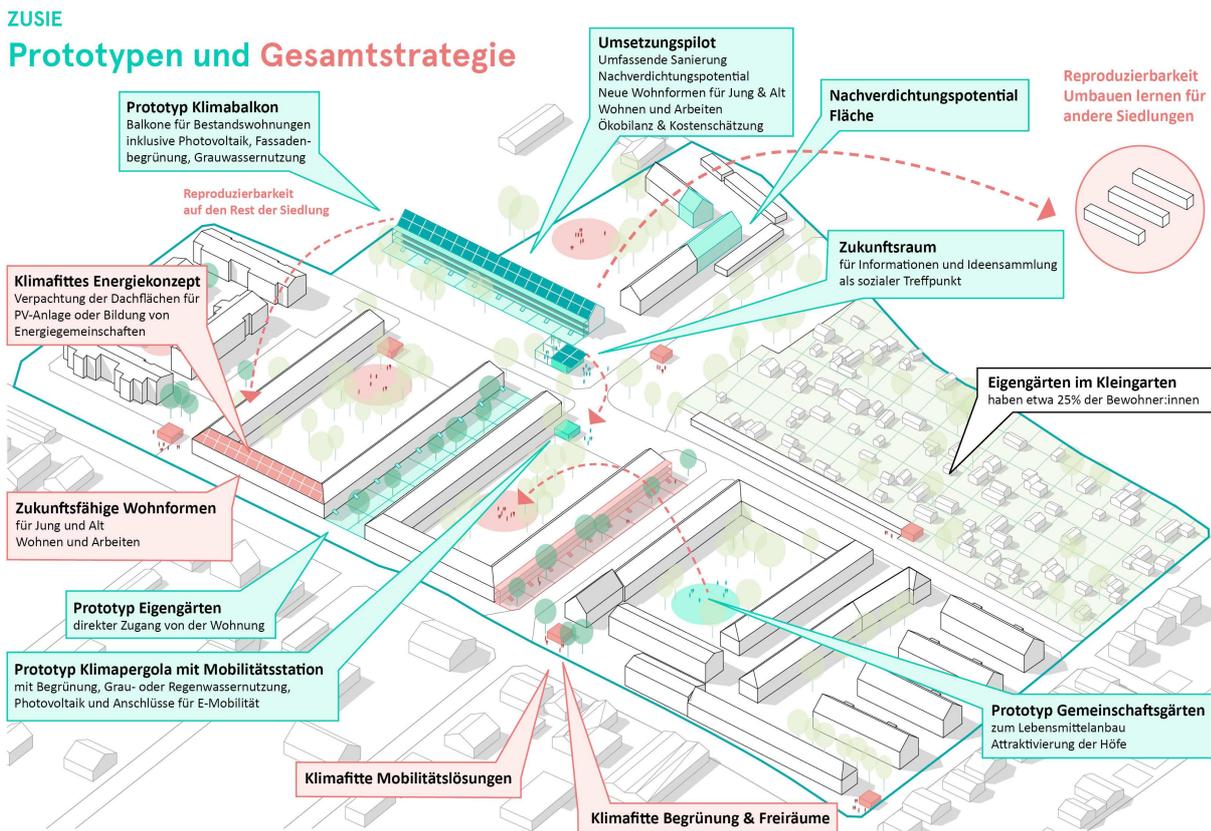
Begleitend zu einzelnen Arbeitsschritten werden Toolboxen für die klimaresiliente Revitalisierung von Siedlungen entwickelt, in anderen Sanierungsprozessen der EGW verankert und für weitere Stakeholder verfügbar gemacht. Zudem werden – ergänzend zu den wirtschaftlichen Bewertungskriterien, die im WGG vorgesehen sind – soziale und ökologische Kriterien entwickelt, die – im Sinne einer Smart City – für die Beurteilung investiver Maßnahmen und damit auch als Entscheidungsgrundlage für Revitalisierung oder Reconstructing herangezogen werden können.


Abb. 7: Übersicht über mögliche Maßnahmen in der Siedlung. © einszueins

4   BISHERIGES FAZIT

Erste Gespräche mit Bewohnerinnen und Bewohnern bestätigen den Handlungsbedarf in der Siedlung. Die angesprochenen Themenfelder aus Sicht der Bewohnerinnen und Bewohner betreffen die Parkplatzsituation und Mobilität, umfassende Sanierungsmaßnahmen, die weiter reichen als ein neuer Anstrich oder eine Sanierung der Fassade, aber auch verschiedene Facetten des sozialen Zusammenlebens in der Siedlung.

„Die Häuser mit Farbe anstreichen wird nicht ausreichen!"

„Zwischen Migrant:innen und Österreicher:innen gibt es Barrieren. Die müsste man abbauen."

„Seit Corona Parken hier auch alle mit den Firmenautos, vor allem die Kleinlaster sind störend!"

„Ich wünsche mir für die Siedlung, dass es nicht schlechter wird! Es hängt an den Leuten – das Miteinander."

„Es gibt Gerüchte, dass abgerissen und neu gebaut wird. Die Blöcke A,B,C, die sind auch am ältesten."

„Die älteren Bewohner:innen ins Boot holen wäre wichtig!"

Abb. 8: Zitate aus Gesprächen mit Bewohnerinnen und Bewohnern im Juni 2023.

Gleichzeitig ist großes Interesse spürbar. Was wird in der Siedlung passieren? Wie kann mitgesrochen und mitgestaltet werden? Wie können verschiedene Bewohnerinnen- Bewohnergruppen involviert werden?

Auch die Gemeinde Zwentendorf war – mit vielfältigen Vertreterinnen und Vertretern – bei den ersten Projekttreffen präsent und bringt sich mit zahlreichen Ideen und Anknüpfungspunkten auf Gemeindeebene in den Prozess ein. Da Themen wie Energieversorgung, Gestaltung von Verkehrslösungen und öffentlichen Räumen, Schaffung von Infrastrukturen sowie etwaige Fördermöglichkeiten auch auf kommunaler Ebene bearbeitet werden müssen, ist die Zusammenarbeit mit den politischen Stakeholdern in der Gemeinde für die kollaborative Entwicklung und praktische Umsetzung geplanter Maßnahmen von zentraler Bedeutung. Das

1082

REAL CORP 2023: *LET IT GROW, LET US PLAN, LET IT GROW*
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

breite Akteursnetz, in welches das Projekt eingebettet ist, bietet daher eine wesentliche Grundlage für das Projekt.

Neben dem Aufbau einer Projektwebsite und der Gestaltung erster Informationsmaterialien wird aktuell zudem eine große Zukunftswerkstatt geplant. Diese soll im September 2023 stattfinden und stellt den Startschuss für das partizipative Entwickeln der gemeinsamen Vision dar sowie den ersten Schritt, um die konzipierten Projektschritte – gemeinsam mit verschiedenen Beteiligten vor Ort – in die Praxis zu übersetzen.

1 ABSTRACT

City examination and evaluation, as an indispensable part of urban planning evaluation, which lays the foundation for improving the governance capacity of territorial space planning by revealing the problems and weaknesses in spatial governance, has attracted more and more attention in China's urban planning. At present, city examination and evaluation of China has formed a relatively clear and complete framework in the overall planning of land and space planning, and its applied range has also expanded from statutory planning to other types of planning. With the continuous promotion of urban renewal in China, higher requirements are put forward for the urgency and refinement of city examination and evaluation. For this reason, focusing on the relatively complete and scientific urban plan annual monitoring and evaluation work in the UK, this paper firstly sorts out the development stages and evolution characteristics of planning monitoring and evaluation in the UK, and summarizes the planning practice and research progress of city examination and evaluation in China. Secondly, this paper compares and analyzes the London's Planning Annual Monitoring and Evaluation Report of the United Kingdom from 2005 to 2021,and the Territorial Space Planning Examination and Evaluation Plan of China from 2020 to 2022 from the aspects of main objectives, areas of concern, technical framework, data collection sources, evaluation index system and evaluation response mechanism, and city examination and evaluation reports of key sample cities in China are discussed in this paper. Finally, in order to obtaining positive enlightenment for the promotion of China's future planning monitoring and evaluation work, this paper puts forward suggestions on the construction of the technical framework and the improvement of the work process which are suitable for the current development stage of China's city examination and evaluation based on the above research results.

Keywords: spatial planning, planning evaluation, London planning monitoring annual report, city examination and evaulation, China

2 INTRODUCTION

City examination is a fundamental work that comprehensively evaluates the development and construction status of cities, formulates targeted countermeasures, optimizes urban development goals, fills the gaps in urban construction, and solves the problem of "urban diseases". It is an important lever for implementing urban renewal actions, coordinating urban planning and construction management, and promoting high-quality development of urban living environment.

City examination and evaluation is receiving increasing attention in planning and development. Currently, China has formed a relatively clear and comprehensive framework for city examination and evaluation in the overall planning of national spatial planning. Its application scope has also expanded from statutory planning to other types of planning. With the continuous promotion of urban renewal actions in China, higher requirements have been put forward for the urgency and refinement of city examination work.

The evaluation of urban planning implementation has been carried out early in foreign countries and has developed relatively well, especially in the UK. The technical framework, working methods, and processes of planning implementation evaluation are relatively mature. In addition, a specific planning implementation supervision system has been formed, and a relatively reasonable planning implementation evaluation and dynamic monitoring mechanism has been established, which facilitates the efficient output of urban planning implementation evaluation results and the resolution of key problems. In the assessment of the implementation of urban planning in the UK, the Annual Monitoring Report on the Planning of the City of City of London over the years, organized and published by the Greater London Authority, is the most typical

and representative official document for the assessment of the Planning of London. It is the most mature planning assessment model with the most objective results and the most far-reaching impact in the world. It is also the core document for the monitoring process and the assessment of the effectiveness of the London plan.

This article aims to explore the historical evolution and development characteristics of planning monitoring and evaluation in the UK, sort out the research progress and practical exploration of city examination and evaluation in China. Through the "Monitoring Report" and "Evaluation Regulations", compare and analyze the work of city examination and evaluation in China and the UK from the aspects of content areas, indicator systems, and response mechanisms. Based on the actual situation in China, summarize the work principles, technical methods, and evaluation mechanisms that should be followed in planning and evaluation, Provide guidance for the construction and improvement of China's city examination and evaluation system.

3   EVOLUTION AND DEVELOPMENT CHARACTERISTICS OF PLANNING MONITORING EVALUATION IN THE UK

3.1 Current Status of monitoring and evaluation work at China and abroad

At present, the practice results of planning evaluation at China and abroad have been widely used in the research of government policy making and planning preparation, and the dynamic feedback mechanism of planning evaluation has also been effective. Planning evaluation has changed from the original "pre-planning" evaluation to the current "planning" evaluation, formed a good monitoring dynamic cycle mechanism, and evolved to a multi-value planning theoretical paradigm.

Internationally, the UK takes the lead in establishing a "Three-stage, Multi-level" planning assessment mechanism, including planning programming assessment, planning implementation assessment and planning review, corresponding to the three stages of "sustainability assessment", "dynamic monitoring report" and planning review document results [1]. The evaluation system of national, regional and local levels has been constructed, and a comprehensive planning guarantee system has been formed [2].

3.2 Evolution of planning assessment in the UK

The United Kingdom began to establish the evaluation system in the planning field in the 1960s, during which the British government introduced many new analytical methods in the formulation and implementation of policies, including cost-benefit analysis and a series of derivative evaluation methods, and the planning balance sheet proposed by Lichfield and a series of evaluation methods based on the planning process derived from it.

From the mid-1970s to the 1980s, the focus on the overall effectiveness of planning policies shifted to economics and efficiency. Most government reports emphasize the 3E's principle: Economy, Efficiency, and Effectiveness.

In the late 1980s, independent testing and evaluation bodies were created in the field of policy evaluation. In this period, the planning evaluation gradually shifted from the quantitative evaluation of results to the non-quantitative evaluation of process, and began to consider the role of political, economic and social influences in the implementation of planning on the planning itself.

In 1997, the Labour government set up central to local assessment bodies. The modern British urban planning monitoring and evaluation system has been comprehensively established, and the evaluation method has been transformed into a dynamic and participatory form [3].

In 1999, the Greater London Authority Act was promulgated, clarifying the responsibility of the Mayor to supervise the implementation of the London Plan, requiring the Mayor to set up a special "implementation and supervision" chapter when preparing the London Plan, requiring annual monitoring of the implementation of the plan. The London Planning proposed that through the establishment of a reasonable monitoring title system, the key data of planning implementation can be tested to understand whether the planning objectives can be achieved and whether the planning policies are effective.

In 2004, The introduction of the Planning and Compulsory Purchase Act established the multi-level statutory system planning in the UK, and clarified the Annual Monitoring Report as the legal document to evaluate the effectiveness of the policy. It is also proposed that the main body of the planning should issue an Annual

Monitoring Report every year to measure the implementation of the planning and provide a basis for government decision-making.

Since 2005, the Annual Monitoring Report has been released to the public every year.

3.3 Content of annual monitoring report

The Annual Monitoring Report (AMR) is a key component of London's Planning Monitoring and Evaluation Management mechanism and is the central document for planning implementation to monitor and assess the effectiveness of the London Plan. The Annual Monitoring Report draws the attention of the Mayor and other departments to emerging trends, provides a comprehensive view of the impact of the Greater London Plan, and serves as an important basis for planning revisions.

The AMR consists of four chapters. The first chapter is an overview, introducing the scope and purpose of the monitoring report, as well as the main data sources. The second chapter is the achievement of key performance indicators, assessing the annual progress of each indicator and the development trend over the past years, and some indicators are implemented at the regional level. The third chapter is supplementary performance evaluation standards and statistical data, including housing, environment, transportation, related planning and other aspects. The fourth chapter is about other data sources, detailing the data sources used in the report.

3.4 Construction of index system

3.4.1   Content of index system

The monitoring indicator system is the core element of the Annual Monitoring Report, which can effectively link up the requirements of the planning content.

The annual inspection report focuses on the six urban development goals established by the 2016 London Plan: Building strong and inclusive communities, Making the best use of land, and Creating a healthy city, Delivering the homes Londoners need, Growing a good economy, and Increasing efficiency and resilience. The overall goal in strategic planning is decomposed into subdivision goals, and quantifiable indicators are further constructed to form detailed key performance indicators. Key performance indicators cover urban spatial layout, public service facilities system, and in recent years, green ecology, economic vitality, public health and employment and office are gradually included [4].

The Annual Monitoring Report forms a clear evaluation basis on the basis of many years of practice, and realizes the planning monitoring under all elements. Key performance indicators are divided into control indicators and development indicators, the control indicator specifies mandatory control, and the development indicator ensures that the development trend develops in the direction of the target.

At the same time, the setting of key performance indicators is not based on the results of data inference, but focuses on the actual development trend. The report includes relevant supplementary performance evaluation criteria and statistical data to make a holistic judgment on program implementation. Based on the test results, the City of London and the Authority will optimize and adjust the planning implementation and government decision-making, ensure the feasibility of the implementation of major strategies, and reserve more flexibility for the next stage and next level of planning assessment.

3.4.2   Index system data source

The Monitoring Report mainly uses the London Development Database (LDD) as the basic data source, and is led by the Greater London Authority to make overall statistics, and is implemented by the district government departments and relevant construction units. From November 2020, data from the London Development Database has been fully integrated into the Planning London Datahub. The Planning London Datahub contains detailed information on planning applications, permits, starts and compleations, updates the economic and social development indicators and project information for Greater London in real time, visualizes the data and shares it with the whole community.

The statistics and summarization of different data according to time frequency ensure the dynamic and immediacy of data. The accuracy, breadth and validity of different kinds of data provide guarantee for the authority and validity of the results of the AMR.

3.4.3 Development history of index system

The calendar version of the London plan will be combined with the mayor's policy ideas, the monitoring index system will be modified and improved.

Since 2004, London has published 17 Annual Monitoring Reports. Among them, AMR1-7 corresponds to the 2004 edition of the Greater London Plan, which mainly established 28 monitoring indicators; AMR8-17 corresponds to the 2011 London Plan and is adjusted to 24 monitoring indicators; The AMR19 under preparation will correspond to the 2021 London Plan and be adjusted to 12 detection indicators. The indicators of the three editions of the London Plan have their own characteristics, but they can be roughly divided into housing and public services, the economy, the ecological environment, transport, history and culture, and other special issues.

Among them, from the 2004 edition to the 2011 edition of the London Plan, the index system is basically stable. There are mainly three changes: first, some indicators have been fine-tuned; second, the target values of some indicators have been raised; third, the corresponding relationship between indicators and planning objectives has been adjusted from one-to-one correspondence to cross-correspondence.

Starting from the 2021 edition of the London Plan, the index system has been greatly simplified: first, the indicators are completely organized according to special issues, and the corresponding relationship with the planning objectives is no longer expounded; second, the number of indicators is reduced to half of the original, and the indicators emphasized in other mayor's strategies or special policies are no longer mentioned; at the same time, in the selection of indicators, it is more pragmatic, more operable, and can better reflect the role of planning approval. The 2021 London Plan inherits only five indicators from the 2011 London Plan and introduces seven new key performance indicators. From the perspective of special issues, the replacement of its adoption indicators also reflects the change of the focus of planning.

This paper focuses on AMR 17 (Table 1), the latest Annual MMonitoring Report published by the Greater London Authority in November 2022. The report continues the monitoring indicator system that has been in place since July 2011, using six strategic indicators and 24 key performance indicators. AMR17 monitored the implementation of the planning policies in the London Plan 2016 and progress towards the programme objectives between 1 April 2019 and 31 March 2020.

AMR19 to be released in the future, prepared from London in March 2023, for the first time uses the latest framework approved by the Mayor of London on 31 May 2022 and will oversee the London Plan published in March 2021. In the London Plan 2021, the "Good Growth" vision goal and six sub-goals are proposed for the first time, aiming at achieving socially and economically inclusive and environmentally sustainable growth. The plan proposes to continue to dynamically assess the sound growth of the city with Annual Monitoring Reports. and establish 12 core monitoring indicator systems covering 8 areas of housing, economy, environment, transportation, health, air quality, culture and heritage (Table 2). As can be seen from the new monitoring indicator system, in order to deal with the current "urban disease" problem, London particularly emphasizes the planning concept of sustainable development, the pursuit of high-quality development and quality of life improvement.

Number	Key Performance Indicators	Aim
1	Maximise the proportion of development taking place on previously developed land	Maintain at least 96% of new residential development to be on previously developed land
2	Optimise the density of residential development	Over 95% of development to comply with the housing density location and the density matrix
3	Minimise the loss of open space	No net loss of open space designated for protection in Local Development Frameworks
4	Increase supply of new homes	Average completion of a minimum of 42,000 net additional homes per year
5	An increased supply of affordable homes	Completion of 17,000 net additional affordable homes per year
6	Reducing health inequalities	Reduction in the difference in life expectancy
7	Sustaining economic activity	Increase in the proportion of working age London residents in employment
8	Ensure that there is sufficient development capacity in the office market	Stock of office planning permissions should be at least three times the average rate of starts over the previous three years
9	Ensure that there is sufficient employment land available	Release of industrial land to be in line with benchmarks in the Industrial Capacity SPG
10	Employment in Outer London	Growth in total employment in Outer London
11-1	Increased employment opportunities for those suffering from	(part 1) – Reduce the employment rate gap between Black, Asian

1088

REAL CORP

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

Number	Key Performance Indicators	Aim
	disadvantage in the employment market	and Minority Ethnic (BAME) groups and the white population
11-2	Increased employment opportunities for those suffering from disadvantage in the employment market	(part 2) – Reduce the gap between lone parents on income support in London versus the average for England and Wales
12	Improving the provision of social infrastructure and related services	Reduce the average class sizes in primary schools
13	Achieve a reduced reliance on the private car and a more sustainable modal split for journeys	Use of public transport per head grows faster than use of the private car per head
14	Achieve a reduced reliance on the private car and a more sustainable modal split for journeys	Zero car traffic growth for London as a whole
15	Achieve a reduced reliance on the private car and a more sustainable modal split for journeys	Increase the share of all trips by bicycle from 2% in 2009 to 5% by 2026
16-1	Achieve a reduced reliance on the private car and a more sustainable modal split for journeys	(part 1) – A 50% increase in passengers transported on the Blue Ribbon Network from 2011-2021
16-2	Achieve a reduced reliance on the private car and a more sustainable modal split for journeys	(part 2) – A 50% increase in freight transported on the Blue Ribbon Network from 2011-2021
17	Increase in the number of jobs located in areas of high PTAL values	Maintain at least 50% of B1 development in PTAL zones 5-6
18	Protection of biodiversity habitat	No net loss of Sites of Importance for Nature Conservation
19	Increase in municipal waste recycled or composted and elimination of waste to landfill by 2031	At least 45% of waste recycled or composted by 2015 and 0% of biodegradable or recyclable waste to landfill by 2026
20	Reduce carbon dioxide emissions through new development	Annual average % carbon dioxide emissions savings for strategic development proposals progressing towards zero
21	Increase in energy generated from renewable sources	Production of 8,550 GWh of energy from renewable sources by 2026
22	Increase in Urban Greening	Increase total area of green roofs in the CAZ
23	Improve London's Blue Ribbon Network	Restore 15km of rivers and streams 2009 – 2015 and an additional 10km by 2020
24	Protecting and improving London's heritage and public realm	Reduction in the proportion of designated heritage assets at risk

Table 1: Key Performance Indicators of AMR17. Source of information: the 17th Annual Monitoring Report

Number	Key Performance Indicators	Aim
1	Supply of new homes	Increase in the supply of new homes over the period (monitored against housing completions and the net pipeline of approved homes), towards meeting the 66,000 net additional homes needed each year up to March 2029.
2	Supply of affordable homes	Positive trend in percentage of planning approvals for housing that are affordable housing (based on a rolling average).
3	Supply of office capacity	Pipeline of planning permissions for office floorspace is at least three times the average office floorspace construction started over the previous three years.
4	Supply of affordable workspace	Positive trend in affordable B1 workspace as a share of total B1 floorspace in planning approvals (based on a rolling average).
5	Availability of industrial land	No overall net loss of industrial and warehousing floorspace in London (B1c, B2 and B8) in designated industrial locations (based on a rolling average).
6	Protection of Green Belt and Metropolitan Open Land	Harm to the Green Belt and Metropolitan Open Land prevented through the referred application process.
7	Carbon emissions through new development	Average on-site carbon emission reductions of at least 35%, compared to Building Regulations 2013 for approved referable development applications.
8	Modal share	Increasing mode share for walking, cycling and public transport (excluding taxis) towards the target of 80 per cent by 2041.
9	Londoners engaging in active travel	Positive trend in provision of cycle parking (based on a rolling average) to support the target of all Londoners doing two ten-minute periods of active travel a day by 2041.
10	Air quality	Positive trend in approved referable development applications demonstrating that they meet at least air quality neutral standard for emissions (based on a rolling average).
11	Impact of development on London's heritage	Positive trend in the reduction of harm and/or an increase in benefits to designated heritage assets in approved referable development applications (based on a rolling average).
12	Provision of cultural infrastructure	No net loss of culture venues and facilities* (based on a rolling average)

Table 2: Key Performance Indicators of AMR19 Framework. Source of information: the 19th Annual Monitoring Report Framework

3.5 System guarantee system

In terms of legal protection, the Annual Monitoring Report is authoritative and effective because it is guaranteed by a perfect legal system.

In terms of operation mechanism, the Annual Monitoring Report is a three-way collaborative assessment compilation mechanism led by local government departments and participated by social organizations and local departments.

Government departments are the main body of planning and evaluation, appointed directly by the mayor, and guide the relevant departments to carry out work, and each special department is responsible for the specific affairs in the corresponding field. The government makes decisions based on the evaluation results, and adjusts and improves the corresponding parts of the plan to ensure a good feedback mechanism.

Social organizations are mainly entrusted by government departments to provide technical services, participate in program discussions, and provide advice and guidance.

The community and local departments act as the grass-roots management bodies to implement the "top-down" views of the Government and collect the "bottom-up" aspirations of the public to form a bridge of communication between the two sides.

The participation mechanism of the three parties provides a guarantee for the continuous improvement of the planning evaluation system.

3.6 Monitoring process

Planning implementation in London is controlled through the issuance of permits, so most of the 24 monitoring indicators can be obtained directly from the builder's application for permission. For example, when the developer intends to build a residential development project, it needs to clarify whether the construction project uses the stock land for construction, whether it occupies open space, the relationship between the development intensity and the Public Transportation Accessibility Level (PTAL) in the region, and whether a certain proportion of affordable housing is built. Borough authorities will verify the accuracy of the data they fill in after applying for a street permit and will eventually upload the data to the London Development Database after granting the permit. Every year, the City of London will conduct a statistical review of the data collected by the London Development Database, and if there are abnormal data, it will ask the district government to re-verify the accuracy of the data.

In the whole process, the construction unit is responsible for data filling, the district government is responsible for data verification and approval of permission, the municipal government is responsible for data screening and feedback of abnormal problems, and finally data analysis and sorting (Fig. 1).

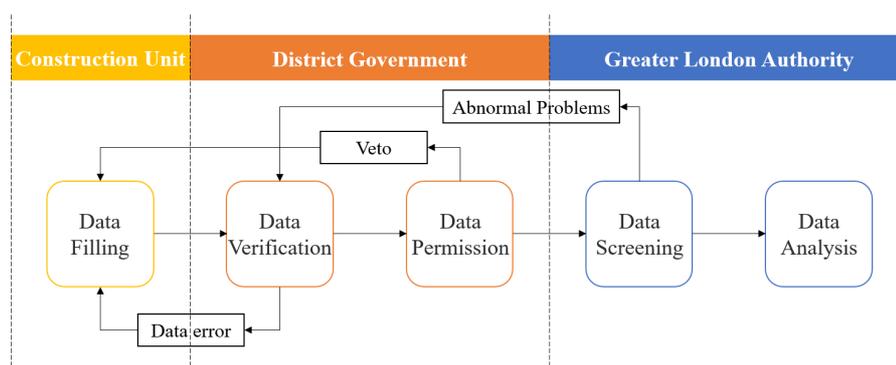

Figure 1: Monitoring processes and departmental responsibilities

4 PROGRESS AND PRACTICE EXPLORATION OF CITY EXAMINATION AND EVALUATION IN CHINA

4.1 Work progress

China attaches great importance to city examination and evaluation. In order to further strengthen the supervision and inspection of planning and improve the scientific implementation of planning, many cities have carried out relevant work of city examination and evaluation. Exploring the establishment of an city examination and evaluation mechanism of "one city examination in one year and one evaluation in five years" has kicked off the prelude of city examination and evaluation in China. In 2019, the Ministry of Housing and Urban-Rural Development selected 11 key cities such as Shenyang and Chengdu to carry out the pilot work of city examination and evaluation, and the sample size increased to 36 in 2020 and 59 in 2021, making good progress.

After entering the era of territorial space planning, city examination and evaluation work has been extended to the whole country. In 2020, the Ministry of Natural Resources deployed and carried out city examination and evaluation under the national land spatial planning system in 107 cities approved by the current State Council, in order to strengthen the supervision and management of national land spatial planning, and clarified the work requirements of "one city examination for one year and one evaluation for five years". In order to further standardize the city examination and evaluation work, the Ministry of Natural Resources

further strengthened cooperation with Beijing and other pilot cities, formulated and formed the City Examination And Evaluation Procedures for Cities in Territorial Space Planning (hereinafter referred to as the Evaluation Procedures), and issued the trial draft, approval draft and official draft of the Evaluation Procedures in October 2020, May 2021 and June 2021 (Fig. 2).

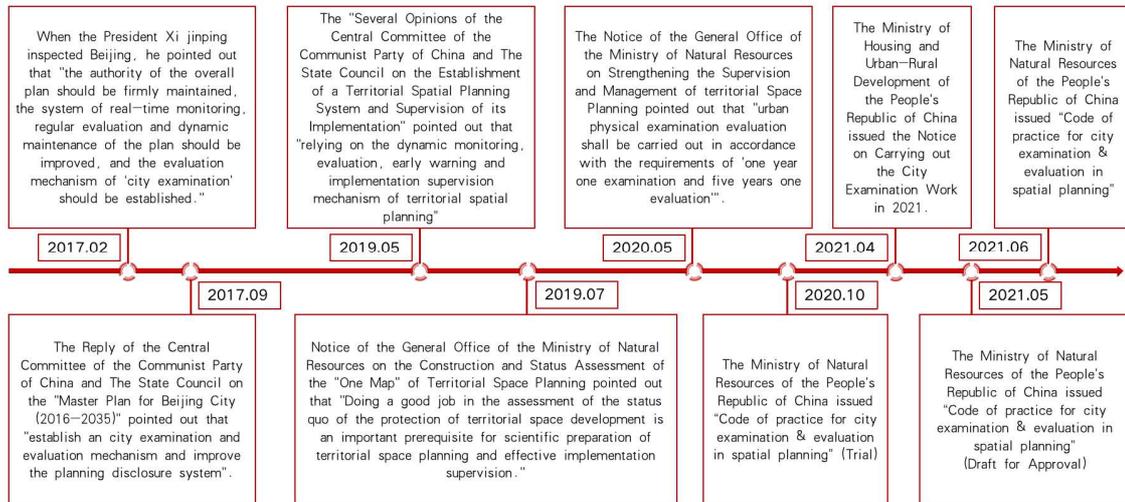

Fig 2: The development progress of China's city examination and evaluation

4.2 Index system

In the city examination and evaluation, the index system can directly reflect the implementation of the city's strategic objectives. Therefore, the index system largely determines the depth of city examination and evaluation. China has two policy documents guiding the establishment of the indicator system, respectively issued by the Ministry of Housing and Natural Resources, and the two documents guide the city examination work in different application contexts, with slightly different focuses.

In April 2021, the Ministry of Housing and Urban-Rural Development issued the "Notice on Carrying out City Examination Work in 2021", which clarified that the city examination index system in 2021 is composed of 65 indicators in 8 aspects: ecological livable, healthy and comfortable, safe and resilient, convenient transportation, features and characteristics, neat and orderly, diverse and inclusive, and innovative vitality. In July 2022, the Ministry of Housing and Urban-Rural Development issued the "Notice on carrying out City examination Work in 2022", which continued the eight aspects proposed in 2021, such as ecological livable, health and comfort, and the number was adjusted from 65 to 69, of which 22 items were added, 18 items were deleted, and 9 items were adjusted. The "Evaluation Procedures" issued by the Ministry of Natural Resources implement the national requirements, and build an indicator system with "safety, innovation, coordination, green, open and sharing" as 6 first-level categories, 23 second-level categories, and 122 indicators. Among the 122 indicators, 33 are basic indicators and 89 are recommended indicators. When carrying out city examination assessment, basic indicators are required, and recommended indicators are optional. In addition, indicators reflecting urban characteristics can be added [5].

With the advancement and deepening of city examination and evaluation, the construction of the national indicator system is diversified, based on local characteristics, and diversified indicators are expanded. For example, as the world porcelain capital, Jingdezhen has added 13 new characteristic indicators, including cultural protection, inheritance and innovation, and foreign exchanges, to focus on the two goals of the world porcelain cultural center city and the new humanistic city [6]. Shanghai city examination and evaluation explores the "linkage between city and district", emphasizing the establishment of a hierarchical and block system of city examination. On the one hand, it encourages the localization of indicators at the ministry and city level in combination with regional characteristics; on the other hand, it encourages the district-level characteristic indicator system based on its own characteristics. [7] For example, Chongming District of Shanghai puts forward a number of characteristic indicators such as "the number of waterfowl species accounting for more than 1% of the global population, the installed capacity of renewable energy, and the green food certification rate".

5 COMPARATIVE ANALYSIS OF THE UK'S "LONDON PLANNING ANNUAL MONITORING AND EVALUATION REPORT" AND CHINA'S " CITY EXAMINATION REGULATIONS FOR LAND AND SPACE MASTER PLAN"

5.1 Key focus areas

Looking at the key focus areas of the Monitoring Report and the Assessment Procedures, both of them are linked to the strategic needs and development concepts at the national level, the UK's Monitoring Report is linked to the six Grand strategy of the London Plan, and China's Assessment Procedures are linked to the five development concepts of "innovation, green, sharing, openness and coordination". However, there are differences in the content of planning and evaluation between the two, as evidenced by the fact that planning and evaluation in the UK focuses more on the needs of citizens, while in China it focuses more on policy needs and spatial control. As a developed country, the early industrialization of the UK was completed, and due to its high efficiency in urban governance, it has a high level of urban planning and management. In the process of planning and implementation, more emphasis is placed on relieving urban employment pressure, improving urban vitality, and advocating for citizen health, with a particular focus on social equity, providing more rights and protection for vulnerable groups and ethnic minorities. The corresponding indicators for the construction of city examination and evaluation revolve around issues such as housing security and poverty.

China advocates high-quality urban development and adheres to the development concept of "people-oriented". However, due to the rapid urbanization process of Chinese cities, there are many contradictions that need to be solved urgently [8]. In the formulation of the content framework of city examination, the focus is on the strategic positioning, regulatory structure, and spatial layout of the city, with strong constraints on the bottom line control of elements, and relatively weak support for the implementation of the supporting system and the implementation guarantee of planning. Therefore, the evaluation indicators for city examinations in China are more prominent in terms of "bottom line thinking", often using per capita values for calculation or the total amount and proportion within the city to characterize the specific indicator situation.

5.2 Data foundation

The "Evaluation Regulations" are based on legal data of national land and space, including national land survey and annual change survey led by the natural resources regulatory department, special survey of natural resources, geographical and national survey and monitoring, aerospace remote sensing images, and other basic status data. Data on various levels of national land and space planning achievements, land use approval, land supply law enforcement supervision, and other management data are supplemented by relevant legal statistical survey data, Including economic and social development statistical data, specialized survey statistical data from various departments, etc; Using spatiotemporal Big data as a reference, mobile signaling data, POI data, traffic IC card data, enterprise information, location services, lighting data, citizen service hotline data, etc. that are publicly released or legally obtained are used according to the relevant standards and regulations of the natural resources management department. For city examination and evaluation indicators, continuous data can be collected for many years to reflect the trend of changes in the indicators; For prominent issues, on-site special research can be conducted to grasp first-hand information; For public demands, various methods such as questionnaire surveys can be used to understand the issues and opinions on housing security public service facilities, municipal public facilities, and urban safety resilience in public spaces.

The Monitoring Report relies on the London Development Database collected by the Greater London Authority as a whole, and summarizes the data according to the corresponding indicators at different times and frequencies. The accuracy and timeliness of the data are fully guaranteed, which avoids some indicators in the Evaluation Procedures without data sources or data statistical caliber deviation, leading to data monitoring failure and disability. The Monitoring Report can truly achieve the goal of planning monitoring and avoiding future problems. Due to the failure to collect data in advance according to the Evaluation Regulations, it is often necessary to screen data on a large amount of data for city examination and evaluation, which affects work efficiency.

5.3 Evaluation index system

The indicator systems of the Monitoring Report and the Evaluation Regulations both cover aspects such as socio-economic, intensive resources, and ecological environment, and have put forward corresponding requirements in terms of public service layout, green transportation, cultural and historical heritage, etc. Both use time series to statistically analyze data and present multiple indicators in the form of evaluation and judgment tables, which can truly reflect the changes in indicators, closely connect with planning and control needs, and facilitate later analysis and summary, providing a judgment basis for early warning feedback in planning evaluation and monitoring. In addition, both of them follow certain data requirements, such as the fact that the data should truly describe the characteristics of indicators and have a certain degree of objectivity; The data should be easy to collect and update, with a certain degree of accessibility; The data should be easy to analyze, process, and quantify, with a certain degree of operability.

Due to the different national conditions between China and the UK, there are significant differences in the guidance and criteria for indicator evaluation and judgment due to the different feedback requirements for the implementation status of planning goals (Table 3). In terms of the orientation of indicator evaluation and judgment, the Monitoring Report emphasizes trend judgment and focuses on the expression of performance development status. Evaluation and judgment are generally expressed as different states such as "developing according to predetermined trends" and "developing towards opposite predetermined trends" [9]; The "Evaluation Regulations" emphasize result monitoring, focusing on a more clear progress situation, and emphasizing the progress completion of each indicator plan implementation. The evaluation judgment is generally expressed as "meeting the target direction, achieving good results" or "slow progress, requiring key progress". In terms of evaluation and judgment criteria, the "Monitoring Report" is guided by more flexible goals, focusing on preset development trends, and is a grasp of the overall performance development goals; The 'Evaluation Regulations' are evaluated based on more rigid standards, comparing the reported value of the evaluation year with the current situation value of the base year, and the planned value of the target year with the reported value of the previous year, with a focus on the differences with the planned target value.

5.4 Evaluation response mechanism

The main differences in the evaluation response mechanism between the Monitoring Report and the Evaluation Regulations are reflected in the dimensions of achievement application, the nature of the planning system, and the strength of supervision and implementation.

5.4.1 Evaluation results application dimension

The Monitoring Report is mainly used to evaluate the effectiveness of the London Plan and its policies, including the progress of implementing the planning objectives and the effectiveness of the planning policies. Its evaluation content also needs to be consistent with the regional plans, mayors, council policy guidelines, and other content. The results of the Evaluation Regulations are mainly applied to comprehensive affairs such as planning approval, planning preparation, planning implementation, and planning management, Providing performance evaluation basis for natural resource management departments and related departments, supporting the preparation of the National Economic and Social Development Plan and the Government Work Report, is beneficial for the evaluation of planning implementation and the improvement of urban governance level.

5.4.2 Nature of planning system

The 'Monitoring Report' belongs to the guiding planning system and belongs to the regional planning monitoring category in the UK planning implementation system. The annual monitoring report can serve as an important basis for local planning, conducting planning downward, and providing development guidance for local planning and community planning. The 'Evaluation Regulations' belong to the controlling planning system , Strictly control the bottom line control elements in city examination and evaluation, focusing on the "one map" of urban and rural construction land changes, as well as the basic geographical elements and analysis evaluation elements in the "one map" of each district's development. Through annual city examination and five-year evaluation, feedback is provided on the relevant content of overall planning, detailed planning, and even special planning.

5.4.3   Supervision and implementation efforts

The Monitoring Report can effectively and dynamically monitor the implementation of the plan. The reason is that the Greater London Authority Act clearly defines the mayor's responsibility for supervising the implementation of the London plan. It ensures the effective monitoring, assessment and review of the facts of the London Plan through top-level planning and clear laws and regulations, and also ensures the interconnection between the planning levels and types, It becomes the core basis for measuring regional planning and future policy directions, and has legal significance.

Content		The Annual Monitoring Report	City Examination and Evaluation In China
Data Sources		The London Development Database	Based on legal data of national territory and space
Data Description		Panel data of evaluation indicators over the years 2004-2020	Evaluation indicators: current status value of the base year, planned value of the target year, reported value of the previous year, and reported value of the evaluation year
Evaluation Description	Positive evaluation	Developing according to preset trends	Meets the target direction and completes well
	Negative evaluation	tends to develop in the opposite direction of presupposition	Slow progress, need to focus on progress

6   SUGGESTIONS FOR THE OPTIMIZATION OF CITY EXAMINATION IN CHINESE CITIES

Through the comparison of "Monitoring Report" and "evaluation procedures", it is found that London's urban planning monitoring and evaluation is advanced in the construction of dynamic monitoring system and the improvement of mechanism. Therefore, according to the current city examination work in our country, the following guidelines and suggestions are put forward.

6.1 Build a complete dynamic monitoring and evaluation system

At present, the city examination of urban planning in China is more focused on the analysis of data information, but lacks the monitoring of the implementation of specific policies. Therefore, it is necessary to further improve and supplement the supervision and feedback part, and gradually form the evaluation framework of "real-time monitoring – comprehensive judgment – feedback implementation – urban governance", so as to achieve an effective connection between territorial planning and city examination and evaluation. Thus, the integrity of urban planning evaluation is enhanced.

6.1.1   Dynamic + normal city examination mode

City examination should focus on dynamic monitoring and evaluation, and build a full chain of dynamic city examination work process of detection – diagnosis – governance – review – monitoring – early warning, so

1094

REAL CORP 2023: LET IT GROW, LET US PLAN, LET IT GROW
Nature-based Solutions for Sustainable Resilient Smart Green and Blue Cities

as to achieve effective integration of city examination, result feedback and urban management. Through the information system, a normal monitoring system of instant monitoring and alarm and timely correction is established, which is timely reflected to the relevant departments, creating a daily reward incentive mechanism for the construction of urban health, and reducing the passive, static and targeted city examination of "city examination due to needs". And according to the specific situation of the city to find the contrast gap, put forward the localization of the construction path. It has gradually shifted from focusing solely on data and indicators to focusing on all aspects of policy making and decision-making.

6.1.2 Multi-level connection and coordination

In addition to the scope of city and district level assessment, the scope of city examination will gradually sink from the city to the micro-scale of streets and communities, and establish a multi-level assessment model of "city – district – street – community", which will also improve the ways and methods of social organizations to participate in urban management. The micro-scale evaluation of towns and communities can reflect the actual needs of the masses, more fully show the construction dynamics of the project, and thus improve the effectiveness of city examination and evaluation. In addition, the connection and coordination with the evaluation work at all levels is becoming more and more important, so it is necessary to pay close attention to the establishment of the provincial and even regional city examination information platform, while doing a good job with the provincial city price increase information system connection and coordination, so as to enhance the stability of city examination and evaluation.

6.1.3 Improve the multi-subject participation mechanism

In addition to the public satisfaction survey and third-party city examination, we will expand more channels for social subjects to participate, and deeply adopt the opinions and suggestions of experts, scholars, representatives of social groups and the masses, so as to effectively reflect the needs of the people and social concerns. Government departments should actively stimulate the initiative of social subjects in the promotion of work, and promote the normal development of city examination more efficiently; In the process of data collection, actively coordinate the staff of the city examination department to maintain the authority and credibility of the data; In the publicity of the work, we will take the initiative to invite representatives of well-known enterprises, experts and scholars in universities and the general public to participate in the city examination work and offer suggestions for urban construction. Grass-roots people should participate in or assist the investigators in the city examination survey, and actively respond to the evaluation of livable conditions and living needs; In terms of reflecting the situation and improving opinions, the government departments' information websites and other formal channels are used to reflect the construction situation or provide improvement opinions.

6.2 Integration of city examination objectives

6.2.1 Strengthen implementation orientation

The strategic goal of London's urban planning monitoring and evaluation has changed from problem-oriented to opportunity-oriented, and there are two main types of city examination in China at this stage, one is the city examination carried out by Beijing and Shanghai, focusing on the implementation of the urban master plan, which is similar to the London's urban planning monitoring and evaluation [11]. The other type is represented by the city examination of the current status of urban development conducted in Guangzhou and Chongqing, which focuses on the problem orientation .The technical framework of dynamic monitoring and evaluation corresponding to different types of city examination is different, and the two should not be confused. Cityexamination for urban development problems has problems such as a huge workload of city examination, the need to collect a large number of city-related data, and sometimes there are conflicts and missing data. The focus of city examination is often biased to a certain aspect of the city, forming a problem of partial overview. The dynamic monitoring for planning and implementation has stronger purpose, more targeted operation, and easier to control the direction of city examination. Therefore, we should strengthen the goal orientation and use development goals to lead the promotion of cityexamination.

6.2.2 Multiple guidance support

In view of the advantages of the city examination index system with flexibility and broad application basis, it can continue to enhance the comprehensive service guarantee ability of city examination and evaluation, and

according to the needs of government policies and departments at all levels, according to the social political and economic conditions of high-quality urban development, urban and rural construction management, urban service facilities and many other management and service requirements. Combined with the evaluation requirements of social and economic planning, territorial spatial planning, urban construction planning, environmental protection planning, etc., on the basis of the concept of comprehensive integration of city examination, a support system with multiple guiding functions is further formed to promote the healthy and high-quality development of the city .Relying on the multidimensional orientation of the indicator system, we will develop a more stable and extensive support system [12].

6.3 Optimize the index system

6.3.1 Widening of data sources

City examination and evaluation should combine traditional economic and social data, including social and economic data, territorial spatial survey data and urban big data, such as mobile signaling data, government data, POI data, LBS data, enterprise information, traffic data and social media data, street view data, remote sensing data and lighting data .In addition, combining with social satisfaction survey, the rational objective data and perceptual subjective survey are integrated. Promote the construction of intelligent data network platforms, efficiently integrate multi-source data information, and promote resource sharing among departments and even for the public. In addition to economic and social macro data sharing, explore the addition of new projects, new facilities and other functions in the information platform to provide more effective information support for the calculation of city examination indicators. Through the use of advanced means such as big data analysis, artificial intelligence, and digital services, the accuracy and scientific nature of city examination assessment are enhanced to achieve real-time dynamic monitoring of urban healthy development [13].

6.3.2 Indicator content deepening

The types of ecological monitoring indicators of London's urban planning monitoring and evaluation are constantly expanding. In order to realize China's ecological civilization construction, respond to the transformation and change of sustainable development, combined with the strategic requirements of ecological priority and green development in territorial spatial planning, natal-based solutions related indicators can be added to the ecological livable dimension, focusing on carbon emission reduction, green infrastructure construction and other aspects. The index system will be deepened and supplemented from the directions of industrial structure upgrading, urban green construction, and residents' green life .

At the same time, according to the changes in the external environment of urban development, urban landscape style, and the requirements of the upper planning, the city examination and evaluation index system of various places is dynamically adjusted to objectively and completely reflect the different characteristics of each stage of urban development, and provide data support for the research and evaluation of the weak links in the implementation of planning. For large cities with good economic development background, incremental changes should be highlighted in the long-term planning, and micro-indicators such as "new projects" and "new facilities" can be added to the index system as a supplement to macro-economic and social monitoring indicators .

6.3.3 Improve database construction

The desirability and completeness of city data determine whether the city examination is carried out smoothly. Without accurate, complete, continuous and desirable urban data, it is impossible to judge the direction of urban development or the implementation of urban facilities. With reference to the construction mode of London development database, urban construction data of different regions, different levels and different fields of the city should be collected regularly through the city examination data information platform to ensure the desirability and continuity of urban dynamic monitoring data. The city database should be connected with the geographic information system (GIS), and the relevant special visual analysis can be carried out through GIS, and the multi-city data management system can be formed by using other data sources. The urban operation monitoring intelligent platform based on the urban database can monitor the urban operation status and urban disaster early warning in real time, and improve the safety and resilience of the city.

7 CONCLUSION

This article focuses on comparing the planning and evaluation of China and the UK, summarizing the historical evolution and development characteristics of planning monitoring and evaluation in the UK. It also explores the research progress and practical exploration of urban health examination and evaluation in China. By comparing and analyzing the "Monitoring Report" and "Evaluation Regulations", optimization suggestions are provided for urban health examination and evaluation in China.

In the future, China's city examination and evaluation needs to pay more attention to: (1) optimizing the city examination indicator system, and selecting indicators should consider objectivity, accessibility, and operability, which can effectively reflect the strategic direction and overall goals of the city (some indicator data is difficult to obtain). Establish corresponding city examination databases (2) Improve the framework of planning and evaluation content, and enhance the comprehensiveness of planning and evaluation. (3) Clarify the criteria for planning evaluation and analysis, ensure the effectiveness of planning evaluation implementation, and improve the top-level design level of planning. (4) Improve the planning monitoring and evaluation system, and enhance the implementation of planning decisions. (5) Improve the application methods of city examination results, so that planning and evaluation can be effectively monitored and monitoring results can be obtained.

By comparing the development process of planning and evaluation in the UK, the following three aspects of city examination and evaluation experience can be obtained: in terms of evaluation orientation, it is necessary to establish a goal orientation that varies from city to city, establish a clear and identifiable problem orientation, and establish an effective result orientation; In terms of indicator system, the breadth of data sources should be expanded, the depth of indicator judgment should be strengthened, and the validity of comprehensive data should be improved; In terms of evaluation mechanism, it is necessary to consolidate the foundation of real-time monitoring, improve comprehensive judgment ability, improve feedback implementation system, improve urban governance feedback mechanism, and form a closed-loop system from real-time monitoring, comprehensive judgment, feedback implementation to urban governance evaluation.
